Contents

Glossary of Terms

Terms	Meaning
AADT	Annual Average Daily Traffic (expressed in vehicles per day)
AA	Appropriate Assessment An assessment carried out under Article 6(3) of the Habitats Directive of the implications of a plan or project, either individually or in combination with other plans and projects, on a European site in view of the site's conservation objectives.
ABP	An Bord Pleanála
Acquisition	Property that is to be purchased by the local authority.
ADMS-Roads model	The ADMS-Roads pollution model is a comprehensive tool for investigating air pollution problems due to networks of roads that may be in combination with industrial sites, for instance small towns or rural road networks.
Alkalinity	Is a measure of the ability of a solution to neutralise acids.
Alluvium	Sediment deposited by flowing water.
Annex I habitat	Habitat types listed on Annex I of the EU Habitats Directive whose conservation requires the designation of Special Areas of Conservation.
Annex II species	Species listed on Annex II of the EU Habitats Directive whose conservation requires the designation of Special Areas of Conservation.
Annex IV species	Species listed on Annex IV of the EU Habitats Directive which are afforded strict protection under EU and national legislation.
aOD	Above ordnance datum
Aquifer	A subsurface layer or layers of rock that store and transmit water in significant quantities.
Arterial Drainage	Artificial drainage work carried out to support natural drainage networks.
Attenuation pond	Water pond used for the collection and slow release of water runoff from the road.
At-Grade Junction	Junction where roads converge at the same level.
At-grade signalised junctions	Road junction, where roads converge at the same level, which is controlled by traffic signals.
AQS	Air Quality Standards
Baronies	The historical subdivision of a county.
Baseflow	The background level of flow of water in a stream or other surface water feature during dry periods (which in many cases will be due solely to groundwater discharge).
Base year	Year used as the beginning or the reference year for constructing a design model or equation.
Batholith	A very large igneous intrusion extending to an unknown depth in the earth's crust.

Terms	Meaning
Bathymetric	Bathymetry is the measurement of the depth of water in oceans, rivers, or lakes. Bathymetric maps look a lot like topographic maps, which use lines to show the shape and elevation of land features.
BCI	Bat Conservation Ireland
Benthic	Relating to the bottom of a sea or lake or to the organisms that live there.
Biodegradation	Biodegradation is the decomposition of organic material by micro-organisms.
Biological Oxygen Demand (BOD)	A parameter used to quantify how fast biological organisms use up oxygen in a body of water. The testing for BOD is not an accurate quantitative test, although it could be considered as an indication of the quality of a water source.
Biotite	Biotite is a name used for a large group of black mica minerals that are commonly found in igneous and metamorphic rocks.
Bivalves	An aquatic mollusc which has a compressed body enclosed within a hinged shell, such as oysters, mussels, and scallops.
Blasting	Breaking apart or blowing up solid rock with explosives
Bored tunnel	The excavation of a tunnel using a machine with circular cross section through rock, i.e. the constructed using a boring machine.
BoCCI	Birds of Conservation Concern in Ireland
BRE	Buildings Research Establishment
BSBI	Botanical Society of Britain & Ireland
Bullaun stone	Bullaun is the term used for the depression in a stone which is often water filled. A Bullaun Stone is a large rock where a basin or bullaun has been carved out.
BWI	BirdWatch Ireland
cSAC	candidate Special Area of Conservation
Calcite	Calcite belongs to the calcite group of minerals, a group of related carbonates that are isomorphous with one another. They are similar in many physical properties, and may partially or fully replace one another, forming a solid solution series.
Catchment	The entire surface area feeding water to a given surface or groundwater feature.
Carriageway	The particular part of the road used by vehicular traffic.
C_6H_6	Benzene
CEMP	Construction Environmental Management Plan
Ch.	Chainage
Cherry picker	A hydraulic crane with a railed platform at the end for raising and lowering people, for instance to work on overhead cables
Chlorophyll	Chlorophyll is a green pigment found in most plants, algae, and cyanobacteria.
CIRIA	Construction Industry Research and Information Association
CO	Carbon Monoxide

Terms	Meaning
CO_2	Carbon Dioxide
Conductivity	Conductivity (or specific conductance) of a solution is a measure of its ability to conduct electricity. It is linked directly to the total dissolved solids in the solution.
Conservation objectives	The overall target for the species and/or habitat types for which an SAC or SPA site is designated in order for the site to contribute to maintaining or reaching favourable conservation status of those species and/or habitat types. For some SAC/SPA sites this includes a detailed set of targets and attributes against which favourable conservation status can be measured.
Construction stage	The stage during which the proposed road development (N6 Galway City Ring Road) will be constructed. This includes advance contracts such as fencing, archaeological testing and the diversion of utilities/services, site set up and mobilisation.
Conveyance	The ability of a river to carry water flow
Climbing lanes	A climbing lane is an additional lane in a road carriageway that allow slower travel for large vehicles ascending a steep grade. Since climbing uphill is difficult for these vehicles, they can travel in the climbing lane without slowing traffic.
Cofferdam	A watertight enclosure pumped dry to permit construction work below the waterline, for example foundations for a bridge structure.
Collection System	A system of gathering, sorting or mixing of waste for the purpose of it being transported to a waste recovery or disposal facility.
Conduit flow	Groundwater flow though large conduits within the rock mass typical of karstic aquifers.
Culvert	A structure that allows water to flow under an obstruction such as a road or railway.
Compulsory Purchase Order (CPO)	National laws which allow local authorities to compulsorily purchase land necessary for the construction or operation of the N6 Galway Ring Road without the necessity of obtaining consent from the owners subject to approval by An Bord Pleanála.
cSAC	candidate Special Area of Conservation
CSO	Central Statistics Office
Cu	Copper
Cumec	A cubic metre per second, as a unit of rate of flow of water
Cumulative Impacts	For definition, see extract from EPA 2017 draft guidelines at end of this document
Cut and cover tunnel	‘Cut and cover’ is an approach used for constructing shallow tunnels in situations where all the ground above the tunnel can be cleared (cut), the structural element for the tunnel is then constructed before the top of the tunnel is covered over with earth, topsoil and grass
DCHG	Department of Culture, Heritage and the Gaeltacht
DAU	Development Applications Unit of the DCHG
dB (decibel)	The unit of sound pressure level, calculated as a logarithm of the intensity of sound.

Terms	**Meaning**
dB(A)	Unit used to measure the intensity of sound. The “A” denotes that levels were “A” weighted
Design year	The design year is the year for which future traffic demand and volume is calculated and is set at 2039 - 15 years following the year of opening of the proposed road development
Design Goal (noise and vibration)	A target limit for noise or vibration adopted during the early design stages of a project, not necessarily having a statutory basis but based on current best practice and the particular circumstances of a given project.
Designated sites	Sites which have special status as protected areas because of their natural and cultural importance.
DHPLG	Department of Housing, Planning and Local Government
DEFRA	UK Department for Environment, Food and Rural Affairs
Diamond junction	A diamond junction is a common type of a grade separated road junction, used where a major road crosses a minor road.
Diffuse flow	Laminar groundwater flow which takes place through the aquifer matrix or grains.
DMRB	Design Manual for Roads and Bridges, UK
“Do-Nothing” Scenario	The environment as it would be in the future should the proposed road development not be developed
Do Minimum Scenario	This scenario assumes that basic maintenance of the road as well as likely and committed transportation schemes are carried out.
Do Something Scenario	This scenario assumes that the proposed road development is constructed as described, and includes other committed road developments and considers the environment should the proposed road development be developed.
DTTaS	Department of Transport, Tourism and Sport
Dolerite	A dark, medium-grained igneous rock, typically with ophitic texture, containing plagioclase, pyroxene, and olivine. It typically occurs in dykes and sills
Doline	A shallow usually funnel-shaped depression of the ground surface formed by solution in limestone regions
Drawdown	A withdrawal of water from a reservoir or repository.
Dykes	A subvertical sheet-like intrusion of magma or sediment.
Effects	For definition, see extract from EPA 2017 draft guidelines below. The term effects and impacts are used interchangeably in this EIA Report to mean the same thing.
Effective rainfall	That part of the total precipitation which remains after evaporation and which is available for vegetation and percolation.
Electromagnetic induction (quadrature) survey	The electromagnetic (EM) induction survey is based on the measurement of the change in mutual impedance between a pair of coils on or above the earth’s surface.
EQS	Environmental Quality Standard
EIA	Environmental Impact Assessment

Terms	**Meaning**
EIS	Environmental Impact Statement. An EIA Report was formerly known as an EIS. Throughout this document, where reference is made to 'environmental impact statement', or 'EIS', it should also be understood to mean 'EIA Report'.
EIA Report / EIAR	Environmental Impact Assessment Report An EIA Report was formerly known as an EIS. Throughout this document, where reference is made to 'environmental impact statement', or 'EIS', it should also be understood to mean 'EIA Report'.
Enabling works	Preparations to make a site ready for construction. It covers activities from site preparation, creation of access routes, and the installation of facilities like security fencing, ramps, and placing of signs.
EPA	Environmental Protection Agency
EPA Digital Soils Data	With the assistance of Teagasc and the Geological Survey of Ireland, the EPA produced a soils map for the Republic of Ireland. This data is available in a digital format which can be used in computer mapping software.
Epikarst	The thin zone near the karst surface. It includes the solutionally modified (karren) bedrock surface and the overlying and included regolith. The epikarst frequently supports a perched aquifer and serves to retard and store infiltrating rainwater. It also serves as a habitat for a variety of organisms that live in the interstices.
Estavelles	Estavelles are orifices with a dual function. They either discharge water as a spring or allow water to sink, depending on groundwater conditions. Typically estavelles are the connection of karst lakes with the karst ground water table.
EU	European Union
European site	Collective term used in national legislation when referring to nature conservation sites protected under the Habitats or Birds Directives (i.e. SAC or SPA sites).
Evapotranspiration	The process by which water is transferred from the land to the atmosphere by evaporation from the soil and other surfaces and by transpiration from plants.
Fault	A planar fracture in rock in which the rock on one side of the fracture has moved with respect to the rock on the other side.
Favourable Conservation Condition	In the context of assessing effects on the QIs/SCIs of European sites and their conservation objectives, favourable conservation condition is achieved when the QI habitats have sufficient range, area and quality, and QI/SCI species have a sufficient population size range and habitat area, to ensure their survival into the medium to long term, along with favourable future prospects in the face of pressures and threats.
Favourable Conservation Status	In the context of assessing the conservation status of Annex I habitats and Annex II/IV species at a national level, favourable conservation status is achieved when the habitats have sufficient range, area and quality, and the species have a sufficient population size range and habitat area, to ensure their survival

Terms	Meaning
	into the medium to long term, along with favourable future prospects in the face of pressures and threats.
Fissure	Natural crack in rock which allows rapid water movement.
FPO	Flora (Protection) Order, 2015
FRA	Flood Risk Assessment
Fracture	A discontinuity across which there has been separation.
Geohazards	Geological conditions capable of causing damage, or loss of property and life, are called geological hazards and commonly referred to as "geohazards".
Geomorphology	the study of the physical features of the surface of the earth and their relation to its geological structures
Geothermal well	Geothermal wells are wells which tap into the natural geothermal energy found beneath the Earth's crust.
GHG	Greenhouse Gases
GI	Ground Investigation
GIS	Geographic Information System
GNI	Gas Network Ireland
Glacial erractics	A boulder transported and deposited by a glacier having a lithology different than the bedrock upon which it is sitting. Erratics are useful indicators of patterns of former ice flow.
Gleys	A subdivision of the podzolic soil group which are characterised by a fluctuating groundwater table or by impeded drainage which causes mottling in the gleyed grey horizon that is overlain by a dark brown or black subsurface horizon.
Grade Separated Junction	Road junction where roads converge and at which at least one road passes over another.
Groundwater	That part of the subsurface water that is in the saturated zone, i.e. below the water table.
Groundwater vulnerability	Vulnerability is a term used to represent the intrinsic geological and hydrogeological characteristics that determine the ease with which groundwater may be contaminated by human activities.
Growth forecasts	The process of attempting to predict the future condition. This involves the use of statistical models utilizing variables sometimes called indicators.
GSI	Geological Survey of Ireland
GTS	Galway Transport Strategy – an overall transport strategy for Galway City and its environs with a clear implementation framework for transportation over the next 20 years.
GWDTE	Groundwater Dependent Terrestrial Ecosystems
Habitat	The dwelling place of a species or community which provides a particular set of environmental conditions.
ha	Hectare (one hectare is equal to 10,000 square meters)
HAWRAT	Highways Agency Water Risk Assessment Tool
HGV	Heavy Goods Vehicle

Terms	Meaning
High growth scenario	This assumes a high growth rate in the population forecasts for the region.
Horizontal Alignment	Direction and course of the roadway in plan.
Hydraulic barrier	A general term referring to modifications of a ground-water flow system to restrict or impede movement of contaminants.
Hydrodynamics	The branch of science concerned with forces acting on or exerted by fluids (especially liquids).
Hydrocarbon interceptor	Trap used to filter out hydrocarbon pollutants from rainwater runoff. It is typically used in road construction to prevent fuel contamination of streams carrying away the runoff.
Hydrometric Area	An area defined by the EPA covering a region of river catchments.
Hypertension	Abnormally high blood pressure and especially arterial blood pressure.
Hummocky	An elevated tract of land rising above the general level of a marshy region.
Hz	Hertz
IEEM	Institute of Ecology and Environmental Management
IFI	Inland Fisheries Ireland
IGI	Institute of Geologists of Ireland
Impact	For definition, see extract from EPA 2017 draft guidelines below. The term effects and impacts are used interchangeably in this EIAR to mean the same thing.
ITS	Intelligent Transport System
In combination impacts/effects	Term for cumulative impacts used when considering impacts on European sites in the context of an NIS/AA – cumulative effects caused by a project currently under consideration together with the effects of any existing or proposed projects or plans.
In-situ	In its original place, for archaeology it refers to the preservation of archaeological sites/features without disturbance.
Intermodal (transport)	Describes the use of multiple modes of transportation (e.g. rail, ship and truck).
Intertidal zone	The intertidal zone, also known as the littoral zone, in marine aquatic environments is the area of the foreshore and seabed that is exposed to the air at low tide and submerged at high tide, i.e. the area between tide marks.
IPCC	Intergovernmental Panel on Climate Change
IPPC	Integrated Pollution Prevention and Control
IRP	Incident Response Plan
Karst	Terrain created by limestone solution and characterised by a virtual absence of surface drainage, a series of surface hollows, depressions and fissures, collapse structures and an extensive subterranean drainage network.

Terms	Meaning
Karstic	Descriptor for bedrock conditions in limestone that contain solution features such as fissures and caves, and potentially, underground watercourses.
Karstification	Formation of the features of karst topography by the chemical, and sometimes mechanical, action of water in a region of limestone, dolomite, or gypsum bedrock.
KER	Key Ecological Receptors
km	Kilometres
kph	Kilometers per hour
kPa	Kilopascal, a unit of pressure measurement
kV	A unit of electromotive force, equal to 1000 volts.
LAP	Local Area Plan
Landscape Character Area (LCA)	Distinct types of landscape which are generic in character in that they may occur in different parts of the country, but wherever they are they share broadly similar combinations of geology topography, drainage patterns, vegetation and historical land use and settlement pattern.
LED	Light-emitting diode: a device that produces a light, especially on electronic equipment
L_{10}	The noise level exceeded for just 10% of a sample period. $L_{10(1hour)}$ is therefore the noise level exceeded for 10% of the time over a period of one hour. $L_{10(18hour)}$ is the arithmetic average of the eighteen $L_{10(1hour)}$ values between 06:00 and 24:00hrs.
L_{90}	The noise level exceeded for 90% of a sample period; typically used as a descriptor for background noise level.
L_{max}	The instantaneous maximum sound level measured during a sample period.
$L_{eq,T}$	The equivalent continuous sound level - the sound level of a steady sound having the same energy as a fluctuating sound over a specified measuring period T. T may be as short as 1 second when used to describe a single event, or as long as 24 hours when used to describe the noise climate at a specified location. $L_{eq,T}$ can be measured directly with an integrating sound level meter.
L_{den}	The day-evening-night composite noise indicator adopted by the EU for the purposes of assessing overall annoyance. L_{day} is the A-weighted long term average sound level as defined in ISO1996-2: 1987, determined over all the day periods of a year. L_{night} is the A-weighted long term average sound level as defined in ISO1996-2: 1987, determined over all the night periods of a year.
$L_{evening}$	The A-weighted long term average sound level as defined in ISO1996-2: 1987, determined over all the evening periods of a year.
L_{day}	The A-weighted long term average sound level as defined in ISO1996-2: 1987, determined over all the day periods of a year.
L_{night}	L_{night} is the A-weighted long term average sound level as defined in ISO1996-2: 1987, determined over all the night periods of a year.

Terms	Meaning
Lithosols	A thin soil consisting mainly of partially weathered rock fragments.
Low growth scenario	This assumes a low growth rate in the population forecasts for the region.
Luft	TA Luft Guidance Technical Instructions on Air Quality Control
Macro-economics	Macroeconomics is a branch of the economics field that studies how the aggregate economy behaves. In macroeconomics, a variety of economy-wide phenomena is thoroughly examined such as, inflation, price levels, rate of growth, national income, gross domestic product and changes in unemployment.
Macro-invertebrates	Animals without backbones that are big enough to see with the naked eye.
Made Ground	Deposits which have accumulated through human activity and may consist of natural materials, e.g. clay and/or man made materials
Magnetometer surveys	A magnetometer is an instrument that measures magnetism—either the magnetization of a magnetic material like a ferromagnet, or the direction, strength, or relative change of a magnetic field at a particular location.
Meander	A meander in general is a bend in a watercourse.
Medium growth scenario	This assumes a medium growth rate in the population forecasts for the region.
Mesotrophic	A lake or pond that has a moderate amount of plants.
mgbl	Metres below ground level
Micro-climatic	The atmospheric conditions affecting an individual or a small group of organisms, especially when they differ from the climate of the rest of the community.
Microelectronic	Microelectronics is a subdivision of the field of electronics that deals with very small and microscopic elements to manufacture electronic components.
Mode share	The share of people using a particular mode of transport (including cycling and walking) within the overall transport usage of an urban area. Modal share can be calculated for passenger and freight (logistics) transport based on different units, such as number of trips, volume, weight, passenger-km or tonne-km.
Morphology	Morphology is the science of the forms of natural water bodies such as rivers, lakes, estuaries, lagoons, coastal zones and seas, as well as with the processes that create and modify these forms.
N6 GCRR	N6 Galway City Ring Road, the subject of the EIAR
N6 GCTP	N6 Galway City Transport Project
N6 GCOB	A previous application to ABP in 2006 for the then defined 'N6 Galway City Outer By-pass' (GCOB)
NHA	Natural Heritage Area
NIAH	National Inventory of Architectural Heritage
NIS	Natura Impact Statement
NMS	National Monuments Service

Terms	Meaning
Notice to Treat	This notice requests property owners whose lands are subject to a compulsory purchase order (CPO) to submit their claim for compensation for lands being taken under the CPO. Land values etc. are assessed with reference to the date of this Notice.
NO_2	Nitrogen Dioxide
NO_x	Nitrogen Oxides
NPF	National Planning Framework
NPWS	National Parks and Wildlife Service
NRA	National Roads Authority
NTA	National Transport Authority
NTS	Non-Technical Summary
O_2	Oxygen
OD	Ordnance Datum
Oligotrophic	Characterized by a low accumulation of dissolved nutrient salts, supporting but a sparse growth of algae and other organisms, and having a high oxygen content owing to the low organic content.
Orbital route	A route that takes traffic around a city rather than through it.
Online/On-line	The route whereby the proposed road development remains on the same alignment as the existing road infrastructure.
OPW	The Office of Public Works
Operational phase	The period of time in which the proposed road is in use.
OS	Ordnance Survey
OSI	Ordnance Survey Ireland
Outcrop	An exposure of bedrock
PAH	Polycyclic Aromatic Hydrocarbons
Paleokarst	The general term for ancient karst features that have been fossilized or preserved. Most commonly these features are filled with lithified sediments.
Paleolandscape	A landscape as it was in ancient times.
Parent material	The bedrock type from which the rock fragments within a till are derived. For instance, the parent material of a Limestone Till is Limestone.
Particulate Matter	Tiny particles of solid or liquid suspended in liquid or gas.
Pb	Lead
Permeability	A measure of the ability of a given rock to transmit water.
PMGs	Project Management Guidelines
PM_{10}	Particulate matter measuring 10 micrometers (microns) in diameter or less.
$PM_{2.5}$	Particulate matter measuring 2.5 micrometers (microns) in diameter or less.
pNHA	proposed Natural Heritage Area

Terms	Meaning
Priority junctions	Priority junctions are the most common form of junction arrangement. They required one or more minor road to yield or stop for the major road traffic flow.
Pre-earthworks drains	Where surface water and sub-surface water from adjoining land will flow towards the road, it will generally be necessary to construct intercepting drains at the tops of cuttings and the toes of embankments. In rural areas these may be ditches rather than filter drains because of their greater capacity and comparative cheapness.
Priority Annex I habitat	Annex I habitat types which are in danger of disappearance, and for which the European Community has particular responsibility in view of the proportion of their natural range which falls within the territory
Protected road	A protected road, as defined under Section 45 (1) of the Roads Act, means a public road or proposed public road specified to be a protected road in a protected road scheme approved by An Bord Pleanála. A protected road scheme approved by An Bord Pleanála may provide for the prohibition, closure, stopping up, removal, alteration, diversion or restriction of any specified or all means of direct access to the protected road from specified land or from specified land used for a specified purpose or to such land from the protected road.
Qbar	The mean annual maxima flow recorded or calculated at a location.
pH	pH is a measure of the acidity or basicity of a solution.
Pluvial flooding	This flooding occurs when surface water accumulating from the result of intense rainfall saturates the urban drainage system, and the excess water cannot be absorbed.
Podzols	A type of soil formed in cool, seasonally humid climatic regions where leaching (percolation of water) is a dominant process.
Proposed Road Development	The proposed N6 Galway City Ring Road which is the subject of assessment of this Environmental Impact Assessment Report and application to An Bord Pleanála.
Proposed Development Boundary	The extents of the lands to be compulsory acquired for the construction and operation of the proposed road development is referred to as the proposed development boundary
QI	Qualifying Interest – Annex I habitat or Annex II species for which a cSAC/SAC is designated under the Habitats Directive.
Radio-tracking	Use of radio receivers, directional antennae and radio-transmitters (attached to the target species) to monitor and record species movements and locations.
Receptors	Receptors are people or other organisms that may have sensitivity or exposure to contaminants by virtue of their age and health (e.g. schools, day care centres, hospitals, nursing homes), status (e.g. sensitive or endangered species), proximity to the contamination, dwelling construction (e.g. basement), or the facilities they use (e.g. water supply well).
Recharge	The addition of water to the zone of saturation; also, the amount of water added.

Terms	Meaning
Regosols	A Regosol is a very weakly developed mineral soil in unconsolidated materials. Regosols are extensive in eroding lands, in particular in arid and semi-arid areas and in mountain regions.
Resitivity	A measure of the resisting power of a specified material to the flow of an electric current.
Rhizome	Underground stem of plants, laterally growing and capable of producing the root and shoot system of a new plant.
Riparian vegetation	Riparian vegetation is the diversity of native vegetation contained on 'land which adjoins or is influenced by a body of water. Riparian habitats have been defined as places 'where terrestrial and aquatic ecosystems meet’.
Rijkswaterstaat (RWS) fire curve	The RWS curve was developed by the Rijkswaterstaat, Ministry of Transport in the Netherlands. This curve is based on the assumption that in a worst case scenario, a 50 m^3 fuel, oil or petrol tanker fire with a fire load of 300MW could occur, lasting up to 120 minutes. The RWS curve was based on the results of testing carried out by TNO in the Netherlands in 1979.
RMP	Record of Monuments and Places
Road bed	The portion of public road which is typically in private ownership over which there is over which there is a public right of way.
Rockhead	A raised rocky area or prominence; a summit or extremity of rock. The upper surface of bedrock.
Rock outcropping	The part of a rock formation that appears above the surface of the surrounding land.
RPS	Record of Protected Structures
RSA	Road Safety Authority
Runoff	Water leaving a drainage area or water running across the land surface.
SAC	Special Area of Conservation
Saturated zone	The zone below the water table in which all pores and fissures are full of water. Also known as the phreatic zone.
SCI	Special Conservation Interest – Annex I bird species for which an SPA is designated under the Birds Directive
Section 85 Agreement	A Section 85 Agreement has been entered into under the provisions of Section 85 of the Local Government Act 2001 between Galway County Council and Galway City Council and approved by Transport Infrastructure Ireland (TII) pursuant to Section 14 of the Roads Act 1993, as amended.
Sensitivity	Vulnerability of a sensitive receptor to change.
SEVESO	Seveso site – sites identified as containing large quantities of dangerous substances.
Severance	Where a portion of land is separated or isolated from the main land holding or where a portion of habitat is separated/isolated form the main habitat area.
SI	Site Investigation

Terms	Meaning
S.I.	Statutory Instrument
Signalised junction	Road junction where roads converge and traffic flow is controlled by traffic signals.
Stopping sight distances	Is the minimum sight distance available on a road at any spot having sufficient length to enable the driver to stop a vehicle upon sight of a hazard while, traveling at the design speed safely without collision with any other obstruction.
striation	Any of a number of scratches or parallel grooves on the surface of a rock, resulting from the action of moving ice, as of a glacier.
SMR	Sites and Monuments Record
SO_2	Sulphur Dioxide
SOx	Sulphur Oxides expressed as Sulphur Dioxide
SPA	Special Protection Area
Sub-catchment	A portion of a river catchment.
Subsoils	The material between the topsoil and the bedrock.
Subtidal zone	Subtidal zone is that portion of a tidal-flat environment which lies below the level of mean low water for spring tides. Normally it is covered by water at all states of the tide. The word is often used as a general descriptive term for a subaqueous but shallow-marine depositional environment.
Substructure	An underlying or supporting structure
SuDS	Sustainable urban drainage systems (SuDS) are a natural approach to managing drainage in and around properties and other developments. They work by slowing and holding back the water that runs off from a site, allowing natural processes to break down pollutants.
Superstructure	A structure built on top of something else.
SPA	Special Protection Area (for birds). Part of the Natura 2000 network of European sites, designated under the EU Birds Directive (79/409/EEC).
TEN-T	The Trans-European Transport Networks (TEN-T) are a planned set of road, rail, air and water transport networks in the European Union. The TEN-T networks are part of a wider system of Trans-European Networks (TENs), including a telecommunications network (eTEN) and a proposed energy network (TEN-E or Ten-Energy).
TII	Transport Infrastructure Ireland
TII PAG	Transport Infrastructure Ireland (TII) Project Appraisal Guidelines
TOC	Total Organic Carbon
Traffic control measures	Are markers, signs and signal devices used to inform, guide and control traffic, including pedestrians, motor vehicle drivers and bicyclists. These devices are usually placed adjacent, over or along the highways, roads, traffic facilities and other public areas that require traffic control.

Terms	Meaning
Trans-national network	Means the organisation mode that governs the functioning of the European projects. The network associates partners from different countries with the aim of following one or more common objectives, without any one of the partners having a higher status than the others. The network appears as the most suitable instrument to operate at the European scale and to work within the given period.
Tufa	A porous rock composed of calcium carbonate and formed by precipitation from water, e.g. around mineral springs.
Turbidity	Turbidity is the measure of relative clarity of a liquid. It is an optical characteristic of water and is an expression of the amount of light that is scattered by material in the water when a light is shined through the water sample. The higher the intensity of scattered light, the higher the turbidity.
Turlough	Seasonal lakes found in the lowland karsts of western Ireland.
Scheme study area	The term “scheme study area”, when used in this EIAR, refers to the wider study area at which constraints were initially identified during the constraints and route selection studies for the project.
Secondary permeability	Permeability derived from fissures, faults and conduits in the rock rather than that provided by the rock matrix itself.
Seep	A diffuse discharge of groundwater.
Seepage	The slow escape of a liquid through porous material or small holes.
Seismic	Geological surveying methods involving vibrations produced artificially by explosions.
Soil retention	Soil water retention is a major soil hydraulic property that governs soil functioning in ecosystems and greatly affects soil management. Soil moisture forms a major buffer against flooding, and water capacity in subsoil is a major steering factor for plant growth.
Stabilisation	The process of making something physically more secure or stable.
Study area	The area studied in order to inform the Environmental Impact Assessment. The study area will vary depending on the environmental factor being considered
Unsaturated zone	The zone between the land surface and the water table, in which pores and fissures are only partially filled with water. Also known as the vadose zone.
µg/m3	micrograms per metre cubed
Vernacular structures	Building constructed from locally available materials following traditional building practice and patterns and not architect-designed.
Vertical Alignment	Direction and course of the roadway in profile.
Viaduct	A long bridge-like structure, typically a series of arches, carrying a road or railway across a valley or other low ground.
Visual Amenity	The value of a particular area or view in terms of what is seen
VOC	Volatile organic compounds (VOC).

Terms	Meaning
Water table	The uppermost level of saturation in an aquifer at which the pressure is atmospheric.
WFD	Water Framework Directive
WHO	World Health Organization
Windblow	Carried or driven by the wind
Windrose	Map diagram that summarizes information about the wind at a particular location over a specified time period.
Windshield Survey	This is a survey carried out from the roads throughout the study area.
Zone of Contribution	The groundwater catchment area that contributes water to a well.
ZoI	Zone of Influence
%ile	Percentile

Extract from EPA EIAR Guidelines August 2017, page 50-52 Table 3.3 Description of Effects[1]

Quality of Effects It is important to inform the non- specialist reader whether an effect is positive, negative or neutral	**Positive Effects** A change which improves the quality of the environment (for example, by increasing species diversity; or the improving reproductive capacity of an ecosystem, or by removing nuisances or improving amenities).
	Neutral Effects No effects or effects that are imperceptible, within normal bounds of variation or within the margin of forecasting error.
	Negative/adverse Effects A change which reduces the quality of the environment (for example, lessening species diversity or diminishing the reproductive capacity of an ecosystem; or damaging health or property or by causing nuisance).
Describing the Significance of Effects ''Significance' is a concept that can have different meanings for different topics – in the absence of specific definitions for different topics the following definitions may be useful (also see *Determining Significance* below.).	**Imperceptible** An effect capable of measurement but without significant consequences
	Not significant An effect which causes noticeable[2] changes in the character of the environment but without significant consequences.
	Slight Effects An effect which causes noticeable changes in the character of the environment without affecting its sensitivities.
	Moderate Effects An effect that alters the character of the environment in a manner that is consistent with existing and emerging baseline trends.
	Significant Effects An effect which, by its character, magnitude, duration or intensity alters a sensitive aspect of the environment.
	Very Significant An effect which, by its character, magnitude, duration or intensity significantly alters most of a sensitive aspect of the environment.
	Profound Effects An effect which obliterates sensitive characteristics.
Describing the Extent and Context of Effects Context can affect the perception of significance. It is important to establish if the effect is unique or, perhaps, commonly or increasingly experienced.	**Extent** Describe the size of the area, the number of sites, and the proportion of a population affected by an effect.
	Context Describe whether the extent, duration, or frequency will conform or contrast with established (baseline) conditions (is it the biggest, longest effect ever?)

[1] Note: the term effects and impacts are used interchangeably in this EIA Report to mean the same thing

Describing the Probability of Effects Descriptions of effects should establish how likely it is that the predicted effects will occur – so that the CA can take a view of the balance of risk over advantage when making a decision.	**Likely Effects** The effects that can reasonably be expected to occur because of the planned project if all mitigation measures are properly implemented.
	Unlikely Effects The effects that can reasonably be expected not to occur because of the planned project if all mitigation measures are properly implemented.
Describing the Duration and Frequency of Effects 'Duration' is a concept that can have different meanings for different topics – in the absence of specific definitions for different topics the following definitions may be useful.	**Momentary Effects** Effects lasting from seconds to minutes
	Brief Effects Effects lasting less than a day
	Temporary Effects Effects lasting less than a year
	Short-term Effects Effects lasting one to seven years.
	Medium-term Effects Effects lasting seven to fifteen years.
	Long-term Effects Effects lasting fifteen to sixty years.
	Permanent Effects Effects lasting over sixty years
	Reversible Effects Effects that can be undone, for example through remediation or restoration
	Frequency of Effects Describe how often the effect will occur. (once, rarely, occasionally, frequently, constantly – or hourly, daily, weekly, monthly, annually)
Describing the Types of Effects	**Indirect Effects (a.k.a. Secondary Effects)** Impacts on the environment, which are not a direct result of the project, often produced away from the project site or because of a complex pathway.
	Cumulative Effects The addition of many minor or significant effects, including effects of other projects, to create larger, more significant effects.
	'Do-Nothing Effects' The environment as it would be in the future should the subject project not be carried out.
	`Worst case' Effects The effects arising from a project in the case where mitigation measures substantially fail.
	Indeterminable Effects When the full consequences of a change in the environment cannot be described.
	Irreversible Effects When the character, distinctiveness, diversity or reproductive capacity of an environment is permanently lost.
	Residual Effects The degree of environmental change that will occur after the proposed mitigation measures have taken effect.
	Synergistic Effects Where the resultant effect is of greater significance than the sum of its constituents, (e.g. combination of SOx and NOx to produce smog).

1 Introduction

1.1 Introduction

Galway County Council on behalf of itself and on behalf of Galway City Council is proposing to develop the N6 Galway City Ring Road (GCRR) around Galway City.

GCC has made a Protected Road Scheme and a Motorway Scheme which are being submitted for approval to An Bord Pleanála (ABP) under Section 49 of the Roads Act 1993, as amended and these Schemes are referred to throughout this report as the proposed road development or the N6 GCRR.

The proposed N6 GCRR, comprises the construction of approximately 6km of a single carriageway from the western side of Bearna Village as far as Ballymoneen Road and approximately 12km of dual carriageway from Ballymoneen Road to the eastern tie-in with the existing N6 at Coolagh, Briarhill, and associated link roads, side roads, junctions and structures, as shown on **Figure 5.1.01** to **5.1.15**. The section of the proposed road development from the tie-in with the R336 Coast Road to the N59 Letteragh Junction will be a protected road[1] and the section from this junction to the tie-in with the existing N6 at Coolagh, Briahill will be a motorway. A full description of the proposed N6 GCRR is provided in **Chapter 5, Description of Proposed Road Development**. A location plan for the proposed N6 GCRR is presented in **Figure 1.1**.

Galway County Council is progressing the proposed N6 GCRR through the statutory process on behalf of itself and Galway City Council under a Section 85 Agreement[2].

The N6 GCRR forms part of, and is identified as a project within the 'Galway Transport Strategy' (GTS). The GTS was prepared by Galway City Council and GCC, in partnership with the National Transport Authority (NTA). The GTS is based on a comprehensive assessment of transport issues facing Galway City and the wider environs and the need to develop a sustainable integrated transport solution to accommodate existing and future travel demand thereby facilitating Galway growing *"in an integrated, sustainable manner that aligns transport investment with settlement patterns, travel movements and also supports a sustainable use of land"* (Galway City Council Development Plan 2017-2023).

The GTS is currently being implemented by Galway City Council, both in terms of the policy objectives established and the delivery of transport projects

---

[1] A protected road, means a public road or proposed public road specified to be a protected road in a protected road scheme approved by An Bord Pleanála. A protected road scheme approved by An Bord Pleanála may provide for the prohibition, closure, stopping up, removal, alteration, diversion or restriction of any specified or all means of direct access to the protected road from specified land or from specified land used for a specified purpose or to such land from the protected road.

[2] A Section 85 Agreement has been entered into under the provisions of Section 85 of the Local Government Act 2001 between Galway County Council and Galway City Council and approved by Transport Infrastructure Ireland pursuant to Section 14 of the Roads Act 1993, as amended.

identified within the strategy. Further details on the GTS are available on Galway City Council's website at the link below:
https://www.galwaycity.ie/galway-transport-strategy

This Environmental Impact Assessment Report (EIAR) is defined as "a statement of the effects, if any, which the proposed development, if carried out, would have on the environment" (EPA, 2017). This EIAR details the consideration of alternatives, consideration and assessment of likely significant effects/impacts, mitigation and avoidance measures to reduce significant adverse effects/impacts, and assessment of residual impacts.

This chapter outlines the background to the proposed N6 GCRR and summarises the application procedure for submission of an application for the N6 GCRR. This chapter also describes the methodology used to prepare this EIAR (formerly referred to as an Environmental Impact Statement (EIS)) and the consultation process that has been carried out to date.

1.2 Environmental Impact Assessment Report - Screening, Scoping, Contents and Methodology

1.2.1 Statutory Requirements

This EIAR (formerly referred to as an EIS) has been prepared in accordance with the relevant provisions of Directive 2011/92/EU[3] on the Assessment of the Effects of Certain Public and Private Projects on the Environment as amended by Directive 2014/52/EU[4]. Directive 2014/52/EU amends EIA law in a number of respects by amending Directive 2011/92/EU.

Article 5 and Annex IV to the EIA Directive 2011/52/EU, (as substituted by Directive 2014/52/EU) and Sections 50(2) and 50(3) of the Roads Act 1993, as amended, specify the information to be contained in an EIAR (referred to as an Environmental Impact Statement (EIS) in Roads Act 1993, as amended) in relation to this proposed road development.

Directive 2014/52/EU was required to be transposed by 16 May 2017 and requires changes in Irish laws, regulations and administrative provisions across a number of legislative codes to reflect the contents of Directive 2014/52/EU. At the time of publication of this EIAR, the changes in Irish laws, regulations and administrative provisions across a number of legislative codes (including the Roads Act 1993 as amended and Road Regulations 1994 as amended) have not yet been implemented. However, this EIAR has been prepared in full accordance and compliance with the provisions of Directive 2014/52/EU. Regard has also been had to the current provisions of the relative Irish legislative codes including the Roads Act 1993 as amended as they continue to apply at this time.

---

[3] Directive 2011/92/EU of the European Parliament and of the Council of 13 December 2011 on the assessment of the effects of certain public and private projects on the environment (codification).
[4] Directive 2014/52/EU of the European Parliament and of the Council of 16 April 2014 amending Directive 2011/92/EU on the assessment of the effects of certain public and private projects on the environment.

Accordingly, this EIAR contains all of the information prescribed by the relevant provisions of the Roads Act, 1993 as amended, the Roads Regulations, 1994 as amended, Article 5 and Annex IV of Directive 2011/92/EU as amended.

Throughout this document, where reference is made to 'environmental impact statement', or 'EIS', it should also be understood to mean 'EIAR'. Likewise, where reference is made to 'EIAR', it should be understood to mean 'environmental impact statement' or 'EIS'.

1.2.2 EIA Screening

The proposed road development exceeds the thresholds set for mandatory Environmental Impact Assessment as specified in Irish legislation. The relevant legislation includes the Roads Act, 1993, as amended and the Roads Regulations, 1994, as amended.

Section 50 (1) (a) of Roads Act, 1993, as amended states the following:

"50(1) (a) A road authority or the Authority shall prepare a statement of the likely effects on the environment ("environmental impact statement") of any proposed road development it proposes consisting of…………

(i) the construction of a motorway,

(ii) the construction of a busway,

(iii) the construction of a service area, or

(iv) any prescribed type of proposed road development consisting of the construction of a proposed public road or the improvement of an existing public road…."

Article 8 of the Roads Regulations, 1994 (*Road development prescribed for the purposes of S. 50(1) (a) of the Roads Act, 1993*) lists the prescribed types of proposed road development which require an EIS (EIAR) as follows:

"8. The prescribed types of proposed road development for the purpose of subsection (1) (a) (iii) of section 50 of the Act shall be—

(a) the construction of a new road of four or more lanes, or the realignment or widening of an existing road so as to provide four or more lanes, where such new, realigned or widened road would be eight kilometres or more in length in a rural area, or 500 metres or more in length in an urban area;

(b) the construction of a new bridge or tunnel which would be 100 metres or more in length"…..

The proposed road development will include approximately 11.9km of dual carriageway and will include a bridge and a viaduct plus two tunnels each of which will be more than 100 metres in length. In addition, the section of the proposed road development from the N59 Letteragh Junction to the tie-in with the existing N6 at Coolagh, Briarhill will be a motorway. Accordingly, the Roads Authority must prepare an EIS (now referred to as an EIAR) for the proposed road development.

Section 2 of the Planning and Development Act 2000, as amended, as inserted by Section 6(c) of the Planning and Development (Strategic Infrastructure) Act, 2006, as amended, defines strategic infrastructure to include all national road development proposals for which an EIS (EIAR) is required. Therefore, all such strategic infrastructure development is dealt with by the Strategic Infrastructure Division of An Bord Pleanála.

1.2.3 Contents of EIAR

This EIAR has been prepared in accordance with the relevant provisions of Directives 2011/92/EU Assessment of the Effects of Certain Public and Private Projects on the Environment as amended by Directive 2014/52/EU and in accordance with the relevant provisions of the Roads Act, 1993, as amended, the Roads Regulation 1993 as amended, Article 5 and Annex IV of Directive 2011/92/EU, as amended.

Article 5 and Annex IV to the EIA Directive 2011/52/EU, (as substituted by Directive 2014/52/EU)[5], and Sections 50(2) and 50(3) of the Roads Act 1993, as amended, specify the information to be contained in an EIAR in relation to this proposed road development.

As discussed previously in **Section 1.2.1**, at the time of publication of this EIAR, the changes in Irish laws, regulations and administrative provisions across a number of legislative codes had not yet been completed in relation to Directive 2014/52/EU. At the time of publication of this EIAR, there are some additional information requirements listed in Article 5 and Annex IV of the EIA Directive, as amended which are currently not listed in Sections 50(2) and 50(3) of the Roads Act 1993, as amended. For example, the Roads Act 1993, as amended, currently refers to an EIS whereas Directive 2014/52/EU now refers to an EIAR.

This EIAR contains all of the information prescribed by the relevant provisions of the Roads Act, 1993 as amended, the Roads Regulations, 1994 as amended and Article 5 and Annex IV of Directive 2011/92/EU as amended by Directive 2014/52/EU.

For clarity on the information to be contained in the EIAR, the relevant sections of the legislation are reproduced below.

Annex IV of the EIA Directive, as amended, specifies the information to be contained in an EIAR and is reproduced in **Table 1.1** below. The information provided in this EIAR meets the requirements for Article 5 and Annex IV to the EIA Directive, as amended.

[5] Annex IV of Directive 2011/92/EU has been replaced in Directive 2014/52/EU

Table 1.1: Annex IV of EIA Directive as amended by Directive 2014/52/EU

ANNEX IV - INFORMATION REFERRED TO IN ARTICLE 5(1) (INFORMATION FOR THE ENVIRONMENTAL IMPACT ASSESSMENT REPORT)
1. Description of the project, including in particular: *(a) a description of the location of the project;* *(b) a description of the physical characteristics of the whole project, including, where relevant, requisite demolition works, and the land-use requirements during the construction and operational phases;* *(c) a description of the main characteristics of the operational phase of the project (in particular any production process), for instance, energy demand and energy used, nature and quantity of the materials and natural resources (including water, land, soil and biodiversity) used;* *(d) an estimate, by type and quantity, of expected residues and emissions (such as water, air, soil and subsoil pollution, noise, vibration, light, heat, radiation) and quantities and types of waste produced during the construction and operation phases.*
2. A description of the reasonable alternatives (for example in terms of project design, technology, location, size and scale) studied by the developer, which are relevant to the proposed project and its specific characteristics, and an indication of the main reasons for selecting the chosen option, including a comparison of the environmental effects.
3. A description of the relevant aspects of the current state of the environment (baseline scenario) and an outline of the likely evolution thereof without implementation of the project as far as natural changes from the baseline scenario can be assessed with reasonable effort on the basis of the availability of environmental information and scientific knowledge.
4. A description of the factors specified in Article 3(1) likely to be significantly affected by the project: population, human health, biodiversity (for example fauna and flora), land (for example land take), soil (for example organic matter, erosion, compaction, sealing), water (for example hydromorphological changes, quantity and quality), air, climate (for example greenhouse gas emissions, impacts relevant to adaptation), material assets, cultural heritage, including architectural and archaeological aspects, and landscape.
5. A description of the likely significant effects of the project on the environment resulting from, inter alia: *(a) the construction and existence of the project, including, where relevant, demolition works;* *(b) the use of natural resources, in particular land, soil, water and biodiversity, considering as far as possible the sustainable availability of these resources;* *(c) the emission of pollutants, noise, vibration, light, heat and radiation, the creation of nuisances, and the disposal and recovery of waste;* *(d) the risks to human health, cultural heritage or the environment (for example due to accidents or disasters);* *(e) the cumulation of effects with other existing and/or approved projects, taking into account any existing environmental problems relating to areas of particular environmental importance likely to be affected or the use of natural resources;* *(f) the impact of the project on climate (for example the nature and magnitude of greenhouse gas emissions) and the vulnerability of the project to climate change;* *(g) the technologies and the substances used.* *The description of the likely significant effects on the factors specified in Article 3(1) should cover the direct effects and any indirect, secondary, cumulative, transboundary, short-term, medium-term and long-term, permanent and temporary, positive and negative effects of the project. This description should take into account the environmental protection objectives established at Union or Member State level which are relevant to the project.*
6. A description of the forecasting methods or evidence, used to identify and assess the significant effects on the environment, including details of difficulties (for example technical

ANNEX IV - INFORMATION REFERRED TO IN ARTICLE 5(1) (INFORMATION FOR THE ENVIRONMENTAL IMPACT ASSESSMENT REPORT)
deficiencies or lack of knowledge) encountered compiling the required information and the main uncertainties involved.
7. A description of the measures envisaged to avoid, prevent, reduce or, if possible, offset any identified significant adverse effects on the environment and, where appropriate, of any proposed monitoring arrangements (for example the preparation of a post-project analysis). That description should explain the extent, to which significant adverse effects on the environment are avoided, prevented, reduced or offset, and should cover both the construction and operational phases.
8. A description of the expected significant adverse effects of the project on the environment deriving from the vulnerability of the project to risks of major accidents and/or disasters which are relevant to the project concerned. Relevant information available and obtained through risk assessments pursuant to Union legislation such as Directive 2012/18/EU of the European Parliament and of the Council (*)[6]or Council Directive 2009/71/Euratom (**)[7] or relevant assessments carried out pursuant to national legislation may be used for this purpose provided that the requirements of this Directive are met. Where appropriate, this description should include measures envisaged to prevent or mitigate the significant adverse effects of such events on the environment and details of the preparedness for and proposed response to such emergencies.
9. A non-technical summary of the information provided under points 1 to 8.
10. A reference list detailing the sources used for the descriptions and assessments included in the report.

Sections 50(2) and 50(3) of the Roads Act 1993, as amended, specify the information to be contained in an EIS now referred to as an EIAR. Sections 50(2) and 50(3) of the Roads Act 1993, as amended, are reproduced in **Table 1.2** below. The information provided in this EIAR meets the requirements of Sections 50(2) and 50(3) of the Roads Act 1993, as amended.

Table 1.2: Sections 50(2) and 50(3) of the Roads Act 1993, as amended

SECTIONS 50(2) AND 50(3) OF THE ROADS ACT, 1993, AS AMENDED
"50 (2) An environmental impact statement shall contain the following specified information—
(a) a description of the proposed road development comprising information on the site, design and size of the proposed road development;
(b) a description of the measures envisaged in order to avoid, reduce and, if possible, remedy significant adverse effects;
(c) the data required to identify and assess the main effects which the proposed road development is likely to have on the environment;
(d) an outline of the main alternatives studied by the road authority concerned and an indication of the main reasons for its choice, taking into account the environmental effects;
(e) a summary in non-technical language of the above information.

[6] (*) Directive 2012/18/EU of the European Parliament and the Council of 4 July 2012 on the control of major-accident hazards involving dangerous substances, amending and subsequently repealing Council Directive 96/82/EC (OJ L 197, 24.7.2012, p. 1).
[7] (**) Council Directive 2009/71/Euratom of 25 June 2009 establishing a Community framework for the nuclear safety of nuclear installations (OJ L 172, 2.7.2009, p. 18)'.

SECTIONS 50(2) AND 50(3) OF THE ROADS ACT, 1993, AS AMENDED
50(3) An environmental impact statement shall, in addition to and by way of explanation or amplification of the specified information referred to in subsection (2), contain further information on the following matters— *(a) (i) a description of the physical characteristics of the whole proposed road development and the land-use requirements during the construction and operational phases,* *(ii) an estimate, by type and quantity, of expected residues and emissions (including water, air and soil pollution, noise, vibration, light, heat and radiation) resulting from the operation of the proposed road development;* *(b) a description of the aspects of the environment likely to be significantly affected by the proposed road development, including in particular—* *—human beings, fauna and flora,* *—soil, water, air, climatic factors and the landscape,* *—material assets, including the architectural and archaeological heritage, and the cultural heritage,* *—the inter-relationship between the above factors;* *(c) a description of the likely significant effects (including direct, indirect, secondary, cumulative, short, medium and long-term, permanent and temporary, positive and negative) of the proposed road development on the environment resulting from—* *—the existence of the proposed road development,* *—the use of natural resources,* *—the emission of pollutants, the creation of nuisances and the elimination of waste,* *and a description of the forecasting methods used to assess the effects on the environment;* *(d) an indication of any difficulties (technical deficiencies or lack of know-how) encountered by the road authority concerned in compiling the required information;* *(e) a summary in non-technical language of the above information;* *to the extent that such information is relevant to a given stage of the consent procedure and to the specific characteristics of the proposed road development or type of proposed road development concerned, and of the environmental features likely to be affected, and the road authority preparing the environmental impact statement may reasonably be required to compile such information having regard, inter alia, to current knowledge and methods of assessment.";*

1.2.4 Structure of EIAR

This EIAR has been prepared by Arup comprising their team of in-house competent experts and external competent experts on behalf of TII, Galway County Council and Galway City Council. Refer to the List of Contributors for further details on the competent experts. Input has also been provided to the EIAR, where necessary from TII, Galway County Council and Galway City Council.

The EIAR comprises four volumes of which this is the second. The four are as follows:

- Volume 1 – Non-Technical Summary
- Volume 2 – Environmental Impact Assessment Report (Main Text)
- Volume 3 – Figures
- Volume 4 – Appendices

The main text of the EIAR has been further divided into the following chapters:

- Chapter 1 – *Introduction*
- Chapter 2 – *Planning and Policy Context*
- Chapter 3 – *Need for the Proposed Road Development*
- Chapter 4 – *Alternatives Considered*
- Chapter 5 – *Description of the Proposed Road Development*
- Chapter 6 – *Traffic Assessment and Route Cross-Section*
- Chapter 7 – *Construction Activities*
- Chapter 8 – *Biodiversity*
- Chapter 9 – *Soils and Geology*
- Chapter 10 – *Hydrogeology*
- Chapter 11 – *Hydrology*
- Chapter 12 – *Landscape and Visual*
- Chapter 13 – *Archaeology, Architectural and Cultural Heritage*
- Chapter 14 – *Material Assets Agriculture*
- Chapter 15 – *Material Assets Non-Agriculture*
- Chapter 16 – *Air Quality and Climate*
- Chapter 17 – *Noise and Vibration*
- Chapter 18 – *Human Beings, Population and Human Health*
- Chapter 19 – Major Accidents, *Inter-relationships, Interactions and Cumulative Impacts*
- Chapter 20 – *Summary of Residual Impacts and Mitigation Measures*
- Chapter 21 – *Schedule of Environmental Commitments*

The format which has been used in this EIAR is the grouped format, in which each topic is addressed in a separate section. This is designed to allow readers to access the issues of interest to them as easily as possible. However, there is an overlap of some topics. For example, effects on human beings are addressed in a number of chapters including **Chapter 12, Landscape & Visual**, **Chapter 15, Material Assets Non-Agriculture, Chapter 16, Air Quality and Climate,** and **Chapter 17, Noise and Vibration**, as well as **Chapter 18, Human Beings, Population and Human Health**. Effects on land are addressed in a number of chapters including: **Chapter 14, Material Assets Agriculture, Chapter 15, Material Assets Non-Agriculture, Chapter 12, Landscape & Visual**, as well as **Chapter 18, Human Beings, Population and Human Health**. It should be noted that the term effects and impacts are used interchangeably in this EIAR to mean the same thing.

Significant effects on environmental topics arising from the vulnerability of the proposed road development to risks of major accidents and/or disasters are addressed in **Chapter 19, Major Accidents, Inter-Relationships, Interactions and Cumulative Impacts**.

Issues not directly addressed in individual chapters and interactions between environmental issues will be described in **Chapter 19, Major Accidents, Inter-Relationships, Interactions and Cumulative Impacts**. Alternatives considered and a description of the proposed road development are presented in **Chapters 4,** and **5** respectively.

As noted in **Section 1.1**, the N6 GCRR forms part of, and is identified as a project within the 'Galway Transport Strategy' (GTS). However, the implementation of the proposed road development is not reliant on the delivery of other components of the GTS. It is a stand-alone development. Therefore, the EIA process for the proposed road development is a stand-alone process. However, the implementation of some objectives of the GTS are reliant on the delivery of the proposed road development. Therefore, where relevant the cumulative impacts of other proposals within the GTS have been included in this EIAR.

In addition, a Natura Impact Statement has been submitted with the application to An Bord Pleanála for approval so as to inform the Appropriate Assessment (AA) process and to assist An Bord Pleanála in carrying out the AA required pursuant to the Planning and Development Act, 2000 (as amended) and the Habitats Directive.

1.2.5 Details of Competent Experts

This EIAR has been compiled by Arup on behalf of GCC with assessment and reporting provided by competent experts for each individual topic. The main author and details of the expertise of each competent expert are provided below in **Table 1.3**.

Table 1.3: Details of Competent Experts

Topic	Main Author – Competency Details
Chapter 1 **Introduction**	**Eileen McCarthy BE (Hons) MIEI CEng, MICE CEng, PE (USA), Arup** **Eileen McCarthy** is an Associate Director with Arup. She holds an honours degree in Civil Engineering from University College Cork and is a Chartered member of the Institute of Civil Engineers in London, a Chartered Member of Engineers Ireland and a licensed professional engineer in USA. Eileen has 30 years' relevant experience and in particular, managed the planning and design for various road schemes including M7 Osberstown Interchange and R407 Sallins Bypass Scheme, M20 Cork – Limerick Motorway Scheme, M7/N24 Ballysimon Road Improvement Scheme, N22 Baile Bhuirne to Macroom Scheme and the Naas Southern Ring Road in Kildare. She has been directly responsible for the project management of the N6 Galway City Ring Road since commencement of work on this application to An Bórd Pleanála in December 2013 and has been assisted as required by members of the design team in compiling this EIAR. Eileen McCarthy supervised the preparation of Chapter 1 of the EIAR.
Chapter 2 **Planning and Policy Context**	**Pauline Byrne MRUP BSc, Brady Shipman Martin – Planning** **Pauline Byrne** is a Regional and Urban Planner with over 18 years' experience in planning in Ireland and internationally. Pauline has a Masters in Regional and Urban Planning (MRUP) from University College Dublin, and a B.Sc. (Mgmt.) from Trinity College Dublin. Pauline is a Partner at Brady Shipman Martin and is head of the Planning Team in the Practice. Pauline has worked on urban planning strategies, planning policy, major city development initiatives, large scale infrastructure projects, public transport initiatives, industrial development initiatives, and arbitration cases, on behalf of Government departments and agencies, Local Authorities, State bodies and State companies, including NTA, OPW, ESB, Bord Na Mona, and the private sector. Pauline has previously inputted to environmental impact assessments in relation to Strategic Planning Policy Context on bus network planning in Dublin for the NTA. Pauline Byrne prepared Chapter 2 of the EIAR with assistance from Eileen McCarthy Arup.
Chapter 3 **Need for the Proposed Road Development**	**Eileen McCarthy BE (Hons) MIEI CEng, MICE CEng, PE (USA), Arup** See above Eileen McCarthy supervised the preparation of Chapter 3 of the EIAR.
Chapter 4 **Alternatives Considered**	**Eileen McCarthy BE (Hons) MIEI CEng, MICE CEng, PE (USA), Arup** See above Eileen McCarthy supervised the preparation of Chapter 4 of the EIAR.

Topic	Main Author – Competency Details
Chapter 5 **Description of Proposed Road Development**	**Eileen McCarthy BE (Hons) MIEI CEng, MICE CEng, PE (USA), Arup** See above Eileen McCarthy supervised the preparation of Chapter 5 of the EIAR.
Chapter 6 **Traffic Assessment and Route Cross Section**	**Andrew Archer, Systra - Traffic** **Andrew Archer** is a Chartered Engineer and Project Director for Systra's operation in Ireland, with over 16 years of diverse and challenging experience in a wide range of transportation planning, policy and engineering projects. Through his work in Europe and the Middle East, Andrew has played a major role in strategic planning and innovative design on a number of key public and private sector transportation projects including land use and transportation studies, development masterplans, transport framework plans, highway scheme appraisal, and conceptual designs of transport infrastructure schemes. Andrew's particular expertise lies in working with clients and stakeholders in a collaborative manner to develop practical and implementable strategies for large scale towns, urban regeneration projects or individual developments. Andrew has also managed and delivered a range of multi-modal transport studies across Ireland, including integrated land use and transportation framework plans, local area plans, traffic management strategies, road safety designs, school traffic management strategies and parking management schemes. **David Conlon, Systra - Traffic** **David Conlon** is an experienced Principal Transport Planning Consultant with 10 years' experience. David joined SYSTRA on the Graduate Development Programme after a short period working with ILTP Consultants. David has a specialist knowledge in the preparation of transport models at a strategic and local level as well as project appraisal. With SYSTRA David has experience of a number of challenging model development projects and was project manager for the development of the National Transport Authority's South East Regional Model (SERM). As Project Manager, David was responsible for the delivery of all aspects of the project including scoping, resourcing, overseeing the technical aspects of the model development, reviewing and issuing reports. David has also performed economic assessments of modelled options using TUBA and has a working knowledge of a wide variety of transportation software that includes SATURN, VISSIM, Paramics, OmniTrans and ArcGIS. Andrew Archer prepared Chapter 6 of the EIAR with assistance from David Conlon.
Chapter 7 **Construction Activities**	**Eileen McCarthy BE (Hons) MIEI CEng, MICE CEng, PE (USA), Arup- General Construction Activities** See above **Janet Lynch BEng, MCTWM, MIEI CEng, Arup - Waste** **Janet Lynch** is a Senior Project Engineer with Arup with over 17 years' experience in Industrial Emissions licensing, EIA and planning including, Resource and Waste Management: Construction and operational waste management plans, Energy from Waste, waste re-use,

Topic	Main Author – Competency Details
	recycling and landfill, Innovative waste treatment technologies; Planning and EIA project management (energy, renewables, industrial, infrastructure); Industrial Emissions (IE) License applications & review (waste, biomass, oil and gas, energy, cement, pharmaceutical); Circular Economy; Water: Tender Assessments for Irish Water and Dublin City Council; Assistant Project Manager for the expansion of Irelands largest water treatment plant at Ballymore Eustace, Co. Kildare in 2006. Janet holds an honours degree in Civil and Environmental Engineering from University College Cork, a FETAC Certificate in Waste Facility Management and a Certificate in Applied Project Management from the IEI and University Limerick. She is a Chartered member of the Chartered Institution of Wastes Management (MCTWM) and a Chartered Member of Engineers Ireland. Janet Lynch prepared the waste section of Chapter 7 of the EIAR. Eileen McCarthy supervised the overall preparation of Chapter 7 of the EIAR.
Chapter 8 Biodiversity	**Aebhín Cawley CEnv MCIEEM, Scott Cawley - Biodiversity** **Aebhín Cawley** is a director of Scott Cawley Ltd. She holds a degree in Zoology from the University of Dublin (Trinity College) and also holds a postgraduate diploma in Physical Planning from the same university. She is a Chartered Environmentalist (CEnv) with the Society for the Environment (Soc Env) and a full member of the Chartered Institute of Ecology and Environmental Management (CIEEM). Aebhín has sixteen years' professional experience, twelve of which have been in ecological surveying and impact assessment for public and private sector projects including road, rail and other major infrastructural projects. Aebhín has been undertaking Appropriate Assessment (AA) work in Ireland since 2002 and has been influential in determining the direction in which AA work is evolving in Ireland. She has delivered lectures and training on AA to a range of public and private sector organisations, including a range of planning authorities, as well as professional institutes. Aebhín regularly prepares AA Screening Statements as well as Natura Impact Statements (NIS) for AA and as such has current experience in best practise in undertaking Appropriate Assessments. Aebhín was the project director for the Biodiversity chapter of the EIAR and the NIS with overall responsibility for the delivery of those reports as well as for high-level input to the survey methodologies, assessment of impacts and development of the mitigation strategy. Aebhín also undertook specific elements of the field survey work. **Andrew Speer MCIEEM, Scott Cawley - Biodiversity** **Andrew Speer** is a principal ecologist at Scott Cawley and specialises in road projects. He holds an honours degree in Zoology from the National University of Ireland, Galway and a post-graduate diploma in Geographic Information Systems (GIS). He is a full member of the Chartered Institute of Ecology and Environmental Management (CIEEM). Andrew has over 11 years' experience as an ecological consultant with experience in Environmental Impact Assessment, GIS and mitigation design for development projects including national road schemes, wind energy projects, light rail, flood relief schemes, infrastructure projects and smaller scale commercial and residential developments. He has comprehensive experience in the preparation of AA Screening Reports and NISs for a range of projects and development plans. Andrew has undertaken and managed a wide range of field surveys including protected species surveys (e.g. badger, otter, newts, bats, wintering birds, breeding birds and aquatic species), habitat surveys and water quality monitoring. He is also an experienced ecological clerk of works for projects such as national road schemes, pipeline works and electricity supply schemes. Andrew has extensive GIS experience on both the

Topic	Main Author – Competency Details
	ArcGIS and Autodesk Map 3D platforms. Andrew was lead ecologist for the Biodiversity chapter of the EIAR and the NIS. He undertook and managed field and desk surveys, carried out the impact assessments and devised the mitigation strategy for flora and fauna on the project. **Paul Scott, Scott Cawley CEcol, CEnv, MIEEM - Biodiversity** **Paul Scott** is Director with Scott Cawley. He holds a first class honours degree in Environmental Biology from the University of Liverpool and a Masters in Pollution and Environmental Control from the University of Manchester. Paul is a Chartered Ecologist (CEcol), a Chartered Environmentalist (CEnv) and a full member of the Chartered Institute of Ecology and Environmental Management (CIEEM). He is on the Council of Bat Conservation Ireland, leads the Dublin Bat Group and All Ireland Nathusius Pipistrelle Working Group and is a licenced and trained bat handler with experience of hand-netting, harp trapping and mist netting of bats in Ireland and the UK. Paul is experienced in the assessment of impacts of major infrastructural developments on all Irish bat species. Paul has prepared ecological guidance notes designed for planners and developers on behalf of the four Dublin local authorities, including advice on compliance with legal protection for bats. Paul undertook specific elements of the field survey work (including bats) and prepared the text relating to bats in the EIAR. Andrew Speer was responsible for the preparation of Chapter 8 of the EIAR under the supervision of Aebhín Cawley with the exception of bats which was prepared by Paul Scott.
Chapter 9 **Soils and Geology**	**Juli Crowley BE MSc Eng MIEI CEng, Arup – Soils and Geology** **Juli Crowley** is a Senior Geotechnical Engineer with Arup with over 12 years of engineering experience. She holds a Structural Engineering Degree from Cork Institute of Technology, a Masters in Geotechnical Engineering from Newcastle University and is a Chartered Engineer with Engineers Ireland since 2011. Juli has worked on a broad range of infrastructure, commercial, private and oil and gas projects at pre-tender stage, detailed design stage and post construction stage and has extensive geotechnical design and construction experience. Juli has prepared the soils and geology impact assessments for projects including the M20 Cork to Limerick Motorway. Juli Crowley prepared Chapter 9 of the EIAR.
Chapter 10 **Hydrogeology**	**Dr. Leslie Brown PhD MSc BSc, Arup - Hydrogeology** **Dr. Leslie Brown** is a senior hydrogeologist with 21-years groundwater expertise in Ireland, the United Kingdom and Middle East. As an academic Dr. Brown’s doctoral studies include delineating extents of groundwater bodies in karst aquifers, mapping surface and subsurface paleokarst features, quantifying karst flow pathways and limestone geology. He has undertaken post-doctoral research into quantifying recharge mechanisms and identification of hydrogeological pathways for catchment studies. As a consultant Leslie has worked with both the public and private sectors advising on hydrogeological matters for road developments, groundwater supply, turlough hydrogeology, determining zones of contribution to groundwater dependant terrestrial ecosystems and aquifer management. He has specialised on the hydrogeology of linear infrastructure since 2000 and is a co-author for the NRA (2009) Guidelines on Procedures for Assessment and treatment of Geology, Hydrology and Hydrogeology for National Road Schemes.

Topic	Main Author – Competency Details
	Dr. Alison Orr PhD MSc BSc, Arup - Hydrogeology **Dr. Alison Orr** is a hydrogeologist with 3 years' experience working in consultancy on projects in both Ireland and the UK. She has worked on road and metro developments, flood relief schemes, contaminated land, groundwater supply, ground source heating systems and determining zones of contribution for group water schemes. Prior to her consultancy work she completed a PhD into the fate and transport of nitrate in different hydrogeological settings across the island of Ireland. Dr Brown prepared Chapter 10 of the EIAR with the assistance of Dr. Orr.
Chapter 11 Hydrology	**Tony Cawley BE M Eng Sc CEng MIEI, Hydro Ltd – Hydrology** **Anthony Cawley** qualified with an honours degree in Civil Engineering from NUI Galway in 1987 and a post graduate master's degree in Engineering Hydrology from NUI Galway in 1990. He is a Chartered Civil Engineer with specialist education and 28 years professional consulting experience in the water engineering field in a wide variety of activities relating to hydrology, hydrogeology and flooding, and hydrodynamic and hydraulic assessment of fluvial and tidal processes. Over that period he has been involved in well over 200 flooding and coastal modelling assessments. Tony has carried out in excess of 100 flood risk assessment studies on rivers, estuaries and coastal areas throughout Ireland. These studies ranged from scoping type assessments to detailed flood risk assessments involving hydrometric measurements river channel survey, hydraulic modelling and flood inundation mapping. Tony has successfully completed and defended at the oral hearing giving expert witness on the hydrology, hydrogeology, geology and soils components of the EIA assessment for numerous road schemes and infrastructure projects over the past 15 years including the M6, M20/M21, N23 and Lansdowne Stadium Redevelopment. He has also been retained as an expert consultant to An Bord Pleanála for the Dublin Docks Gateway and Alexandra Basin projects in respect to flooding and hydrodynamic processes and is experienced in the requirements of SEA and AA. Tony has been a Hydrology Expert on behalf of ESB involved in Court proceedings in respect to the River Lee Flooding of Cork City in November 2009 UCC v's ESB. He was a lecturer in hydrology and hydraulics at the Hydrology and Civil Engineering Department at NUI Galway and currently lectures in Hydrology at the University of Limerick (2011 to date). Tony has provided training courses in Hydrology to the Western and Northwestern Fisheries Board and to Engineers Ireland, and Irish Rail and NRDO Design Offices. Tony Cawley prepared Chapter 11 of the EIAR.
Chapter 12 Landscape and Visual	**Thomas Burns B Agr. Sc. Dip. EIA Mgmt MILI EFLA. Brady Shipman Martin – Landscape and Visual** **Thomas Burns** is a Partner and landscape planner with Brady Shipman Martin. Thomas joined Brady Shipman Martin as a Landscape Architect after graduating from University College Dublin, in 1989. Thomas completed a post-graduate Diploma in Environmental Impact Assessment Management also in University College Dublin, in 1994 and was appointed an Associate of the Practice in 1997. Thomas became a Partner in 2002.

Topic	Main Author – Competency Details
	Thomas has a strong background in environmental, landscape and planning issues across a wide range of disciplines, including assessment and master-planning. For over 20 years, Thomas has been involved in the masterplanning, planning, environmental assessment and construction of a diverse range of projects, and as part of his involvement, has regularly given expert evidence at planning hearings and other public inquiries. Thomas has been directly involved in the environmental and landscape and visual assessments of many key national infrastructure projects, including over 750km of the national roads programme including the M20 Cork to Limerick Motorway Scheme, the M7 Osberstown Interchange and R407 Sallins Bypass, the Shannon LNG Facility, the Corrib Gas Terminal, T2 Terminal at Dublin Airport and the Dublin DART Underground project. Given his experience on National Roads, Thomas was commissioned by the TII to raft Guidelines for Landscape Treatments on National Roads in Ireland. He has also brought his environmental and landscape planning experience to projects such as the Strategic Environmental Assessment aspect of various statutory plans and programmes, including County Meath Development Plan 2013-2019; the Department of Environment IOSEA 5 and as well being part of the wider project team that carried out the Environmental Assessment of Food Harvest 2020. Thomas is an active member of the Irish Landscape Institute (ILI), where he was Chairperson of the Professional Practice Committee since its inception in 1995 until 2011. Thomas also previously served as the ILI Representative on the Council of the European Foundation of Landscape Architecture (EFLA) from 1997 to 2000. Thomas Burns prepared Chapter 12 of the EIAR.
Chapter 13 Archaeology, Architectural and Cultural Heritage	**Faith Bailey MA BA MCIfA, IAC Archaeology – Archaeology, Architectural and Cultural Heritage** **Faith Bailey** is a Senior Archaeologist and Cultural Heritage Consultant with IAC Ltd. She holds an MA in Cultural Landscape Management (archaeology and built heritage) and a BA in single honours archaeology from the University of Wales, Lampeter. Faith is a licence eligible archaeologist, a member of the CIfA and has over 13 years' experience in the sector. Faith has been responsible for the production and delivery of a large number of archaeological and built heritage desk top assessments, surveys, EIA, master plans, LAP/SEA and management plans associated with all sectors of development in the Republic and Northern Ireland. Archaeological and Architectural EIA for large scale road schemes, include the M7 Osberstown Interchange and R407 Sallins Bypass Scheme, the M11 Enniscorthy Bypass in County Wexford and the N22 Ballyvourney-Macroom Bypass in County Cork. Faith's in-depth knowledge of the planning systems and heritage legislation within both the Republic of Ireland and Northern Ireland, twinned with the excellent working relationship with clients and statutory authorities makes her one of the most experienced archaeological and cultural heritage consultants currently operating within the sector. Faith Bailey prepared Chapter 13 of the EIAR.

Topic	Main Author – Competency Details
Chapter 14 Material Assets Agriculture	**Con Curtin, Curtin Agricultural Consultants Ltd – Material Assets Agriculture** **Con Curtin** is an agricultural consultant with an undergraduate honours degree in Agricultural Science from University College Dublin (1987), a Level 6 Certificate in Agricultural Land Drainage (awarded by Teagasc in 2016) and has 30 years' experience working in the agricultural consultancy sector. He has worked for three years with ADAS (Agricultural Development and Advisory Service) in the UK as an agricultural advisor, and since 1990 as an agricultural consultant in Ireland. In 1996 he established his own company, Curtin Agricultural Advisers Ltd. Con divides his time between general consultancy work for his farmer clients (dairy, pigs, beef, sheep and equine) and Land Use / Agricultural Environmental Impact Reports for consulting engineers. Con has prepared Land Use / Agricultural Impact Reports for linear developments such as railway schemes, electricity overhead lines and major roads schemes (15 No. since 1998) including; M20 Cork to Limerick Motorway Scheme (80km); N22 Baile Bhuirne to Macroom (25km); M7 Castletown to Nenagh (40km); N25 New Ross Bypass (13.5km); N25 Waterford Bypass (40km); and N6 Galway City Outer Bypass (21km – 2006 planning application). He has prepared constraints and route selection reports and presented oral evidence at public hearings for most of these road projects. He has prepared the Land Use Impact Report for the North - South 400kV Interconnection Development (140km) in Counties Meath, Cavan, Monaghan, Armagh and Tyrone. Con has carried out land damage assessments for Bord Gais along gas pipelines in Northern Ireland and the Republic of Ireland and advises on drainage issues. **Michael Sadlier, EVC - Equine** **Michael Sadlier** graduated as a veterinary surgeon from University College Dublin in 1983. Since then, he has worked in veterinary practice around the world, specialising in equine medicine and surgery. He has also achieved numerous post graduate qualifications – a certificate in Equine Stud Medicine from the Royal College of Veterinary Surgeons in 1989, membership by examination of the Australian College of Veterinary Scientists in Equine Surgery in 1992 and achieved a Certificate in Equine Surgery from the Royal College of Veterinary Surgeon in Equine Orthopaedic in 1995. He is currently a Partner in a Six Partner Multi-Site Veterinary Hospital on the Curragh, Co. Kildare that employs another 13 veterinary surgeons and 22 support staff. The practice provides a referral facility for the whole of Ireland and is a world recognised centre of excellence. He is currently an elected member of the Veterinary Council of Ireland, which is the statutory regulatory body for the profession in Ireland. He has been the Irish representative on the National Council of the British Equine Veterinary Association for the past 8 years. Michael was a Past Chairman of the Equine Committee of Veterinary Ireland, the representative body for the profession in Ireland. He also has served on the Board of Directors of Veterinary Ireland and on the Board of Governors of the Irish Equine Centre. He is a regular speaker at veterinary meetings, nationally and internationally. Michael Sadlier has provided expert equine veterinary opinion to TII on the potential effects the following road schemes (M8, M17, N4, N11, N18, N22 N30, N60 and N61) would have on selected equine properties. He has also provided expert equine veterinary opinion to Iarnrod Eireann on the proposed Navan to Dunboyne Rail development, Bord Gais on Baunlusk to Great Island Gas Pipeline and Eirgrid on the North-South Interconnector and Cork-Kildare 400kV Line and the potential impacts these schemes would have had on numerous equine properties on

Topic	Main Author – Competency Details
	the proposed routes. He has also assessed the effects the proposed incinerator at College Proteins in Nobber, Co. Meath would have on surrounding equine holdings. Con Curtin prepared Chapter 14 of the EIAR with assistance from Michael Sadlier.
Chapter 15 Material Assets Non Agriculture	**Eileen McCarthy BE (Hons) MIEI CEng, MICE CEng, PE (USA), Arup – private dwellings** See above **Dr. Craig Bullock**, **Optimize Consultant – Commercial Properties** **Dr. Craig Bullock** has a PhD in Environmental and Resource Economics (UCD, 2004) and a Diploma in Environmental Impact Assessment (UCD, 2001). He has written over 40 peer-reviewed papers in environmental policy/economics and socio-economics. Craig has over 17 years' experience working in the field of environmental impact assessment (Human Beings and Social/Socio-Economic assessment) and over 20 years in the fields of environmental policy analysis, environmental economics and socio-economics. He manages his own consultancy www.optimize.ie which was registered in 1999 and has also been a part-time research fellow in University College Dublin since 2001. During this time Craig has worked on over 30 environmental impact assessments of road projects, public transport, flood mitigation, waste water treatment, peat extraction, residential and hotel development. This experience has included large scale projects such as the DART Underground development, Swords-City Centre Bus Rapid Transit and the M20 motorway scheme. He has acted as specialist witness for many of these projects. **Gareth Maguire BSc. MRIAI, RIBA, BDP – University Masterplanner** **Gareth Maguire** is an Architect Director with BDP in Dublin. BDP are a large multi-disciplinary practice with over 700 professionals across the globe. BDP are working in third level campuses across Ireland on various major development projects. He leads the BDP Architects group in Ireland. Gareth has over 25 years' experience of working as an Architect and Master planner across Ireland and the UK. Gareth holds a first class honours degree in Architecture from Queens University Belfast, a Post graduate diploma in project management from Trinity College Dublin and a masters in Architecture from Glasgow School Art, University of Glasgow. He is a Chartered Member of the Royal Institute of Architects in Ireland (MRIAI) and a member of the Royal Institute of British Architects (RIBA), Gareth is an architect and urbanist who specialises in campus masterplanning. He has completed a number of major campus master plans recently for Maynooth University, Limerick Institute of Technology and also Haulbowline Island along with the Irish Maritime Cluster in Ringaskiddy, Cork. In the past he has also been involved with the University of Limerick campus 2020 Masterplan proposals for the expansion of their campus across the River Shannon into County Clare. This is now one of the largest university sports campus' in Ireland.

Topic	Main Author – Competency Details
	He also sits with Maynooth University and LIT's Capital Development Advisory Committees advising on the appropriate development and integration of numerous live projects within their campuses. He is currently designing a major new sports campus for Maynooth University as part of their immediate future campus expansion programme. His various projects currently include a major masterplan and public realm upgrade for the upgrading of Clanbrassil Street in Dundalk, Haulbowline Island Visioning Masterplan and proposals for Waterford Institute of Technology's Carriganore Sports and Technology Campus. **Michael Saddlier – Equine** See above Eileen McCarthy supervised the preparation of Chapter 15 of the EIAR with assistance of Dr. Craig Bullock for the assessment of commercial properties, Gareth Maguire in relation to NUIG Sporting Campus and Michael Saddlier for Galway Racecourse.
Chapter 16 **Air Quality and Climate**	**Sinead Whyte MSc CMIWEM, Arup – Air Quality and Climate** **Sinead Whyte** has over 18 years' experience as an Environmental Consultant. She holds a MSc in Experimental Physics and is Chartered for over 10 years with the Institute of Water and Environmental Management. She has prepared numerous Air Quality and Climate Impact Assessments for infrastructural developments including DART Underground, M20 Cork to Limerick Motorway, M7 Osberstown Interchange and R407 Sallins Bypass and N9/N10 Kilcullen to Powerstown. Sinead presented expert witness evidence at the An Bord Pleanála oral hearings into these developments. Sinead Whyte prepared Chapter 16 of the EIAR.
Chapter 17 **Noise and Vibration**	**Jennifer Harmon BSc- AWN Consulting Limited – Noise and Vibration** **Jennifer Harmon** is Senior Acoustic Consultant at AWN Consulting. She has worked as a consultant since 2000, specialising in acoustics since 2001. She holds a BSc in Environmental Science, a Diploma in Acoustics and Noise Control and is a full member of the Institute of Acoustics (IOA). Jennifer has extensive experience in the field of environmental noise and vibration impact assessment, noise control engineering, building and room acoustics. Jennifer has prepared noise and vibration impact assessments for a wide range of transport projects across Ireland including new road schemes, road realignment and upgrade projects, light and heavy rail projects and landside air-noise. Her experience in road traffic noise impact assessment includes extensive baseline studies, detailed transport noise models, noise mitigation design and construction impact assessments. Jennifer Harmon prepared Chapter 17 of the EIAR.

Topic	Main Author – Competency Details
Chapter 18 Human Beings, Population and Human Health	**Dr. Craig Bullock, Optimize Consultant - Socio-Economic Assessment** See above **Health assessment** **Dr. Martin Hogan, EHA Occupation Health Hygiene Consultants – Health** **Dr. Martin Hogan** is a medical doctor, registered with the Irish Medical Council as a Specialist in Occupational Medicine since 1997. He has 20 years' experience in assessing Human Health impacts of proposed developments and has contributed to many Environmental Impact Statements. He has given evidence in over 20 Oral Hearings including transport infrastructure such as road, rail and airport development, as well as waste management including landfills and incinerators. His specialist interests include Occupational Medicine in the Pharmaceutical and Chemical industry and Environmental Medicine. He lectures in Toxicology in University College Cork. He is a past National Speciality Director of Occupational Medicine in Ireland and a past Dean of the Faculty of Occupational Medicine of the Royal College of Physicians of Ireland. He is the President of the Organising Committee for ICOH 2018 and a member of the Board of ICOH (International Commission on Occupational Health). **John Cronin BA, John Cronin & Associates – Irish Language** **John Cronin** is a cultural heritage and conservation consultant with 24 years' postgraduate experience garnered in the public and private sectors. He holds a B.A. in Archaeology and Geography from University College Cork and was awarded postgraduate degrees in planning and conservation from University College Dublin. Since entering private practice in 2000, Mr. Cronin has specialised in assessing the impact of development on cultural heritage resources and has acted as consultant to The Heritage Council, the National Inventory of Architectural Heritage and Fáilte Ireland. Mr. Cronin has prepared cultural heritage assessments for environmental impact assessments throughout Ireland (both within Northern Ireland and the Republic of Ireland). Since 2006, John Cronin & Associates have prepared language impact assessments for numerous development projects within Gaeltacht areas. Noteworthy assessments have included: • N59 Maigh Cuilinn (Moycullen) Bypass Road Development, County Galway • N6 Galway City Outer Bypass 2006, County Galway • Housing Development, Ballynabooly, Dingle, County Kerry • Tourism Development, Cloghan Lodge, Ballybofey, County Donegal • Residential development, Rathkieran, The Glen, Ballinskelligs, County Kerry Dr. Craig Bullock and Dr. Martin Hogan with assistance from John Cronin on the Irish Language both prepared Chapter 18 of the EIAR.

Topic	Main Author – Competency Details
Chapter 19 Major Accidents, Inter-relationships, Interactions and Cumulative Impacts	**Eileen McCarthy BE (Hons) MIEI CEng, MICE CEng, PE (USA), Arup** See above Eileen McCarthy supervised the preparation of Chapter 19 of the EIAR.
Chapter 20 Summary of Mitigation Measures and Residual Impacts	**Eileen McCarthy BE (Hons) MIEI CEng, MICE CEng, PE (USA), Arup** See above Eileen McCarthy supervised the preparation of Chapter 20 of the EIAR.
Chapter 21 Schedule of Environmental Commitments	**Eileen McCarthy BE (Hons) MIEI CEng, MICE CEng, PE (USA), Arup** See above Eileen McCarthy supervised the preparation of Chapter 21 of the EIAR.

1.2.6 EIAR Scoping

"Scoping" is a process of deciding what information should be contained in an EIAR (EIS) and what methods should be used to gather and assess that information[8]. Informal EIAR (EIS) scoping of N6 Galway City Ring Road (GCRR) was carried out in order to determine the content and extent of the matters which should be covered in the environmental information to be included in the EIAR. As part of the EIAR scoping process, a scoping report was issued to all relevant statutory and non-statutory consultees. These consultees are included in **Section 1.4** of this report. Comments received during this consultation phase were reviewed and considered in the preparation of this document.

1.2.7 EPA Guidelines and other guidelines

This EIAR has been prepared with due regard to the guidelines on the preparation of environmental impact assessment reports published by the EPA. These are contained in:

- Guidelines on the information to be contained in Environmental Impact Statements, 2002, EPA
- Advice Notes on Current Practice (in preparation of Environmental Impact Statements), 2003, EPA

Moreover, the EIAR has been prepared having had due regard to:

- Draft Guidelines of the information to be contained in Environmental Impact Assessment Reports, 2017, EPA
- Revised Guidelines on the Information to be Contained in Environmental Impact Statements (Environmental Protection Agency, draft September 2015)
- Advice Notes for Preparing Environmental Impact Statements Draft September 2015
- European Union (2013) Guidance on Integrating Climate Change and Biodiversity into Environmental Impact Assessment
- European Commission (2017) Guidance on the preparation of the Environmental Impact Assessment Report (Directive 2011/92/EU as amended by 2014/52/EU
- European Commission (2012) Interpretation suggested by the Commission as regards the application of the EIA Directive to ancillary/associated works
- European Commission (2006) Clarification of the application of Article 2(3) of the EIA Directive
- European Commission (1999) Guidelines for the Assessment of Indirect and Cumulative Impacts as well as Impact Interactions
- Transport Infrastructure Ireland (formerly National Roads Authority) (2008) Environmental Impact Assessment of National Road Schemes – A Practical Guide

[8] EPA 2015 Revised Guidelines on the information to be contained in EISs, Draft Sept 2015.

1.3 Background

This section provides some background to the proposed road development. **Section 1.3.1** gives an overview of the N6 Galway City Outer Bypass which was an earlier project for a bypass of Galway City that went through the planning process in 2006. **Section 1.3.2** outlines the development of the transport solution to address the very serious traffic issues facing Galway City and the Galway Transport Strategy (GTS).

1.3.1 N6 Galway City Outer Bypass

The N6 Galway City Outer Bypass, an earlier scheme, was previously developed and submitted to An Bord Pleanála (ABP) for approval on 1 December 2006. A brief summary of its history is outlined below.

Consultants were appointed in 1999 to undertake feasibility studies, route selection, design and planning for the N6 Galway City Outer Bypass. The resultant scheme including the Compulsory Purchase Order (CPO) and Environmental Impact Statement (EIS) was submitted to An Bord Pleanála (ABP) on 1 December 2006. This scheme consisted of 21.4km of mainline, 9km of link roads, associated junctions and a major bridge crossing of the River Corrib. This scheme is referenced as the N6 Galway City Outer Bypass (2006) together with the acronym of 2006 GCOB throughout this report.

On 28 November 2008, ABP delivered its decision in respect of the 2006 GCOB. ABP considered that the need for an outer bypass of Galway City connecting the existing N6 on the east to the R336 Coast Road on the west as an essential part of the strategic transport network of the Galway area had been established.

ABP granted approval for the eastern part of the scheme, the section from the N59 Moycullen Road east to the existing N6, inclusive of both junctions at the N59 Moycullen Road and the existing N6. In its decision, ABP noted its consideration of all data presented and granted approval as it considered that the part of the road development being approved would be an appropriate solution to the identified traffic needs of the city and surrounding area. ABP noted that there would be a localised severe impact on the Lough Corrib candidate Special Area of Conservation (cSAC) [9].

However, given that a section of the proposed road development would cut through Tonabrocky Bog which is:

- part of the Moycullen Bogs Natural Heritage Area (NHA)
- an active Blanket bog listed as a priority habitat in Annex I of the EU Habitats Directive
- the site of a population of Slender cotton grass which is a legally protected and vulnerable species

ABP was not satisfied that this part of the proposed road development, between the N59 Moycullen Road and R336 Coast Road, would not be prejudicial to the preservation of the Tonabrocky bog habitat or that the significant adverse effects

[9] Reference ABP decision 07.ER.2056

on the environment would not be avoidable or could not be better addressed by an alternative route[10], and that therefore ABP considers that this part of the proposed road development would be contrary to the proposed planning of sustainable development of the area.

An application was made by a third party to the High Court seeking leave to issue judicial review proceedings against the ABP decision which granted approval of the eastern section of the 2006 GCOB under Article 6(3) of the Habitats Directive (92/43/EEC), as amended. The basis for the request for a review was that ABP had erred in its interpretation of Article 6 of the Habitats Directive (92/43/EEC), as amended, in arriving at the conclusion that the effect of the 2006 GCOB road scheme on the Lough Corrib cSAC designated site would not constitute an adverse effect on the integrity of the site.

The High Court undertook a judicial review of the ABP decision. The High Court decision of 9 October 2009 upheld ABPs decision to approve the eastern part of the scheme. On 6 November 2009, the third party was granted leave to appeal to the Supreme Court against the High Court decision of 9 October 2009. The Supreme Court sought the opinion of the Court of Justice of the European Union (CJEU) on an interpretation of the Habitats Directive.

The opinion of the CJEU was delivered on the 11 April 2013 (Case C-258/11). The opinion concluded on two significant points:

1. The 2006 GCOB would have an adverse effect on the integrity of the Lough Corrib cSAC due to the removal of 1.47ha of Limestone pavement (a habitat type for which the cSAC was selected)
2. Given that the 2006 GCOB would have an adverse effect on the integrity of the cSAC, the proposed scheme could not be authorised under Article 6(3) of the Habitats Directive. It could only be authorised under Article 6(4) of the Habitats Directive

The CJEU opinion (i.e. Case C-258/11) established that the loss of a relatively small area of Priority Annex I habitat, where it is a habitat for which the Lough Corrib cSAC is selected, would adversely affect the integrity of the Lough Corrib cSAC and that the provisions of Article 6(4) must apply in granting consent for the project i.e.

6(4) "If, in spite of a negative assessment of the implications for the site and in the absence of alternative solutions, a plan or project must nevertheless be carried out for imperative reasons of overriding public interest, including those of a social or economic nature, the Member State shall take all compensatory measures necessary to ensure that the overall coherence of Natura 2000 is protected. It shall inform the Commission of the compensatory measures adopted".

Following receipt of the CJEU opinion, the Supreme Court quashed the earlier ABP decision to grant approval of the eastern section of the 2006 GCOB under Article 6(3) of the Habitats Directive, as amended.

As the decision of the Supreme Court was that the original 2006 GCOB scheme could not be granted approval per Article 6(3) of the Habitats Directive, the next recourse to secure planning was to advance the scheme under Article 6(4) of the

Habitats Directive. Noting what ABP in its decision on the 2006 GCOB stated, namely that the need for an outer bypass of Galway City connecting the M6/N6 national primary road at Garraun to the R336 regional coast road, being an essential component of the strategic transport network of the Galway area, had been established and having reviewed the requirements of Article 6(4), it was decided to reassess the work to date to ensure that all possible alternatives were investigated in advance of proceeding under Article 6(4). Therefore, the process of developing a transportation solution for Galway City and its environs had to recommence from the start at Phase 1, feasibility and concept stage, to ensure that all possible alternatives were fully investigated.

Further consideration of the N6 Galway City Outer Bypass (2006) is detailed in **Chapter 4, Alternatives Considered**.

1.3.2 Development of a Transport Solution for Galway

The need for the proposed road development has been considered at both a regional level in terms of its strategic function, and at a local level in terms of providing an integrated transport solution for the city and environs. Therefore, the development of the transport solution has involved a wide selection of stakeholders, all of whom had an integral part in developing the vision but more critically all have an integral part in ultimately delivering the solution also.

Galway County Council, Galway City Council, Transport Infrastructure Ireland[10] (formerly known as National Roads Authority) and the National Transport Authority (NTA) collaborated in developing a transport vision for Galway where all elements of transport are working together to achieve an integrated sustainable solution. This section summarises the development of this transport vision, part of which includes the proposed road development.

The N6 Galway City Transport Project (GCTP) refers to the initial studies undertaken for the transport solution in Galway. The Galway Integrated Transport Management Programme (ITMP) began as the transport strategy developed by Galway City and County Council in partnership with the NTA in parallel to the N6 GCTP and is now referred to as the Galway Transport Strategy (GTS). The GTS has taken into account and seeks to achieve the objectives laid down in Smarter Travel. The N6 Galway City Ring Road is the road component of the transport solution identified in the N6 GCTP and orbital route identified in the GTS and the subject of this EIAR. This confirms that the proposed road development has been designed in accordance with the objectives of Smarter Travel and the above listed policies.

[10] The Minister for Transport, Tourism and Sport signed the order for the merger of the National Roads Authority (NRA) with the Railway Procurement Agency (RPA) to establish a single new entity called Transport Infrastructure Ireland (TII). The National Roads Authority is known as Transport Infrastructure Ireland (TII) since 1 August 2015. All references to guidance documents and standards within this report will retain the *NRA* reference until such time as these documents are updated.

1.3.2.1 N6 Galway City Transport Project

The initial studies for this transport solution were undertaken as part of the N6 Galway City Transport Project (GCTP). The N6 GCTP recognised that Galway has a transport problem and confirmed that there is a strong need to address the transport issues facing the city and surrounding areas at present, and to underpin future growth by establishing a long-term strategy for transport to, within and around the city. The studies undertaken for the N6 GCTP confirmed that a new River Corrib bridge crossing is possible and identified a preferred location for this crossing. The proposed road development which incorporates this river crossing is now referred to as the N6 Galway City Ring Road (GCRR) and is the subject of this EIAR.

Further details on the studies (such as constraints and options development) carried out as part of the N6 GCTP are provided in **Chapter 4, Alternatives Considered** of this EIAR.

1.3.2.2 Galway Transport Strategy

In parallel to the N6 GCTP, Galway City Council and Galway County Council, in partnership with the NTA developed an overall transport strategy for Galway City and its environs culminating as Galway Transport Strategy (GTS) which provides Galway City and its environs with a clear implementation framework for transportation over the next 20 years. The GTS aims to address the current and future transport requirements for the city and its environs, which encompasses the city and its connectivity to surrounding towns and villages, including Bearna, Oranmore, Moycullen and Claregalway.

Consultation with key stakeholders and the public was undertaken throughout to inform the development of the strategy. This strategy was subsequently endorsed by the elected members of both the City and County Council and forms part of the current Galway City Development Plan and Galway County Development Plan.

The GTS included an evaluation of transport options for all modes, and affirmed the strategic need for an orbital route around the city centre and a new crossing of the River Corrib, in order to implement the level of service required for each mode of transport, including walking, cycling, public transport and private vehicle.

In order to achieve a connected city and environs, the GTS seeks to deliver an integrated network of ‘links’ (routes) and ‘nodes’ (stops and interchange locations) along which people can travel seamlessly, changing corridors and modes as necessary to make their journey. Traffic within the city’s central area needs to be managed to make it a more comfortable environment for pedestrians and cyclists, and to ensure that public transport travelling through the city is reliable at all times of the day. This is essential to achieve a travel mode shift in favour of public transport. Key aims of the GTS are therefore to reduce vehicular movement through the city centre, to reduce vehicle speeds in the core city centre area, and to prioritise active modes (walking and cycling) and public transport in the city centre. The strategy therefore provides for routing of traffic which currently passes through the centre (to reach edge-of-centre locations) to more suitable orbital routes around the core city centre area.

The GTS recognised that some journeys across the city are not always convenient by non-car modes and considered it necessary to provide a resilient/reliable cross-city route via an orbital route for travel by road. The GTS requires the additional orbital traffic capacity so as to facilitate the re-allocation of existing road space for use by pedestrians, buses and cyclists, and noted that, unless additional capacity is provided for traffic, the overall objectives for the GTS will not be met.

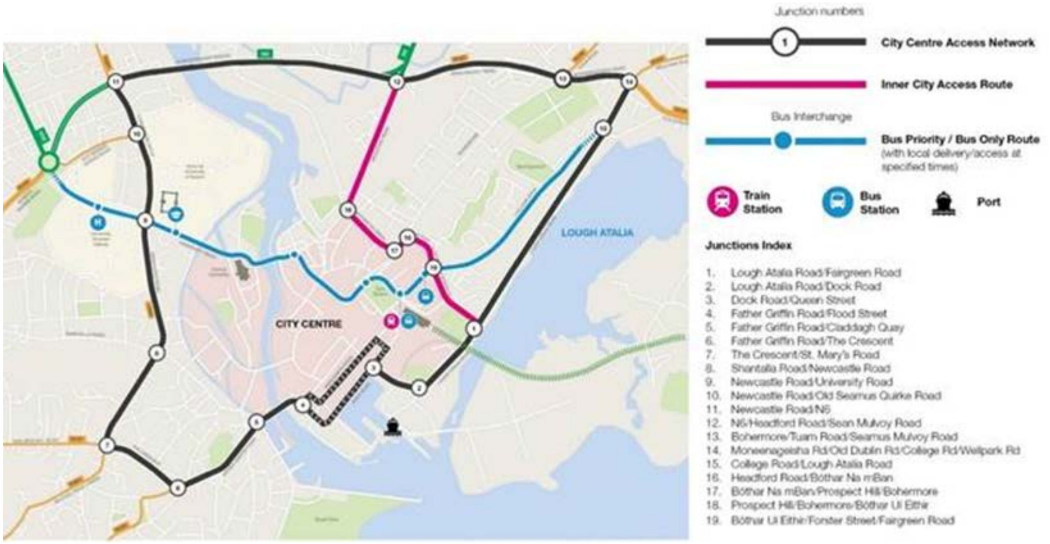
There are currently four crossings of the River Corrib and each bridge is currently at capacity. The GTS proposes to make one of these crossings available for public transport only, forcing traffic to divert out to the Quincentenary Bridge. Therefore, an additional crossing of the River Corrib is required to effectively implement the orbital route. This additional crossing of the River Corrib is being progressed as part of the N6 Galway City Ring Road (GCRR). ABP also considered in the 2006 GCOB Scheme that the need for an additional crossing of the River Corrib had been established.

A new road link to the north of the city is proposed as part of the GTS to deliver the necessary capacity and support the delivery of sustainable transport measures, particularly within the city centre. This new link road is being progressed as part of the N6 Galway City Ring Road (GCRR).

The routes through and around the city have been classified on different levels in order to separate journeys by type and assign the most suitable journey types to each road network or alternative mode. Heavy traffic flows that do not have a destination within the city centre will be encouraged to undertake their journeys via alternative routes, and through-traffic is to be removed from the city centre as much as is feasible. In doing so, and by adopting policies intended to change the hierarchy of transport users in the city at present, capacity can be released and safeguarded in the core city centre area, and subsequently this capacity can be used to prioritise sustainable transport modes.

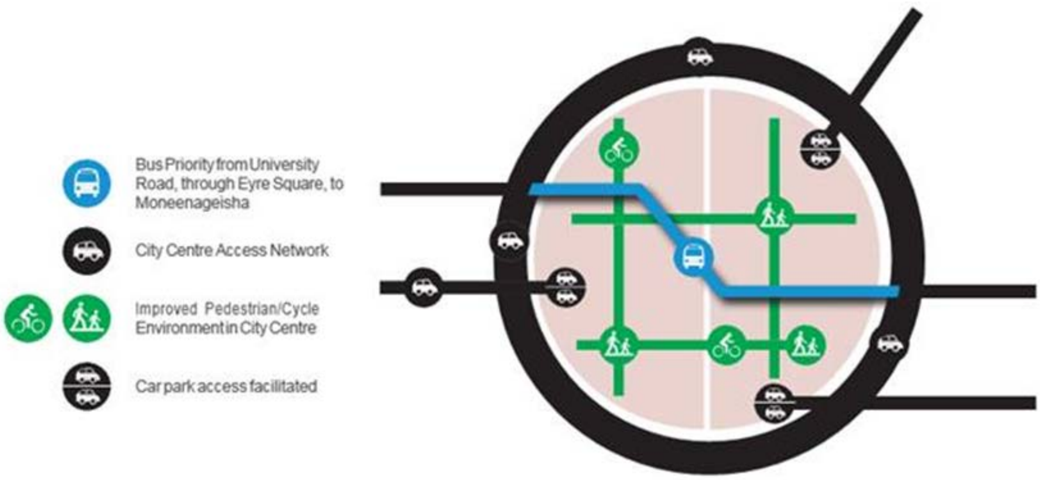
The GTS aims to remove non-essential motorised traffic from the core city centre area (i.e. traffic travelling through the city centre whose origin and destination lie outside the city centre). This will be achieved using a combination of routes around the city centre (termed the ‘City Centre Access Network’ shown in black in **Plate 1**), and will prioritise other modes within the core city centre area via the ‘Cross-City Link’ (shown in blue on **Plate 1**), a proposed corridor through the core city centre area with higher levels of priority allocated to walking, cycling and public transport over private car traffic.

Plate 1: City Centre Access Network



The core city centre area inside of the City Centre Access Network, will see road space reallocated to prioritise public transport and active modes. This will in turn facilitate public realm improvements along the Cross-City Link corridor, but requires changes in movements for private cars within the city centre to facilitate this. The city centre remains accessible, but priority is no longer given to the private car in this area or to the through movement in this area. This is best explained graphically in **Plate 2** below.

Plate 2: Cross-City Link Concept



Closing down and limiting access through the city within the area inside of the City Centre Access Network will facilitate a modal shift in the core area, whilst also shifting traffic out to the orbital route, which is the proposed road development. It is sequential: modal shift occurs within the core, and non-core traffic is shifted out to the orbital route. Therefore, the proposed road development, which is the subject of this EIAR, is a necessary component of the Galway Transport Strategy in order to deliver the transport solution for Galway. The achievement of maximum modal shift is contingent on the construction of the proposed road development (refer to **Chapter 6, Traffic Assessment and Route Cross-Section**).

The EIA process for the proposed road development is a stand-alone process and is not reliant on the other components of the GTS. Nevertheless, where relevant, the cumulative impacts of other proposals within the GTS will be assessed as part of the EIA process where applicable.

1.4 Consultation Process/Non-Statutory Consultation

Extensive consultation has taken place via public information sessions and discussions with key stakeholders, relevant statutory bodies, property owners, local organisations and utility/service providers throughout the constraints and route selection stages, design stage and during the EIA process.

Key stakeholders and statutory bodies included:

- An Bord Pleanála
- Galway County Council
    - Chief Executive
    - Director of Services for Planning, IR, Community, Enterprise & Economic Development
    - Director of Services for Water Services and Environmental
    - Director of Services for Roads, Transportation, Marine and General Services
    - Director of Services for Housing, Corporate & Emergency Services
- Galway City Council
    - Chief Executive
    - Director of Services for Planning & Transportation
    - Director of Services for Finance, Management Services Unit and Water Services
    - Director of Services for Economic Development, Community & Culture, Corporate Services, ICT and Human Resources
    - Director of Services for Housing & Social Inclusion, Environment & Recreation and Amenity
- The Minister for the Environment, Community and Local Government (now referred to as Minister for Housing, Planning, and Local Government with community and rural affairs forming a new department)
- The Minister for Communications, Energy and Natural Resources (now referred to as Minister for Communications, Climate Action and Environment)
- The Minister for Transport, Tourism and Sport
- The Minister for Arts, Heritage, Regional, Rural and Gaeltacht Affairs (now referred to as Minister for Culture, Heritage and Gaeltacht)
- Development Applications Unit of the Department of Arts, Heritage, Regional, Rural and Gaeltacht Affairs
- Department of Agriculture, Food and the Marine

- West Regional Authority
- Iarnród Éireann
- Córas Iompair Éireann
- Bus Éireann
- City Direct
- Galway Harbour
- Transport Infrastructure Ireland (TII)
- An Chomhairle Ealaíon (The Arts Council)
- Fáilte Ireland
- An Taisce
- The Heritage Council
- Waterways Ireland
- Environmental Protection Agency (EPA)
- Health and Safety Authority
- Commission for Energy Regulation
- Health Service Executive
- Office of Public Works
- Bat Conservation Ireland
- Bird Watch Ireland
- Irish Raptor Study Group
- Irish Georgian Society
- Geological Survey of Ireland
- American Chamber of Commerce
- Galway Chamber of Commerce
- Inland Fisheries Ireland
- Inland Waterways Association of Ireland
- Irish Wildlife Trust
- Met Éireann
- Irish Farmers Association
- Irish Peatland Conservation Trust
- National Museum of Ireland
- National University of Ireland, Galway
- Galway City Development Board
- Galway County Development Board

1.4.1 Public Consultation

Four public information sessions were held as follows and are discussed further below:

- Public Consultation No. 1 as part of the Constraints Study in July 2014 over two days
- Public Consultation No. 2 as part of the Options Development in January/February 2015 over four days
- Public Display No. 3 of the Emerging Preferred Route Corridor for the N6 Galway City Ring Road in May/June 2015 over two days. The Galway Transport Strategy also formed part of this consultation
- Public Display No. 4 of the Design of the N6 Galway City Ring Road in November 2016

Feedback received from the public consultations informed the constraints study and development of route options and the design of the emerging preferred route once selected. The local knowledge received at the public consultation and through submissions received identified new constraints and informed the development of route options and selection of the emerging preferred route corridor (EPRC). It also reinforced the traffic problems experienced in Galway City and its environs and need for an integrated transport solution which was multi-modal. This led to a parallel study of public transport and smart mobility measures which culminated in the Galway Transport Strategy (GTS). The historical importance of Menlough Village and the extents of communities across the study area were better understood post public consultation. The consultations with the public also reinforced the significant constraints present restricting the development of a new road and whilst some of the significant impacts were unfortunately unavoidable some positive changes were implemented into the design. Some of these include: the junction strategy in the Bearna Area and the retention of the mass path in Parkmore; landscape and visual improvement including the lowering of the proposed road development from an overbridge to at-grade junction at Cappagh Road and changing from an overbridge at Hynes' Boreen in Castlegar to being in a cutting to at-grade; moving the N59 Letteragh Junction further west and revision of the Coolagh Junction. 'Green reinforced embankments' instead of concrete retaining walls have also been incorporated into the design where the proposed road development is in close proximity to dwellings. These enhancements and others made to the design following feedback from public consultations is detailed further in **Chapter 4, Alternatives Considered**.

1.4.1.1 Public Consultation No. 1 – Constraints

As part of the Constraints Study, public consultation sessions were held on Monday 14 July 2014 in the Westwood Hotel, Dangan from 10:00am to 9:00pm and on Tuesday 15 July 2014 in the Pillo Hotel, Headford Road from 10:00am to 9:00pm.

The initial results of the constraints study were displayed to the public at the consultation sessions. The aim of this was to receive feedback from the public and gain invaluable information from their local knowledge of constraints that may have been overlooked.

Representatives from Arup and Galway County Council were in attendance to assist the public in explaining the material on display. Over 100 people signed the attendance register.

The main feedback from this public consultation was as follows:

1. The scheme study area should extend further west and north
2. Concerns were raised in relation to the restrictions on lands located along the road of the N6 Galway City Outer Bypass (2006)
3. An additional crossing of the River Corrib was required and this new bridge should not adversely affect the navigation of the River Corrib
4. Current traffic and congestion issues, including inadequacies in the current public transport network were highlighted. Bus frequencies, routes and infrastructure need to be improved
5. Provision of a connection to the R336 west of Bearna
6. Proposals to tunnel under the Limestone pavement
7. Provision of school buses would provide a safe mode of transport for children and ease congestion at peak morning times
8. Additional constraints were identified

Full details of this consultation and submissions received from the public are contained in **Appendix A.1.1**.

1.4.1.2 Public Consultation No. 2 – Options

Public consultation sessions were held on Wednesday 28 and Thursday 29 of January 2015 in the Westwood Hotel, Dangan, from 2.00pm to 8.00pm, and on Tuesday 3 and Wednesday 4 of February 2015 in the Menlo Park Hotel from 2.00pm to 8.00pm. Over 1,450 people signed the attendance register over the four days of public consultation sessions.

These sessions formed part of the option selection process. Boards documenting the options examined to date and their feasibility were displayed, along with proposed solution options incorporating public transport, smarter travel and road-based components. Maps showing proposed road-based solutions with the constraints gathered during the Constraints Stage were also displayed. Representatives of Arup and Galway County Council were available throughout the sessions to answer questions and explain the material on display as needed. The aim of the public consultation sessions was to receive feedback and suggestions from the public regarding the proposed solutions. Submissions from the public of suggestions of possible modifications to the options presented, or additional information on further constraints, which may not have been taken into account at Constraints Stage, were welcomed both during the consultation sessions and afterwards, until the 6 March 2015.

Individual meetings with landowners, stakeholders, business owners and residents within the scheme study area were held in the weeks following the formal consultation. These were held at the request of the private individuals and drawings were prepared for each one to show the proximity of their property to the proposed road component options. Feedback from these meetings and submissions received were noted and any further constraints were sent to the full design team including the environmental specialists for inclusion in their assessment.

The main feedback from this public consultation are as follows:

- Greater importance given to the protection of environmental habitats over humans
- Viability of going back to the 2006 GCOB scheme
- Impacts of demolition to homes and businesses
- Impact on the environment, noise and air pollution
- Impact to communities and cultural heritage of many townlands e.g. Menlough, Castlegar, Coolagh, Rahoon, Dangan/Bushypark, Knocknacarra and Bearna
- Impact on recreational amenities such as NUIG Sporting Campus
- Health and safety of primary school children in close proximity to proposed routes
- Impact to commercial businesses and local economy of Galway
- Implementation of improved public transport and smarter mobility

Full details of this consultation and submissions received from the public are contained in **Appendix A.1.2**.

1.4.1.3 Public Display of Emerging Preferred Route Corridor

Public display sessions were held on 25 and 26 May 2015 on the Emerging Preferred Route Corridor (EPRC) at two locations in Galway, one west of the River Corrib and one east of the River Corrib. Details of the EPRC and the route selection process were on display over the two-day period and were available at the project office until the end of August 2015.

Galway City Council in conjunction with the National Transport Authority (NTA) also consulted with the public over this two-day period on the details of the Integrated Transport Management Programme (ITMP) (now referred to as the GTS). The display boards for the ITMP were moved to City Hall for unattended viewing following the public display sessions.

The joint presentation and consultation on the overall solution was very worthwhile as it afforded the public an opportunity to see how the component parts of the solution fit together to deliver an overall transport solution.

The general feedback on the road component of the transport solution included commentary on the following issues:

1. Implementation of improved public transport and smarter mobility should be prioritised over a road scheme
2. Greater importance given to the protection of environmental habitats over humans
3. Viability of going back to the N6 Galway City Outer Bypass (2006) route in the Bearna area
4. Impacts of demolition to homes and businesses
5. Impact to communities and cultural heritage of many townlands e.g. Castlegar, Coolagh, Dangan/Bushypark and Bearna

Further design iterations were necessary to minimise and reduce the extent of the impacts on the residential communities; this process formed part of the *Phase 3 Design* work.

Full details of this consultation and submissions received from the public are contained in **Appendix A.1.3**.

1.4.1.4 Public Display of Design of the proposed road development

A public display to provide an update on the design development of the N6 Galway City Ring Road was held in both Galway County and City Council Offices during normal working hours Monday to Friday from the 14 November to 2 December 2016.

General feedback on the proposed design included queries on the project's planning process and specific requests from landowners for design changes in the vicinity of their property to better mitigate the impact of the proposed road development. This is further detailed in **Chapter 4, Alternatives Considered**.

1.4.1.5 Continuous public consultation

A project website was created and used to keep the public informed at all stages as the N6 GCRR project progressed.

Over 950 individual property owner meetings, including many home visits, took place between the design team and property owners and such consultation informed the design of the proposed road development and the environmental impact assessment.

All property owners identified as owning lands to be acquired to facilitate the construction of the proposed road development received written correspondence in October 2016 with a copy of the design with respect to their property. As part of the final consultation process, written communication was issued to all property owners again in May 2018 with a copy of the final design with respect to their property and an explanation of the next steps.

1.5 Difficulties Encountered during the Study

No significant difficulties were encountered during the preparation of this EIAR. Any technical limitations associated with assessment of an environmental aspect are detailed in the relevant EIAR chapter.

2 Planning and Policy Context

2.1 Introduction

This chapter addresses the strategic planning policy context and strategic transport policy for the N6 Galway City Ring Road, hereafter referred to as the proposed road development. The purpose of this chapter is to set out the relevant strategic and statutory land use and planning policy context, and strategic transport policy context for the proposed road development.

Please refer to **Chapter 5, Description of Proposed Road Development** for description and overview of the route of the proposed road development.

This chapter sets out the current strategic transport policy and objectives, and the planning policy and objectives pertinent to the proposed road development.

It is set out as follows:

- European Context (**Section 2.2**)
- National Objectives (**Section 2.3**)
- Regional Policies, Guidance and Objectives (**Section 2.4**)
- Local Policies, Guidance and Objectives (**Section 2.5**)

An overall conclusion on how the European, national, regional and local policies support the proposed road development is included in **Section 2.6** and references in **Section 2.7**.

The proposed road development is congruent with current transport policy and planning policy as set out in the various policy documents over the past number of years. Specific details for each of the policies and how the proposed road development complies with these, and more local and regional policies, are outlined below.

2.2 European Context

The EU Sustainable Development Strategy (EU SDS, 2001, reviewed 2009), is a framework for a long-term vision of sustainability in which economic growth, social cohesion and environmental protection go hand in hand and are mutually supporting. In developing EU Transport Policy, the EU states in its 2009 review *Mainstreaming sustainable development into EU policies: 2009 Review of the European Union Strategy for Sustainable Development (pp. 6)* that it is essential to take account of all aspects of sustainability (such as emissions, noise, land occupancy and biodiversity) and to base any action on a long-term vision for the sustainable mobility of people and goods that covers the entire transport system, and on complementary efforts at EU, national and regional levels.

The EU SDS dedicates one of its seven key challenges to sustainable transport, with the overall objective to 'ensure that our transport systems meet society's economic, social and environmental needs whilst minimising their undesirable impacts on the economy, society and the environment'. The EU SDS operational objectives and targets include:

- Decoupling economic growth and the demand for transport with the aim of reducing environmental impacts
- Achieving sustainable levels of transport energy use and reducing transport greenhouse gas emissions
- Reducing pollutant emissions from transport to levels that minimise effects on human health and/or the environment
- Achieving a balanced shift towards environment friendly transport modes to bring about a sustainable transport and mobility system
- Reducing transport noise both at source and through mitigation measures to ensure overall exposure levels minimise impacts on health
- Modernising the EU framework for public passenger transport services to encourage better efficiency and performance

The Europe 2020 strategy unites two flagship initiatives under the sustainable growth priority to tackle the issue of sustainable transport:

- 'Resource efficient Europe' supports the shift towards a resource-efficient, low-carbon economy. This flagship initiative provides a framework for actions in many policy areas including transport. One of the key components is a roadmap presenting a vision for a transport system by 2050 that promotes clean technologies
- 'An industrial policy for the globalisation era' highlights ten key actions for European industrial competitiveness, including a more efficient European transport infrastructure and services.

It is within this broader EU policy context that the proposed road development is set. The proposed road development meets these objectives by providing the necessary infrastructure to support the economic growth of Galway and the Western Region and will also enable other public projects be realised and facilitates the effective implementation of the Galway Transport Strategy which includes improved public transport, walking and cycling measures for Galway City and its environs. This is further detailed in **Chapter 3, Need for the Proposed Road Development**.

2.2.1 Ten-T Connecting Europe

As of January 2014, the European Union (EU) has a new transport infrastructure policy, entitled *Infrastructure - TEN-T - Connecting Europe* that connects the continent between East and West, North and South. This policy aims to close the gaps between Member States' transport networks and to remove bottlenecks that still hamper the smooth functioning of the internal market. It is recognised that integrated transport networks are essential to a single market.

The aim of the EU's Transport Policy is to promote a mobility that is efficient, safe, secure and environmentally friendly. Congestion is not just a nuisance for road users; it also results in an enormous waste of fuel and productivity. Many manufacturing processes depend on just-in-time deliveries and free flow transport for efficient production. Congestion costs the EU economy more than 1% of GDP – in other words, more than the EU budget. To reduce this, the EU needs more efficient transport and logistics, better infrastructure and the ability to optimise capacity use.

The EU Commission also recognises that Europe needs transport which is cleaner and less dependent on oil. Moving towards low-carbon and more energy efficient transport, as well as developing more efficient urban and intermodal transport solutions as alternatives are essential to developing a more environmentally friendly transport policy.

The European Transport Infrastructure (TEN-T) includes the core transport routes in all EU Member States for all transport modes: air, rail, road, maritime and inland waterways and consists of two planning layers, namely the core transport network and the comprehensive transport network. The core network represents the major transport corridors connecting Europe and it stretches from Ireland through the United Kingdom and onto mainland Europe. This core network is supported by the comprehensive network. The proposed road development is classified as part of the TEN-T comprehensive road network[1] shown in **Plate 2.1** below as it is a strategic link in the road network in the West Region functioning in accordance with the European Union's (EU) TEN-T transport policy.

[1] http://ec.europa.eu/transport/infrastructure/tentec/tentec-portal/map/maps.html

Plate 2.1: TEN-T Network Ireland (Source Transport Infrastructure Ireland)

The objectives of the proposed road development align with the European Union's land transport policies given that the following targets are among the objectives of the proposed road development, whose targets meet those set out in the EU SDS operational objectives and targets, as set out above (ref: **Chapter 3**, **Section 3.3** of this report for the Project Objectives):

- Segregation of the interface of by-passable traffic from urban traffic
- Increase journey time certainty
- Reduce journey times
- Implement sustainable transport policies for shorter commutes
- Improve accessibility to Galway City and the connectivity of key strategic services within Galway, such as NUIG and Galway University Hospital
- Improve accessibility of the Galway urban area to its main markets
- Ensure connectivity and accessibility of this region to the single European market, including the port of Rossaveel, Connemara Airport and the Gaeltacht areas which lie west of the city along the R336
- Improve linkages between the west and east sides of the city and the county
- Improve accessibility of the Gaeltacht areas to the remainder of the county and country
- Recognition of the role of Galway City as a gateway to the west and Connemara, and the consequent socio-economic benefits of enhanced connectivity of

Galway City to national markets, enhanced tourism accessibility, and the national transport system
- Improvement to the TEN-T network to ensure connectivity of the west of Ireland to the single European market

The proposed road development forms part of the TEN-T comprehensive road network in Ireland and is of strategic importance in a European context as it has a key role in delivering congestion relief, reducing greenhouse gas emissions and strengthening economic cohesion. This is further detailed in **Chapter 3, Need for the Proposed Road Development**.

2.3 National Objectives

2.3.1 Building on Recovery: Infrastructure and Capital Investment Plan 2016-2021

This Capital Plan presents the Government's new framework for infrastructure in Ireland over the period 2016-2021. A recovering economy, jobs growth, and strengthening public finances means the Government revised its capital expenditure commitments for the remainder of the decade recognising that '*High quality infrastructure is an important element of a modern society and economy. It strengthens economic growth through enhancing efficiency, productivity and competitiveness*'.

The transport capital allocation in this Capital Plan is largely framed by the recommendations and priorities set out in the 2015 Department of Transport, Tourism and Sport (DTTaS) *Strategic Investment Framework for Land Transport,* which centre on:

- maintaining and renewing the strategically important elements of the existing land transport system
- addressing urban congestion
- maximise the contribution of land transport networks to national development, including providing access to poorly served regions

The Capital Plan incorporates the following key objectives relevant to this proposed road development:

- €6 billion for investment in the national, regional and local road network over the 7-year period, with €4.4 billion to ensure the existing extensive network throughout the country is maintained and strengthened, with €1.6 billion for new projects
- It supports the proposed road development specifically by reference to supporting the commencement of the '*Galway By-Pass'* subject to planning permission

The proposed road development is consistent with these recommendations, priorities and objectives as set out in the DTTaS 2015 investment framework, and the Capital Plan, as it seeks to deliver the N6 Galway City Ring Road, address urban congestion in Galway City, and enhance national development through improved connectivity to west Galway.

This connectivity is essential to ensure the viability of the western parts of the county which have a very high quality tourist offering which is dependent on connectivity to achieve its potential.

County Galway has a thriving tourism industry which contributes to the national tourism industry. There were over 1.3 million overseas visitors to Galway in 2015 alone, generating an estimated €475 million in revenue (Fáilte Ireland Regional Tourism Performance by County 2015, Oct. 2016). At the time of publication of this report, data for 2016 was unavailable but initial findings indicate an increase in tourism across Ireland in 2016. Approximately, two thirds of the tourists visit the area in the period from May to September, with one of the main attractions being Connemara with its scenic landscapes and unpolluted environment. Tourism traffic, together with local recreation traffic accessing the beaches at the west of the city, add to the traffic volumes on this linear transport corridor in this summer period. Galway is also located on the Wild Atlantic Way which is a new initiative by Fáilte Ireland to encourage tourism into the west and is likely to generate additional traffic into the area.

Tourism is a vital industry to ensure the viability and survival of the South Connemara region, which is linked to overall improved social provision, quality of life and environmental sustainability.

A review of the Capital Plan was published in August 2017 as there was a significant improvement in economic performance of the country which enabled the allocation of additional capital investment for increased public capital investment over the period of the Capital Plan. The increased expenditure is targeted to achieve specific outcomes which achieve value for money.

Following the allocation of this increased capital investment, the Government published a new 10 year national investment plan for the period 2018-2027, namely the National Development Plan 2018-2027, which closely aligns with the key objectives of the National Planning Framework to ensure the money is spent in accordance with an overall plan.

2.3.2 Smarter Travel, A Sustainable Transport Future, 2009 and Irelands National Cycle Policy Framework, 2009 to 2020

"*Smarter Travel – A Sustainable Transport Future*" is a policy framework approved by Government in 2009 which sets out how the vision of a sustainable travel and transport system can be achieved. The policy acknowledges that "*transport is vital for our economy. As an island nation we need good transport connections with our trading partners; we also need to ensure efficient movement on the island. Safe and comfortable travel is also a key element of a good quality of life. The issue is not to restrict travel and transport but to facilitate smarter ways of meeting these needs*". Chapter 3 of the policy document outlines five key goals which form the basis of the Policy as follows:

- *Improve quality of life and accessibility to transport for all and, in particular, for people with reduced mobility and those who may experience isolation due to tack of transport*
- *Improve economic competitiveness through maximising the efficient of the transport system and alleviating congestion and infrastructural bottlenecks*
- *Minimise the negative impacts of transport on the local and global environment though reducing localised air pollutants and greenhouse gas emissions*
- *Reduce overall travel demand and commuting distances travelled by the private car*
- *Improve security of energy supply by reducing dependency on imported fossil fuels*

Key actions set out in the Smarter Travel policy to achieve this vision include:

- Actions to reduce distance travelled by private car and encourage smarter travel, including focusing population growth in areas of employment and to encourage people to live in close proximity to places of employment and the use of pricing mechanisms or fiscal measures to encourage behavioural change
- Actions aimed at ensuring that alternatives to the car are more widely available, mainly through a radically improved public transport service and through investment in cycling and walking

In keeping with Smarter Travel policy, a national cycle policy was announced in 2009. *Ireland's National Cycle Policy Framework, 2009 to 2020* sets out to create a strong cycling culture in Ireland with a target level of 10% of all trips to be made by bike by 2020. The key to achieving the Government target of 10% commuting by bike by 2020 is threefold; firstly, planning at all levels needs to consider cyclist needs; secondly, transport infrastructure must provide cycle friendly safe direct routes; and finally, education and communication is necessary to foster a cycling culture from a young age.

Over the years, Galway City and Galway County Council have developed a number of plans and strategies to help achieve national Smarter Travel policy objectives. These include:

- Galway Metropolitan Smarter Travel Area Action Plan 2010-2015
- Galway City and Environs Walking and Cycling Strategy (2010)
- Galway Transport Strategy (2016)

In 2010, Galway City and Galway County Council developed the *Galway Metropolitan Smarter Travel Area Action Plan 2010-2015* which was in line with the first key goal of the Smarter Travel national policy and set out to develop Galway and its hinterland as a sustainable travel area. This Plan assumed that the 2006 N6 Galway City Outer Bypass (GCOB, 2006) was delivered.

In 2010, Galway City and Galway County Council also developed the *Galway City and Environs Walking and Cycling Strategy (2010)* which sought to deliver on national cycle policy at the Galway City level, again in line with the first key goal of the policy to provided facilities for pedestrians, cyclists and non-motorised users (NMU). Proposals included a greenway from the city centre to Bearna and from the city centre to Oughterard.

In 2016, Galway City and Galway County Council in partnership with the National Transport Authority developed the *Galway Transport Strategy* (GTS). This strategy builds on the previous transport studies carried out for the Galway Region and sets out an overview of the proposed actions and measures for implementation, covering infrastructural, operational and policy elements. These consolidated proposals will provide Galway City and its environs with a clear implementation framework for the next 20 years and will underpin the objectives of the current and future Galway City and Galway County Development Plans. Smarter Travel forms the core principle of the Galway Transport Strategy. The GTS is further detailed in **Section 2.5.1** below with a background to the GTS included in **Chapter 1, Introduction**.

The GTS is currently being implemented by Galway City Council, both in terms of the policy objectives established and the delivery of transport projects identified within the strategy. The N6 GCRR forms part of, and is identified as a project within the ‘Galway Transport Strategy’ (GTS).

The GTS aligns with the Key Goals set out above in its efforts to align land use and transportation policy, and in seeking to deliver viable and attractive alternatives to the private car in Galway.

The proposed road development forms part of the actions set out in the Galway Transport Strategy (GTS) and it aligns with smarter travel policies both at a national level and local level. In developing the GTS, cognisance was taken of the Smarter Travel policy to ensure maximum uptake of public transport. Therefore, the GTS aligns with the Smarter Travel policies in so far as full implementation of the GTS (of which the N6 GCRR is a significant component) results in an improvement of 16% in modal shift to public transport.

It is necessary to resolve existing traffic congestion issues in Galway in order to achieve smarter travel policies. The proposed road development will assist with the removal of traffic congestion from within Galway City and its environs by transferring existing and future traffic from the existing road network to the new road infrastructure. Therefore, journey times will reduce and journey time certainty will increase for both public transport and private vehicle users. The reduction in traffic congestion will also help to realise other proposed actions in the Galway Transport Strategy because the existing road space can be reallocated for cyclists, pedestrians and to reconfigure the public transport network. This will result in reducing the number of short commuter journeys by car by facilitating journeys by bicycle which are faster, cheaper, and more sustainable and generate health benefits.

Improvements to the Galway bus network have been identified as necessary to better cater for existing and future travel patterns in Galway City. The reallocation of road space for public transport will assist with the delivery of an improved bus network.

Achieving the targets as set out in Smarter Travel policies will deliver a more attractive, vibrant and economic Galway City and environs with associated health and environmental benefits, all of which are necessary for sustainable travel into the future. The proposed road development aligns with these policies both at a national and local level.

Smarter Travel – A Sustainable Transport Future notes that efficient movement of goods is vital to our competitiveness and economic welfare with the majority of goods currently moved by road. It also acknowledges that investment in roads will remove bottlenecks, ease congestion and pressures in town and villages. Therefore, the actions set out in the policy seek to balance the multiple functions of the road network whilst still achieving the overall key goals.

The policy document sets out 49 Actions identified to achieve these key goals. The provision of the proposed road development supports a number of the 49 actions contained within the Smarter Travel Policy, and is neutral with the remaining as detailed in **Table 2.1** below.

Table 2.1: Smarter Travel Action Compliance Assessment

Action Number	Compliance	Comments
1	Supportive	The reallocation of road space to facilitate the provision of new and improved pedestrian and cycling facilities promotes walking and cycling to access community facilities and public transport throughout Galway City. The proposed road development provides such facilities in all areas of overlap with proposed GTS measures including but not limited to Cappagh Road, Ballymoneen Road, N59 Link Road, Letteragh Road, Rahoon Road, N59, N84, N83[2], Castlegar Road, Parkmore Link Road, Ballybrit Crescent, City East Business Park Junction. Refer **Section 5.5.4.2 Pedestrian and Cyclist Provision**.
2	Supportive	Provision of new pedestrian and cycle facilities in all areas of overlap with proposed GTS measures including but not limited to Cappagh Road, Ballymoneen Road, N59 Link Road, Letteragh Road, Rahoon Road, N59, N84, N83, Castlegar Road, Parkmore Link Road, Ballybrit Crescent, City East Business Park Junction supports the sub-actions under Action 2 relating to integration.
3	Supportive	The proposed road development comprises two local authority areas, namely Galway City Council and Galway County Council, with Galway County Council progressing the proposed road development through the statutory process on behalf of itself and Galway City Council. In parallel, Galway City Council and Galway County Council, in partnership with the NTA developed an overall transport strategy for Galway City and its environs culminating in the Galway Transport Strategy (GTS), of which the proposed road development is a key component. The GTS provides Galway City and its environs with a clear implementation framework for transportation over the next 20 years. This coordination will ensure coordination and integration of development planning between local authorities across the Gateway of Galway.

[2] Formally known as the N17 Tuam Road.

Action Number	Compliance	Comments
4	Supportive	The provision of the pedestrian and cycle facilities noted in Action 1 above is supportive of Action 4 in promoting more sustainable travel patterns, such as cycling and walking. The provision of a dedicated bus lane on the N83 is supportive of Action 4 in promoting more sustainable travel patterns. The Parkmore Link Road links the Ballybrit and Parkmore Industrial Estates and facilitates the interchange of bus routes servicing these Industrial Estates thus increasing the level of provision of public transport into the whole of the north eastern quarter of the city. It also provides a shorter direct route with full provision of appropriate infrastructure along the desire line for both pedestrians and cyclists to the Industrial Estates of Parkmore and Ballybrit.
5	Neutral	The provision of the proposed road development will not impact on e-working targets for the public sector. All existing broadband and telephony services impacted by the proposed road development will be reconnected to ensure no loss of service.
6	Neutral	The provision of the proposed road development will not impact on establishment of e-working centres. All existing broadband and telephony services impacted by the proposed road development will be reconnected to ensure no loss of service.
7	Supportive	The proposed road development does provide segregated safe routes for pedestrians from the N59 at Bushypark to Letteragh Road. It then connects to dedicated cycleways and footways on the N59 Link Road South to the Gort Na Bró Link Road. These cycleways and footways connect into the existing networks in the area which feed four major secondary schools on Threadneedle Road, Ballymoneen Road and Taylors Hill. This link road also provides safe routes to connect the residential areas of Letteragh Road to Rahoon Road thus avoiding the existing circuitous route via Seamus Quirke Road. The reduction in traffic volumes within Galway City will also assist improving the safety within the city centre for vulnerable road users and provide the platform for future enhancements to pedestrian and cycle amenities as per the GTS.
8	Supportive	The proposed road development will provide dedicated safe routes for vulnerable road users on the west of the city that connects housing developments to the schools. Provision is also made to connect the major business parks on the east of the city by means of the Parkmore Link Road. The Parkmore Link Road facilitates the interchange of bus routes servicing these Industrial Estates supporting a modal shift to non-motorised forms of transport for commuting to workplaces within the whole of the north eastern quarter of the city. It also provides a shorter direct route with full provision of appropriate infrastructure along the desire line for both pedestrians and cyclists to the Industrial Estates of Parkmore and Ballybrit. A southbound bus lane, dedicated cycle lanes and pedestrian facilities are provided on Ballybrit Crescent Road which provide safe routes from Parkmore East Industrial Estate through the Lynch Junction. All other signalised junctions within the proposed road development provide facilities for vulnerable road users to safely negotiate the junctions.

Action Number	Compliance	Comments
9	Supportive	The provision of the proposed road development does not actively promote personalised travel plans. However, it offers the opportunity to individuals to reconsider their existing travel patterns and move towards a more sustainable travel plan especially in the Parkmore/Ballybrit area and in the western suburbs of Knocknacarra/Rahoon/Westside. In addition, the wider GTS supports such initiatives throughout the city centre.
10	Neutral/Supportive	The provision of the proposed road development will not impact on the promotion of freight policy. There will be a reduction in traffic volumes on the dedicated access route to Galway Port, thus facilitating the efficient movement of goods to/from the port. The reduction in congestion in Galway City and environs will improve the efficiency of road based freight traffic.
11	Neutral	The proposed road development will not impact on the implementation of fiscal measures aimed at reducing car use.
12	Supportive	The provision of a dedicated bus lane on the N83 promotes more sustainable travel patterns. The Parkmore Link Road facilitates the interchange of bus routes servicing these Industrial Estates. A southbound bus lane is provided on Ballybrit Crescent Road to facilitate the bus route from Parkmore East Industrial Estate through the Lynch Junction. These combined measures increase the level of provision of public transport into the whole of the north eastern quarter of the city, into which combined workforce of 10,000 travel daily. The provision of the proposed road development will reduce the current congestion experienced in Galway City Centre and facilitates the provision of a public transport corridor through the city centre with public transport only allowed on the Salmon Weir Bridge, Eglington Street and College Road.
13	Supportive	The provision of a dedicated bus lane on the N83 forms part of the provision of a reliable bus service into the large urban area of Galway City. The Parkmore Link Road facilitates public transport between the Ballybrit and Parkmore Industrial Estates and facilitates the interchange of bus routes servicing these Industrial Estates, again ensuring a reliable public transport to the north eastern quarter of the city. The provision of the proposed road development will reduce the current congestion experienced in Galway City Centre and facilitates the provision of a public transport corridor through the city centre with public transport only allowed on the Salmon Weir Bridge, Eglington Street and College Road.
14	Supportive	The provision of the proposed road development supports the action to provide a dedicated public transport route along the N83 corridor, thus facilitating access from the rural area of Claregalway to the city centre. The provision of the Parkmore Link Road connects the Ballybrit and Parkmore Industrial Estates and facilitates the interchange of bus routes servicing these Industrial Estates, In the wider GTS measures, it is envisaged to use this route to link to a future Park and Ride. A southbound bus lane is provided on Ballybrit Crescent Road to facilitate the bus route from Parkmore East Industrial Estate through the Lynch Junction. In the wider GTS measures, it is

Action Number	Compliance	Comments
		envisaged that this route could link to a future Park and Ride site in the Coolagh Roundabout area.
15	Supportive	The provision of the proposed road development supports Action 15, through the provision of dedicated high quality safe pedestrian and cycling facilities linking the residential areas and employment areas. It will be possible to cycle from Cappagh Road to Parkmore West Industrial Estate on a dedicated cycle path, i.e. from the western city limits to the north-eastern city limits. The reduction in traffic volumes in Galway City Centre due to the transference of traffic to the new alignment will afford the opportunity to improve the cycling infrastructure.
16	Supportive	The provision of the proposed road development supports Action 16, through the provision of dedicated high quality safe pedestrian facilities on the N59 Link Road North and South, the Parkmore Link Road, Ballybrit Crescent Road and all the signalised junctions. The reduction in traffic volumes in Galway City Centre will afford the opportunity to further improve the pedestrian infrastructure.
17	Neutral	The proposed road development does not utilise State owned lands for the provision of walking and cycling facilities. However, the walking and cycling facilities provided all link into the greater strategy for walking and cycling in Galway and environs which ultimately gives access to the wider greenway network.
18	Neutral	The provision of the proposed road development will not impact on the establishment of car sharing website and initiatives.
19	Neutral	The provision of the proposed road development will not impact on the establishment of car club schemes.
20	Neutral	The provision of the proposed road development will result in reduced traffic volumes in Galway City Centre, thereby facilitating the advancement of other schemes to give traffic priority to other forms of motorised transport.
21	Neutral	The provision of the proposed road development will not impact on the implementation of integrated ticketing systems on the public transport network.
22	Supportive	The provision of the Parkmore Link Road and the bus lane on Ballybrit Crescent Road facilitate the establishment of future park and ride sites along major public transport modes. These provisions form part of the overall plan for park and ride facilities in the GTS.
23	Supportive	Signalised junctions are provided within the proposed road development to enhance operational safety and performance and to facilitate the efficient movement of all road users. Dedicated crossing points for pedestrians and cyclists are provided at each junction location. The traffic reductions in Galway City Centre will afford the opportunity to improve the pedestrian priority at the key junctions.
24	Neutral / Supportive	The provision of the proposed road development will not impact on the implementation of an on-line integrated journey planner. The work on the development of the overall transport strategy

Action Number	Compliance	Comments
		was managed by the National Transport Authority in parallel, thus ensuring integration of all transport modes.
25	Supportive	The proposed road development provides investment for new dedicated, safe walking and cycling routes linking residential areas to employment areas and the city centre. The reduction in traffic volumes in the city centre will facilitated further improvement to the pedestrian and cycling infrastructure within the city centre. The proposed road development will provide economic benefits through alleviation of the congestion and journey time reliability.
26	Neutral	The implementation of the proposed road development will not impact on the restructuring of the air navigation system in Europe and Ireland.
27	Neutral	The implementation of the proposed road development will not impact on the public service obligation for regional air transport services.
28	Neutral	The implementation of the proposed road development will not impact on the maritime transport sector emissions.
29	Neutral	There will be a reduction in traffic volumes on the dedicated access route to Galway Port, thus facilitating the efficient movement of goods to/from the port. The reduction in congestion in Galway City and environs will improve the efficiency of road based freight traffic.
30	Supportive	The provision of the proposed road development will provide a safer road for motorised traffic, removes traffic including heavy goods vehicles from congested urban areas and facilitates the reallocation of the existing road space for public transport and non-motorised transport, thus supporting a mobility that is efficient and is a safer environment for active modes.
31	Neutral	The implementation of the proposed road development will not impact meeting the 10% target for Bio-fuels by 2020.
32	Neutral	The implementation of the proposed road development will not impact in meeting the 10% target for electric vehicle technology by 2020.
33	Neutral	The implementation of the proposed road development will not impact on the implementation of fuel efficient vehicle fleets in the public sector.
34	Neutral	The implementation of the proposed road development will not impact on the implementation of VRT and Motor Tax systems.
35	Neutral	The implementation of the proposed road development will not impact the Sustainable Energy Ireland (SEI) initiatives to introduce energy efficient technologies to the transport sector.
36	Neutral	The implementation of the proposed road development will not impact on efficient driving module of the national driver test and implementation of on-board technologies to encourage eco-driving behaviour.
37	Neutral/Supportive	The implementation of the proposed road development will not impact the introduction of a Sustainable Travel and Transport

Action Number	Compliance	Comments
		Bill. The proposed road development will however support sustainable modes of transport through the provision of new pedestrian and cycle facilities and new bus lanes as part of the development. It also facilitates the further public transport, cycling and walking measures included in the overall GTS.
38	Neutral	The implementation of the proposed road development will not impact on the interdepartmental working group.
39	Neutral	The implementation of the proposed road development will not impact on the establishment of the National Sustainable Travel Office.
40	Neutral	The implementation of the proposed road development will not impact on the establishment of the Dublin Transportation Authority.
41	Neutral	The proposed road development will not impact on the strategy of the Dublin Transportation Authority.
42	Supportive	The proposed road development forms a key component of the overall GTS, which is developed to achieve sustainable travel and transport services in Galway City and environs. The proposed road development assists in modal shift through the provision of bus lanes and safe segregated pedestrian and cycle facilities connecting residential areas and employment areas.
43	Neutral	The proposed road development will not impact on the sustainable transport initiatives between Northern Ireland and the Republic of Ireland.
44	Supportive	The proposed road development will assist in delivering a modal shift of transport to more sustainable forms of transport through the provision of bus lanes and dedicated, safe routes for pedestrians and cyclists to access the employment centres, education centres and residential areas, whilst also alleviating congestion in Galway City Centre, affording the opportunity to further improve facilities for road based public transport and facilities for pedestrians and cyclists.
45	Supportive / Neutral	The proposed road development forms a key component of the GTS which has been presented to the elected members and staff of Galway City Council and Galway Council. The endorsement of the GTS by the elected members is the basis to implement the sustainable travel.
46	Neutral	The proposed road development will not impact on the introduction of branding to support the concept of smarter travel.
47	Neutral	The proposed road development will not impact on the introduction of fund to support innovative sustainable travel projects.
48	Supportive	The results of the National Travel, Transport and Mobility Household Survey 2012 were utilised in the development of the NTA Western Regional Model. This model was used for the multi-modal transport analysis undertaken for the proposed road development to ensure that the travel patterns in the off-peak periods are addressed in the model.

Action Number	Compliance	Comments
49	Neutral	The proposed road development will not have an impact on the biennial reporting on the progress of the Smarter Travel Policy.

2.3.3 Forfás Regional Competitiveness Agendas

Forfás was Ireland’s national policy advisory body for enterprise and science until 2014 when it was dissolved and integrated with the Department of Jobs, Enterprise and Innovation. Forfás' policy functions included the provision of independent and rigorous research, advice and support in the areas of enterprise and science policy. This work informed the Department of Enterprise, Trade and Employment and wider Government in its responses to the fast-changing needs of the global business environment.

In their suite of seven Regional Competitiveness Agendas (RCAs): *Overview, Findings & Actions of December 2009*, Forfás assessed how each region could strengthen its competitive environment in support of enterprise. The RCAs proposed specific actions to address barriers to development and focused efforts on realising the potential of each region. The N6 Galway City Outer Bypass (GCOB, 2006) is listed under Priority Actions for Physical Infrastructure in the West.

The additional Forfás publication of 2012, entitled *Overview of Main Infrastructure Issues for Enterprise*, was published post the publication of the Infrastructure and Capital Investment 2012-2016 (November 2011). It noted the need to develop smarter solutions to leverage the significant investments already made and improve our competitiveness and a *Galway ring road* is listed as a priority:

“Given the limited capital resources available in the short to medium term, it is critical that we prioritise investment that will support economic recovery and sustainable growth. These include the completion of the Cork and Galway ring roads and two short sections of the Atlantic Corridor (Galway - Limerick-Cork) which will improve the mobility of people and goods in and between Ireland’s main regional cities. Improving public transport in the main cities is critical to enhance mobility for all urban transport users.”

This was subsequently continued through to the *Building on Recovery: Infrastructure and Capital Investment Plan 2016-2021* produced by the department of Public Expenditure and Reform, as referenced above at **Section 2.3.1**.

The proposed road development is identified as a project at a national level which is necessary to support economic recovery and sustainable growth because of its ability to improve mobility of people and goods into and out of Galway, and is vital to the economic recovery of the Western Region as a whole. This is further detailed in **Chapter 3, Need for the Proposed Road Development**.

2.3.4 National Planning Framework

The National Planning Framework now represents the overarching national planning policy document, of direct relevance to the planning functions of regional and planning authorities, including An Bord Pleanála and from the 16 February 2018 it replaces the National Spatial Strategy (NSS).

The National Planning Framework (NPF), together with the new ten-year National Development Plan, are jointly named *Project Ireland 2040: Building Ireland's Future* and will provide the framework for future development and investment in Ireland. It is the overall Plan from which other, more detailed plans will take their lead, hence the title, National Planning 'Framework', including city and county development plans and regional strategies. The National Planning Framework will be a tool to assist the achievement of more effective regional development. The National Planning Framework also has statutory backing.

The National Planning Framework (NPF) focuses on ten strategic outcomes:

- Compact Growth
- Enhanced regional accessibility
- Strengthened Rural Economies and Communities
- Sustainable Mobility
- A strong economy, supported by Enterprise, Innovation and Skills
- High quality international connectivity
- Enhanced amenity and heritage
- Transition to a low carbon and climate resilient society
- Sustainable management of water and other environmental resources
- Access to quality childcare, education and health services.

(Ref: *Project Ireland 2040, Building Ireland's Future*).

The objectives of the NPF will be applied on a regional basis through statutory Regional Spatial and Economic Strategies (RSESs), see **Section 2.4.1.1** below. The RSESs must accord with the NPF and in turn, local authority development plans which address further detailed local matters, must be in accordance with the RSESs.

Section 2 of the NPF sets out the strategy to plan for population and economic growth. The NPF supports as a key element of the strategy "*ambitious growth targets to enable the four cities of Cork, Limerick, Galway and Waterford to each grow by at least 50% to 2040 and to enhance their significant potential to become cities of scale*." (NPF Section 2.2). It further sets national policy objectives arounds population and employment growth.

Section 3.3 of the NPF focuses on the Northern and Western Region. It focuses on Galway as one of the country's five main cities and as a key driver for the west of Ireland. The NPF states that Galway needs to "*address recent growth legacy issues and build on key strengths including a world class med-tech cluster, third level institutions embedded within the City, a vibrant arts and cultural scene, year round* *tourism and an attractive natural setting*". It states that *"challenges to be addressed include housing choice and affordability, transport / mobility and urban quality, especially outside the core-city centre area*". The NPF targets a population growth to 2040 of 40,000-45,000 people for Galway City and Suburbs, to achieve a total population of at least 120,000 total population (Table 2.1 NPF).

"*Key future growth enablers*" set out for Galway include:

- Progressing the sustainable development of new greenfield areas for housing and the development of supporting public transport and infrastructure, such as at Ardaun
- Improving sustainable transport links
- Provision of a Citywide public transport network (The National Development Plan 2018-2027 states that the Bus Connects network of five high performing cross-city routes will be delivered in Galway)
- Development of a strategic cycleway network
- Delivery of the Galway City Ring Road

"*Enhanced Regional Accessibility"* is one of the National Strategic Outcomes in the NPF. This seeks enhanced connectivity between centres of population and improved accessibility to the northern and western region, and seeks to advance orbital traffic management solutions including the proposed road development to achieve these objectives.

The National Development Plan 2018-2027 seeks the delivery of major national infrastructure projects in the interest of regional connectivity and names the N6 Galway City Ring Road as one such major project (Section 1.7 and 5.2).

The proposed road development is situated within this national planning framework as a key growth enabler for Galway City and the western region.

2.3.4.1 National Spatial Strategy 2002-2020

The National Spatial Strategy (NSS) 2002 to 2020 was a twenty-year national planning framework designed to deliver more balanced social, economic and physical development between regions. The NPF replaced the NSS on the 16 February 2018. The NPF builds on many of the objectives of the NSS particularly the strategy that the main cities and surrounding hinterlands of Cork, Galway, Limerick and Waterford can deliver more balanced growth to the regions, to counterbalance the growth of the Dublin region.

The NSS provided the policy framework for all regional and local plans, including the Regional Planning Guidelines for the West Region (referenced below), which are to be replaced by the Regional Spatial and Economic Strategies (RSES) for each of the three new regions of the Northern & Western Region (relevant to Galway), the Midland & Eastern Region, and the Southern Region, under the NPF In the absence of the RSES for the Northern and Western Region, it is considered that the framework which the NSS provides for the Regional Planning Guidelines for the West Region (see Section 2.4.1 below), and consequently for the Galway City and Galway County Development Plans, should be referenced. This is captured in **Plate**

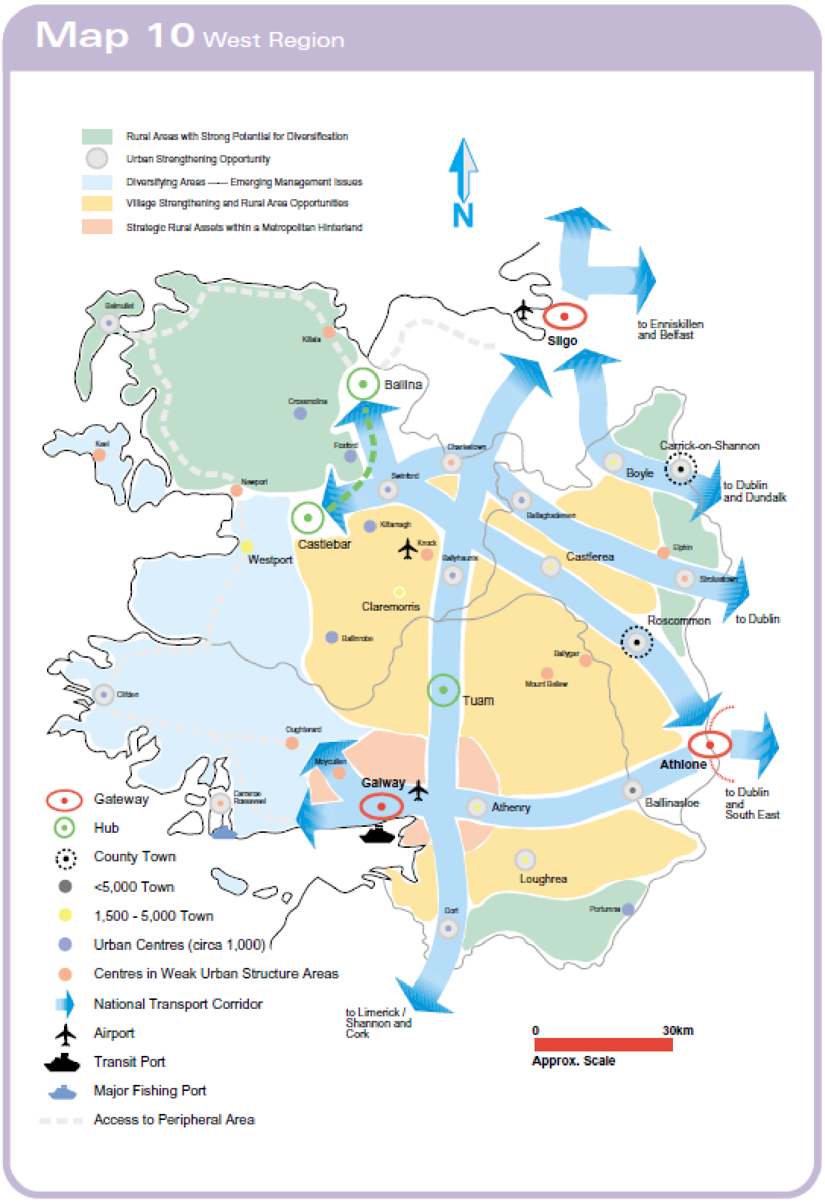
2.2 below which sets out the framework structure for the West Region in terms of urban-rural structure, transport connectivity, infrastructure provision etc. which has been reflected in the regional and city/county level plans. With regard to the proposed road development, this extract from the NSS shows the national transport corridor extending from the existing N6 on the east of Galway City across the River Corrib to the west of Galway in order to serve Connemara and Galway County.

The goal in all of the NSS was that this spatial restructuring would lead to:

- *strategically placed, national scale urban areas, acting as gateways, which individually and in combination will be key elements for delivering a more spatially balanced Ireland and driving development in their own regions*

(reference Section 3.1 of NSS).

Plate 2.2: National Spatial Strategy – West Region



2.3.5 Climate Change Act 2015

The Climate Action and Low Carbon Development Act 2015 provides for the establishment of a national framework with the aim of achieving a low-carbon, climate-resilient, and environmentally sustainable economy by 2050. The Act provides the tools and structures to transition towards a low-carbon economy and it anticipates that it will be achieved through a combination of:

- a national mitigation plan (to lower Ireland's level of greenhouse gas emissions)
- a national adaptation framework (to provide for responses to changes caused by climate change)
- tailored sectorial plans (to specify the adaptation measures to be taken by each Government ministry)

The Act obliges "relevant" bodies to have regard to the following factors in the performance of their functions:

- the most recent approved national mitigation plan
- the most recent approved national adaptation framework and approved sectorial adaptation plans
- the furtherance of the national transition objective
- the objective of mitigating greenhouse gas emissions and adapting to the effects of climate change in the State

The Act also provides for the establishment of an independent national expert advisory council on climate change which was formally established on 18 January 2016. The heads of the Environmental Protection Agency, the Sustainable Energy Authority of Ireland, Teagasc and the Economic and Social Research Institute are members of the Advisory Council.

The functions of the Advisory Council are to advise and make recommendations to the Minister and the Government in relation to matters such as the preparation of a national mitigation plan, a national adaptation framework, a sectoral adaptation plan, or any policy that is proposed to be submitted to the Government for approval in relation to the reduction of greenhouse gas emissions and adaptation to the effects of climate change in the State.

The Advisory Council is required to conduct an annual review of the progress made during the previous year in achieving greenhouse gas emissions reductions and furthering a transition to a low-carbon, climate-resilient and environmentally sustainable economy. The Advisory Council is to produce an annual report on its findings and recommendations stemming from its annual review.

The proposed road development supports the principles of the Climate Action and Low Carbon Development Act 2015 in so far as it provides the necessary strategic infrastructure which has sufficient capacity to cater for the traffic needs of Galway and its environs which in turn reduces bottle necks and congestion within the city itself, even allowing for any increased traffic generated by the proposed road development. The proposed road development with the GTS measures in place results in a 16% increase in modal shift to public transport at Design Year when compared with the Do Minimum scenario, i.e. the non-scheme scenario. Essentially this means that vehicle trips are removed from the existing traffic and these passengers become public transport users, all of which is a benefit to reducing emissions. Every shift, however small, from the private vehicle to public transport or walking or cycling is a positive and is a gain in terms of climate action. Therefore, as the proposed road development facilitates the effective implementation of the Galway Transport Strategy it is supporting the principles of the Climate Action and Low Carbon Development Act 2015, even allowing for any increased traffic generated by the proposed road development.

An appraisal of the proposed road development under the heading of Climate is included in **Chapter 16, Air Quality and Climate**.

2.3.6 National Mitigation Plan 2017

The first National Mitigation Plan was published in July 2017 by the Department of Communications, Climate Action and Environment. The Plan is designed to be a whole-of-Government approach to tackling greenhouse gas emissions, particularly, in the key sectors i.e. electricity generation, the built environment, transport and agriculture. The objective of this Plan is to transition Ireland to a low carbon, climate resilient and environmentally sustainable economy by 2050.

The National Mitigation Plan recognises the inter-relationship between settlement patterns, transport and land use planning, and seeks solutions to effectively meeting travel demand in a manner that avoids congestion and limits transport emissions.

As set out in **Section 2.3.5** above the proposed road development facilitates the effective implementation of the Galway Transport Strategy and in doing so it is supporting the principles of the National Mitigation Plan, even allowing for any increased traffic generated by the proposed road development.

An appraisal of the proposed road development under the heading of Climate is included in **Chapter 16, Air Quality and Climate**.

2.3.7 National Action Plan for Social Inclusion (2007-2016) and Update 2015-2017

The National Action Plan for Social Inclusion 2007 – 2016 (NAPinclusion) identified a wide range of targeted actions and interventions to achieve the overall objective of reducing consistent poverty.

The plan prioritised 12 high level goals and identified up to 150 actions across Departments and agencies with a remit in social policy, as part of a strategic approach to make a decisive impact on poverty over the period to 2016.

Relevant goals and actions set out in the NAP inclusion which reference improved accessibility for all sectors of the community, include improvements to public transport (section 3.1 Vision), improved access to public transport (section 5.6.3, Section 4.1 Vision, Section 5.1 Vision), access to buildings and infrastructure (section 5.6.2), improvements to rural transport provision (section 6.3.7).

As a result of dynamics in economic, social and political contexts, certain NAPinclusion goals and actions became out of date or less relevant. Current priorities and policies indicated that updating of NAPinclusion for its remaining two years 2015-2016 was required and an extension of one year to the Plan to coincide with other related Strategy reviews at Government level. This updating process was carried out as a transitional measure pending a full review of NAPinclusion in 2017.

The proposed road development will provide the necessary infrastructure for strategic traffic accessing Galway and the Western Region. It will also enable other public projects be realised and facilitates the effective implementation of the Galway Transport Strategy which includes improved public transport, walking and cycling measures for Galway City and its environs. This is further detailed in **Chapter 3, Need for the Proposed Road Development**.

2.4 Regional Policies, Guidance and Objectives

2.4.1 Regional Planning Guidelines (RPGs) for the West Region (2010-2022)

The *Regional Planning Guidelines (RPGs) for the West Region 2010 – 2022* (adopted 2010) set out the planned direction for growth for the West Region, within which Galway County and City is located, up to 2022 by giving regional effect to national planning policy under the National Spatial Strategy (NSS). The RPGs inform and direct the City and County Development Plans of each of the Councils in the West Region, comprising Galway City and Galway County, Roscommon, Mayo.

The RPGs recognise that the West Region has a significant and valuable resource in its natural heritage environment with a wide variety of species and habitats of local, national and international importance, the extent of which enhances the quality of life but also represents a real challenge in achieving sustainable development.

The RPGs acknowledge that the West Region has experienced difficulties in the past due to its peripheral location along the Atlantic seaboard and on the periphery of the EU. For the West Region to achieve critical mass and growth and ultimately offer an alternative development corridor to the east coast corridor, strong communication links are required to achieve this through well-developed road, rail and air links as they are key stimuli for 'corridor' growth.

Section 3.5.2 of the RPGs, sets out specifically the need for a reduction in transport costs by improving the road networks particularly the *M6 and potential Galway Outer Bypass* as part of the economic development of the region. Section 5.2.1 of the RPGs outlines the necessary road priorities for the Region, including the *Galway City Outer Bypass*.

As outlined above, the proposed road development is necessary to support economic recovery and sustainable growth of the Western Region as a whole which is of overriding public interest at a national level as the country moves towards sustainable growth and recovery.

2.4.1.1 New Regional Assemblies

Three new Regional Assemblies came into being on 1 January 2015, namely the Northern & Western (relevant to Galway), the Midland & Eastern and the Southern Regional Assemblies, following on from the enactment of the Local Government Reform Act 2014 and Putting People first – Action Programme for Effective Local Government. Galway and the West Region has been subsumed into the Northern & Western Regional Assembly.

At the same time as the publication of the draft National Planning Framework in November 2017, three Regional Assemblies of all 31 local authorities across the country began the preparation of new Regional Spatial and Economic Strategies (RSESs), framed in the light of the NPF but extending its approach at more detailed levels to shape local planning and economic development in each local authority area.

Each Regional Assembly published an Issues Paper for public consultation (submissions made by 16 February 2018). Key spatial and economic issues to be addressed are set out in the Northern & Western Regional Assembly (NWRA) Issues Paper, with reference to the National Planning Framework. These include issues such as location of development, provision of infrastructure including transportation, provision of educational and healthcare facilities, economic development and regional economic performance.

A key focus for the RSES will be the preparation of a co-ordinated Metropolitan Area Strategic Plan (MASP) for Galway (and potentially for other identified urban locations). The MASP will be provided with "*statutory underpinning to act as twelve-year strategic planning and investment frameworks for the city metropolitan areas*". The purpose of the MASP will be "*to provide high level long term strategic development focus on areas such as the identification of strategic growth areas, infrastructure (particularly transport and water services), regeneration, the location of housing and employment and metropolitan scale amenities such as regional parks and cycle networks.*" (see section 2.1.1 of the NWRA Issues Paper).

The RSES also seeks to enhance regional performance by identifying regional strengths and opportunities and identifies the Region's strong employment base, both multi-national operations and SMEs, and the Region's strong educational base, (NUIG identified as ranked in the top 1% of global universities). It also identifies the Region's "*internationally important environmental assets*", and the "*desire to protect these assets for the value they contribute*" to the lifestyle and economy of the Region (acknowledged as important to tourism), as well as for their intrinsic value (see sections 3,4, and 5 of the Issues Paper).

Among the "Critical Enabling Infrastructural priorities" for the Region identified by the NWRA as being "*crucial to the ability*" of the major urban centre's to harness potential and "*act as Regional drivers*" are the completion of the N6 Galway City

Ring Road, and the full implementation of the Galway Transportation Strategy (see section 6.3 of the Issues Paper).

The NWRA Issues Paper recognises the proposed road development as critical to the spatial and economic success of the Region.

2.5 Local Policies, Guidance and Objectives

The proposed road development passes through two local authority areas – Galway City Council and Galway County Council.

Both Galway City and County Councils are committed to intensifying public transport delivery and usage to deliver growth and improve quality of life in Galway. Both the Galway City Development Plan 2017-2023 and Galway County Development Plan 2015-2021 support the proposed N6 GCRR as part of the GTS which is the overall transport strategy.

2.5.1 Galway Transport Strategy (GTS) 2016

Galway City Council and Galway County Council, in partnership with the National Transport Authority (NTA), prepared a Galway Transport Strategy which aims to address the current and future transport requirements of Galway City and its environs, including Bearna, Oranmore, Moycullen and Claregalway. The NTA are the national body responsible for public transport and are fully committed to the delivery of a sustainable transport solution for Galway City and its environs. As Galway City and its environs continue to develop as the principal economic centre serving the West of Ireland, there is a critical need to address the transportation issues facing the city and surrounding areas, and to underpin future growth by establishing a long-term strategy for transport to, across, within and around the city.

While Galway has a compact walkable core, outside of the city centre, the suburbs have developed as a succession of low density residential and employment areas, which has led to a predominance of private car usage as a means of travel. As a result, the transport difficulties currently experienced across the city, particularly at peak travel times, are having a significant effect on the quality of life of residents, and are also impacting on the economic functionality of the city.

The Galway Transport Strategy (GTS) consists of a number of proposed measures combined under an overall vision "*to create a connected city region driven by smarter mobility*". The GTS builds on previous transport studies carried out for the Galway Region, and sets out an overview of the proposed actions and measures for implementation, covering infrastructural, operational and policy elements (as an 'Integrated Transport Management Programme'). These consolidated proposals will provide Galway City and its environs with a clear implementation framework over the next 20 years and will be used to secure funding to deliver projects in a phased manner based on priority needs. Ultimately, the GTS will underpin the objectives of the current and future Galway City and Galway County Development Plans.

The major components proposed under the GTS comprise:

- changes to the traffic network, including provision of a new cross-city link public transport corridor, and the N6 Galway City Ring Road (the proposed road development), and reallocation of road space to prioritise walking, cycling, public transport
- an enhanced local public transport network and regional public transport service focused on an enhanced, integrated high quality bus service
- provision of the Bearna Greenway, the Galway City to Oranmore Cycleway (part of the Galway to Dublin Cycleway) and the Galway to Oughterard Greenway
- a range of other additional cycling, pedestrian and public realm improvements including increased options for cycling in and across the city centre, improved pedestrian facilities, pedestrian prioritisation and way finding and legibility
- complementary measures including education and behavioural change measures and continued investment in Intelligent Transport Solutions (ITS) to increase efficiency, safety and co-ordination across transport networks (Smarter Mobility), and further emphasis on land use and transport integration

The proposed road development represents a key element of the GTS in planning for the future transport requirements of Galway City and its environs. The GTS, incorporating the N6 GCCR, will allow the city to 'breathe' again.

It provides an additional crossing of the River Corrib, thus facilitating the reduction of congestion on city centre roads, and allows the reallocation of road space in the city network to non-private car modes of transport, thereby improving the attractiveness of non-car modes of transport in the city for short and medium distances. This is further detailed in **Chapter 3, Need for the Proposed Road Development**.

2.5.2 Galway City Council

2.5.2.1 Galway City Development Plan 2017-2023

The Galway City Development Plan 2017-2023 as varied, hereafter referred to as the City Development Plan, sets out Galway City Council's policies for the sustainable development of Galway City to 2023. It establishes the vision for Galway City "*to be a successful, sustainable, competitive, regional centre that creates prosperity, supports a high quality of life and maintains its distinctive identity and supports a rich cultural experience*."

The strategic goals for the city to realise this vision are set out as:

1. Achieve a high quality of life for all citizens through the provision of a good quality, attractive, built environment, through the protection of the unique natural environment and through facilitation of key economic, cultural and social supports
2. Enable the city to fulfil its role as a National Gateway, a Regional centre and contribute to the economic recovery through the provision of balanced and sustainable economic opportunities for growth, innovation and investment

across all employment sectors and allow the role of the Gateway to harness the strengths and maximise the economic development for the whole West Region

3. Promote the reduction of greenhouse gas emissions through proactive measures in line with EU commitments to tackle climate change and reduce vulnerability to the harmful effects of climate change, in particular sea level encroachment and extreme weather events, through specific adaptation measures
4. Apply the principle of sustainability particularly where it relates to the uses of land, buildings, water, energy, waste and through the encouragement of sustainable modes of transport and the integration of transportation with land use
5. Aspire to make Galway an equal and inclusive city, particularly through facilitating all forms of social inclusion in the built environment, including in the public realm, housing, community facilities, in access to employment opportunities and public transportation
6. Protect the distinctive and diverse natural environment in the city and strengthen the green network and linkages, recognising the biodiversity value of the amenity, the range of recreational benefits this provides, the potential through facilitating active and healthy lifestyles, it can have on the quality of general health and well-being and the value it has for providing an attractive city setting
7. Encourage a sense of collective identity and a shared vision through civic engagement on projects such as the development of a Local Economic and Community Plan for Galway and also on the promotion of specifically focused projects such as the European Capital of Culture 2020, that will promote the unique form and character of the city, give opportunities for the development of cultural, community and other beneficial infrastructure and enhance and diversity the city economy (Galway City secured the European Capital of Culture 2020 designation in July 2016)

The City Development Plan's Core Strategy includes for Galway to continue to be the regional growth centre and to create the synergies for wider prosperity in the West Region. It focuses on the development of key regeneration locations in the city centre to reinforce the "*prime role of the city centre in both Galway City and the Gateway Region*". The Strategy focuses a significant amount of new residential development and population growth in the Ardaun area of the city (see **Section 2.5.2.2** below), while acknowledging that "*other residential areas of the city will grow but at a more constrained rate and in character with the established nature of development*". It designates the key centres of commercial, retail and local community activities are located "*to co-ordinate with the prime role of the city centre*". (Section 1.4 Galway City Development Plan).

The Core Strategy is further supported and informed by the Galway Transport Strategy (GTS) set out in **Section 2.5.1** above.

The transport strategy for the city in the City Development Plan aims "*to integrate sustainable land use and transportation, facilitating access and choice to a range* *of transport modes, accessible to all sections of the community that ensures safety and ease of movement to and within the city and onward connectivity to the wider area of County Galway and the West Region*." The City Development Plan notes that while the implementation of various measures stemming from the Galway Transport Unit have made improvements to the transport network, "..*serious traffic congestion still prevails which impacts on peoples' quality of life and the economy of the city, and the regional role of Galway as Gateway*".

The City Development Plan sets out that these issues have now been assessed in the preparation of the Galway Transport Strategy 2016 (see **Section 2.5.1** above), prepared by Galway City Council and Galway County Council in partnership with the NTA.

In this regard, the City Development Plan incorporates Policy 3.3 Galway Transport Strategy (GTS) which aims to "*Continue to progress a sustainable transport solution for the city through the implementation of measures included in the GTS and required supporting projects in particular the N6 GCRR project*".

The City Development Plan furthermore, incorporates the GTS through other policies and provisions including Policy 3.2 Land Use and Transportation;

"Facilitate the future development of Galway City and environs within the strategic framework of the Galway Transport Strategy and the associated implementation phasing to ensure that the city has the necessary transport infrastructure and services to support its continued growth and development."

Other policies in the Plan that integrate the GTS with City objectives are:

- Policy 3.4 Traffic Network, which specifically references the N6 Galway City Ring Road (GCRR) project by "…supporting the reservation of a corridor route to accommodate an orbital route as provided for in the N6 GCRR project."
- Policy 3.5 Public Transport
- Policy 3.6 Cycling and Walking
- Policy 3.7 Road and Street Network and Accessibility, which also specifically supports the N6 GCRR
- Policy 3.10 Specific Objectives emphasises the principles and objectives of the GTS, with specific reference to the N6 GCRR
- Economic Activities (Chapter 5) Strategy which incorporates specific reference to the delivery of the GTS and the N6 GCRR, to "Enhance the economic performance of Galway as a Gateway and regional growth centre..."
- Policy 5.1 Enterprise supports the "…implementation of the phased plan of transportation measures as proposed for in the Galway Transport Strategy (GTS) including for public transport, walking and cycling, and a strategic new road, the N6 GCRR"
- Section 8.7 Urban Design Public Realm incorporates principles and objectives of the GTS in relation to improving the quality and experience of the public realm and city environment

- Chapter 10 City Centre/Area Based Plans reflect the principles and objectives of the GTS, including the delivery of the proposed N6 GCRR, and resulting potential for city centre wide improvements to public realm and urban environment, and improved pedestrian and cycle facilities, networks and linkages
- Chapter 11 Land Use Zoning Policies and Objectives, Section 11.2 Land Use Zoning General states that "Priority will be given to the reservation of the N6 GCRR Preferred Route Corridor and the associated land requirements over other land use zonings and specific objectives"

The overall Transport Strategy of the City Development Plan is to:

- Support and facilitate the integration of land use and transportation
- Support the Galway Transport Strategy (GTS) and the associated implementation programme which will deliver a high quality public transport network, and encourage the use of other sustainable modes of transport
- Support the proposed road development in conjunction with Galway County Council and Transport Infrastructure Ireland in order to develop a transportation solution to address the existing congestion on the road network and reduce the negative impact of vehicular traffic on the functioning and experience of the city centre and to facilitate city bound, cross-city, cross-county and strategic east-west movements
- Support the reduction in greenhouse gas emissions through the promotion of sustainable land use and transportation

The Galway City Development Plan 2017-2023 fully integrates the aims, objectives, and strategies of the GTS into core policies and strategies, which includes the proposed road development.

2.5.2.2 Ardaun Local Area Plan 2018-2024

Galway City Council has prepared a Draft Local Area Plan (LAP) for lands situated at the area known as Ardaun on the east side of the city (164ha), approximately 5km from the city centre. The Draft LAP was subject to a public consultation period from 7 September to 20 October 2017. It was further subject to material alterations, which were put to public consultation during January-February 2018 and adopted in April 2018.

The Core Strategy of the Galway City Development Plan 2017-2023 identifies Ardaun "*as a key development area that can accommodate long term growth in population, economic activity and employment opportunities*" (Section 1.1 Ardaun LAP), and the preparation of a LAP for the area is a specific objective of the Development Plan (Policy 8.7). This supports regional planning policy where the "*West Regional Planning Guidelines 2010-2020 consider Ardaun as the most optimal area for growth in the city and environs*" (LAP 1.3).

The LAP seeks to deliver the concept of an urban village, with the principal urban village centre in the southern section of Ardaun i.e. south of the N6/M6 corridor, with two urban nodes / local centres north of this corridor, linking to surrounding areas including the existing Coolagh Village. It is anticipated that the area can support a population of over 8,000 people and also function as a mixed use business and retail district (LAP Section 1.2).

Strategic Goal 4 of the LAP (Section 3) supports the development of sustainable transport modes as proposed in the Galway City Development Plan and the Galway Transport Strategy. This Strategic Goal is further supported by the policy to "*Promote interconnectivity between all modes of transport, in particular sustainable and public transport modes in order to efficiently link Ardaun with the main hubs for activity including the city centre in accordance with the GTS*". This is further supported in Section 4.5 of the LAP by a key objective to "*Support and facilitate the provision of an integrated public transport network to service Ardaun through the implementation of the Galway Transport Strategy and in conjunction with relevant transport providers, NTA and other stakeholders*."

This LAP reserves the preferred route corridor of the proposed road development as it traverses the LAP area, as per Galway City Development Plan objectives, Section 1.4 and Section 3.10.

The development strategy of the LAP acknowledges and aligns with the Galway City Development Plan, the Galway Transport Strategy, and the proposed road development.

2.5.3 Galway County Council

2.5.3.1 Galway County Development Plan 2015-2021

The Galway County Council Development Plan (2015-2021) which includes a Variation to incorporate GTS, hereafter referred to as the County Development Plan, sets out the aspirations for Galway County within its lifetime and the near future. As noted in the background to the plan, it aims to "*sets out an overall strategy for the proper planning and sustainable development of the functional area of Galway County Council*". With reference to local, regional, national and European policies the plan sets out the main strategies for the County in the areas of:

- Spatial Strategy, Core & Settlement Strategy, including for development of lands at Ardaun as part of the City and County development strategy
- Urban & Rural Housing
- Economic Tourism & Retail Development
- Roads & Transportation
- Water, Wastewater, Waste Management & Extractive Industry
- Energy/Renewable Energies & Communications Technology
- Climate Change & Flooding
- Heritage, Landscape & Environmental Management
- Cultural, Social & Community Development
- Agriculture, Fishing, Marine Resources & Forestry

The County Development Plan further sets out its vision for the County which is to "*enhance the quality of life of the people of Galway and maintain the County as a uniquely attractive place in which to live, work, invest and visit, harnessing the potential of the County's competitive advantages in a sustainable and environmentally sensitive manner*."

The strategic aims of the County Development Plan (Refer to Section 1.7) include:

1. Promote regional development and growth through harnessing the competitive advantages of County Galway
2. Afford suitable protection to the environment
3. Recognise the importance of living landscapes while ensuring they are managed in a sustainable and appropriate manner
4. Seek balanced urban and rural development
5. Encourage and support the development of inclusive communities
6. Ensure integrated development
7. Promote sustainable mobility
8. Promote An Ghaeltacht as an Irish speaking community
9. Facilitate the development of infrastructural projects which will underpin sustainable development
10. Enhance and protect the built heritage and natural environment
11. Integrate climate change consideration in planning and delivering work programmes

The principle of sustainable development is a major component of the County Development Plan which is reflected in the Plan's policies and objectives. The Core Strategy in the County Development Plan is supported and informed by the GTS.

The Galway County Development Plan 2015-2021 retains the objectives of the previous County Development Plan to provide a solution to congestion, to provide better connection from all parts of the County to the trans-national network, and to improve safety levels on all public roads. "*The integration of land use and transportation shall continue to be the overarching strategic aim of the Galway County Development plan 2015-2021*" (Refer Section 5.1).

The County Development Plan further states that "*the timely provision of high quality transportation infrastructure within County Galway is critical to the County's socio-economic development and in the promotion of social and economic well-being*". (Refer Section 5.1).

The County Development Plan transportation objectives (Section 5.1.1) include the following strategic aims among others:

- *"To provide a safe and efficient network of transport to serve the needs of the people and the movement of goods and services to and within County Galway*
- *Provide access for all in an integrated manner with an enhanced choice of transport options including the Rural Transport Programme*

- *To promote and encourage the use of alternative sustainable modes of transport and to promote the use of transport energy from renewable resources*
- *To safeguard the strategic transport function and carrying capacity of the motorway and national road network and associated junctions in order to provide for the safe and efficient movement of inter-urban and inter-regional traffic"*

In relation to the Galway Gateway and west of the County, the County Development Plan incorporates objectives to enhance connectivity and access across the region, and to deliver on the transportation needs of the Galway Gateway, its environs and the west of the County, as per Policy TI2 and TI8 and Objective TI 15, as follows:

Policy TI 2 – Development of an Integrated and Sustainable Transport System

It is the policy of the Council to promote the development of an integrated and sustainable high quality transport system for the county, which includes the specific areas identified in the Galway Transport Strategy (GTS), which shall:

a) Promote closer co-ordination between land use and sustainable transportation;

b) Continue the provision of a range of transport options within Galway and in collaboration with Galway City Council, the National Transport Authority (NTA), Transport Infrastructure Ireland(TII), other statutory agencies and transport providers, including safe road network, a range of bus and rail services, adequate facilities for walking and cycling and opportunities of air and water-based travel.

Policy TI 8 –Transportation Infrastructure Requirements for the Gateway and West of the County

It is the policy of Galway County Council to work with Galway City Council and all relevant statutory bodies including the National Transport Authority (NTA) and Transport Infrastructure Ireland (TII) to deliver an appropriate infrastructural response to the transportation needs of the Galway Gateway, its environs and the west of the County as part of the proposed measures of the Galway Transport Strategy (GTS) including the plan level environmental protection policies and mitigation measures set out in the GTS. This shall include the provision of new infrastructure such as potential park and ride facilities, bus corridors, greenways, cycling and walking routes and the N6 Galway City Ring Road (GCRR) which are all integral in the delivery of the GTS with a view to relieving congestion, improving travel times, increased safety of all road users and enhancing connectivity and access within the region and enhanced accessibility of the western region in a national and international context. Any such solution shall have due regard to the necessity to protect the environment and will comply fully with the requirements of the Habitats Directive

Objective TI 1 – Sustainable Transportation

Support and facilitate 'Smarter Travel' initiatives contained in the Galway Transport Strategy (GTS) and other initiatives together with the plan level environmental protection policies and mitigation measures set out in the GTS, which will improve sustainable transportation within the County including public *transport, electric and hybrid vehicles, car clubs, public bike schemes, park and ride/park and stride facilities, improved pedestrian and cycling facilities, as appropriate.*

Objective TI 15 - Transportation Infrastructure Requirements for the Gateway and West of the County

It is an objective of Galway County Council to work with all other relevant bodies including the National Transport Authority (NTA), Transport Infrastructure Ireland (TII) and Galway City Council to deliver the necessary improvements to transportation infrastructure, including new infrastructure if necessary and the plan level environmental protection policies and mitigation measures set out in the GTS. This shall include the provision of new infrastructure such as potential park and ride facilities, bus corridors, greenways, cycling and walking routes and the N6 Galway City Ring Road (GCRR) as set out in the Priority Transportation Infrastructure Objectives 2015-2021 in Table 5.1 which are all integral in the delivery of the GTS with a view to secure the medium and long term economic and social development of Galway Gateway and the west of the County. Any such investment or project shall be carried out with due regard to the necessity to protect the environment and in full compliance with the provision of relevant legislation, including the Habitats Directive

The performance targets of the proposed road development align with the strategic aims of the County Development Plan as they include the following targets:

- Reduction of journey times which will promote regional development through improved connectivity to markets and journey time reliability
- Improve connectivity to the Gateway of Galway by providing high capacity linkages connecting east and west sides of the county
- Support sustainable transport policies for shorter commutes which will enable delivery of improved living landscapes
- Protection of existing residential communities and minimise environmental impacts which could make Galway a uniquely attractive place in which to live, work, invest and visit, in a sustainable and environmentally sensitive manner

The proposed road development is included as one of the priority transport infrastructure objectives in the County Development Plan and is fully supported by this plan.

2.5.3.2 Bearna Local Area Plan 2007-2017 (Adopted 17 December 2007 and Amended 20 December 2012)

The Bearna Local Area Plan (LAP) sets out a Strategic Vision for Bearna to be '*…an attractive, prosperous and sustainable settlement with a hiqh quality built and natural environment, a range of supporting services, facilities and amenities and a high quality of life for the local community*.' It also promotes the creation of a settlement that, *inter alia*:

- Is well connected to, but has strong local identity separate from, nearby settlements, in particular Galway City to the east and Na Forbacha to the west
- Has an appropriate level of services and infrastructure to support existing and future development in a manner that protects and is complementary to the environment, heritage, character and amenities of the village, including: an adequate road network, traffic management and parking facilities; improved public transport with regular bus services; safe routes for pedestrians and cyclists; and adequate wastewater disposal, water supply and surface water drainage

The Bearna LAP at Section 2.7 supports a new road that would bypass the village, with the stated view that it would have '*…..a positive impact for Bearna in that it will facilitate easy access to and from Bearna while reducing the volume of through traffic in the village. This would have a positive impact on the village centre and would help to create a more cycle and pedestrian friendly environment'*.

The Development Strategy of the Bearna LAP clearly sets out that it supports the funding and construction of a bypass of Bearna which now takes the form of this proposed road development.

The Galway County Development Plan was varied to incorporate the Bearna Local Area Plan. Public consultation on the variation, referenced as Proposed Variation No 2(a) to the Galway County Development Plan (CDP) 2015-2021, was sought during the period 1 December 2017 to 8 January 2018. This Variation was adopted in July 2018.

The Variation No. 2(a) Bearna Plan, has, as its Strategic Vision at Section 1.2, to seek "*the achievement of the overall objectives set out for the village in the Galway County Development Plan*". Transportation and Movement Objectives set out in the Variation, refers to Chapter 5 of the Galway County Development Plan, as set out in **Section 2.5.3.1** above. It has, as its Strategic Vision Statement "*'To promote Bearna as a sustainable and vibrant coastal village, which maintains its attractive character, capitalises on its existing and future accessibility strengths, while offering a pleasant environment for a growing community, for living, shopping, education, business, recreation and tourism, all balanced against the need to safeguard and enhance the environmental sensitivities of the area, for present and future generations to come'*. This is informed by guiding principles, which carry forward those of the Bearna LAP.

This Variation, therefore endorses the overall objectives of the Galway County Development Plan, and consequently the objectives of the GTS and this proposed road development.

2.5.3.3 Gaeltacht Local Area Plan, 2008 – 2018

Gaeltacht Na Gaillimhe is the most populous of the Country's Gaeltacht areas. It stretches from Claregalway, which is east of the city of Galway to Cloch na Rón in west Connemara, a distance of approximately 100km, and from Oileáin Árainn northwards to the Mayo border. The Gaeltacht Local Area Plan, 2008–2018 was prepared and adopted in February 2008 and amended and extended in 2013.

The purpose of the plan is to put in place controls and guidelines, consistent and compatible with the Galway County Development Plan, to facilitate the provision of infrastructure so that the younger generations will be encouraged to remain in their native area, out of choice, and develop its economy in a way that is both language and culture friendly, thus halting the decline in population. The Gaeltacht Local Area Plan sets out the strategic development principles relating to roads and transport infrastructure in **Section 3.3.2** and identifies a bypass of Galway City as being of importance to advancing the development of the social and economic advantage of the Gaeltacht and developing an integrated approach to planning.

The aims of the proposed road development align with this Gaeltacht Local Area Plan as it seeks to provide the necessary additional infrastructure to maintain existing rural communities by providing connectivity to them.

The Galway County Development Plan was varied to incorporate the Gaeltacht Local Area Plan. Public consultation on the proposed variation, referenced as Proposed Variation No 2(b) to the Galway County Development Plan (CDP) 2015-2021, was sought during the period 1 December 2017 to 8 January 2018. This Variation was adopted in May2018.

The Variation No. 2(b) Gaeltacht, has, at its Strategic Vision at Section 1.2, "*The Gaeltacht area is a unique and special place, and it is important that it retains that distinctive cultural heritage and natural beauty through the principles of sustainable development, whilst meeting the needs and aspirations of both the residents' and visitors alike. Achieving the objectives of the Galway County Development Plan in order to sustain and develop the local economy and improve the quality of life for local residents*."

This Variation supports the County Development Plan, and its objectives, which include the proposed road development.

2.5.4 Údarás na Gaeltacht Strategic Plan, 2014 - 2017

The main strategic themes of Údarás na Gaeltachta's Strategic Plan 2014 - 2017 are:

1. Support and develop language, community and cultural resources
2. Enhance innovation and competitiveness through the development of enterprise and natural resources

The Plan has four key objectives under each strategic theme set out above, of which the objectives pertaining to the second theme of innovation and competitiveness are most pertinent here:

1. Encourage a strong innovative enterprise culture which will create and sustain wealth and employment in the Gaeltacht by supporting new and established businesses to maintain and increase their employment
2. Develop new opportunities for the Gaeltacht's coastal resources through innovation in a changing economic environment

3. Stimulate the development of tourism as a driver of economic development in the Gaeltacht
4. Facilitate the provision of essential infrastructure in order to expand the enterprise capacity of the Gaeltacht

As the proposed road development seeks to deliver essential infrastructure to the western region, it aligns with the Údarás na Gaeltacht Strategic Plan.

2.6 Conclusion

As outlined in **this chapter**, the proposed road development is congruent with current European, national, regional and local transport policy and planning policy as set out in the various policy documents over the past number of years.

In recent years, there has been a major shift towards sustainable transport which is reflected in the policies discussed earlier. The changing demographics in our society whereby population is migrating to cities to avail of employment opportunities, education and improved living conditions necessitates the promotion of a wholly sustainable transportation network. Our cities are undergoing fundamental change as they strive to become living spaces for an increased population which is concentrated in a smaller tighter space. Key to a thriving urban experience is the ability to navigate a city at leisure whether as a pedestrian, a cyclist, or in a vehicle. Therefore, congestion relief through reallocation of the provision of space for cars in the city centre to other modes of transport, is key to creating more people friendly environments, additional public space, and essentially better cities.

The proposed road development functions to relieve congestion in the city. It is a key component of the Galway Transport Strategy which seeks to create a vision for Galway whereby additional space is reallocated for public transport, cycling and walking in the city centre area, all of which fosters sustainable and healthy behaviours. Reducing congestion also allows the city to prosper and connect with markets to become a thriving economic centre, in which it is attractive to work, live and play. Such a city in turn supports the Western Region and provides balanced regional development. The GTS, incorporating the N6 GCCR, will allow the city to ‘breathe’ again.

3 Need for the Proposed Road Development

3.1 Introduction

This chapter of the EIAR outlines the need for the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development.

The need for the proposed road development arises directly from the necessity to address the very serious transport issues facing Galway City and its environs. A transport solution has been developed and the proposed road development forms an essential part of this solution.

The existing transport issues currently facing Galway City and its environs is presented in **Section 3.2** below. The overall objectives of the proposed road development are presented in **Section 3.3**. The development of the transport solution is outlined in **Section 3.4** with the specific project need is defined in terms of its strategic fit and priority within the National Road Programme in **Section 3.5**. Its potential to solve existing transport issues in Galway City and its environs, its function as part of TEN-T network and the specific need in terms of economy, safety, physical activity, environmental, accessibility and social inclusion and integration is detailed in **Section 3.6** and **3.7** with an overall need for the proposed road development and the benefits it offers outlined in **Section 3.8**.

3.2 Galway Transport Issues

The total breakdown of the existing transport network in Galway occurs on a frequent basis as there is no resilience in the network e.g. wet afternoon, road maintenance, vehicle collision and/or signal outage. This random unpredictable shutdown of Galway's transport network costs millions and has the real potential to prohibit Galway functioning as a city or economic engine for the Western Region.

The transport issues facing Galway City and its environs as a result of the inadequacy of the existing road network are wide ranging with associated consequential impacts as noted below:

- Congestion throughout the city road network
- Over capacity of existing junctions
- Journey time unreliability due to uncertain quantum of delay
- Journey time variability throughout the day
- Peak hour traffic delays
- By-passable traffic is in conflict with internal traffic
- Strategic traffic is in conflict with local traffic
- Inadequate transport links to access markets within the city
- Inadequate transport connections from Galway onwards to Connemara

- Lack of accessibility to the Western Region as a whole
- Prolonged journey times and delays on the current bus network, due in part to the limited available road space in the city centre for introducing bus priority which both reduces its attractiveness to passengers and increases costs of operating
- Limited road space on most of the principal roads, which reduces opportunities for safe and comfortable cycling
- Connectivity issues on the National and Regional road network resulting in significant volumes of cross-county and strategic travel demand between east and west Galway being concentrated and funnelled through the city area in order to cross the River Corrib
- The impact of traffic congestion on the city’s reputation, particularly with regard to inward development
- Accessibility issues due to traffic congestion for businesses and community facilities in Galway City and its environs and the Business Parks in Parkmore and Ballybrit
- The routing of thousands of vehicles per day through the city centre brings with it associated and unmitigated impacts on businesses, public facilities, homes and non-motorised road users
- The stop/start nature of urban driving and platooning of vehicles behind slow moving vehicles adds to the levels of pollution experienced by locals and visitors
- Severance effects of traffic congestion is experienced in urban areas and traffic speeds are increasing in rural areas as local roads are used to avoid the congested national road network

There is a critical need to address the transport issues in Galway City and its environs. As a Gateway to the Connemara and the Western Region, **connectivity and accessibility to and through Galway City** is essential in aiding the region to revitalise, improve and develop into the future. As Galway City and its environs continues to grow, it is crucial to **safeguard the future development** of the city as the principal economic centre in the west of Ireland and to ensure that its development is sustainable. In addition, providing **well developed transport links** via roads, rail and air to the Western Region enables enterprises and the local economy of the west to grow and develop as a viable alternative to the east coast corridor which is of significant public interest at a national level. The existing road network is analysed to establish the underlying issues so that the appropriate transport solution is implemented.

3.2.1 Overview of Existing Road Network

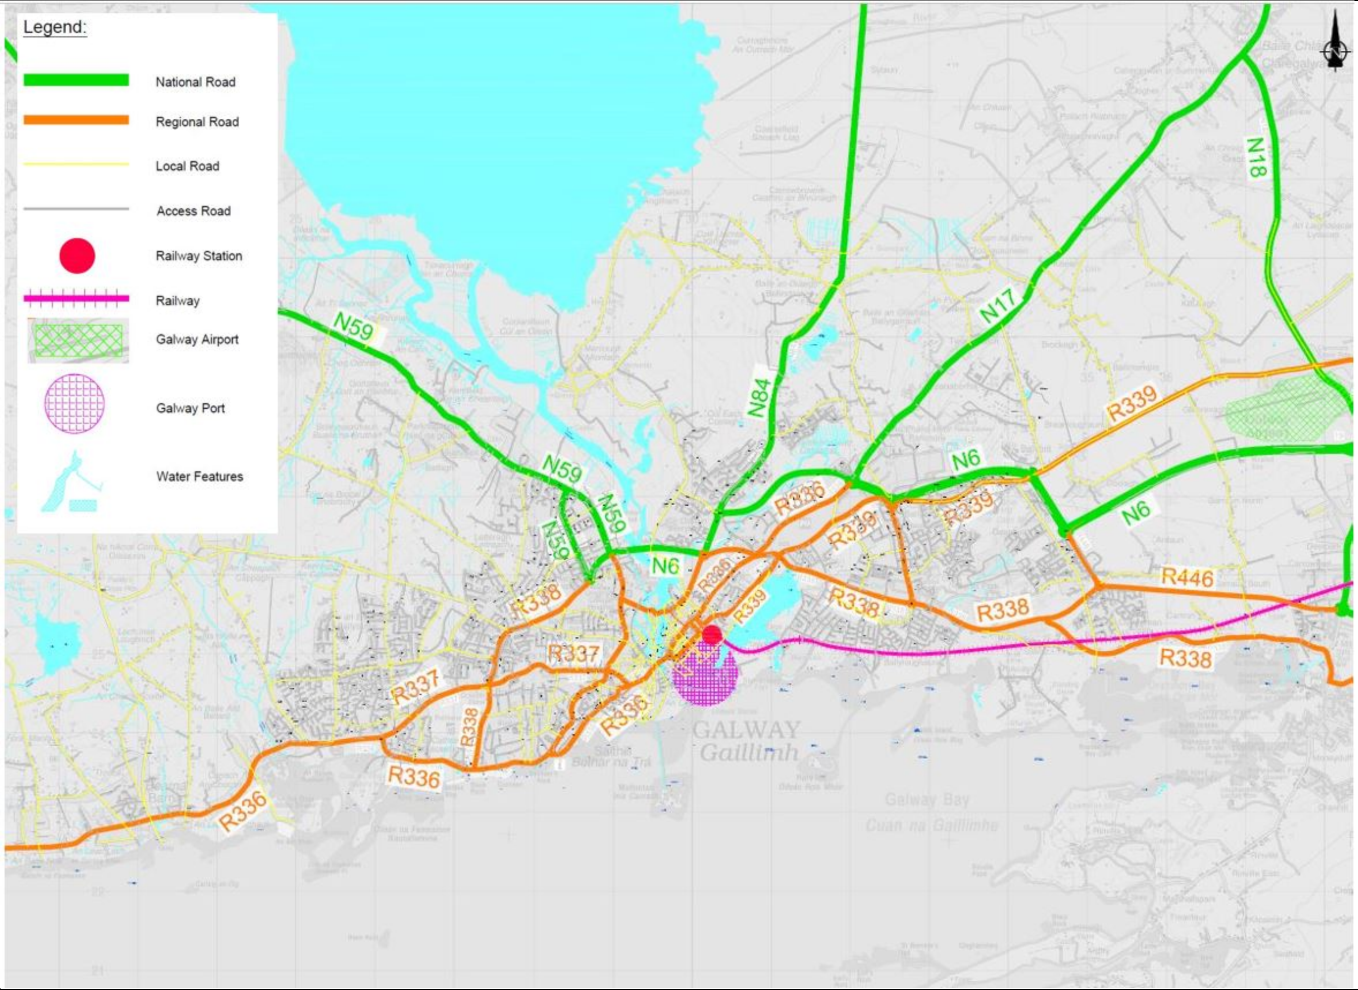
An understanding of the existing road network is critical in the development of a transport solution.

The existing road network which is described in **Chapter 6, Traffic Assessment and Route Cross-Section,** consists of the existing N6, a National Primary route which connects the N6 on the east side of Galway at Coolagh to the N59 Moycullen Road and the R338 on the north-west side of Galway at Newcastle. The existing N6 passes though the environs of Galway City, namely Briarhill, Ballybrit, Ballybane and Terryland on the east side of River Corrib and Newcastle on the west of the river. The existing N6 terminates at the R338 at the at-grade roundabout junction, Browne Roundabout, with the N59. The R338 continues in a westerly direction to the Coast Road, the R336. Whilst the existing N6 bypasses Galway City Centre, a large portion of the traffic on the N6/R338 is not fully bypassing Galway City environs, rather it is using the existing N6 and the R338 to move in an east/west direction across the city, refer **Plate 3.1** below.

The existing N6 is a four lane carriageway between the M6/N6 and the N59 Moycullen Road, with a varying median width, and a number of at-grade junctions comprising of at-grade roundabouts and signalised junctions. The R338 varies in cross section consisting of four lanes, two of which are bus lanes as far at the Deane Roundabout and two lanes for traffic from there to the R336 Coast Road. There are various forms of at-grade junctions including roundabouts, signals and priority junctions on the R338 from its junction with the N59 Moycullen Road as far as the R336.

The existing road network is at capacity and insufficient to cater for the current travel demand in Galway City, its environs and the Western Region. Therefore, the transport solution must address the existing road network capacity. The key performance indicators used to assess the capacity of the existing road network include an analysis of the existing travel patterns to understand the requirements of the ultimate transport solution, analysis of journey time and assessment of junction capacity.

Plate 3.1: Existing Road Infrastructure



3.2.2 Existing Travel Patterns

An understanding of existing travel patterns is critical in the development of a transport solution. Initial feasibility studies identified the zones of employment, education, retail and residential, i.e. these are known as zones of traffic generators and attractors. These zones are shown on **Plate 3.2**. This graphic shows the residential areas interwoven with the key attractors with the resultant travel desire lines also displayed, and demonstrates how the River Corrib divides this city.

Early studies identified that Galway has a transport problem, and moreover it has is a multifaceted transport problem that needs more extensive analysis to fully understand all the issues. For this reason, the traffic analysis was carried out using the detailed multi-modal traffic model, i.e. the Western Regional Traffic Model, which was developed by the National Transport Authority.

Analysis of the Western Regional Traffic Model provided a very clear and reliable picture of travel patterns in and around Galway City and the wider region, including data on multiple modes of travel, namely (i) public transport, (ii) private vehicles, (iii) cycling and (iv) pedestrians.

Analysis of the travel patterns informed the understanding of travel demand in Galway City and its environs, which in turn has guided the selection of an optimum transport solution which matches demand. Capacity for the current demand and more critically demand into the future was of critical importance in developing this transport solution – there are not multiple opportunities or indeed multiple alternatives, therefore, it is imperative that this solution is the correct solution for the future.

Plate 3.2: Traffic Generators and Attractors

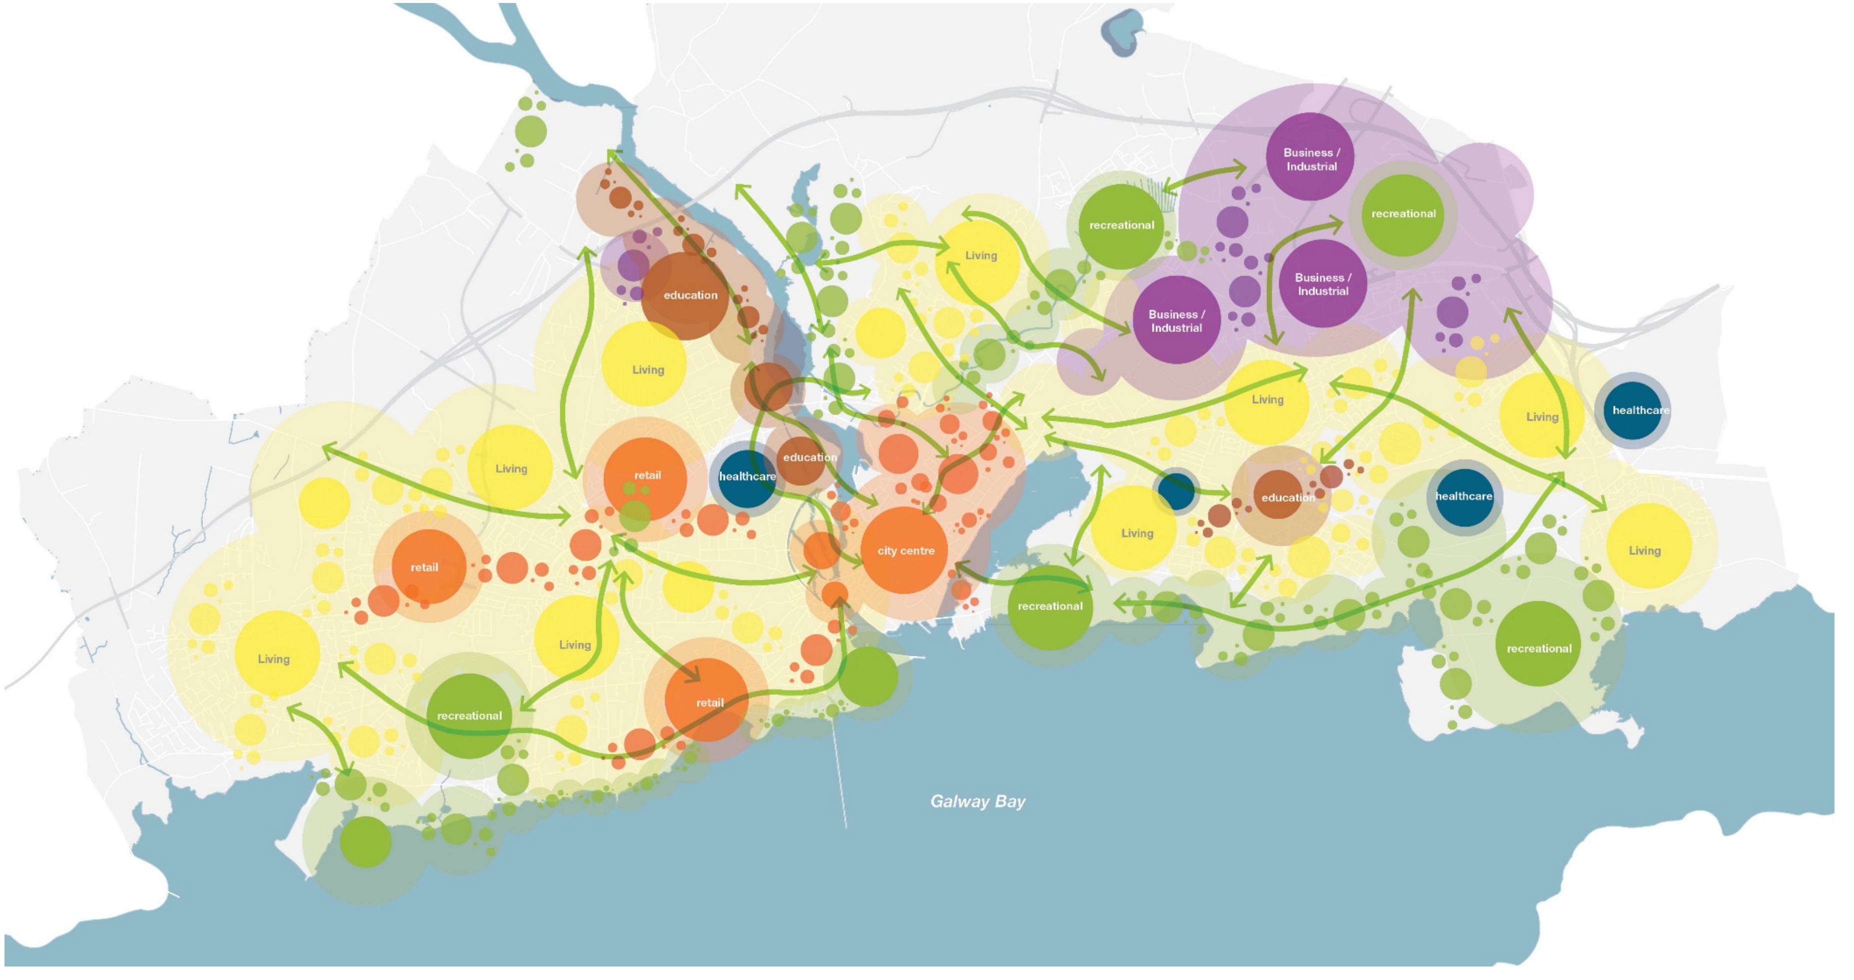


Plate 3.3 below is a schematic diagram to illustrate the travel patterns for private car trips to, from or through Galway City in the 2012 Base Year morning peak hour (extracted from the traffic model, ref **Chapter 6, Traffic Assessment and Route Cross-Section**). Red arrows show movements that cross the River Corrib and green arrows show movements that do not cross the River Corrib.

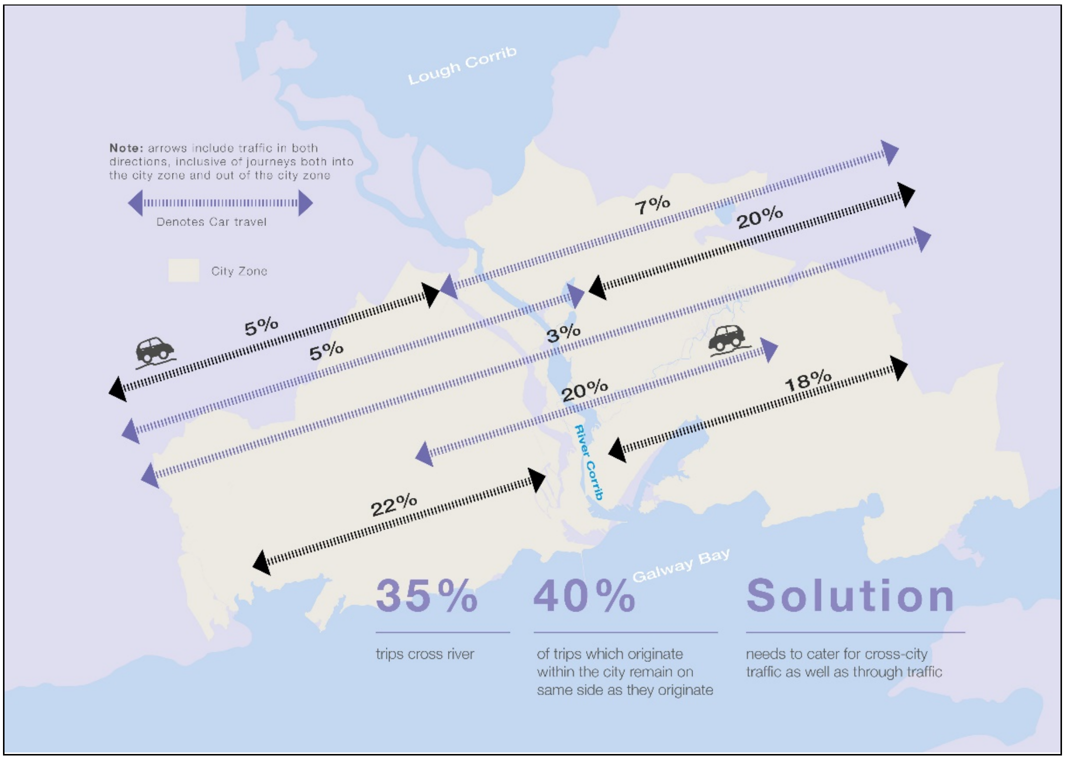
As shown in **Plate 3.3**:

- 35% of all journeys into and out of the city zone and around Galway City (city zone) cross the River Corrib, of which approximately 9% are bypass traffic (i.e. 3% of 35%)
- 40% of all journeys originate and terminate within the city zone on the same side of the city as where they started i.e. do not cross the river
- Approximately 20% of all journeys are within the city zone and cross the river

Plate 3.3: Travel Patterns 2012 Base Year Morning Peak Hour



This analysis shows that the transport solution must be multi-modal catering for the following various demands:

- High proportion of short journeys within the city zone can be accomplished via public transport, cycling or walking i.e. approximately 40% of journeys commencing in the city which remain on the same side of the city as they started are short trips, both in time and distance
- A further 20% of journeys are from one side of the city to the other are also short journeys, making them clear targets for a shift to public transport

- Improved connectivity to the national road network for those on the western side of the River Corrib which is only possible at present by using one of the city centre bridge crossings

Whilst the overall transport solution clearly must serve a multi-modal demand, this analysis of demand also shows that the transport solution must separate the conflicting demands and serve them via differing appropriate transport modes so that this significant infrastructural investment is protected and secured for the future.

The lack of such a multi-modal transport network has wider impacts on all transport modes including the following:

- Impacts on the public transport network which results in prolonged journey times and delays on the current bus network
- Reduces opportunities for safe and comfortable cycling
- Peak hour traffic delays
- Thousands of vehicles per day travel unnecessarily through the city centre which brings with it associated and unmitigated impacts on businesses, public facilities, homes and non-motorised road users

3.2.3 Journey Time Reliability

Analysis of travel surveys, journey times and delays on the existing network was carried out to establish a set of measurable key performance indicators (KPI) to define the existing problems and with which to compare future potential solutions.

An analysis of observed journey times on three key routes around Galway and its environs as shown on **Plate 3.4** below was carried out to show the variance in journey times between the peak and off-peak periods in the Base Year. The difference between the peak and off-peak journey times is a measure of the level of congestion during the peak, and increasing congestion results in worsening journey time reliability.

Observed travel times in 2012 Base Year on each of the existing N6, the N84 Headford Road and N83[1] Tuam Road, in the inbound direction in the morning peak period versus the off-peak period are tabulated in **Table 3.1** below.

This assessment of journey time shows that the travel times on these three key routes in the morning peak hour are on average more than double the off-peak travel times.

[1] Formally known as the N17 Tuam Road.

Plate 3.4: Journey Time Reliability Routes

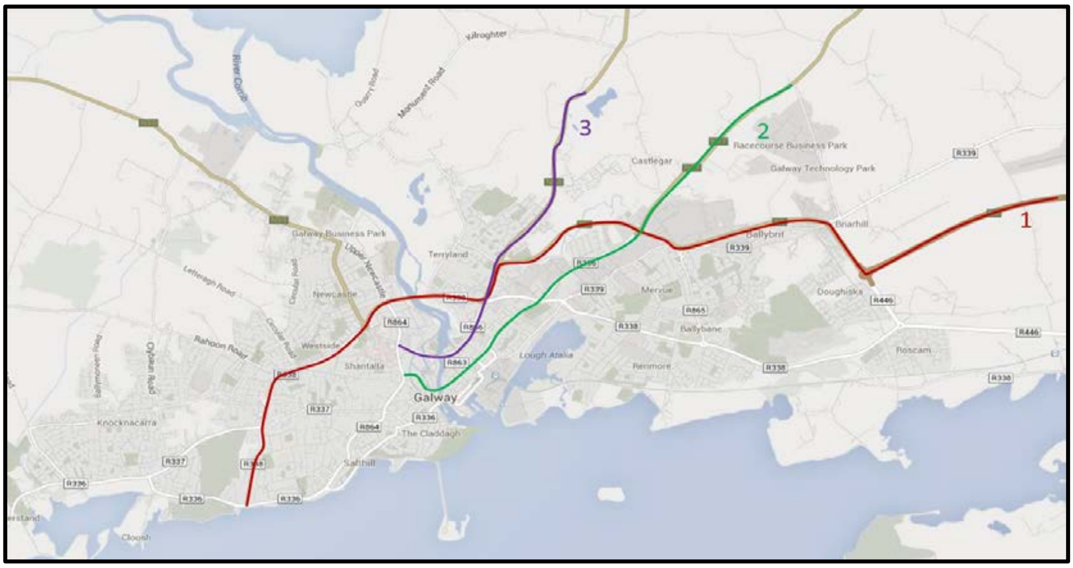


Table 3.1: Journey Time Reliability

		2012 Observed Journey Times (minutes)			
		Off-peak average hour	**Morning peak hour**	**Difference**	**% Difference**
Inbound	Route 1 IN	14	28	14	100%
	Route 2 IN	14	25	11	79%
	Route 3 IN	8	19	11	138%
	Average	12	24	12	105%

Journey time unreliability is a significant detractor to incoming businesses seeking to locate in the area, to tourism due to difficulties of scheduling timetables and also to indigenous industries attempting to get goods out to national markets.

Bus connections in City Centre rely on 15/20/30 minute schedules. These schedules are not achievable due to congestion within the city centre. Connections are then missed with the resultant being that cross city bus trips take over an hour.

Therefore, the transport solution must address journey time unreliability as again this has wider impacts including the following:

- Unreliable transport links to access markets within the city
- Unreliable transport connections from Galway onwards to Connemara
- Lack of accessibility to the Western Region as a whole
- Peak hour traffic delays
- Prolonged journey times and delays on the current bus network
- Difficulty of attracting businesses to Galway City and its environs

3.2.4 Junction Capacity Assessment

Congestion arises due to capacity failures of the existing junctions. This congestion is crippling and stifling city living as well as cutting off access from the wider region to employment and services in the city. These existing junctions are expected to perform the dual role of accommodating traffic wishing to circulate around the city as well as traffic on the radial routes trying to access the city.

An assessment of the volume/capacity (V/C) ratio was undertaken at signalised junctions and roundabouts, plus other key junctions where main roads intersect as shown on **Plate 3.5**. Max turn V/Cs show the maximum volume-to-capacity ratio for the turns at each junction. This indicator is useful for highlighting the problem junctions, compared to the average V/C or average delay, which can be dominated by the high-volume low-delay movements. The volume to capacity ratios are then related to level of delay and congestion at the junctions.

Plate 3.5: Volume/Capacity Ratios at Junctions (2012)

Plate 3.5 shows the number of junctions with a max turn V/C within standard ranges of 0.85-1.00, 1.00-1.15 and >1.15. Junctions with a V/C ratio greater than 1 have exceeded their capacity. Ideally junctions should operate at a V/C ratio of < 0.85, which would allow 15% spare capacity in the junction to cope with an unexpected event or natural growth.

This analysis demonstrates that the existing network is restricted by junction capacity. The junctions on the critical corridors accessing the city, namely the junctions of the N84, N83 and N59 Junctions with the existing N6, have all currently exceeded their capacity at peak hour as shown on **Plate 3.5** above. These junctions are operating at greater than 100% of their capacity, which in turn leads to the significant delays at these junctions. As these junctions are the main arteries into the city and the main junctions on the circumferential route around the city, this is a significant issue for the Gateway of Galway.

In addition, approximately 40% of all junctions on the key access routes across Galway City and its environs are operating above 85% capacity. This demonstrates that the network is finely balanced with minimal spare capacity to allow for any unforeseen event or natural growth. This is significant as grid-lock on a city wide scale is evident in the event of an unforeseen occurrence such as an accident, significant weather event, temporary traffic management associated with regular maintenance works on the existing road network, seasonal events and particular match day events.

Therefore, the transport solution must address junction capacity as again this has wider impacts including the following:

- Congestion throughout the city road network
- Journey time unreliability and journey time variability throughout the day
- Peak hour traffic delays
- Limits access to markets within the city and onwards to Connemara
- Delays to the National and Regional road network
- Accessibility issues for the entire Western Region

3.2.5 Long Term Impacts

The potential long term impacts on the social and economic fabric of Galway will be significant if transport issues are not addressed. Macro-economic impacts which may arise could include any or all of the following:

- Disincentive for Foreign Direct Investment (FDI) to invest in Galway City due to congestion costs in terms of both goods and labour
- Decline in the quality of the urban environment due to increased congestion and pollution may lead to reduced attractiveness of Galway City for labour force location
- Decline in the quality of the urban environment could exacerbate the already existing trend to live outside the city limits and commute to Galway for work, increasing congestion and reducing the potential for any investment in public transport or alternative means of travel, to make an impact
- May lead to further relocating of other activities away from the city core e.g. retail, business, employment, leisure, reducing the strength of Galway as a Gateway City
- Impact on the economic development of the wider western region as access is compromised (labour, goods, tourism)
- Suppressed travel movements either side of the River Corrib, resulting in isolation of areas of the city and county
- Overall, can lead to the decline of Galway City to act as a Gateway on the western corridor, and act as a regional counter balance to the east

- Create two separate city areas either side of River Corrib, with the city and county to the west declining

Social impacts resulting from the above could include:

- Create a challenging environment in accessibility terms for some sectors of society, particularly those most dependent on non-private car travel, as investment in public transport will be harder to justify over a more dispersed city fabric
- Potential reduction in range of employment options available which could impact the profile of residents in the city and corresponding impacts on communities
- Reduction in quality of life indicators

Given the potential long term impacts above, there is a strong need to address the transportation issues facing the city and surrounding areas at present, and to underpin future growth by establishing a long-term strategy for transport to, within and around the city.

3.2.6 Significant constraints for developing new transport infrastructure

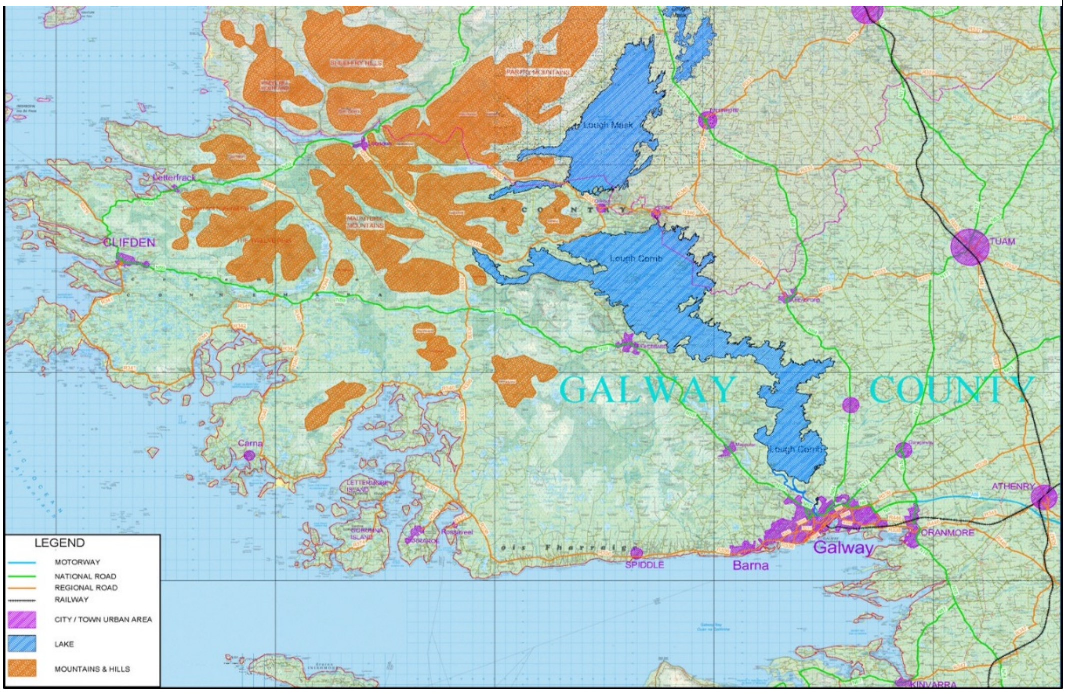
Galway is a city of contrasts in terms of its physical development and transport requirements. While Galway has a compact walkable core, outside of the city centre, the suburbs have developed as a succession of low density residential areas interspersed with employment areas, leading to a predominance of private car usage as a means of travel. There are significant constraints for developing new transport infrastructure in Galway which arise principally due to:

1. the physical form of the city
2. the limited space available
3. the built environment and residential areas on both sides of the River Corrib
4. the presence of designated sites of international significance

Galway City is physically constrained as it is divided in an east west direction by the River Corrib and a sea inlet known as Lough Atalia, bounded along the entire southern boundary by Galway Bay and the northern boundary by Lough Corrib, all of which are natural barriers to free movement and development. There are currently four bridges crossing the river, which cumulatively carry approximately 80,000 vehicles per day. Three of the four bridges are within the city centre, thus drawing traffic into the city for the sole purpose of crossing the river.

Galway County and Connemara as far west as Clifden and onto Letterfrack are equally dependent on this narrow funnel for access, as access to this area is restricted by the extents of Lough Corrib heading north, the Twelve Bens mountains, the Maamturk mountains and the many smaller lakes. **Plate 3.6** below highlights that access to this area is via the bridges across the River Corrib in Galway City due to the physical natural constraints.

Plate 3.6: Existing Natural Constraints



In summary:

- The low density of the suburbs of Galway has led to reliance on private car usage as a means of travel and makes it difficult to develop an economically efficient public transport solution
- Galway City is divided by the River Corrib as it flows between Lough Corrib and Galway Bay with significant trip attractors, employment centres, education centres and residential areas located on both sides of the river
- Lough Corrib forms a natural division between the east and west of County Galway and the distance between Lough Corrib and Galway Bay is only 4.5km[2] within which lies Galway City, very much at the heart of County Galway
- The city is located in the middle of areas which are rich in natural heritage with a wealth of natural habitats. This has resulted in significant areas around Galway City being designated of international importance

3.3 Project Objectives

The overall ambition of the proposed road development is to achieve a number of specific objectives under a number of multi criteria categories. These multi criteria are outlined by the Department of Transport in *Guidelines on a Common Appraisal Framework for Transport Projects and Programme March 2016*. By considering the objectives under these headings, it is the intention to provide a project which is attractive to all, delivers the road component of the overall transport solution for

[2] Distance measured from south shore of Lough Corrib to Spanish Arch at Galway Docks

Galway and its environs, provides benefit to the local and the larger regional population of Galway and the western region and is cognisant of the sensitive environment into which it is interwoven. The multi criteria headings are as follows:

- Economy
- Safety
- Environment
- Physical Activity
- Accessibility & Social Inclusion
- Integration

Each of these objectives are linked to the European, national, regional and local polices set out in **Chapter 2, Planning and Policy Context**. Every endeavour has been made to ensure these objectives were met as much as possible in the development of the proposed road development. The specific objectives under each of the headings are detailed below.

The ***'Economic'*** objectives of the proposed road development include:

- Encourage local, regional, national and international development
- Reduce journey times
- Increase journey time certainty
- Support the economic performance of the Gateway of Galway as the only large employer in the region
- Provide benefits to the transport infrastructure
- Improve connectivity to the Gateway of Galway
- Improve linkages between the west and east sides of the city and county
- Deliver a cost effective project

The ***'Safety'*** Objectives of the proposed road development include:

- Segregation of the interface of strategic traffic from local traffic
- Reduction in road traffic collisions
- Provision of safer urban streets

The ***'Environmental'*** Objectives of the proposed road development include:

- Minimise impacts on designated Natura 2000 sites
- Avoid impacts to National Monuments
- Minimise impacts to the architectural, cultural or linguistic heritage of the area
- Take due cognisance of the importance of the existing landscape
- Seek to preserve existing well established communities
- Reduce noise and air impacts on sensitive receptors
- Deliver a sustainable transport solution

The ***'Physical Activity'*** Objectives of the proposed road development include:

- Improve accessibility to Galway City
- Improve opportunities for walking in the core city centre area by creating more walkable environments
- Reallocation of road space for the provision of additional cycling facilities on less congested urban streets

The ***'Accessibility and Social Inclusion'*** Objectives of the proposed road development include:

- Improve accessibility to Galway City
- Interconnection of the Galway City and its environs road network to the national motorway network
- Improve accessibility of Galway urban area to its main markets
- Improve accessibility of the Gaeltacht areas to the remainder of the county and country
- Reduce disadvantage of the Gaeltacht areas
- Implement sustainable transport policies for shorter commutes
- Improve urban environment of Galway City centre
- Support the improvement of the public transport hub linking Galway to other Gateways
- Support the current development strategy and settlement strategy

The ***'Integration'*** Objectives of the proposed road development include:

- Support the development of critical-mass of regional population centres
- Integration of Galway City and its environs (including western parts of Galway County) into the national economic development agenda
- Support balanced social and economic development at a national level
- Support balanced social and economic development at a city-region level
- Understanding of the development, land-use and transportation pressures in the Galway urban area and their impact on the delivery of a successful city region at Galway
- To deliver on Galway's potential as Ireland's fourth largest city and an important residential, educational, employment and service centre for a wide regional hinterland, contributing to the national urban hierarchy
- Recognition of the role of Galway City as a gateway to the west and Connemara, and the consequent socio-economic benefits of enhanced connectivity of Galway City to national markets, enhanced tourism accessibility, and the national transport system
- Improvement of the TEN-T network to ensure connectivity of the west of Ireland to the single European market.

These project objectives were used to guide the development of a transport solution for Galway City and its environs. A subsequent appraisal of these objectives against the need for the proposed road development and how these objectives were met is presented in **Section 3.7** below.

3.4 Development of a Transport Solution for Galway

3.4.1 Overview

As outlined previously in **Chapter 1, Introduction**, the initial studies for a transport solution were undertaken as part of the N6 Galway City Transport Project (GCTP). In parallel to the GCTP, Galway City Council and Galway County Council, in partnership with the NTA developed an overall transport strategy for Galway City and its environs, and is referred to as the Galway Transport Strategy (GTS). The GTS is the transport solution for Galway.

The GTS took into account the existing transport issues as described in **Section 3.2** above. The traffic issues in Galway City and its environs were carefully considered and analysed with the aim of finding a transport solution to create a safer, smarter and sustainable transport system for Galway City and its environs taking into account travel demands, existing infrastructure and environmental constraints.

The GTS included an evaluation of transport options for all modes, and affirmed the strategic need for an orbital route around the city and a new crossing of the River Corrib, in order to implement the level of service required for each mode of transport, including walking, cycling, public transport and private vehicle. The provision of an additional crossing of the River Corrib would facilitate the reduction of congestion on city centre roads, and allow the reallocation of road space in the city network to non-motorised modes of transport, thereby facilitating the effective implementation of all the elements contained in the GTS, namely the improvement of public transport, cycling and walking measures. A new road link to the north of the city is proposed as part of the GTS to deliver the necessary capacity and support the delivery of sustainable transport measures, particularly within the city centre.

The initial studies carried out as part of the N6 GCTP confirmed that a new River Corrib bridge crossing is possible and identified a preferred location for this crossing.

The N6 Galway City Ring Road (GCRR) will deliver the additional crossing of the River Corrib and the new link road as proposed by the GTS. Therefore, the proposed road development forms an essential part of the GTS, it delivers the road component of the overall transport solution for Galway City and its environs, provides benefit to the local and the larger regional population of Galway and the western region and is cognisant of the sensitive environment into which it is interwoven.

The need for the proposed road development, the N6 Galway City Ring Road, is justified as it will deliver the following:

- By tackling the city's congestion issues, it will provide a better quality of life for the city's inhabitants and provide a much safer environment in which to live
- By reducing the number of cars on the roads within the city centre and improving streetscapes, workers and students are facilitated to commute using

multi-modal transport means. This includes travelling on foot, by bicycle and on the public transport system

- Provides connectivity to the national roads via junctions to maximise the transfer of cross-city movements to the new road infrastructure, thus releasing and freeing the existing city centre zone from congestion caused by traffic trying to access a city centre bridge to cross the River Corrib
- Attracts traffic from the city centre zone thus facilitating reallocation of road space to public transport leading to improved journey time reliability for public transport
- Caters for the strong demand between zones on either side of the city
- Provides additional river crossing with connectivity back to the city either side of the bridge crossing
- Facilitates improved city centre environment for all due to reduced congestion, thus encouraging walking and cycling as safe transport modes

The need for the proposed road development in terms of delivering the road component of the transport solution for Galway, in the context of how such a development can address the transport issues raised in **Section 3.2** above is discussed below.

3.4.2 Existing Road Network Issues

The existing road network is at capacity and insufficient to cater with the current travel demand in Galway City, its environs and the Western Region. The proposed road development will replace the role of the existing N6/R338 road network. By serving strategic traffic currently trying to cross the city via the existing N6 as well as the strategic traffic that is currently trying to rat-run through the city using the existing city street network due to the congestion levels on the national road network, the proposed road development will free up road space in the city centre that can be used by other modes of transport. The city at its heart serves a strategic function as the economic engine for the Western region and must be free of congestion to enable it to do so. This is supported in terms of policy from national to local level which is outlined in **Chapter 2, Planning and Policy Context**.

3.4.3 Existing Travel Patterns

The need for the proposed road development, the N6 Galway City Ring Road, is justified as it serves the existing travel demands as follows:

- Caters for the strong demand between zones on either side of the city
- Facilitates crossing the River Corrib without negotiating the city centre
- Provides this additional river crossing with connectivity back to the city either side of the bridge crossing
- Attracts traffic out from the city centre zone thus facilitating reallocation of road space to public transport leading to improve journey time reliability for public transport

- Facilitates improved city centre environment for all due to reduced congestion, thus encouraging walking and cycling as safe transport modes
- Improves connectivity to the Western Region i.e. the county areas and hinterland beyond the city zone
- Provides essential city street links to better distribute traffic
- Provides connectivity to the national roads via junctions to maximise the transfer of cross-city movements to the new road infrastructure, thus releasing and freeing the existing city centre zone from congestion caused by traffic trying to access a city centre bridge to cross the River Corrib
- Provides a high quality road with limited access

3.4.4 Journey Time Reliability

The proposed road development seeks to address this issue through relief of the traffic congestion by removal of traffic both through modal shift, provision of additional road space and separation of bypass traffic.

The traffic modelling of the proposed road development, which is discussed in **Chapter 6**, **Traffic Assessment and Route Cross-Section**, demonstrates how the proposed road development achieves these goals which form the basis of the need for the proposed road development. The proposed road development provides connectivity to the national roads via junctions to maximise the transfer of cross-city movements to the new road infrastructure, thus releasing and freeing the existing city centre zone from congestion caused by traffic trying to access a city centre bridge to cross the River Corrib. This reduction in congestion will lead to lower collision rates and improve conditions for vulnerable road users.

3.4.5 Junction Capacity Assessment

The proposed road development is required to resolve this constant lingering problem of junctions with no spare capacity on the existing N6 route and existing network which frequently results in grid-lock in the city. This links to the congestion relief discussed in **Section 3.2.1.3**, all of which promotes the need for the proposed road development.

3.5 Strategic Fit and Priority within the National Road Programme

Transport Infrastructure Irelands (TII) primary function under the Roads Act 1993, is to secure the provision of a safe and efficient network of national roads. For this purpose, it has overall responsibility for the planning and delivery of new national roads, road network management and maintenance on national roads.

The objective of the TII capital expenditure programme is to improve the safety and efficiency of the national road network to make it fit for freight, business and social travel. Developing, maintaining and operating the national road network in a safe, cost effective and sustainable manner generates an improved quality of life and national economic competitiveness.

The three strategic priorities for TII are summarised as follows:

"Priority 1 – Asset Management, Network Rehabilitation and Network Operations;

Priority 2 – National Secondary Roads Improvements, Bottleneck Improvement Projects, Safety Projects and Traffic Management Projects; and

Priority 3 – Network Improvement Projects."

The proposed road development links four national routes around Galway City, namely N59, N84, N83 and N6. It also links a number of regional routes including the R336, which accesses south Connemara, refer **Plate 3.1**. The proposed road development is the mechanism to convey traffic east to west from the north and south and effectively encompasses all three of TII priorities whereby the existing primary road network is rehabilitated and improved, providing safety benefits and congestion/bottleneck improvements.

Investment in the proposed road development adds value to the overall strategic national roads network for the country, see also **Chapter 2, Planning and Policy Context**.

3.6 TEN-T Comprehensive Road Network

As discussed in **Chapter 2, Planning and Policy Context**, the proposed road development forms part of the TEN-T comprehensive road network and as such has a strategic function. This is discussed under various headings which are fundamental to understanding the purpose of TEN-T and to understanding why the proposed road development is of strategic importance.

TEN-T Classification

- The proposed road development was developed to be part of Ireland's comprehensive network in accordance with the European Union's (EU) TEN-T[3] Transport Policy
- The EU's TEN-T Transport Policy aims to create connectivity between regions, remove bottlenecks that hamper the smooth functioning of the EU's internal market and to promote a sustainable, multi-modal network for passengers
- The proposed road development has been developed as a high-quality road as part of the TEN-T comprehensive network to deliver the objectives of TEN-T both on a strategic national and European level, as well as on a regional level to the Western Region. The proposed road development is intended to support the economic and social development of the Western Region, by ensuring the connectivity and accessibility of this region to the single European market

Connectivity, Accessibility and Social Inclusion

- One of the principal aims of TEN-T is to improve cohesion throughout the EU by ensuring the connectivity and accessibility of all regions, including the EU's outermost and remote regions. The proposed road development will improve

[3] http://ec.europa.eu/transport/infrastructure/tentec/tentec-portal/map/maps.html

linkages between the west and east sides of the country, as well as improving the connections between the Western Region and the wider internal market within the EU

- It will improve the accessibility of Galway City to its main markets, by facilitating the crossing of the River Corrib without the need to go through the city centre. The proposed road development will protect the interconnection of Galway City and its environs road system to the national motorway network. This will increase the connectivity of key strategic services within Galway, such as NUIG and Galway University Hospitals, to the national motorway network
- The proposed road development will also improve the accessibility of Gaeltacht areas to the remainder of the county and country, thereby reducing the economic and social disadvantages of the Gaeltacht areas, as it will provide the capacity required for national and international traffic serving the Western region whilst also connecting the county to the national network
- Access to this strategic route is limited to the junctions provided along the route, which will protect the asset in the future and the proposed road development has been designed to ensure that it is not misused as a ‘hop on hop off’ network for local traffic. Junctions have been restricted to the western tie-in with the R336 Coast Road, Bearna Moycullen Road, Cappagh Road, Ballymoneen Road and the national roads, N59, N84, N83 and the existing N6. This level of provision is deemed necessary to serve the strategic travel demand, as the traffic accessing Galway City is of a strategic nature, whilst also providing connections for users from the Western Region to the national road network

Removing Infrastructural Bottlenecks

- The TEN-T aims to increase efficiency throughout the transport network by removing bottlenecks and congestion. Currently, Galway City experiences transport problems across the city, particularly during peak hours, which is impacting on the economic capability of the city. The road and street network of Galway City is ill-suited to the high traffic flows currently prevalent and contributing to increased congestion and delay, affecting quality of life and impacting on the functionality of the city
- The effects of this congestion and bottlenecks extend to the wider county and region, due to the large number of people commuting daily for work or education to the city from the surrounding towns, villages and rural areas. The congestion and infrastructural bottlenecks impact the connectivity of the Western Region to the rest of the country and the internal markets of the EU
- The proposed road development is a key element of the GTS as it aims to resolve the congestion which is restricting the Western Region currently and is experienced by all travellers using various transport modes

Sustainable Transport Choices for Passengers

- TEN-T aims to promote sustainable travel by creating a multi`-modal transport network, which meets the mobility and transport needs of its users. The N6 GCRR will reduce congestion and car dependency by attracting traffic from the city centre zone, which will facilitate a reallocation of road space. This will improve capacity and reliability of public transport and will facilitate greater opportunities for cycling and walking within the city centre core area

- By providing opportunities for a multi-modal transport system, the N6 GCRR promotes the reduction of greenhouse gas emissions as it facilitates the advancement of a low-carbon and more energy efficient transport system, whilst also providing accessibility and connections to the city. This also reduces the level of air pollution within the city centre. The GTS aims to relieve traffic congestion in the urban centre of Galway which in turn will facilitate a modal shift to public transport, cycling and walking, all of which promotes the reduction of greenhouse gas emissions as it facilitates the advancement of a low-carbon and more energy efficient transport system

Therefore, it can be concluded that the proposed road development serves a dual purpose for the following reasons:

- it provides for the strategic need of the TEN-T comprehensive road network and connects Galway City and the Western Region to the national road network
- it provides an additional crossing of the River Corrib, thus facilitating the reduction of congestion on city centre roads, and allowing the reallocation of road space in the city network to non-motorised modes of transport, thereby facilitating the effective implementation of all the elements contained in the GTS, namely the improvement of public transport, cycling and walking measures

There is no tension between these two functions, in so far as the whole transport strategy has been developed so that traffic is segregated and directed to the most appropriate mode, which allows the road component to serve the function for which it is designed. By serving strategic traffic currently trying to cross the city via the existing N6 as well as the strategic traffic that is currently trying to rat-run through the city using the existing city street network due to the congestion levels on the national road network, the proposed road development will free up road space in the city centre that can be used by other modes of transport. The city at its heart serves a strategic function as the economic engine for the Western Region and must be free of congestion to enable it to do so. It is critical to understand the strategic function of the proposed road development and to understand why it is classified as part of the TEN-T comprehensive road network as discussed above.

3.7 Appraisal Framework for Transport Projects

In accordance with the Department of Transport’s “Guidelines on a Common Appraisal Framework for Transport Projects and Programmes” (updated March 2016), the need for the proposed road development is described below against the six criteria of Economy, Safety, Physical Activity, Environment, Accessibility and Social Inclusion and Integration. The importance of providing a sustainable development is also considered.

3.7.1 Economy

Recent national developments mean that, more than ever, each region of the country has a crucial role to play in returning Ireland's economy to enterprise driven growth. The delivery of dynamic, competitive regions that provide quality and sustainable employment opportunities will involve not only the enterprise development agencies, but also a wide range of stakeholders including local authorities, higher education institutes and the business community at local, regional and national levels.

The proposed road development will provide an economic benefit to Galway City and environs. Whilst there is a profitable business opportunity during the construction phase for contractors and suppliers, the true economic benefit will be realised once the proposed road development is completed. Accessibility to businesses and community facilities in Galway City and its environs and the Business Parks in Parkmore and Ballybrit will be better facilitated by the proposed road development and the resulting reduction in congestion. It will also bring with it benefits to business and public facilities in Galway City centre by reducing noise and air pollution. This all translates into economic prosperity for the Western Region, with Galway City as a thriving city at the core, which in turn will play a part in reviving the Irish economy.

The proposed road development will provide a high quality roadway asset designed in accordance with current TII Design Standards and Guidance.

An efficient integrated transport infrastructure is necessary to reduce levels of congestion and allow economic growth. The proposed road development facilitates this improvement by providing relief to the national, regional and local road network, whilst also improving accessibility of the public transport network and allowing advancement of sustainable transport planning at a local level.

3.7.2 Safety

The existing traffic volumes and HGVs on the existing road network leads to traffic congestion on a consistent basis. As outlined in **Chapter 6, Traffic Assessment and Route Cross-Section**, the proposed road development provides connectivity to the national roads via junctions to maximise the transfer of cross-city movements to the new road infrastructure, thus releasing and freeing the existing city centre zone from congestion caused by traffic trying to access a city centre bridge to cross the River Corrib. This reduction in congestion will lead to lower collision rates and improve conditions for vulnerable road users.

Providing improved road infrastructure generates significant safety benefits to the network at two levels, firstly via the transfer of high volumes of traffic to the safer roads and secondly via a reduction in distances travelled on less safe existing roads. Modern technology and information systems which form part of new road infrastructure also gives greater security to road users. Opportunities for further safety benefits present through the provision for vulnerable road users through reallocation of road space on the existing network. Safety and security on our road network is of national interest and a key part of government policy over the past decades.

3.7.3 Physical Activity

The latest Common Appraisal Framework (CAF) update has included an additional criterion for appraisal namely Physical Activity. The existing N6/R336 is a deterrent to physical activity due to lack of attractive provision for vulnerable road users – cycling and walking adjacent to heavily congested commuting routes and requirement to negotiated complex multi-phase traffic signals at crossings. Whilst the N6 GCRR does not necessarily provide for increased levels of activity in itself, the objective set at the outset is to create opportunities for walking in the core city centre area and to reallocate road space for the provision of additional cycling facilities. The N6 GCRR meets this project objective as it is part of an overall strategy whereby road space is reallocated to cyclists and pedestrians once traffic is removed from the city centre to the proposed ring road.

3.7.4 Environment

The proposed road development is going to have negative impacts on the receiving environment including, unfortunately, a significant level of property demolitions that are unavoidable. From the outset of the design of the proposed road development every effort was made to avoid property demolitions where possible. However, there are still property impacts and it is proposed that 69 non-agricultural properties will be acquired or demolished (refer to **Chapter 5, Description of the Proposed Road Development** and **Chapter 15, Material Assets Non-Agriculture** for further details).

Whilst this is a significant number of property impacts with the associated impacts on families in these properties, the overall context of the impacts is assessed against the potential benefits that can be accrued from the proposed road development. The proposed road development provides the very significant and very much needed benefits to the EU transport network, the Western Region and County Galway as well as the built-up environment of Galway City and environs and the location required for the road infrastructure.

The routing of thousands of vehicles per day through the city centre brings with it associated and unmitigated impacts on businesses, public facilities, homes and non-motorised road users. These impacts include noise and air pollution. The stop/start nature of urban driving and platooning of vehicles behind slow moving vehicles adds to the levels of pollution experienced by locals and visitors. The proposed road development provides an additional crossing of the River Corrib, thus facilitating the reduction of congestion on city centre roads, and allows the reallocation of road space in the city network to non-motorised modes of transport, thereby reducing the level of pollution within the city centre.

Additional impacts on the receiving environment at present include severance effects of traffic congestion in urban areas and traffic speeds in rural areas as local roads are used to avoid the congested national road network. This severance will be reduced by the transfer of traffic to the proposed road development.

As outlined in **Chapter 2, Planning and Policy**, the Climate Action and Low Carbon Development Act 2015 provides for the establishment of a national framework with the aim of achieving a low-carbon, climate-resilient, and environmentally sustainable economy by 2050. There is a national need to lower Ireland's level of greenhouse gas emissions and the government have made a commitment to reduce Ireland's carbon footprint.

The proposed road development will facilitate the advancement of a low-carbon and more energy efficient transport system, as well as developing more efficient urban and intermodal transport solutions by removing traffic from the city centre and freeing up space for cycling and walking facilities as well as improved bus transport. This will also bring an additional positive impact on air quality where traffic is diverted away from the receptors along the existing road network within the city centre as a result of the proposed road development.

From an environmental perspective, European, National and Local legislation requires that the environmental impacts associated with major roads projects are identified and measures taken to avoid, minimise or mitigate these impacts. The proposed road development will be constructed to the increasingly high standard of environmental mitigation practice. Refer to individual sections of this EIAR for an in-depth discussion of potential environmental impacts and details of how these will be avoided, minimised and mitigated.

The need for the proposed road development from an environmental sustainability perspective is to deliver an integrated, sustainable transport solution that aligns transport investment with settlement patterns, travel movements and also supports a sustainable use of land. The proposed road development as part of the GTS, satisfies this need as it offers opportunities that will reduce congestion and car dependency through facilitating a reallocation of road space to improve capacity and reliability of public transport and to facilitate cycling and walking within the city centre core area, with a resultant 16% increase in public transport trips in 2039 when compared to the scenario of not progressing the scheme, all of which promotes the reduction of greenhouse gas emissions, whilst also providing accessibility and connections to the city.

3.7.5 Accessibility and Social Inclusion

As a Gateway to the Connemara and the Western Region, connectivity and accessibility to and through Galway City is essential in aiding the region to revitalise, improve and develop into the future. Accessibility and connectivity for areas within the county is of significant public interest and a key driver for this proposed road development; however, given that any proposed infrastructure seeking to link either side of the county will traverse areas of the city, then accessibility to and from and within the city is inextricably linked to this proposed road development.

Providing well developed transport links via roads, rail and air to the Western Region, enables enterprises and the local economy of the west to grow and develop as a viable alternative to the east coast corridor which is of significant public interest at a national level.

The Galway Transport Strategy (GTS), which is an overall transport strategy for Galway City and its environs for the next twenty years, consists of a number of proposed measures combined under an overall vision "*to create a connected city* *region driven by smarter mobility*”. The proposed road development is among the major components proposed under the GTS. Other components include provision of a new cross-city link; an enhanced local public transport network and regional public transport service; provision of greenways as well as a range of other additional non-greenway cycling, pedestrian and public realm improvements; and complementary measures. The proposed road development is needed for the effective implementation of all the elements contained in the GTS as it will free up existing roads within the city centre to facilitate the improvement of public transport, cycling and walking measures.

Provision of reliable transport infrastructure facilitates improved access to employment, education, vital services such as hospitals and amenities for all users. Reallocation of existing road space within the urban network will facilitate better provision of public transport which improves accessibility to all of the above services, in particular for lower income groups, vulnerable road users and the elderly. This in turn generates a healthier environment within the urban network where the population density is higher.

More sustainable and reliable infrastructure links to and from the Gaeltacht areas of the Western Region, enables Irish language speakers to remain in their native areas out of choice, and develop its economy in a way that is both language and culture friendly, halting the recent decline in population. This is of public interest as it is of national interest to preserve our heritage including our native language.

In tackling the city’s congestion issues, the proposed road development will provide a better quality of life for the city’s inhabitants and provide a much safer environment in which to live. By reducing the number of cars on the roads within the city centre, improving streetscapes, workers and school children are facilitated to commute using multi modal transport means. This includes travelling on foot, by bicycle and on the public transport system. As a result, more sustainable travel is supported and encouraged. This is of overriding public interest at a local level in Galway itself, but more importantly for the entire Western Region as Galway is at the core of the region and needs to be able to function efficiently to serve the region.

A detailed analysis of the impact of the proposed road development on society is presented in **Chapter 18, Human Beings, Population and Human Health**.

The need for the proposed road development from an Accessibility and Social Inclusion perspective is driven by a need to provide connectivity to the national roads via junctions to maximise the transfer of cross-city movements to the new road infrastructure. This will release the existing city centre zone from congestion caused by traffic trying to access a city centre bridge to cross the River Corrib, which allows reallocation of existing road space within the urban network, all of which will facilitates better provision of public transport with improved accessibility to all other transport modes for many more sectors of society.

3.7.6 Integration

Chapter 2, Planning and Policy Context sets out how the proposed road development is integrated into European, national, regional and local plans and policies.

The EU states that it is essential to take account of all aspects of sustainability (such as emissions, noise, land occupancy and biodiversity) and to base any action on a long-term vision for the sustainable mobility of people and goods i.e. sustainability of the entire transport system (ref EU Sustainable Development Strategy (EU SDS, 2001), reviewed 2009). The proposed road development facilitates the effective implementation of the GTS and the development of a sustainable transport solution for Galway City and its environs. The proposed road development also forms part of the TEN-T comprehensive road network in Ireland and is of strategic importance as it has a key role in delivering congestion relief and strengthening economic cohesion, as set out in **Section 2.2** and **3.6** of this EIAR.

At national level, the proposed road development fits into the Capital Plan as it serves to relieve urban congestion and provide connectivity to Galway so that Galway can contribute to the overall national development, refer to **Section 2.3.1** of this EIAR. "*Smarter Travel – A Sustainable Transport Future*" is a national policy framework which also drives the need for the proposed road development in order to secure a reallocation of road space for other modes such as public transport, cycling and walking, refer to **Section 2.3.2** of this EIAR. The proposed road development is identified as a project at a national level which is necessary to support economic recovery and sustainable growth because of its ability to improve mobility of people and goods into and out of Galway, and is vital to the economic recovery of the Western Region as a whole, which again is outlined in **Section 2.3.3** and **Section 2.3.4** of this EIAR. The proposed road development is also needed to deliver on national policy in respect of modal shift as it fits within an overall transport strategy which encourages a modal shift to a form of public transport that is associated with less emissions per capita than private car use, thus releasing and freeing the existing city centre zone for the reallocation to walking and cycling facilities and public transport, refer to **Section 2.3.5** of this EIAR.

These national policies are translated into regional and local policies as set out in the various development plans and local area plans, refer to **Section 2.4** and **Section 2.5** of this EIAR. The Galway Transport Strategy, which is the overall strategy for the next twenty years, requires delivery of an orbital route in order to deliver on all components proposed in the strategy and therefore, underpins the need for the proposed road development.

3.8 Overall need for the Proposed Road Development

The overriding need for the N6 Galway City Ring Road (GCRR) is underpinned by the fact that a modern economy requires world-class road transport infrastructure that is sustainable from an economic, social and environmental perspective. An efficient transport network which works for Galway City and environs will improve access to the Western Region, enhancing its attractiveness for inward investment and new employment opportunities and will contribute to enhanced competiveness by reducing transport costs.

The need to deliver the N6 Galway City Ring Road is supported in terms of policy from European to local level. The N6 GCRR is congruent with current transport policy and planning policy as set out in the various policy documents over the past number of years. Specific details for each of the policies and how the N6 GCRR complies with these and more local and regional policies are outlined in **Chapter 2, Planning and Policy Context**.

The specific project need is defined in terms of its potential to solve existing transport issues in Galway City and environs which include but are not limited to the following:

- Congestion throughout the city road network due to capacity failures at existing junctions
- Journey time unreliability and variability throughout the day
- Peak hour traffic delays
- By-passable traffic is in conflict with internal traffic
- Safety concerns as a result of traffic congestion
- Strategic traffic is in conflict with local traffic
- Inadequate transport links to access markets within the city
- Accessibility issues for Galway City and the Western Region as a whole
- Prolonged journey times and delays on the current bus network
- Reduced opportunities for safe and comfortable cycling
- Connectivity issues on the National and Regional road network
- Impact of traffic congestion on the city’s reputation, particularly with regard to inward investment

As a Gateway to the Connemara and the Western Region, connectivity and accessibility to and through Galway City is essential in aiding the region to revitalise, improve and develop into the future. Providing well developed transport links via roads, rail and air to the Western Region enables enterprises and the local economy of the west, to grow and develop as a viable alternative to the east coast corridor which is of significant public interest at a national level.

More sustainable and reliable infrastructure links to and from the Gaeltacht areas of the Western Region enables Irish language speakers to choose to remain in their native areas, and develop its economy in a way that is both language and culture friendly, halting the recent decline in population. It is of public interest at national level to preserve our heritage including our native language.

Galway City itself is a destination for strategic traffic to locations east and west of the River Corrib. The proposed road development addresses the need to connect these strategic destinations.

In tackling the city’s congestion issues, the proposed road development will provide a better quality of life for the city’s inhabitants and provide a much safer environment in which to live. By reducing the number of cars on the roads within the city centre and improving streetscapes, workers and students are facilitated to commute using multi modal transport means. This includes travelling on foot, by bicycle and on the public transport system. As a result, more sustainable travel is supported and encouraged and smarter travel policies both at a national level and local level are achieved. This is of overriding public interest at a local level in Galway itself, but more importantly for the entire Western Region as Galway is at the core of the region and needs to be able to function efficiently to serve the region.

The proposed road development will assist with the removal of traffic congestion from within Galway City and its environs by transferring existing and future traffic from the existing road network to the new road infrastructure. Relief of congestion in the city is essential to facilitate the improvement of the existing public transport network through measures such as the reallocation of road space, provision of a cross-city high frequency bus network, park and ride facilities, and or complementary traffic measures such as bus priority at junctions. Therefore, journey times will reduce and journey time certainty will increase for both public transport and private vehicle users. The reduction in traffic congestion will also help to realise other proposed actions in the Galway Transport Strategy because the existing road space can also be reallocated for cyclists and pedestrians. This will result in reducing the number of short commuter journeys by car by facilitating journeys by bicycle which are faster, cheaper, and more sustainable and generate health benefits.

Achieving the targets as set out in Smarter Travel policies will deliver a more attractive, vibrant and economic Galway City with associated health and environmental benefits, all of which are necessary for sustainable travel into the future. The proposed road development aligns with these policies and this project is necessary to firstly resolve the congestion issues which are currently restricting maximum implementation of the Smarter Travel policies by supporting sustainable transport policies for shorter commutes.

The need for an integrated transport solution which will relieve the congestion which is restricting Galway currently guided the development of the Galway Transport Strategy, of which the N6 GCRR is a key element, as this congestion is experienced by all travellers using various transport modes.

Therefore the functionality of the N6 GCRR is twofold. It provides for the strategic need of the TEN-T comprehensive road network and connectivity of Galway City and the West Region to the national road network, as well as providing a solution to relieve the city centre roads of unnecessary strategic traffic and providing the necessary road space for other modes of transport, namely walking, cycling and public transport. These two functions are complementary and the need for the N6 GCRR is supported by the policies below:

- Policies at European Union level, as expressed in the EU Sustainable Development Strategy, at national level in the Climate Action and Low Carbon Development Act 2015 and subsequent policies at regional and local levels, have identified the need for a sustainable transport solution to the type of traffic issues currently experienced in Galway City and its environs which can be alleviated through the delivery of the Galway Transport Strategy of which the N6 Galway City Ring Road is a key element. It is also consistent with Smarter Travel, A Sustainable Transport Future, 2009 and Irelands National Cycle Policy Framework, 2009 to 2020

- Policies at European Union level, as expressed in the TEN-T Regulations, supplemented by policies at national, regional and local levels, have identified an objective for a high quality road to connect Galway to the core Trans-European road network
- Connectivity and accessibility to markets, employment and tourism offerings in Galway City and its environs, underpins the economic development of the Western Region as a whole, with Galway City as the hub
- The proposed road development is consistent with the recommendations, priorities and objectives as set out in the DTTaS 2015 investment framework and the Capital Plan, as it seeks to deliver the N6 Galway City Ring Road, address urban congestion in Galway City, and enhance national development through improved connectivity to Galway
- The proposed road development is a component of an overall transport strategy driven by a need to relieve traffic congestion in the urban centre of Galway which in turn facilitates a modal shift to public transport, cycling and walking

The N6 GCRR represents the best solution to the transport issues described above and supports more sustainable travel for the following reasons:

- It will provide a **strategic route,** forming part of the TEN-T comprehensive network, across the River Corrib without the need to go through the city
- This strategic route will be of a **high standard** cross-section and will provide the **capacity required for the strategic traffic** serving the city and connecting the county to the national network
- Improves **connectivity to the Western Region** i.e. the county areas and hinterland beyond the city zone and provides the necessary connectivity to all the national roads and the Western Region and for those living within Galway and the rest of the country
- Moreover, access to this strategic route is limited to the junctions which will **protect the road asset in the future** and means that its **capacity is secure**
- This route is of European importance given that the **TEN-T comprehensive network designation** extends west of the city to the terminus of N6 GCRR and will provide a link to the Western Region of the standard of a comprehensive route in accordance with TEN-T
- Provides for **strategic traffic accessing Galway City** and connectivity with zones of traffic generators and attractors
- This route provides connections to **essential city links** to better distribute traffic
- It meets the functionality of the **road component of the overall intermodal transport solution** and enables the reallocation of existing road space within the city to public transport and smart mobility measures and is part of a

sustainable holistic transport solution. Thus, facilitating a **more efficient public transport system** and the provision of a **multi-modal choice of travel**

- **Improves safety** levels for all public road users
- By **tackling the city's congestion issues**, it will provide a **better quality of life** for the city's inhabitants and provide a much **safer environment** in which to live
- By **reducing the number of cars** on the roads within the city centre and improving streetscapes, workers and students are facilitated to commute using **multi-modal transport means**. This includes travelling on foot, by bicycle and on the public transport system
- Provides connectivity to the national roads via junctions to maximise the transfer of cross-city movements to the new road infrastructure, thus **releasing and freeing the existing city centre zone from congestion** caused by traffic trying to access a city centre bridge to cross the River Corrib
- Attracts traffic from the city centre zone thus facilitating reallocation of road space to public transport leading to **improved journey time reliability for public transport**
- **Caters for the strong demand** between zones on either side of the city
- Provides additional river crossing with **connectivity back to the city** either side of the bridge crossing
- Facilitates **improved city centre environment** for all due to reduced congestion, thus **encouraging walking and cycling** as safe transport modes

4 Alternatives Considered

4.1 Introduction

The EIA Directive as amended by Directive 2014/52/EU requires that the Environmental Impact Assessment Report (EIAR) contains *"a description of the reasonable alternatives studies by the developer, which are relevant to the project and its specific characteristics, and an indication of the main reasons for the option chosen, taking into account the effects of the project on the environment[1]"*. (Article 5(1)(d).

The EIAR is to also *include "a description of the reasonable alternatives (for example in terms of project design, technology, location, size and scale) studied by the developer, which are relevant to the proposed project and its specific characteristics and an indication of the main reasons selecting the chosen option, including a comparison of the environmental effects"* (Annex IV).

Also, pursuant to section 50(2)(d) of the Roads Act 1993 (as amended) the EIAR (or EIS as then was under the Roads Act) is to contain *"an outline of the main alternatives studied by the road authority concerned and an indication of the main reasons for its choice, taking into account the environmental effects"*.

This chapter of the EIAR describes the reasonable alternatives considered in terms of project design, technology, location, size and scale studied and the main reasons for the selection of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, including a comparison of the environmental effects of the alternatives of the proposed road development, to address the very serious transport issues facing Galway City and its environs. This assessment of alternatives is also fully compliant with the provision of the Roads Act 1993 (as amended).

Following on from the initial feasibility study, taking cognisance of the decision of An Bord Pleanála and the Supreme Court and the opinion of the European Court of Justice on the 2006 GCOB Scheme and the key constraints of the Lough Corrib candidate Special Area of Conservation (cSAC) the alternatives which were considered are outlined below:

- 'Do-Nothing Alternative'
- 'Do-Minimum Alternative': which includes road and non-road schemes, including smart mobility measures, which have been committed or are likely to proceed in the short term
- 'Do-Something Traffic Management Alternatives': This alternative was based on all feasible measures, options and schemes identified as part of the studies for the Galway Transport Strategy

[1] Article 5(1)(d) of the EIA Directive, as amended by Directive 2014/52/EU

- 'Do-Something Road Based Alternatives': includes initial road based alternatives discounted, upgrading of the existing road infrastructure and River Corrib crossing alternatives

An outline of this chapter is as follows:

- **Section 4.2** gives an overview of the traffic issues
- **Section 4.3** summarises the key constraints to developing a transport solution
- **Section 4.4** describes the 'Do-Nothing Alternative'
- **Section 4.5** describes the 'Do-Minimum Alternative'
- **Section 4.6** describes the 'Do-Something Traffic Management Alternatives' including improvement of Public Transport only
- **Section 4.7** describes the 'Do-Something Road Based Alternatives'
- **Section 4.8** summaries the optimisation of the preferred route corridor of the road based solution
- **Section 4.9** provides a summary of the optimum transport solution

4.2 Overview of Traffic Issues

In considering alternatives, it was essential at the outset to identify the cause of the existing traffic problems and issues within Galway City and its environs in order to develop an appropriate solution to the problem. A key driver for this process was to minimise the impact to the natural and built environment.

The initial work in understanding the cause of the transport issues focused on gathering information and data from a wide variety of sources and utilising various mechanisms to examine the existing transportation issues, including a review of the previous 2006 GCOB Scheme, current policy documents, 2011 Census data for Galway City and its environs including Galway County and the Western Region and site visits in Galway. The transport issues were reviewed against the 2016 Census data also and it was noted that Galway City is continuing to grow and the transport issues remain unchanged. This is detailed in **Chapter 3, Need for the Proposed Road Development** and **Chapter 6, Traffic Assessment and Route Cross-Section**.

The transport issues facing Galway City and its environs are summarised below:

- Congestion throughout the city road network
- Over capacity of existing junctions
- Journey times unreliable due to uncertain quantum of delay
- Journey time variability throughout the day
- Peak hours traffic delays
- By-passable traffic is in conflict with internal city traffic
- Strategic traffic is in conflict with local traffic

- Inadequate transport links to access employment centres/shopping/commercial districts within the city
- Inadequate transport connections from Galway onwards to Connemara
- Lack of accessibility to the Western Region as a whole
- Lack of available space to facilitate the improvement of non-motorised modes of transport

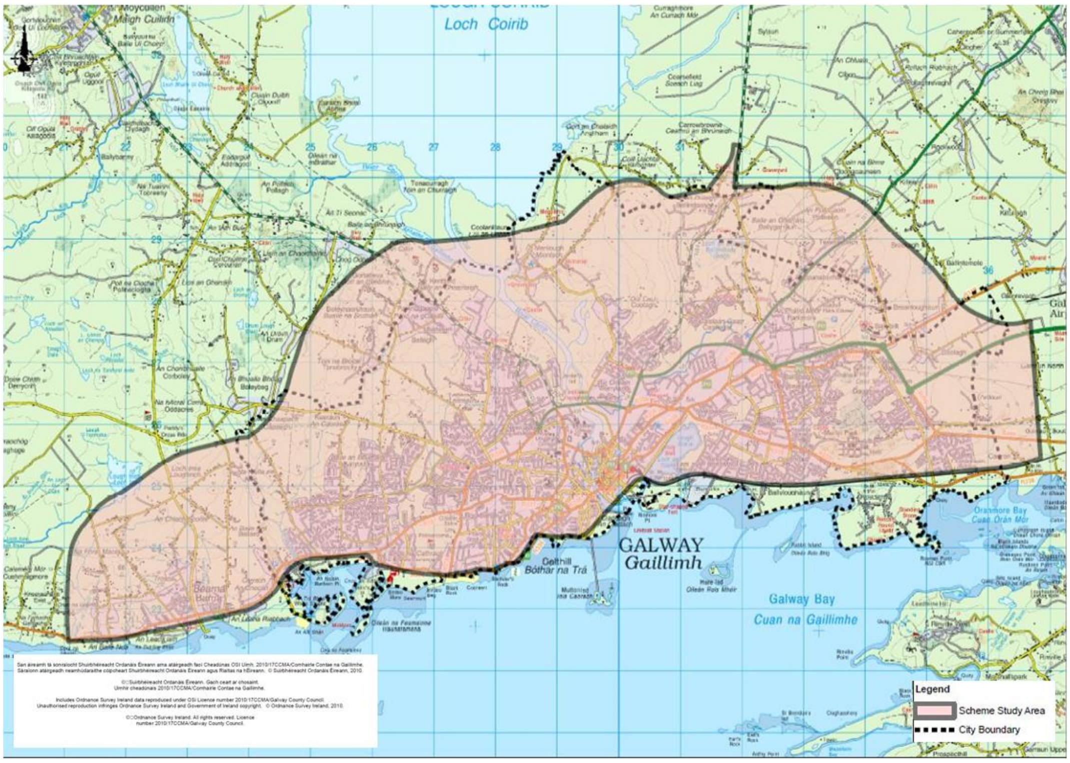
Essentially, traffic congestion in Galway City and its environs is crippling and stifling city living as well as cutting off access from the wider region to employment and services in the city. The total breakdown of the transport network in Galway occurs on a frequent basis as there is no resilience in the network e.g. wet afternoon, road maintenance, vehicle collision and signal outage. This random unpredictable shutdown of Galway's transport network costs millions and has the real potential to prohibit Galway functioning as a city or economic engine for the Western Region.

The Galway Transport Strategy (GTS) as discussed in **Chapter 3, Need for the Proposed Road Development** has identified a transport solution to create a safer, smarter and sustainable transport system for Galway City and its environs taking into account travel demands, existing infrastructure and environmental constraints. Alternatives considered will be assessed against this overarching strategy in place for Galway.

4.3 Significant Constraints

A constraints study was undertaken within the study area shown in **Plate 4.1**, which essentially is the area within which it is possible to develop a transportation solution for Galway City and its environs. Constraints of a physical and environmental nature that may affect the development of a possible solution were identified within the study area.

Plate 4.1: Study Area



As part of the Constraints Study, public consultation sessions were held in July 2014. Comments from the public were invited and the results of the consultation were recorded in the Constraints Study.

The issues that were considered in the Constraints Study included:

- the existing infrastructure, land use, topography and physical features
- identification of sites or areas of environmental significance or sensitivity
- planning, development and socio-economic character
- technical constraints

The constraints study identified that there are significant constraints for developing new transport infrastructure in Galway which arise principally due to (i) the physical form of the city (ii) the limited space available (iii) the built environment and residential areas on both sides of the River Corrib, and (iv) the presence of designated sites of international significance.

These constraints are described in more detail below:

- The development of low density residential suburban areas in a linear pattern has led to reliance on private car usage in Galway as a means of travel and makes it difficult to develop an economically efficient public transport solution
- Galway City is divided by the River Corrib as it flows between Lough Corrib and Galway Bay with significant trip attractors, employment centres, education centres and residential areas located on both sides of the river

- Lough Corrib forms a natural division between the east and west of County Galway and the distance between Lough Corrib and Galway Bay is only 4.5km[2] within which lies Galway City and its population, very much at the heart of County Galway
- The city is located in the middle of areas which are rich in natural heritage with a wealth of natural habitats. This has resulted in significant areas around Galway City being designated of international importance

The physical form of the city in terms of the built and natural environment and residential areas on both sides of the River Corrib, together with the limited available space between the lake and the bay, plus the presence of the designated sites presents significant constraints for developing new infrastructure for the city. The presence of these constraints focuses attention on the importance of considering reasonable alternatives in order to minimise the impact on the human environment and the designated sites.

These significant constraints are depicted on **Plate 4.2** below.

A full description of the constraints study is documented in *Chapter 4* of the *N6 Galway City Transport Project Route Selection Report*.

[2] Distance measured from south shore of Lough Corrib to Spanish Arch at Galway Docks

Plate 4.2: Significant constraints

4.4 'Do-Nothing Alternative'

The need for the proposed road development is set out in **Chapter 3, Need for the Proposed Road Development**, with the requirements for intervention at a European, National, Regional and local level evident to address the transport issues currently experienced in Galway City and its environs.

The 'Do-Nothing' alternative comprised an examination of the existing transportation network and infrastructure and its ability to meet future transportation demands, in the absence of any upgrade works other than routine maintenance. This option did not provide for any investment in the transportation network and infrastructure of Galway City and its environs.

The 'Do-Nothing' alternative will only compound existing significant congestion issues experienced across the city, particularly during peak hours, which is impacting on the economic capability of the city. The road and street network of Galway City is ill-suited to the high traffic flows currently prevalent and contributing to increased congestion and delay, affecting quality of life and impacting on the functionality of the city. The effects of this congestion and bottlenecks extend to the wider county and region, due to the large number of people commuting daily for work or education to the city from the surrounding towns, villages and rural areas. The congestion and infrastructural bottlenecks impact the connectivity of the Western Region to the rest of the country and the internal markets of the EU.

The assessment for the 'Do-Nothing' alternative concluded that it:

- would not offer a positive economic benefit as it would not serve to reduce the existing congestion which is the cause of the journey time problems
- would result in a further decrease in efficiency of the transportation infrastructure over time
- would not offer any improvement to safety as it is essentially a continuation of the existing situation whereby many junctions make no provision for vulnerable road users
- would not benefit from smart mobility/public transport initiatives as it does not facilitate any improvement on these fronts
- does not involve any construction works, and therefore does not directly create significant benefits or dis-benefits to the environment. However, this scenario may lead to increased traffic congestion and its associated environmental impacts
- would not facilitate the implementation of the Galway Transport Strategy measures

Additionally, Galway City and County Councils have identified various projects and plans which are likely to be implemented in the short-term, giving certainty to the fact that the 'Do-Nothing' option in the overall sense of undertaking no transportation improvement measures is not a real option. The identification of these schemes rendered the 'Do-Nothing' option redundant and it was discounted from further consideration. The committed schemes are considered below in the 'Do-Minimum' alternative.

It is noted that for the purposes of the EIA, the 'Do-Nothing' alternative where the proposed road development does not progress in isolation also needs to be considered and this is what is assessed in the subsequent chapters of this EIAR. The assessment for this 'Do-Nothing' alternative concluded that it:

- would not offer a positive economic benefit as it would not serve to reduce the existing congestion which is the cause of the journey time problems
- would result in a further decrease in efficiency of the transportation infrastructure over time
- would not offer any improvement to safety as it is essentially a continuation of the existing situation whereby many junctions make no provision for vulnerable road users
- would not benefit from smart mobility/public transport initiatives as there would be no new crossing of the River Corrib and it does not facilitate any improvement on these fronts
- does not involve any construction works, and therefore does not directly create significant benefits or dis-benefits to the environment. However, this scenario may lead to increased traffic congestion and its associated environmental impacts
- would not facilitate the full implementation of the Galway Transport Strategy measures

4.5 'Do-Minimum Alternative'

The 'Do-Minimum' alternative followed on from the 'Do-Nothing' alternative.

The traditional definition of the 'Do-Minimum' alternative could not be applied to the transport issues in Galway City and its environs:

"The Do-Minimum alternative will generally comprise an investigation of the feasibility of an online upgrade of the existing route that would be capable of delivering the required levels of service and safety in accordance with the applicable design standards[3]"

This definition had to be modified due to the planned and likely investment in transportation infrastructure. A more realistic 'Do-Minimum' alternative was one which included planned and likely transportation schemes, including numerous smart mobility measures, and provided a realistic overview of the transportation networks of Galway City and its environs should major investment not be provided.

In addition, the feasibility of an on-line upgrade of the existing route is assessed as a 'Do-Something' alternative as it is quite an extensive scheme and is excluded from the 'Do-Minimum' alternative.

Therefore, the 'Do-Minimum' alternative involved an examination of the existing transportation networks and infrastructure and existing policy and plans for Galway

[3] National Roads Authority Project Management Guidelines 2010

City and its environs. In this scenario, the existing transportation networks and infrastructure combined with likely and committed transportation schemes were examined to determine their ability to meet future transportation demands.

Likely and committed transportation schemes were identified following consultation with Galway City Council, Galway County Council, the National Transport Authority and Transport Infrastructure Ireland. Transportation schemes in the 'Do-Minimum' alternative include:

- Merlin Park Hospital Bus Access
- N59 Dangan Upgrade
- Kirwan Roundabout Upgrade
- Terryland Right turn lane on the existing N6
- Browne Roundabout Upgrade
- Cross-Middle St. Pedestrianisation
- Dock Road Corridor
- Dublin Road Bus Lane
- Monivea Road Corridor
- M17/M18 Motorway
- N59 Maigh Cuilinn (Moycullen) Bypass

The assessment of the 'Do-Minimum' alternative concluded that:

- Whilst it would achieve a more economic benefit than the 'Do-Nothing' alternative it would not serve to reduce the existing congestion sufficiently such that the overall transportation issues would be solved and a significant economic benefit would not be achieved
- The Do-Minimum will not achieve sufficient results to ensure a further decrease in efficiency of the transportation infrastructure over time would not arise. In the Do-Minimum alternative, the total network delay in the morning peak hour rapidly increases by 70% relative to the Base Year[4], far more than the increase in trips, indicating capacity issues on the network
- Whilst the individual projects would contribute to improving safety at a local level, overall the Do-Minimum alternative would not offer a significant improvement to safety as traffic will continue to increase on the existing network without any release of capacity in the highly trafficked urban areas
- Whilst the individual projects would contribute to benefiting some public transport/smarter travel initiatives at a local level, overall the Do-Minimum alternative would not achieve sufficient results to enable the full implementation of improvements to the public transport and cycling alternatives as capacity will be restricted
- This alternative does not relieve sufficient traffic congestion and the associated environmental effects in the city centre

[4] Base Year is the year for which the baseline traffic data is based on.

- would not facilitate the complete implementation of the Galway Transport Strategy measures

The 'Do-Minimum' alternative was discounted as it does not meet the project objectives for the reasons noted above. The 'Do-Minimum' alternative was compared also against the Design Year[5] and the findings listed above were the same.

4.6 'Do-Something Traffic Management'

The Traffic Management Measures alternative represents alternatives that seek to respond to transportation problems by maximising the value of existing infrastructure without construction of major new infrastructure. The Traffic Management Measures alternative can include some or all of the following:

- Local road safety improvements
- Fiscal or traffic control measures to manage demand
- Public transport priority, capacity and/or public transport services
- Improvements to pedestrian and/or cycling provision
- Intelligent Transport Systems (ITS) to improve reliability, safety and operation capacity

4.6.1 Public Transport Only Option

The 'Public Transport Only' element of this alternative was developed and analysed as part of the initial studies on the N6 Galway City Transport Project (GCTP). This alternative includes all measures, options and schemes identified by Galway City Council in conjunction with the National Transport Authority as a result of the recommendations of the Galway City Council study entitled *Galway Public Transport Feasibility Study* of 2010, namely:

- A Bus Rapid Transit (BRT) operating at a 10-minute frequency from Knocknacarra to the West, through the city centre, to Oranmore in the East
- All existing city bus services increased to 10-minute frequency
- Bus priority measures at signalised junctions along the BRT corridor
- Re-allocating road space on the Salmon Weir Bridge from general traffic to Public Transport only
- Light Rail with bus feeders and complementary services

It should be noted that the Galway Public Transport Feasibility Study from 2010 assumed that the Galway City Outer Bypass (GCOB) as proposed by the 2006 planning application was in place, thereby making it possible to consider reallocation of road space on the Salmon Weir Bridge. However, this Public

[5] Design Year is 15 years after the year of opening the proposed road development (2039)

Transport Only Alternative as modelled in the initial studies on the N6 GCTP does not include for the 2006 GCOB.

The mode share analysis shows that there is a low public transport mode share of just 5.0% in the 2012 Base Year. This reduces slightly to 4.9% in the 2034 Do-Minimum due to increased car ownership offsetting the increase in congestion. The 'Public Transport Only' alternative increases public transport mode share to 5.8% in 2034, which is a 17% increase in public transport trips relative to the Do-Minimum 2034. However due to the overall low public transport mode share, this represents less than a 1% reduction in car trips. Full implementation of the 'Public Transport Only' alternative, as defined above, has a negative impact on the congestion and the key performance indicators identified to test performance vis-à-vis the project objectives. Analysis shows that it results in a 2% increase of delay to every vehicle journey across the key routes identified as the key performance indicators, when compared to the 2019 Do-Minimum. The 'Public Transport Only' alternative does not provide an adequate transport solution as it does not reduce congestion levels in the city when considered in isolation. Therefore, the 'Public Transport Only' alternative does not represent an effective 'Traffic Management Alternative' that responds to transportation problems as it does not resolve these problems in isolation. Analysis on the Public Transport Only Option demonstrated that it does not provide a solution in isolation, however it does form part of the overall holistic transportation solution and is included in the Galway Transport Strategy.

4.6.2 Galway Transport Strategy

Through consultation with key stakeholders including TII, NTA, Galway County Council and Galway City Council, it was agreed that a wider integrated transport strategy was required for Galway to identify the level of service requirements for each mode of transport; including walking, cycling, public transport and private vehicle. The more comprehensive 'Traffic Management Alternative' culminated in the Galway Transport Strategy which provides Galway City and its environs with a clear implementation framework for transportation over the next 20 years. This is an incremental strategy which seeks to implement sustainable transport solutions to manage traffic demand. A portion of these incremental measures will provide some relief to the traffic problems experienced in Galway City and its environs however, to fully realise the overall transport solution all measures are required.

The development of this strategy involved reviewing and consolidating various existing transport proposals, including the bus study noted in **Section 4.6.1** above, and a light rail study amongst other measures to form a coherent and integrated transport strategy for Galway City and its environs. It followed a structured approach and methodology through a process of:

- Assessment of existing and projected future levels of travel demand, journey types to be served, and evaluation of existing levels of transport service provision
- The development and testing strategy options by individual transport mode and in combination to meet forecasted levels of travel demand

- The development of specific proposals which were subsequently brought together under the overall strategy

This transport strategy seeks to deliver an integrated network of ‘links’ (routes) and ‘nodes’ (stops and interchange locations) along which people can travel seamlessly, changing corridors and modes as necessary to make their journey. The most suitable travel modes to address the travel demand for different types of journey was examined so that the measures developed are targeted at particular movements (rather than adopting a universal mode-share target for all journeys in and through Galway). The shape and operational characteristic of the network for each mode is fundamental in achieving an appropriate usage of that mode. This means that unless the network links match the journeys people want to make then usage of the network will be limited, regardless of the quality of the service in question.

The range of different journey types in Galway City and its environs requires bespoke solutions for each travel mode in order to develop an integrated package of measures such that the ‘sum of the parts’ improves transport conditions and journey choices for all in Galway. A synopsis of the range of solutions for each travel mode is outlined below:

- Pedestrians and cyclists: Traffic within the city centre needs to be managed to make it a more comfortable environment for pedestrians and cyclists
- Cyclists: Provision of high quality dedicated cycling facilities and additional measures giving priority to cyclists are required to encourage an uptake in cycling both for commuting and as a leisure activity in the city and surrounding areas
- Public Transport: Access through the city for public transport must be reliable at all times of the day to achieve a travel mode shift in favour of public transport. To achieve this, it is necessary to reduce vehicular movement through the city centre, to reduce vehicle speeds in the core city centre area, and to prioritise active modes (walking and cycling) and public transport in the city centre. The strategy therefore includes for routing of traffic which currently passes through the centre (to reach edge-of-centre locations) to more suitable orbital routes around the core city centre area
- Cross-city route: For journeys not possible by non-car modes, a reliable cross-city route is necessary. Providing additional orbital traffic capacity will increase the opportunities for re-allocation of existing road space for use by pedestrians, buses and cyclists, which is identified as a key traffic management objective of the strategy
- Parking: Availability of on-street parking will be reduced and access routes to off street parking facilities will be rationalised and managed to minimise car circulation within the city centre. A parking pricing structure will be put in place which sets the cost of city centre parking at a level that does not undermine travel by public transport

It is important to note that the choice of mode for public transport (e.g. bus, light rail, demand responsive) is to a large extent secondary to the development of a network with appropriate coverage and frequency. This aspect is well described in a good practice guide[6] as follows:

"Getting the network right is usually more important than the often debated and studied choice between bus and rail systems. Mode selection for new parts of the network should normally come after an overall network strategy has been created. Then the roles of different bus and rail systems can be conceived as specialised tasks within the network, and the different advantages of the various public transport modes and types of lines may be more easily exploited."

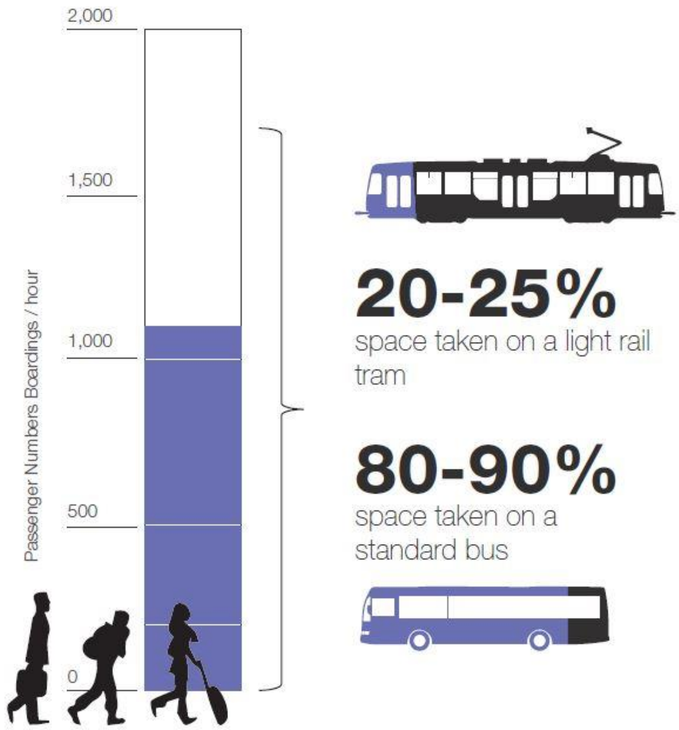
As such, the type of public transport network configuration that best suits Galway, both in terms of alternative modes and network configuration was considered and assessed in detail. The layout identified by the GTS was developed as a function of catchment areas based on residential and commercial land use, in order to maximise the potential number of passengers and journeys. The most appropriate mode for public transport in Galway City and its environs was assessed using the Western Regional Model (WRM) to test the potential passenger use of high frequency public transport services. This looked at bus-based or light rail-based options on the busiest corridors in Galway, with additional buses on other corridors. The results provide a basis for identifying the public transport system best suited to Galway City and its environs.

Transport modelling to test the potential passenger use of high frequency public transport services along the busiest corridors in Galway, looking at a bus-based or light rail-based options on these indicated that with high-frequency services in place, the maximum single directional passenger demand would only be approximately 1,100 over a 1-hour period (in the AM Peak).

As illustrated in **Plate 4.3**, this broadly equates to 80-90% of the passenger capacity of a frequent bus service, and less than 25% of the capacity of a frequent light rail service.

[6] Network Design for Public Transport Success – Theory and Examples, Institute of Transport Economic/Civitas

Plate 4.3: Estimated Maximum Occupancy of Public Transport System Options



In addition, the typical carrying capacity of a range of public transport systems, from the standard single-decker bus to a heavy rail system, is shown in

Table 4.1. It can be seen that frequency is the key factor in maximising the carrying capacity of any public transport system. For example, the table below shows that a double decker bus operating at a 10-minute frequency can carry up to 450 passengers an hour, which is close to the carrying capacity of a light rail system operating once every 30 minutes (518 passengers).

Table 4.1: Typical Carrying Capacities of Public Transport Systems

	Standard Single Decker Bus	**Standard Double Decker Bus**	**Articulated Bus / Tri-Axle Double Decker Bus**	**Light Rail**	**Heavy Commuter Rail Service**
Design Capacity (Persons)	**30 People**	**75 People**	**102 People**	**259 People**	**409 People**
Frequency (minutes)					
30	60	150	204	518	818
20	90	225	306	777	1227
15	120	300	408	1036	1636
10	180	450	612	1554	2454

	Standard Single Decker Bus	Standard Double Decker Bus	Articulated Bus / Tri-Axle Double Decker Bus	Light Rail	Heavy Commuter Rail Service
Design Capacity (Persons)	**30 People**	**75 People**	**102 People**	**259 People**	**409 People**
Frequency (minutes)					
6	300	750	1020	2590	4090
5	360	900	1224	3108	4908
4	450	1125	1530	3885	6135
3	600	1500	2040	5180	8180
2	900	2250	3060	7770	12270

The figures set out in **Table 4.1** indicate that a light rail service would provide capacity far in excess of what is practically required in Galway City and its environs. Hence, when considering the greater cost of building and operating light rail services at the same frequency as bus services, it is clear that bus-based public transport represents the most appropriate system for Galway City and its environs over the period considered in the Galway Transport Strategy.

It is important that the proposed bus network facilitates a high level of public transport accessibility across Galway City by provision of a network of high-frequency cross-city services with guaranteed and reliable journey times. It must be supported by strong potential for interchange between services so that it will provide linkages from most parts of the city and will connect with transport services from suburban towns.

The public transport network and type of system (or mode) is also dependent on a number of further considerations:

- **Street Network:** Galway is an historic city and its layout and road network reflect a city that has developed over many years with some roads and streets, especially in the city centre, being very narrow, resulting in turning movements being difficult for some modern public transport vehicles to navigate.
- **Network or Corridor:** The most successful public transport networks and services are generally those that offer a consistently high frequency throughout the day on a network of services, and hence can attract a broad variety of trip purposes such as commuter trips, trips to education and trips for retail and leisure activities.

It was concluded that a high-quality bus-based public transport service will most appropriately cater for the forecasted passenger demand and provide significant flexibility in terms of network options and the ability to integrate with other modes. In particular, a bus-based public transport network can cater for high volumes of demand along combined corridor sections (for example through the city centre) whilst diverging out to efficiently provide greater direct catchment within less-dense suburban areas of Galway.

Having identified the most appropriate form of public transport solution to serve Galway, a further key consideration was the form of network upon which bus services should be reorganised and developed. The primary consideration was whether concentration should be given to increased orbital bus services (for example, via the Quincentenary Bridge) versus services through the city centre.

Analysis from the transport modelling undertaken confirmed the patronage for an orbital service would be approximately half of what would use an equivalent service routed via the city centre. This outcome clearly indicated that cross-city bus services via the city centre will be both more attractive to passengers and more financially viable than operating orbital services. This guided the final bus network and service pattern adopted in the GTS, which is currently being developed by the NTA and Galway City Council.

The reallocation of road space to public transport in the city centre will be accompanied by an associated improvement in the public realm as improvement to the quality of the receiving environment for passengers' onward journeys on foot is viewed as a component of the public transport offering. Finally, to shift the focus within the city centre to walking, cycling and public transport and measures to manage demand on the transport infrastructure are needed to enhance the function of the city for these users. This may include measures such as managing and controlling the availability and cost of parking, restricting traffic flow from certain streets, reducing speed limits, providing additional pedestrian crossings at key locations and a reduced emphasis on facilitating through-traffic.

A number of scenarios were developed, with an increasing level of provision and investment in each subsequent scenario. These scenarios were tested in the Western Regional Model (WRM) as discussed in **Section 3.2.2** of **Chapter 3**, **Need for the Proposed Road Development** and the scenario which included the proposed road development with the other transport measures performed better overall in providing a safer city centre and a more socially inclusive transport network by improving accessibility. This scenario includes the following measures:

- An upgraded and integrated public transport network
- City centre public transport prioritisation, including the use of the Salmon Weir Bridge solely for public transport
- Improvements to walking and cycling infrastructure and priority, including an additional city centre crossing of the River Corrib solely for use by non-motorised vehicles
- Integrated Park & Ride facilities
- Demand management measures
- Full orbital bypass of Galway City Centre from the N6 to the R336 Bearna Road linking the N6, N83[7], N84 and N59 national roads

As the sum of the individual measures in the Galway Transport Strategy (GTS) effectively comprises the overall holistic transport solution for Galway, a sensitivity

[7] Formally known as the N17 Tuam Road.

test was carried out on the effective implementation of the GTS against each of the "Do-Something" scenarios of the same year. As the GTS is a 20-year strategy, this sensitivity test has only been carried out in 2039, Design Year. The results of this sensitivity test are presented in **Section 6.6.3.1** and show a similar pattern to results for the test results for the DS Core Scenario tests (Do-Minimum and Do-Something Scenarios for 2024 Opening Year and 2039 Design Year). In general, the opening of the proposed road development, in conjunction with the other measures proposed in the GTS, has a positive impact on the majority of Journey Time routes analysed, particularly in the AM and PM peak periods.

The results below show more negative impacts on journey times than the DS Core Scenario tests. The reason for this is that the GTS contains a number of proposals which limit capacity on the city centre network, as a result of increased active mode and public transport priority measures in the city centre, and therefore adds delay to certain sections of the network. Also, traffic management arrangements proposed in the GTS result in the lengthening of some journey time routes which in turn adds to the total journey times.

In order to implement the level of service required for each mode of transport, including walking, cycling, public transport and private vehicle as outlined in the GTS, a new crossing of the River Corrib is required. Alternative options for the new River Corrib Crossing were considered as part of the road component for the N6 GCTP. These alternatives are outlined below in **Section 4.7**.

As noted above the GTS is an incremental strategy which seeks to implement sustainable transport solutions to manage traffic demand. A portion of these incremental measures will provide some relief to the traffic problems experienced in Galway City and its environs however, to fully realise the overall transport solution a new crossing of the River Corrib is still required in order to facilitate the public transport options identified and the modal shift envisaged in the GTS.

4.7 'Do-Something Road Based Alternatives'

As noted in **Section 4.3** the Lough Corrib forms a natural division between the east and west of County Galway and the distance between Lough Corrib and Galway Bay is only 4.5km. Numerous alternatives for connecting the east and west of Galway City and County were considered. Alternatives across Lough Corrib and Galway Bay or a tunnel from the far west of the study area to the east were all considered and discounted as outlined below in **Section 4.7.1**. Alternatives for a new crossing of the River Corrib were considered and these alternatives are outlined in **Section 4.7.2**. The appraisal for the selection of the preferred river crossing and associated route for the preferred road based alternative is outlined in **Section 4.7.3**.

4.7.1 Initial Alternatives Discounted

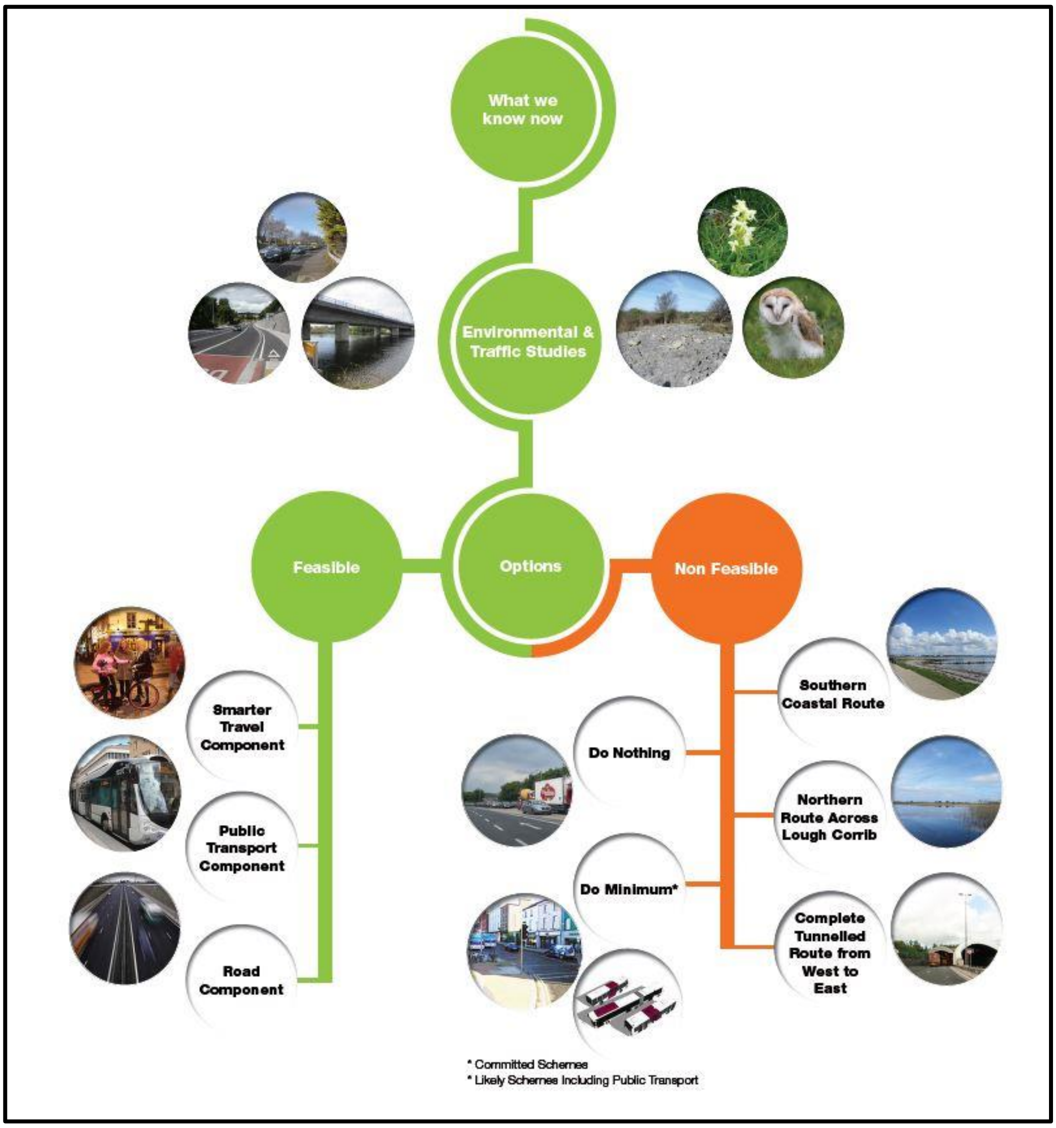
An assessment of the following alternatives discounted them from further consideration as they were deemed not to meet the project objectives outlined in **Chapter 3, Need for the Proposed Road Development**:

- Lough Corrib Route Options

- Coastal Route Options
- Tunnel over project extents

These discounted options were presented graphically at Public Consultation No. 2 in **Plate 4.4** below.

Plate 4.4: Discounted Options – Public Consultation No. 2



4.7.1.1 Lough Corrib Route Options

The alternative of linking the eastern and western areas of County Galway by crossing Lough Corrib on a viaduct was considered.

Lough Corrib has significant ecological importance, being part of the Lough Corrib cSAC and Lough Corrib SPA, and is an area of immense scenic amenity. The ecological constraints associated with this alternative make crossing Lough Corrib by viaduct difficult. Any crossing of this lough would involve a significant structure making its incorporation into the landscape extremely difficult and it would have significant visual impacts.

Traffic analysis shows a strong demand coming from all over the county to the city and back. It also highlights the fact that, the further the proposed route for the road based alternative is from the city the less attractive it would potentially be to motorists and the less impact it would have on reducing the existing transportation issues of the city. Any proposal to introduce a viaduct across Lough Corrib would at a minimum be located 4.5km from the existing cross city route – the N6 and R338. There is therefore limited benefit from a traffic perspective to locating a new west to east connection across Lough Corrib.

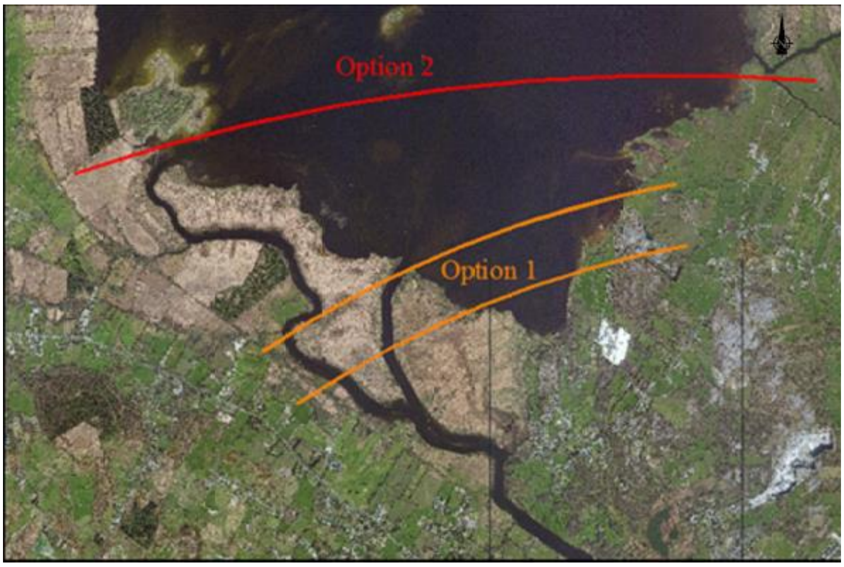
Crossing Lough Corrib by viaduct would not meet the project objectives for the following reasons:

- It would not reduce journey times on key routes
- It would not provide a cost effective project
- It may have a significant impact on Lough Corrib cSAC and Lough Corrib SPA
- It would not take due cognisance of the importance of the existing landscape
- It may not support the development of critical mass regional population centres as it will not support the development of Galway City as a Gateway

As alternatives were available which have a lesser impact on the environmental constraints, which would have a higher patronage and provide a greater benefit to the local economy than a crossing of Lough Corrib, further examination of a viaduct crossing on Lough Corrib was discounted.

The Lough Corrib Route Options are shown in **Plate 4.5** below.

Plate 4.5: Lough Corrib Route Options



4.7.1.2 Coastal Route Options

The alternative of linking the eastern and western areas of County Galway with a route along the coastline was considered.

The Coastal Route Option required a significant bridge structure across the mouth of Galway Harbour which would likely impact on boat traffic and the operation of the harbour and docks area. The bridge would be elevated and visible from all areas surrounding the harbour including the Claddagh, South Park and the Spanish Arch, all of which comprises an area of immense scenic beauty and high amenity. It would impact visually on the landscape of both the city and Galway Bay and required at least one crossing of the Dublin to Galway railway line.

The ecological constraints associated with this alternative also made the Coastal Route Option difficult. Galway Harbour has environmental importance including Galway Bay Complex cSAC and Inner Galway Bay SPA.

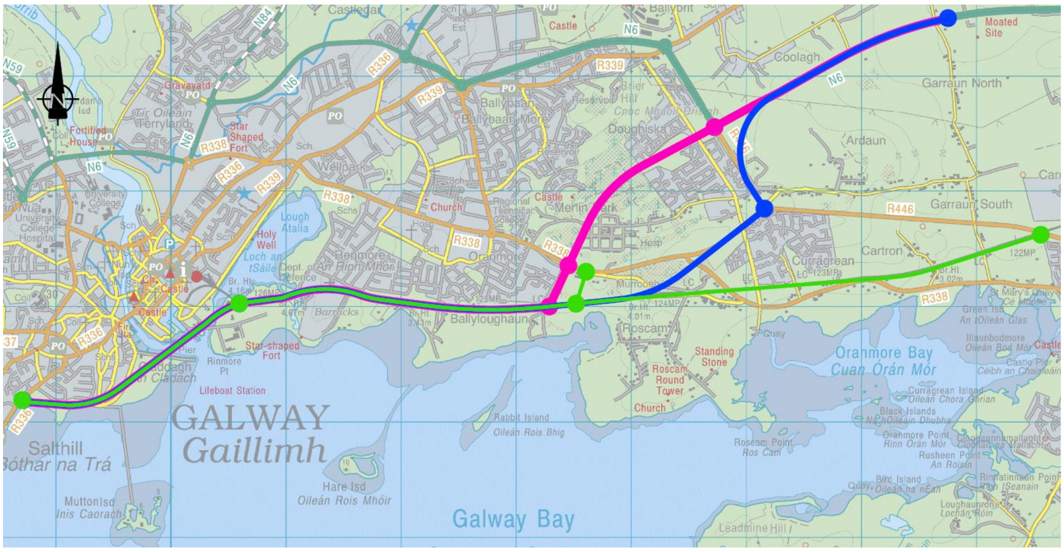
This alternative did not meet the project objective to provide a connection to some or all of the national roads leading into the city, namely the N59, N84, N83, and N6/M6 to the east, in order to create an integrated national road network around the city. This could potentially result in no improvement on journey times and journey time reliability which is another project objective.

In summary, a Coastal Route Option did not meet the project objectives for the following reasons:

- It would not provide journey time reliability on the key routes
- The crossing of the harbour may have a significant impact on Galway Bay Complex cSAC and Inner Galway Bay SPA
- The crossing of the harbour would not take due cognisance of the importance of the existing landscape

As alternatives were available which have a lesser impact on the environmental constraints, which would have a higher patronage and better meet the project objectives than a coastal route, further examination of this alternative was discounted.

Plate 4.6: Lough Corrib Route Options



4.7.1.3 Tunnel Over Project Extents

Following on from the above alternatives, the linking of the eastern and western areas of County Galway with a tunnel from the N6 to the R336 was considered.

This alternative does not meet the project objectives to provide a connection to some or all of the national roads leading into the city, namely the N59, N84, N83, and N6/M6 to the east, in order to create an integrated national road network around the city. This would not show an improvement on journey times and journey time reliability which is another project objective. Equally, traffic demand does not justify the very significant cost of such a tunnel and potential environmental impacts. Therefore, a tunnel from east to west was discounted as it is not deliverable and not justified. However, inclusion of shorter sections of tunnel to avoid significant constraints was considered worthy of further study in the solution development process.

As alternatives were available which would have a higher patronage and better meet the project objectives than an east-west tunnel, further examination of this alternative was discounted.

4.7.2 River Corrib Crossing Alternatives

The development of route options for a new crossing of the River Corrib and a road based alternative included designs which avoided existing properties as identified on OS and aerial mapping as much as possible. The N6 Galway City Outer Bypass, 2006 was including in these route options. During the course of the development and appraisal of these alternatives it became evident that more detailed information was available along the route of the 2006 Galway City Outer Bypass than other areas of the scheme study area and hence the development of these alternatives was paused until the necessary detailed environmental studies were undertaken on the entire study area. Detailed ecological surveys, ground investigations at Rahoon and archaeology geophysics at Ballybrit were carried out before the route options were further progressed.

In parallel to this a study was undertaken to identify an on-line option which reutilised as much of the existing road infrastructure including the existing N6 as outlined in **Section 4.7.2.1**.

Once the environmental studies and on-line option development were completed the route option development process recommenced. Based on the initial route options, OS and aerial mapping, transport demand analysis and the results of the ecological surveys, option development zones were developed by the Design Team.

Option development zones were areas within the scheme study area which from a human beings and ecological perspective the more beneficial route options could be developed whilst also bearing in mind the need to connect back to the city to effectively resolve existing transportation issues. It should be noted that all route options developed within these option development zones still had to be assessed by all other environmental specialists, which further reduced the zones available for route option development. Therefore, the situation arose where route options were developed outside of these zones to reduce the impact on other key environmental constraints with the necessary mitigation measures included in the design of the route option.

Plate 4.7 illustrates the available option development zones through the Lough Corrib cSAC at the River Corrib crossing. A number of route options were then refined and developed by the engineering team within the established option development zones commencing from the River Corrib crossing locations in so far as reasonably possible within the confines of engineering standards and all other constraints.

The development of these feasible route options was a two-stage process with the initial routes developed known as Stage 1 Route Options. These route options comprised on-line options which include an upgrade of the existing infrastructure, partial on-line/off-line options and total new construction off-line and are shown below on **Plate 4.8** and a schematic of these options is shown on **Plate 4.9**.

Plate 4.7: Option Development Zones

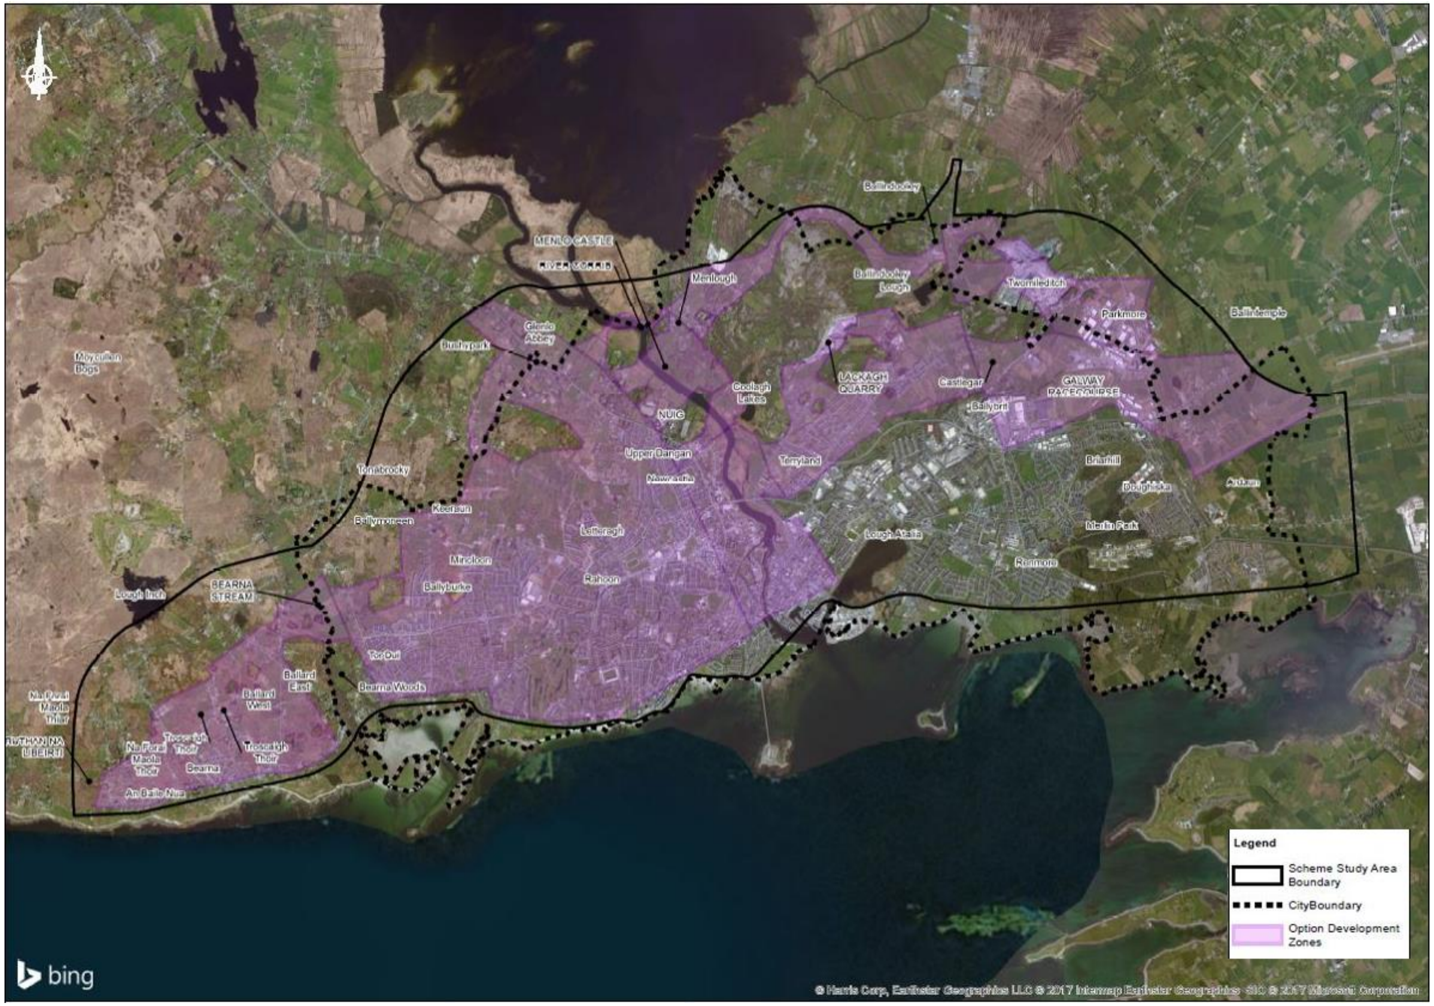


Plate 4.8: Stage 1 Route Options

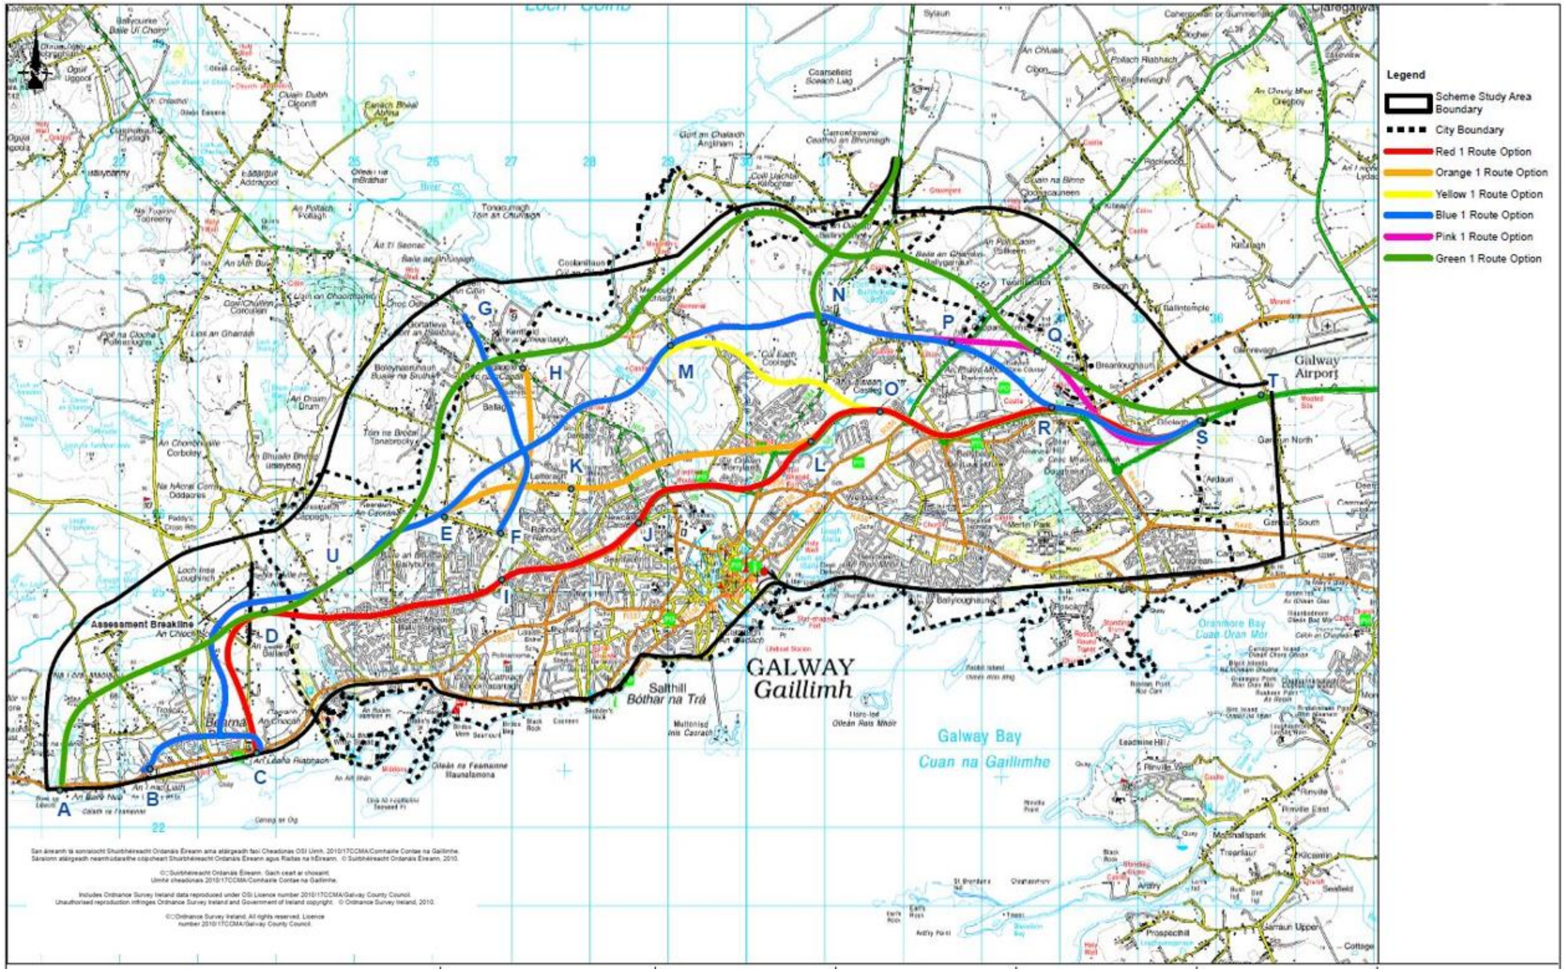

Plate 4.9: Stage 1 Route Options – Schematic

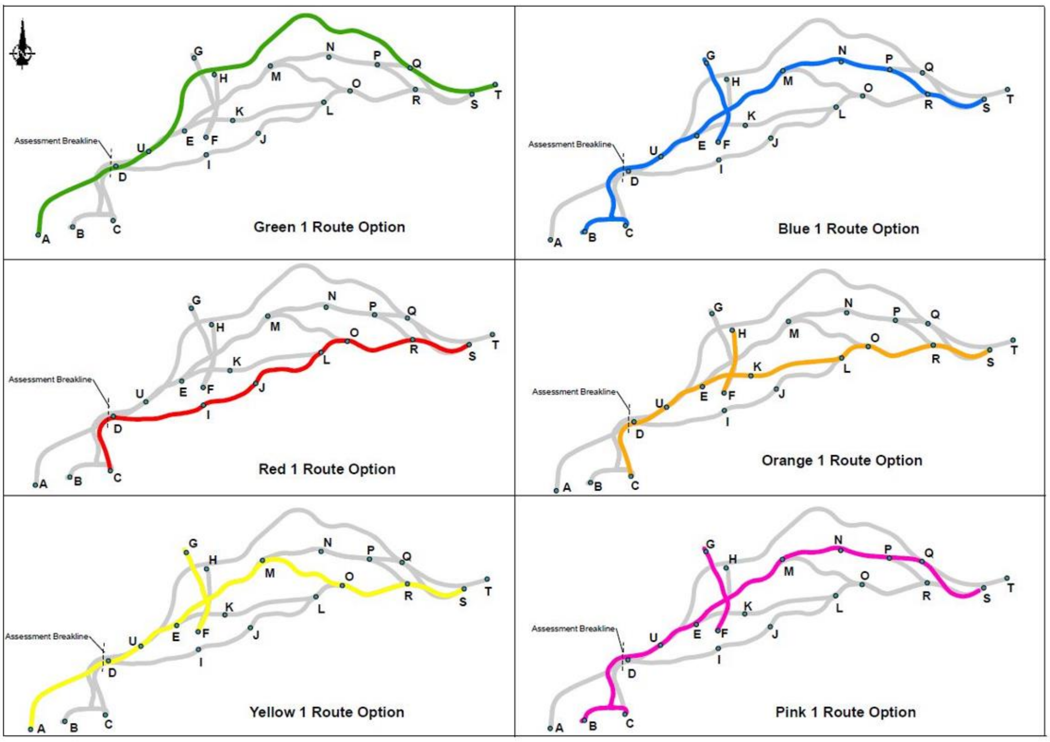

An assessment was completed on these Stage 1 Route Options which included two environmental workshops. These Stage 1 Route Options were presented to the public at Public Consultation No. 2 in January/February 2015. Following public consultation and further studies, the route options were refined and became Stage 2 Route Options. An assessment and appraisal was completed on the Stage 2 Route Options. The Stage 2 Route Options are shown on **Plate 4.10** and a schematic of these options is shown on **Plate 4.11**.

Plate 4.10: Stage 2 Route Options

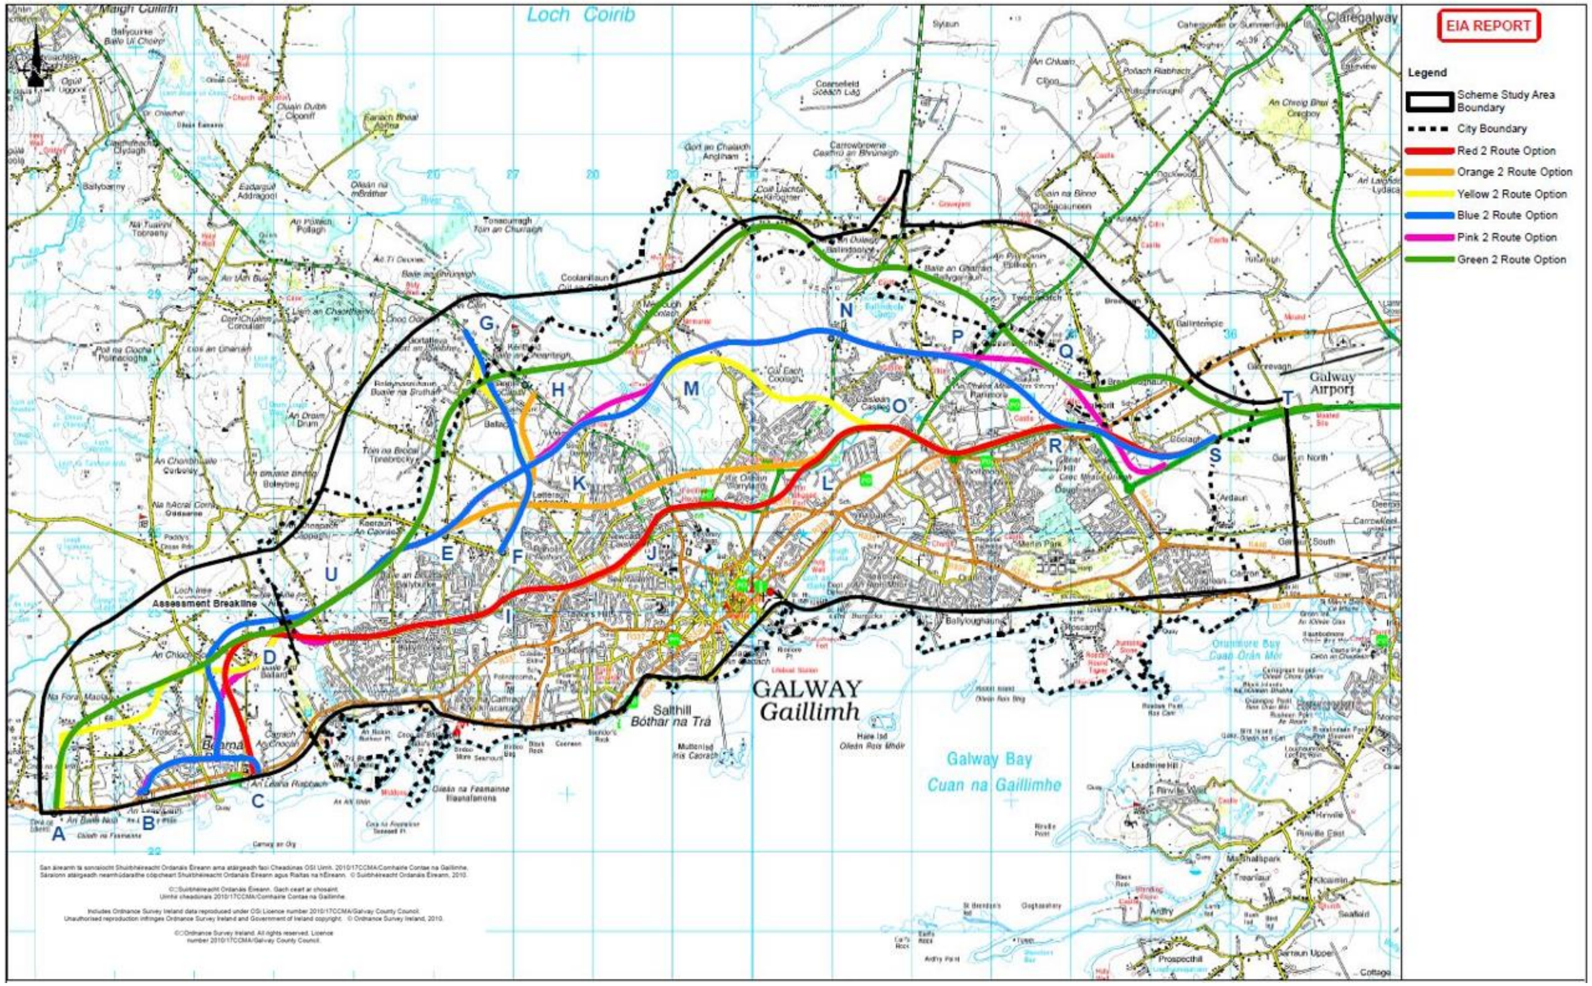

Plate 4.11: Stage 2 Route Options – Schematic

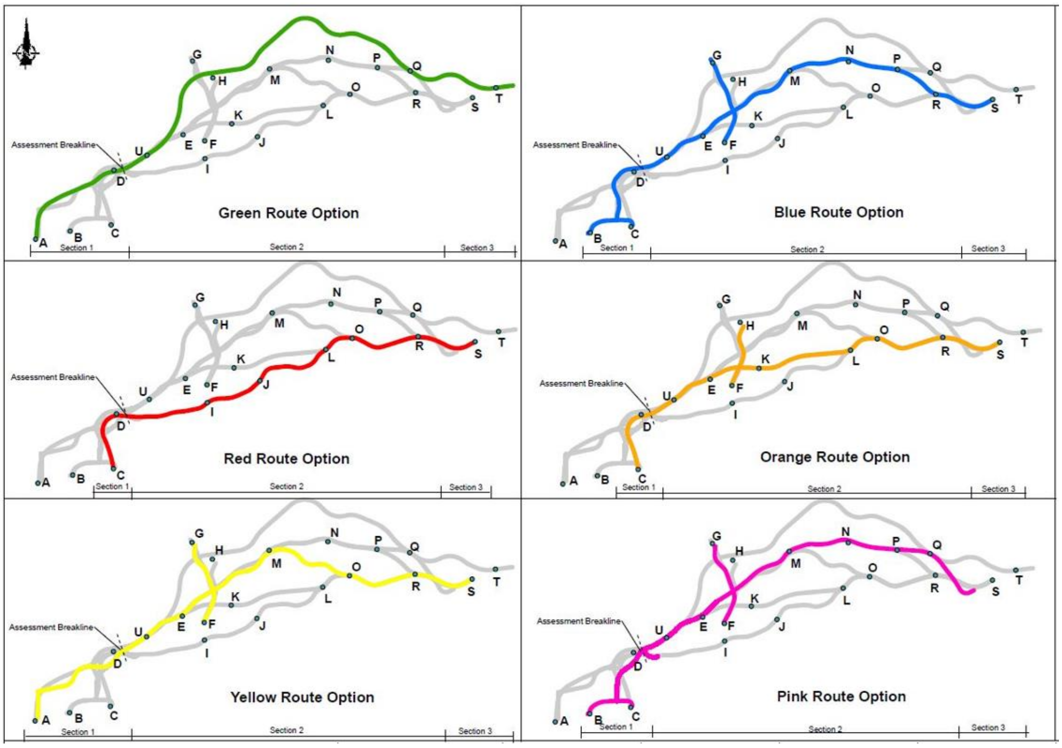

In addition to these route options which are detailed in **Section 4.7.2.1** and **4.7.2.2** below, the 2006 GCOB Route Option (**Section 4.7.2.3** and **Plate 4.12**), a modification of the 2006 GCOB Route Option, the Cyan Route Option (**Section 4.7.2.4** and **Plate 4.13**)) and a switch between two of the off-line route options (**Section 4.7.2.5** and **Plate 4.14**) were also considered as alternatives.

Given the urban environment, density of residential development and the presence of the designated European sites in the scheme study area, a horizontal and vertical alignment for each of the route options was designed. The vertical alignment for some of the route options included sections of tunnels to reduce the impact on key constraints identified.

Plate 4.12: 2006 GCOB Route Option

Plate 4.14: 'Switch' between the Green and Blue Route Options

4.7.2.1 Stage 1 Route Options

Red Route Option (On-line Route Option)

A full study was undertaken on the upgrading of existing road infrastructure and the development of an on-line route option, where the existing transportation networks and corridors are reused and enhanced where appropriate.

The outcome of this study was a recommendation on which on-line route option to carry forward. This On-line Route Option commenced at a signalised junction at the eastern end of Bearna Village and proceeded north along new road alignments to join the existing Western Distributor Road at a proposed signalised junction at the existing Cappagh Road Roundabout. It followed the existing Western Distributor Road to Bóthar Stiofáin and includes the replacement of all the existing roundabout junctions along Western Distributor Road with signalised junctions.

At the Rahoon area it connected via a tunnel from Bóthar Stiofáin, through a residential area in Rahoon, to the Seamus Quirke Road and was depressed underneath Seamus Quirke Road and Browne Roundabout via a cut and cover tunnel. It included connectivity via a roundabout and slip roads at Gort na Bró. It continued east to the existing Quincentenary Bridge along the existing N6. The existing local road network was to be retained above the proposed mainline over the extents of Seamus Quirke Road. The existing local road network was accommodated by provision of a second bridge crossing over the River Corrib immediately south of the existing Quincentenary Bridge.

To the east of the River Corrib, the On-line Route Option passed behind the existing shopping centre at Terryland and re-joined the existing N6 to the east of the N84 Junction at the Kirwan Roundabout. A split grade separated junction was provided between the existing N6 and the proposed On-line Route Option in this area, with west facing slips to/from the On-line Route Option immediately east of the river crossing and east facing slips to/from the On-line Route Option immediately east of the existing N84 Junction at Kirwan Roundabout.

The On-line Route Option utilised the existing N6 corridor to connect to the M6/N6 on the east side of Galway at Coolagh. It was depressed under the N83 and Ballybane Roads but had full connectivity to both roads via signalised diamond junctions. A full diamond grade separated junction was provided to the south of the existing Briarhill Junction, which was designed to accommodate Parkmore Industrial Park, Ballybrit Business Park, City East Business Park and the Briarhill area of the city.

The On-line Route Option was deemed a feasible option and was carried forward as the Red Route Option for assessment as part of the route selection process.

Orange Route Option

The Orange Route Option commenced at the same point as the Red Route Option to the east of Bearna, and followed the path of the Red Route Option around Ballard. It diverged from the Red Route Option and travelled through Ballyburke, towards Letteragh, where it entered a tunnel. It crossed under the River Corrib in the tunnel and emerged in Terryland, to the east of the existing Kirwan Roundabout. The

Orange Route Option then followed the Red Route Option along the existing N6 with all junctions upgraded to grade-separated junctions.

There was a link road associated with the Orange Route Option which commenced on the N59 at Ballagh and finished at the northern end of Bóthar Stiofáin, connecting to the mainline of the Orange Route Option with a grade separated junction.

Yellow Route Option

The Yellow Route Option commenced at a junction with the R336 to the west of Bearna and travelled north-east, keeping to the north of Bearna and passing through the townlands of An Chloch Scoilte, Na hAille, Ballyburke, Letteragh and Dangan. It crossed the River Corrib to the south of Menlo Castle, then turned south-east and passed through the townlands of Coolagh and Castlegar. It joined the Red Route Option to the west of the junction with the N83 and followed the Red Route Option eastwards along the existing N6, with all junctions upgraded to grade separated junctions.

There was a link road associated with the Yellow Route Option which commenced on the N59 at Gortacleva and finished at the northern end of Bóthar Stiofáin, connecting to the mainline of the Yellow Route Option with a grade separated junction.

Blue Route Option

The Blue Route Option commenced with a junction on the R336 on the western outskirts of Bearna and proceeded along an existing relief road parallel to and north of the R336. The remainder of the Bearna Inner Relief Road, to tie back to the existing R336 in the eastern outskirts of Bearna, was included as part of the Blue Route Option. From the relief road the Blue Route Option travels north-east through the townlands of An Chloch Scoilte, Na hAille, Ballyburke, Letteragh and Dangan before crossing the River Corrib to the south of Menlo Castle. It then continued east towards Lackagh Quarry, entering a tunnel to pass beneath the Annex I habitat within the Lough Corrib cSAC and emerging in the quarry, before passing through the townlands of Castlegar and Ballybrit. The Blue Route Option enters a second tunnel to pass underneath the racecourse at Galway Racecourse, emerging above ground in the vicinity of Briarhill, and followed the Red Route Option to its eastern extremity.

There was a link road associated with the Blue Route Option which commenced on the N59 at Gortacleva and finished at the northern end of Bóthar Stiofáin, connecting to the mainline of the Blue Route Option with a grade separated junction.

Pink Route Option

The Pink Route Option commenced to the west of Bearna at the same point as the Blue Route Option, and followed the same path as the Blue Route Option as far as Castlegar. It then diverged to the north of the racetrack at Galway Racecourse, and entered a tunnel on the eastern side of the N83. This tunnel passed under the racecourse access road. This route option passed to the south-east of Coolagh Village and connected to the existing N6.

There was a link road associated with the Pink Route Option which commenced on the N59 at Gortacleva and finished at the northern end of Bóthar Stiofáin, connecting to the mainline of the Pink Route Option with a grade separated junction.

Green Route Option

The Green Route Option commenced at the same point as the Yellow Route Option to the west of Bearna and travelled north-east, keeping to the north of Bearna and passing through the townlands of An Chloch Scoilte, Na hAille, Keeraun, Tonabrocky and Bushypark before crossing the River Corrib to the north of Menlo Castle. The Green Route Option proceeded north-east through Menlough to Ballindooley and south-east through Cappanabornia, around the back of Galway Racecourse in a tunnel beneath the racecourse access road, where it briefly overlapped with the Pink Route Option. It passed through the northern part of Coolagh Village before terminating at the existing N6 to the east.

4.7.2.2 Stage 2 Route Options

This section details the major amendments and alterations made to the route options between Stage 1 and Stage 2. Each amendment and alteration improved on previous designs and options in order to address concerns raised and issues identified through public consultation. Details of the extensive public consultation undertaken as part of the proposed road development are set out in **Chapter 1, Introduction**. A plan layout and schematic of the Stage 2 Route Options outlined below are shown on **Plates 4.10** and **4.11**.

Red Route Option

1. Further traffic assessment identified capacity issues on the mainline from the N83 to the N6 at Briarhill. This required the addition of a lane in each direction of travel. The additional westbound lane terminates at the diverge ramp of City East Business Park grade separated junction. The additional eastbound lane commences at the merge ramp from the N83 grade separated junction. The lanes terminate prior to joining the existing N6.

Orange Route Option

1. The link road from the N59 at Bushypark Church to Bóthar Stiofán in Knocknacarra was re-aligned to take account of residentially zoned lands. The junction with the N59 remains a signalised junction.
2. Further traffic assessment identified capacity issues on the mainline from the N83 to the N6 at Briarhill. This required the addition of a lane in each direction of travel. The additional westbound lane terminates at the diverge ramp of City East Business Park grade separated junction. The additional eastbound lane commences at the merge ramp from the N83 grade separated junction. The lanes terminate prior to joining the existing N6.

Yellow Route Option

1. The route option corridor from the R336 to Knocknacarra was modified in order to minimise impacts to residential properties and communities in the Bearna area.

2. The link road from the N59 at Glenlo Abbey to Bóthar Stiofán in Knocknacarra was re-aligned in order to take account of residentially zoned lands and to minimise impacts to residential properties and communities. The realignment also necessitated provision of a signalised junction connection at the N59.
3. Further traffic assessment identified capacity issues on the mainline from the N83 to the N6 at Briarhill. This required the addition of a lane in each direction of travel. The additional westbound lane terminates at the diverge ramp of City East Business Park grade separated junction. The additional eastbound lane commences at the merge ramp from the N83 grade separated junction. The lanes terminate prior to joining the existing N6.

Blue Route Option

1. The layout of the Bearna Inner Relief road was modified to minimise impacts to residential properties.
2. The junction layouts on the N84 and N83 were re-examined. Further traffic assessment and design work was undertaken in order to minimise the impacts to residential properties and communities in the Castlegar area from the N84 to the N83.

Pink Route Option

1. The layout of the Bearna Inner Relief road was modified on its western extents to match the previous Part 8 planning application for this section of the route option. At its eastern extents the layout was modified to minimise impacts to residential properties.
2. The route corridor from Bearna Village to Knocknacarra was modified in order to minimise impacts to residential properties and communities in the Bearna area.
3. The link road from the N59 at Glenlo Abbey to Bóthar Stiofán in Knocknacarra was re-aligned in order to take account of residentially zoned lands and to minimise impacts to residential properties and communities in the Bushypark area. The realignment also necessitated provision of a signalised junction connection at the N59.
4. The N59 grade separated junction was re-examined and further design work undertaken in order to minimise the impacts to residential properties and communities in the Circular Road area.
5. The mainline alignment was modified in the vicinity of the National University of Ireland, Galway (NUIG) and St. James' National School, Bushypark in order to minimise impacts to the recreational, commercial business and educational facilities in the area.
6. The junction layouts on the N84 and N83 were re-examined. Further traffic assessment and design work was undertaken in order to minimise the impacts to residential properties and communities in the Castlegar area from the N84 to the N83.
7. The junction layout at Coolagh/Briarhill was re-examined and further design work undertaken in order to minimise the impacts to residential properties and communities in the Coolagh area.

Green Route Option

1. The route corridor from the N83 to the N6 was modified in order to minimise impacts to residential properties and communities in the Coolagh/Briarhill area.
2. The split junction layout at Coolagh/Briarhill was re-examined and further design work undertaken in order to minimise the impacts to residential properties, educational facilities and communities in the Coolagh area.

4.7.2.3 N6 Galway City Outer Bypass (2006)

As noted in **Chapter 1, Introduction**, the eastern section of the N6 Galway City Outer Bypass (GCOB 2006) from the existing N6 to the N59 was approved by An Bord Pleanála (ABP) in 2008. At that point in time, the N6 GCOB 2006 scheme was assessed on the premise that the loss of a relatively small area of Priority Annex I habitat would not adversely affect the integrity of the Lough Corrib cSAC, and the scheme was taken forward on the basis of Article 6(3) of the Habitats Directive.

The N6 GCOB 2006 was one of the first road based alternatives considered as it was previously progressed through planning and there was also significant knowledge and detail available on this route option (refer to **Plate 4.12**).

Upon completion of the detailed ecological surveys and the definition of the option development zones, it was possible to comparatively assess and rank other road based alternatives with the N6 GCOB 2006 Route Option.

4.7.2.4 Cyan Route Option

The Cyan Route Option is a reconfiguration of the 2006 GCOB to address the issues raised by ABP in its refusal of the western section of the 2006 GCOB. This route option reflects the 2006 GCOB route option to the east of the River Corrib (i.e. approved by ABP in 2008) but with the addition of a grade separated junction on N83 at the crossing point. It follows an alternative route to 2006 GCOB to the west of the River Corrib (i.e. refused by ABP in 2008) in order to address the issues raised by ABP (refer to **Plate 4.13**).

4.7.2.5 Green – Blue Switch Route Option

This ‘Green - Blue Switch Route Option’ shown on **Plate 4.14**, provided an alternative route option which included the Stage 2 Green Route Option from the R336 to and including, the River Corrib crossing point. It then connected with the Stage 2 Blue Route Option before entering into Lackagh Quarry and followed the path of the Stage 2 Blue Route Option to the N6.

4.7.3 Appraisal of River Corrib Crossing Alternatives

4.7.3.1 Overview of environmental considerations

An appraisal of all of the following route options for the road based alternatives outline above was completed:

- Stage 2 Red Route Option
- Stage 2 Orange Route Option
- Stage 2 Yellow Route Option
- Stage 2 Blue Route Option
- Stage 2 Pink Route Option
- Stage 2 Green Route Option
- N6 GCOB 2006
- Cyan Route Option
- Green to Blue Switch Route Option

The routes were split into three sections for the purposes of the appraisal. The Galway City boundary line represents the assessment break line between Section 1 and 2 as this is the point at which route options merge and it becomes possible to switch between route options. The Bearna section, i.e. R336 to the Galway City boundary (Section 1) was assessed independently to ensure that the optimum solution for Bearna is obtained. An additional break down at the existing N6 tie-in at Briarhill, Coolagh was incorporated in order to compare the junction layouts at the existing N6 tie-in and is referred to as Section 3.

Table 4.2 below gives a summary of the potential environmental impacts on each of the route options.

Table 4.2: Key Potential Significant Environmental Impacts

Route Option	Significant Environmental Impacts
Stage 2 Red Route Option	• Material Assets Non-Agriculture – see **Table 4.3** (Property Acquisition Assessment) below • Noise and Vibration/Air and Climate – Constructability • Human Beings – Community Impacts and Constructability • Landscape & Visual – Constructability • Archaeology, Architecture and Cultural Heritage – Rahoon archaeological site • Planning – Conflict with vision for the city development and does not allow the city to implement other objectives • Engineering – Constructability

Route Option	Significant Environmental Impacts
	• Ecology – Unlikely to have adverse effects on the integrity of the Lough Corrib cSAC
Stage 2 Orange Route Option	• Material Assets Non-Agriculture – see **Table 4.3** (Property Acquisition Assessment) below • Ecology – Unlikely to have adverse effects on the integrity of the Lough Corrib cSAC • Engineering and soils and geology – Constructability through limestone and granite • Potential construction waste due to the construction of the proposed tunnel • Potential hydrogeological impacts and in turn indirect ecological impacts
Stage 2 Yellow Route Option	• Material Assets Non-Agriculture – see **Table 4.3** (Property Acquisition Assessment) below • Human Beings – Community Impacts • Ecology – Likely to have adverse effects on the integrity of the Lough Corrib cSAC
Stage 2 Blue Route Option	• Material Assets Non-Agriculture – see **Table 4.3** below and potential impacts on NUIG Sporting Campus, Galway Racecourse and Dangan Nurseries • Ecology – Unlikely to have adverse effects on the integrity of the Lough Corrib cSAC
Stage 2 Pink Route Option	• Material Assets Non-Agriculture – see **Table 4.3** (Property Acquisition Assessment) below and potential impacts on NUIG Sporting Campus, Galway Racecourse and Dangan Nurseries • Ecology – Unlikely to have adverse effects on the integrity of the Lough Corrib cSAC
Stage 2 Green Route Option	• Material Assets Non-Agriculture – see **Table 4.3** (Property Acquisition Assessment) below • Human Beings– Menlough, Killoughter Ballindooley and Bushypark communities • Landscape and Visual – Menlo Castle, Menlough, Killoughter and Ballindooley communities • Archaeology, Architecture and Cultural Heritage – Menlo Castle and Menlough Village • Ecology – Likely to have adverse effects on the integrity of the Lough Corrib cSAC

Route Option	Significant Environmental Impacts
N6 GCOB 2006	• Material Assets Non-Agriculture – see **Table 4.3** (Property Acquisition Assessment) below • Landscape and Visual – Menlo Castle • Archaeology, Architecture and Cultural Heritage – Menlo Castle • Human Beings – Menlo Castle in terms of the amenity value • Ecology - adverse impact on the site integrity of the Lough Corrib cSAC per the European Court decision, potential to impact on Lough Inch River which is known to contain Freshwater pearl mussels downstream, significant impact on the Moycullen Bog Complex NHA from a hydrogeological and hydrological perspective both at Tonabrocky and in the vicinity of Lough Inch
Cyan Route Option	• Material Assets Non-Agriculture – see **Table 4.3** (Property Acquisition Assessment) below • Landscape and Visual – Menlo Castle • Archaeology, Architecture and Cultural Heritage – Menlo Castle • Human Beings – Menlo Castle in terms of the amenity value • Ecology - adverse impact on the site integrity of the Lough Corrib cSAC per the European Court decision
Green to Blue Switch Route Option	• Material Assets Non-Agriculture – see T**able 4.3** (Property Acquisition Assessment) below • Landscape and Visual – Menlo Castle • Archaeology, Architecture and Cultural Heritage – Menlo Castle • Human Beings – Menlo Castle in terms of the amenity value • Ecology – potential impacts due to River Corrib Bridge

A comparative assessment of the property acquisition on each of the above options was also undertaken and is outlined in **Table 4.3** below, with the number split into the relevant three sections.

Table 4.3: Property Demolition Assessment – Route selection phase

Route Option	Residential Demolitions			Commercial Demolitions			Total
	Section 1	Section 2	Section 3	Section 1	Section 2	Section 3	
Red	14	73	7	0	19	0	113
Orange	14	32	7	0	9	0	62
Yellow	**2**	97*	7	**0**	11	0	117
Blue	6	42	6	0	6	0	60
Pink	3	**42**	**1**	0	**6**	**0**	52
Green	17	54	5	0	10	0	86
2006 GCOB	*Note sectional division not equivalent on old GCOB, and there are alternatives which better meet the project objectives than the old GCOB.*						10
Cyan**	16	25	0	0	0	0	41
Green – Blue Switch Route Option	17	62	6	0	2	0	87
Emerging Preferred Route Corridor	**2**	**42**	**1**	**0**	**6**	**0**	**51**
N6 GCRR	**9**	**43**	**2**	**0**	**7**	**0**	**61**

*An apartment block accounts for 37 residential acquisitions

** Cyan Route Option is a reconfiguration of the 2006 GCOB to achieve the current scheme objectives

4.7.3.2 N6 GCOB 2006 Appraisal

Full analysis showed that there are other alternatives which better meet the project objectives in terms of capturing existing travel demand than the N6 GCOB 2006 Route Option and which do not impact on the integrity of the Lough Corrib cSAC. When compared with the option development zones, i.e. areas within which from a human being and ecological perspective options could be developed, it was also evident that the N6 GCOB 2006 Route Option was located outside these zones over the majority of its length.

It should be noted that the boundary of the Lough Corrib cSAC was extended post lodgement of the N6 GCOB 2006 planning application with ABP, resulting in a greater length of this N6 GCOB 2006 Route Option crossing through the Lough Corrib cSAC and therefore having a greater impact on its integrity than originally anticipated in the N6 GCOB 2006 Environmental Impact Statement.

While the N6 GCOB 2006 had the least number of property acquisitions, as noted previously the western section did not receive planning permission from ABP under the earlier application due to potential environmental impacts in the area of Tonabrocky Bog pNHA. Therefore, the property acquisitions are not a true reflection of the likely property impacts of a new scheme that would meet the present project objectives. Further, the N6 GCOB 2006 would not deliver the optimum intermodal transport solution as extensive traffic modelling shows that it would not deliver relief to congestion to the same level as other road based alternatives.

Further still, in terms of the N6 GCOB 2006:

- It does not provide connection with the N83 Tuam Road, a national road, thereby providing a lesser level of connectivity
- It does not provide any connection to the key employment centres at Parkmore and Ballybrit and, therefore, minimal relief to the existing congestion at the eastern city extents
- It has an adverse impact on the site integrity of the Lough Corrib cSAC per the European Court decision
- It has potential to impact on Lough Inch River which is known to contain Freshwater pearl mussels downstream
- It has a significant impact on the Moycullen Bog Complex NHA from a hydrogeological and hydrological perspective both at Tonabrocky and in the vicinity of Lough Inch
- It has a profound impact on the curtilage of Menlo Castle from a cultural heritage perspective and on the amenity value from Human Beings perspective
- It has less impacts on communities and amenities with an overall improvement in the level of severance experienced, but at the expense of longer journey times and less relevant journey possibilities between east and west

and so it was not advanced further.

4.7.3.3 Cyan Route Option Appraisal

As can be seen from **Table 4.3**, the Cyan Route Option has more property acquisitions than the N6 GCOB 2006. This is as a result of the alternative route on the west to minimise the environmental impacts identified in the earlier decision of ABP, plus the addition of the N83 Tuam Road Junction. The Cyan Route Option would not deliver the optimum intermodal transport solution as extensive traffic modelling shows that it would not deliver relief to congestion to the same level as other road based alternatives.

Further still, in terms of the Cyan Route Option:

- It does not provide a direct connection to the key employment centres at Parkmore and Ballybrit and, therefore, minimal relief to the existing congestion at the eastern city extents
- It has an adverse impact on the site integrity of the Lough Corrib cSAC per the European Court decision
- It has a profound impact on the curtilage of Menlo Castle from a cultural heritage perspective and on the amenity value from Human Beings perspective

and so it was not advanced further.

4.7.3.4 Green – Blue Switch Route Option Appraisal

This route option provided an alternative crossing of the River Corrib, connecting the Green Route Option west of the river with the Blue Route Option east of the river with the benefit of the avoidance of impacts to NUIG Sporting Campus and reduction of direct impacts on the Dangan area west of the River Corrib, and the avoidance of Menlough Village to the east of the River Corrib.

An assessment of this route option showed however that:

- the connection between the Stage 2 Green and Blue Route Options at Menlough had a greater impact on Menlo Castle from an architectural and cultural heritage (profound impact) and landscape and visual and human being amenity value perspective than either the Green or Blue Route Options considered alone
- the direct impact on residential properties for this alternative route option is also greater with the highest number of residential acquisitions when compared to that of the Blue or Green Route Options considered alone
- this route option has potentially an impact on flood risk in the vicinity of the River Corrib and its floodplains
- due to the presence of soft and peat soils, the location of the River Corrib Bridge crossing presents a major negative in terms of soils and geology
- this route option would result in significant impacts to a qualifying interest of the Lough Corrib cSAC habitat (Alkaline fen) on the west bank of the River Corrib in Lough Corrib cSAC and would adversely affect the integrity of the Lough Corrib cSAC
- this route option is also potentially the most damaging with respect to the local Lesser horseshoe bat population given its proximity to Menlo Castle and the core foraging area

and so it was not advanced further.

4.7.3.5 Remaining Route Options Appraisal

Each of the remaining route options were ranked with respect to their impacts for each environmental discipline as follows: Preferred (P), Intermediate (I), and Least Preferred (LP). These terms are used to comparatively assess route options in either Section 1, Section 2 or Section 3 and should not be interpreted to compare the significance of impacts between these sections. For example, by virtue of the fact that route options in Section 2 cross a European site whereas in Section 1 they do not, the route option(s) assigned a ranking of LP in Section 2 for ecology are likely to have a much greater impact on the ecological environment than the route option(s) assigned a ranking of LP in Section 1.

The overall ranking for each route option in terms of the environment took into consideration the overall number of preferred, intermediate and least preferred rankings. During the course of the assessment process *Human Beings, Ecology, Landscape and Visual, and Material Assets – Non Agricultural* were identified as disciplines which had key significant constraints. For example, impacts on human beings such as communities and residential property acquisitions and impacts on ecology such as on European sites were all key significant constraints which required further consideration during the decision making process. Therefore, these disciplines are shown in italics in the summary tables and are referred to as "key environmental disciplines" below.

Section 1

The Yellow Route Option is the preferred route option overall for Section 1. It has five preferred, five intermediate and two least preferred rankings. Of the five preferred rankings, three are for key environmental disciplines. Of the two least preferred rankings, one of these was for a key environmental discipline (ecology), however as noted above, route options in Section 2 cross a European site whereas in Section 1 they do not, therefore ecological constraints in Section 1 are not as significant as those in Section 2. The Yellow Route Option has the lowest number of least preferred rankings overall.

The Pink Route Option has been assigned an Intermediate ranking overall for Section 1. The Pink Route Option has one preferred, seven intermediate and four least preferred rankings. The Pink Route Option has no key environmental discipline which has a preferred or least preferred ranking.

The Blue Route Option has also been assigned an Intermediate ranking overall for Section 1. The Blue Route Option has one preferred, six intermediate and five least preferred rankings. Of the five least preferred rankings, one of these was for a key environmental discipline (landscape and visual). This route option has no preferred rankings for a key environmental discipline.

The Red, Orange and Green Route Options have all been assigned a Least Preferred ranking overall for Section 1.

The Red Route Option has six preferred, two intermediate and four least preferred rankings. Of the four least preferred rankings, three are for key environmental disciplines. The Orange Route Option has seven preferred, one intermediate and four least preferred rankings. Of the four least preferred rankings, three are for key environmental disciplines. The Green Route Option has one preferred, five intermediate and six least preferred. Of the six least preferred, three are for key environmental disciplines

In conclusion, the Yellow Route Option is the preferred route option for Section 1.

Section 2

The Orange and Pink Route Options are both the preferred route options overall for Section 2. The Blue Route Option has been assigned an intermediate ranking overall for Section 2. The Red, Yellow and Green Route Options have all been assigned a least preferred ranking overall for Section 2. The overall rankings are discussed further below. In addition, given that the Lough Corrib cSAC is one of the more significant constraints in Section 2, ecology ranking is also discussed in more detail below.

<u>Orange Route Option</u>

The Orange Route Option has been assigned a preferred ranking for Section 2. The Orange Route Option has the greatest number of preferred rankings (six), two intermediate and four least preferred. Of the four least preferred rankings, none are for a key environmental discipline. The Orange Route Option includes a 3.5km tunnel and therefore many of the environmental constraints are not directly impacted, therefore it has been assigned a preferred ranking overall.

The Orange Route Option is the preferred route option from an ecological perspective as it avoids direct impacts on the Lough Corrib cSAC and as a significant length of this route option is either predominantly online or underground, its impact is reduced on many of the other ecological receptors identified within the scheme study area.

It should be noted that whilst the tunnel avoids direct impacts on the environmental constraints a 3.5km tunnel has the potential to indirectly impact on groundwater and groundwater dependant habitats within the Lough Corrib cSAC and Galway Bay Complex cSAC.

<u>Pink Route Option</u>

The Pink Route Option has also been assigned a preferred ranking for Section 2. The Pink Route Option has the second highest number of preferred rankings (four), six intermediate rankings and two least preferred. Of the two least preferred rankings, none are for a key environmental discipline. Of the preferred rankings, one is for a key environmental discipline (Material Assets Non-Agriculture). The Pink Route Option has the lowest number of least preferred rankings taking all environmental disciplines into consideration.

The Pink Route Option is ranked as intermediate from an ecological perspective in Section 2.

Both the Pink and Blue Route Options are similar from an ecological perspective as although they avoid any direct impacts to Annex I habitats within the boundary of the Lough Corrib cSAC, they will result in some degree of habitat loss within the designated site. Pink Route Option has a larger footprint than the Blue Route

Option within the Lough Corrib cSAC and a greater impact than the Blue Route Option on Annex I habitat overall in this section.

Blue Route Option

The Blue Route Option has been assigned an intermediate ranking overall for Section 2. It has one preferred ranking, seven intermediate, and four least preferred. Of the four least preferred rankings, one is for a key environmental discipline (landscape and visual). This route option has no preferred rankings for a key discipline.

The Blue Route Option is ranked as intermediate from an ecological perspective in Section 2. Blue is slightly more preferred than the Pink Route Option from an ecological perspective due to its smaller footprint within the Lough Corrib cSAC and lesser impact than the Pink Route Option on Annex I habitat overall in this section.

However, other negative impacts were experienced by other environmental disciplines for the Blue Route Option, for example the Material Assets Non-Agricultural impacts on NUIG Sporting Campus and other commercial properties in the vicinity and Landscape and Visual impacts.

Red Route Option

The Red Route Option has been assigned a least preferred ranking overall for Section 2. The Red Route Option has three preferred rankings, one intermediate and eight least preferred. Of the eight least preferred, three are key environmental disciplines. This route option has one preferred ranking for a key discipline (Ecology).

The Red Route Option is ranked as preferred from an ecological perspective in Section 2. The Red Route Option is one of the route options with the lowest overall impact on the Lough Corrib cSAC, the lowest impact on Annex I habitats of all the route options and, by virtue of being predominantly on-line, is likely to have the least impact on most other ecological receptors.

Although the Red Route Option is preferred for ecology, it has been assigned a Least Preferred ranking overall because, potential significant/profound impacts have been identified on the Red Route Option for landscape and visual, archaeology and heritage, material assets non-agriculture and human beings. Other negative impacts are also experienced for other environmental disciplines such as soils and geology, air and climate, planning and noise and vibration. The cumulative impact of all of the other significant/profound negative impacts experienced by the other environmental disciplines means that this route option has been assigned a ranking as least preferred overall.

Yellow Route Option

The Yellow Route Option has been assigned a least preferred ranking overall for Section 2. The Yellow Route Option has one preferred, four intermediate, one intermediate/least preferred and six least preferred. Of the six least preferred rankings, four are for key environmental disciplines.

The Yellow Route Option is ranked as least preferred from an ecological perspective in Section 2 because it is the route option with the greatest potential for impacts to qualifying interests (QI) Annex I habitat within the Lough Corrib cSAC. The Yellow Route Option was found to likely result in adverse effects on the integrity of Lough Corrib cSAC.

Green Route Option

The Green Route Option has been assigned a least preferred ranking overall for Section 2. The Green Route Option has one preferred, four intermediate and seven least preferred. Of the seven least preferred rankings, three are key environmental disciplines.

The Green Route Option is ranked as least preferred from an ecological perspective in Section 2 as it is likely to result in indirect impacts to QI Annex I habitat within the Lough Corrib cSAC but less than that associated with the Yellow Route Option. Green Route Option was found to likely result in adverse effects on the integrity of Lough Corrib cSAC.

In conclusion, the Orange and Pink Route Options are both Preferred for the Environmental Appraisal for Section 2. The Blue Route Option is ranked as intermediate whilst Red, Yellow and Green Route Options are ranked as least preferred for Section 2.

Section 3

All route options have a similar number of preferred, intermediate and least preferred rankings however the Pink Route Option is the preferred for Section 3. It has five preferred, two intermediate and five least preferred rankings. Of the five preferred rankings, two are for key environmental disciplines (landscape and visual and material assets non-agriculture). Of the five least preferred rankings, one is for a key environmental discipline (ecology), however ecological impacts in Section 3 are not on a European site. All other route options are ranked intermediate as they are all similar in the number of preferred, intermediate and least preferred rankings.

In conclusion, the Pink Route Option is the preferred option for Section 3.

4.7.3.6 Conclusion of appraisal

An overall summary of the rankings for the engineering, environmental and economic appraisals for each of the alternatives considered is presented in **Table 4.4** below, including those which were discounted as they were unfeasible or did not meet the project objectives as outlined in **Sections 4.4**, **4.5**, **4.6** and **4.7.1** for the purposes of comparison only.

The rankings for the Red, Orange, Yellow, Blue, Pink and Green Route Options represent those for Section 2 of those route options, i.e. the length from the city boundary at Bearna to the tie-in with the existing N6 at Coolagh as this section is most comparable to all other alternatives. **Tables 4.5** and **4.6** below present the appraisals for Section 1 and Section 3 of these route options separately.

During the course of the assessment process *Human Beings, Ecology, Landscape and Visual and Material Assets Non-Agriculture* were identified as disciplines which had key significant constraints. For example, impacts on human beings such as communities and residential property acquisitions and impacts on ecology such as on European designated sites were all key significant constraints which required further consideration during the decision making process. Therefore, these disciplines are shown in italics in the tables below.

Red and Orange Route Options

The assessment of the Red and Orange Route Options through Section 2 concluded that they are not feasible in so far as they are not deliverable or realisable as they create disproportionate impacts on the sensitive urban environment of Galway City and on its inhabitants, communities and neighbourhoods. The scale and nature of the infrastructure required for the on-line portion of these options is of significant magnitude; this is because the route option would be retrofitted into a sensitive urban environment. The design legacy of such significant heavy engineering solutions associated with these options is likely to radically permanently impact on the experience and image of the city. The scale of this harm is so significant as to deem them to be at significant variance with some of the scheme objectives.

The timescale for the construction of the Red Route Option is of the order of six years, and again the enormity of this construction and the scale of impact could be detrimental to the economy of Galway City, the improvement of which is set as a project objective, as well as having a significant impact on the daily lives of all those impacted by it. The cost of the construction of the Orange Route Option is of such an order as to be the least cost effective alternative, whilst noting that delivery of a cost effective solution is a project objective. It should also be noted that whilst the tunnel avoids direct impacts on many environmental constraints a 3.5km tunnel has the potential to indirectly impact on groundwater and groundwater dependant habitats within the Lough Corrib cSAC and Galway Bay Complex cSAC and their site integrity.

The impacts of the Red and Orange Route Options are considered to be on such a large scale as to be disproportionate to the over-riding need for the road based alternative. Equally as further mitigation by avoidance is very unlikely to improve these route options, these route options were not advanced further.

Yellow Route Options

The Yellow Route Option through Section 2 has similar issues on the on-line section as the Orange and Red Route Options on the eastern side of the city. It has a very significant impact on human beings in the Ballinfoyle area off the Headford Road, with the acquisition of 24 residential properties and an apartment block (37 residential units).

In addition, the Yellow Route Option is likely to have adverse effects on the integrity of Lough Corrib cSAC; and of the route options available, would affect the Qualifying Interests (QI) habitats of the cSAC to the greatest degree. Therefore, the Yellow Route Option was not advanced as there were alternatives available for crossing the Lough Corrib cSAC.

Blue, Pink and Green Route Options

In reviewing all remaining route options (i.e. Blue, Pink and Green), consideration was given to the number of residential properties to be acquired. In each section, an assessment was undertaken under various criteria which sought to balance the potential impact on human beings and ecological constraints and other constraints.

It is acknowledged that the Green Route Option is likely to result in adverse effects on the integrity of Lough Corrib cSAC however it was brought forward for further analysis because it offers an alternative route option which avoids direct impacts on NUIG Sporting Campus and Galway Racecourse.

In the assessment of all route options cognisance was taken of the submissions received as part of the extensive public consultation carried out in respect of the project to minimise the potential impacts on human beings and properties.

The outcome of the robust assessment is that the route option selected was a combination of route options which had the least number of residential properties acquired in each section, i.e. Yellow in Section 1 (modified to reduce potential property impacts), Pink in Section 2 and Pink in Section 3, as shown in bold on **Table 4.2** above, whilst also being the least impacting on the receiving environment. In fact, if the route was further out from the city or in close to the city, there would have been more acquisitions.

4.7.3.7 N59 Link Road Appraisal

During Environmental Workshop No. 4, a review of the constraints and the potential impacts of the N59 Link options was completed in order to select the optimum link connection.

There are three options to connect the N59 to the mainline when the mainline is offset from the N59:

- Orange N59 Link
- Yellow N59 Link/Pink2 N59 Link
- Blue N59 Link

It should be noted that each of the N59 Link Options could be connected with the mainline of the route options, e.g. Orange, Yellow, Blue and Pink. The principal differences between the link options are as follows:

1. The Yellow N59 Link, Pink N59 Link and Blue N59 Link connect to the N59 in the vicinity of Glenlo Abbey whereas the Orange N59 Link connects approximately 1km further south, closer to the city, adjacent to Bushypark Church.
2. The Yellow N59 Link, Pink N59 Link and Blue N59 Link cross at least two local roads whereas the Orange N59 Link does not interact with any local road.
3. The junction form at Glenlo Abbey for the Blue N59 Link will be a priority junction with the N59 realigned along the proposed link and the old N59 tying into it.
4. The junction form at Bushypark Church for the Orange N59 Link will be a signalised junction.
5. The junction form at Glenlo Abbey for the Yellow N59 Link and Pink N59 Link will be a signalised junction.

An engineering appraisal of the N59 Link Road options above under the relevant headings of geometry, length, junction strategy, constructability and traffic was completed.

This assessment showed that the Orange N59 Link is the shortest link with minimal interaction with the surrounding local road network, but the traffic figures on this link are much lower than on the link options to the north namely the Yellow N59 Link, Pink N59 Link and Blue N59 Link. This was attributed to the fact that the mainline of the Orange Route Option did not offer equivalent connection opportunities on the east side of the city as the Yellow, Pink and Blue Route Options. Therefore, the Orange N59 Link was subsequently tested in the traffic model with the emerging preferred route corridor. This showed that the traffic volumes on this link were greater than any of the other link options under consideration. Therefore, from an engineering perspective the preferred N59 Link is the Orange N59 Link.

An environmental appraisal was also carried out on the N59 Link with the key differences being the consideration of human beings and non-agricultural material assets. As noted in above, *Human Beings, Ecology, Landscape and Visual, and Material Assets – Non Agricultural* were identified as disciplines which had key significant constraints. For example, impacts on human beings such as communities and residential property acquisitions and impacts on ecology such as on European designated sites etc. were all key significant constraints which required further consideration during the decision making process.

The Orange N59 Link was the preferred route option from an environmental perspective. It has seven preferred, two intermediate and three least preferred rankings. Three of the seven preferred rankings were for a key environmental discipline, landscape and visual, material assets non-agriculture and human beings. Of the three least preferred rankings, one of these was for a key environmental discipline (ecology). However ecological impacts due to the Orange N59 Link are not on a European site.

The Yellow and Pink N59 Links have been assigned an intermediate ranking. They have five preferred, seven intermediate and no least preferred rankings. Of the preferred rankings, one of these was for a key environmental discipline (ecology).

The Blue Route Option is least preferred from an environmental perspective. The Blue Route Option has two preferred, three intermediate and seven least preferred rankings. Of the five least preferred rankings, three of these were for a key environmental discipline (landscape and visual, material assets non-agriculture and human beings).

On review of the engineering and the environmental assessments of the N59 Link, the overall preference is the Orange N59 Link.

4.7.3.8 Emerging Preferred Route Corridor

The Emerging Preferred Route Corridor (EPRC) was developed as an amalgamation of different route options over two sections, namely R336 to the Galway City boundary and the Galway City boundary to existing N6.

The consensus from the comparative assessment was that the Red, Yellow and Orange Route Options through Section 2 were not feasible in so far as they are not deliverable or realisable due to impacts on the environment including persons, as outlined above. Equally as further mitigation by avoidance is unlikely to improve these route options and these route options were discounted.

Therefore, the preferred route option is the Yellow/Green Route Option over the initial part of Section 1, connecting the Pink Route Option at Barr hAille and follows the path of the Pink Route Option to its termination at the N6 in Coolagh, with the exception of the N59 Link. The N59 Link will comprise the link as presented in the Orange Route Option with a slight modification to tie to the Pink Route Option.

At this point of the route selection process, it was clearly acknowledged and identified that significant engineering infrastructure was required to enable advancement of this preferred route.

As set out at **Section 4.3**, there are a number of constraints within which to work and therefore any proposed road development has to be cognisant of and recognise the constraints existing in a city environment, such as Galway City, that includes Lough Corrib, the River Corrib, Galway Bay and the surrounding natural environment, the presence of designated sites as well as the constraints of the built environment including residential areas of the city itself. These have increased the complexity of the proposed road development and significant engineering interventions are required to address such constraints including:

- River Corrib bridge structure over River Corrib
- Lackagh Tunnel structure beneath Lough Corrib cSAC
- A viaduct structure over non-designated habitat in Menlough

In addition, the desire to reduce the impact of the proposed road development on lands which serve a wide community has driven some significant engineering interventions namely:

- A viaduct structure extending from the River Corrib Bridge to traverse NUIG Sporting Campus
- Galway Racecourse Tunnel structure under the racecourse

Proximity and direct connectivity of the proposed road development are required to serve the strategic traffic accessing Galway City and to deliver the optimum intermodal transport solution within Galway City and its environs with the attendant benefits of the proposed road development. This makes it complex as impacts to the human environment increase with proximity to the urban environment. In addition, it is further complicated and guided by the presence of the designated sites with which any transport solution will interact.

These significant engineering elements formed part of the design measures on the EPRC. Without these significant engineering measures, the Green Route Option would be preferred over Pink, Blue or Yellow Route Options from an ecological perspective through Section 2. However, the Green Route Option had significantly more residential acquisitions as well as significant cultural heritage impacts on Menlough Village.

The provision of the River Corrib Bridge, Menlough Viaduct, Lackagh Tunnel and Galway Racecourse Tunnel are significant infrastructure in proximity to the urban environment but are a justified and proportionate response to deliver a solution in the correct location to solve the transport issues facing Galway City and its environs.

The Emerging Preferred Route Corridor is presented below in **Plate 4.15**.

Plate 4.15: Emerging Preferred Route Corridor

4.8 Route Optimisation

Although the route of the proposed road development has been designed to skirt the city and lands zoned for development, the avoidance of all properties is unfortunately not possible given the linear development of the city with housing along every road radiating out of the city.

The proximity of the proposed road development to the urban environment, which is necessary to provide the optimal transport solution, results in the unfortunate but unavoidable demolition of 44 dwellings to facilitate construction, and the acquisition of a further 10 dwellings due to the impacts on those properties. This is a significant impact on the people living in these homes. However, this must be viewed and considered and balanced with the overall benefits that this proposed road development presents for the future of Galway and its environs and connectivity to the Western Region.

Once chosen, the design of the emerging preferred route corridor (EPRC) has been refined in as much as possible to eliminate and reduce impacts on the human environment. Significant design measures such as steeper earthwork slopes, steepened green embankments and retaining walls have been incorporated in the design to minimise the impact on the human environment. Additional mitigation measures such as noise barriers, landscaping, planting, earth bunding are also utilised to minimise the overall impact on the receiving environment.

Further from an ecological perspective the proposed road development would not have any adverse impacts on the integrity of any European sites.

The process of producing the design from a route corridor was an iterative process. Inputs were received from the environmental specialists, public consultations, submissions, stakeholder commentary and from the over 950 individual landowner meetings and work focused on minimising impacts on homeowners, stakeholders and the environment and refining the layout in order to improve performance.

The incorporation of these inputs resulted in approximately 20% of the length of the route moving outside the published EPRC, which was published in May 2015. Of this 20% only 4% of the route moved wholly outside the EPRC. The more significant alterations which arose as a result of this optimisation are outlined below.

4.8.1 General

Amendments made throughout the length of the proposed road development include development of accommodation works via consultation with directly impacted property owners, refinement of local junction and access arrangement layouts in order to improve accessibility and performance and horizontal alignment alterations in order to minimise impact on property owners. An overview of the major amendments is outlined in the subsequent sections.

4.8.2 Na Foraí Maola to Ballymoneen Ch. 0+000 to 5+640

Following on site consultation meetings and subsequent feedback with landowners in the area of Na Foraí Maola, Troscaigh, Aille, Cappagh, and Ballymoneen area in September 2015 a number of alternative design alteration options were considered. The following is a list of design changes adopted following this consultation:

Na Foraí Maola & Troscaigh Thiar

The design of the proposed road development at Na Foraí Maola and Trosciagh Thiar has evolved since the publishing of the EPRC. The roundabout junction at Na Foraí Maola Thiar which only provided a connection to the local road on the south was removed and replaced with an overbridge link midway between Na Foraí Maola and Troscaigh Road. This also replaced the proposed EPRC overbridge on Troscaigh Road. This overbridge maintains connectivity for pedestrians and local traffic whilst limiting direct access to the proposed road development which has been identified as a strategic route within the TEN-T network. Local access from these areas to the proposed road development are provided at the R336 roundabout in An Baile Nua and Bearna Moycullen Roundabout only.

The horizontal alignment of the mainline of the proposed road development as it changes direction between the R336 Baile Nua and Na Foraí Maola Thiar was changed to a more desirable radius of 510m for a design speed of 85km/h.

Troscaigh Thoir

In Troscaigh Thoir the proposed alignment of the mainline of the proposed road development moved further north away from residential properties on the Ann Gibbons Road. The at-grade roundabout on the Bearna to Moycullen Road moved further south to reduce impacts on a planning permission for a dwelling.

Aille

The proposed mainline of the proposed road development was changed from going over Aille Road on an embankment and bridge structure to go under Aille Road in a cutting and overbridge structure. This was mainly to reduce visual impacts to residential properties north of the proposed road development. The existing Aille local road will be raised by c. 3.5 - 4m at the centre point of the proposed road development to provide adequate headroom and to reduce the excavation depth in rock cutting along the alignment mainline of the proposed road development.

Cappagh

The alignment mainline of the proposed road development was changed at Cappagh Road from an embankment and overbridge to an at-grade roundabout junction. This alteration was incorporated to the design to reduce the landscape and visual impacts of the embankment of the proposed road development on residential properties north and south of the proposed road development and also to provide direct access to the proposed road development from Cappagh Road.

Subsequent to this design change a detailed traffic analysis of traffic movements on all junctions across the proposed road development was undertaken. This analysis recommended that the Cappagh Road Roundabout be changed to a signalised junction to improve overall volume to capacity ratios and also to improve pedestrian and cyclist safety due to its location within the urban environment.

Ballymoneen Road

For similar reasons to the Cappagh Road junction outlined above this same design change was adopted at the Ballymoneen Road Junction where by the roundabout has been replaced with a signalised junction.

4.8.3 Letteragh Junction Area Ch. 7+600

The underbridge at Letteragh Road on the N59 Link Road South was removed and replaced with an at-grade junction with a consequent alteration to the horizontal alignment of the proposed road development. This alteration was incorporated into the design for the following reasons:

- Minimises landscape and visual impacts of bridge over Letteragh Road
- Provides connectivity to National University Ireland, Galway (NUIG) core area and University Hospital Galway (UHG)
- Reduces the traffic on the adjacent local road as reduces diversionary routes to access the proposed road development

The direct connection of the N59 Link Road South to Bóthar Stiofáin was removed and redirected to Gort na Bró Road. This alteration was incorporated into the design as it is a more appropriate connection point for the following reasons:

- Eliminates the conflict between direct accesses from existing homes and traffic accessing the proposed road development
- Minimises impacts on homes on Bóthar Stiofáin
- Separates heavy goods vehicles accessing the Galway West Retail Park from the local movements and vulnerable road users directly accessing onto Bóthar Stiofáin

The horizontal alignment of the proposed road development and the N59 grade separated junction moved westwards by c.150m in order to minimise direct impacts on properties. The diamond grade separated junction was also changed from roundabouts to signalised junctions to improve overall volume to capacity ratios and also to improve pedestrian and cyclist safety along the proposed N59 Link Road.

The mainline also changed from going under the N59 Link Road to going over to reduce overall excavation depths in the rock cutting.

4.8.4 Dangan Bushypark Area

The proposed mainline of the proposed road development moved slightly west c.15-20m in the Dangan/Bushypark area to reduce direct impacts to a local primary school and residential properties. The alignment over the River Corrib was amended to reduce the overall span and skew over the river.

4.8.5 Castlegar Area Ch. 8+300 to 8+800

The horizontal alignment of the proposed road development moved northwards and the elevation was reduced in order to minimise direct impacts on residential properties.

4.8.6 N83/Parkmore Junction Ch. 13+600 to 14+000

The partial grade separated junction on the N83/Parkmore Link Road was replaced with a full movement junction. This alteration was incorporated into the design for the following reasons:

- Caters for the predicted traffic demand utilising the Parkmore Link Road to/from the east
- Improves the capacity of the existing N6 Briarhill Junction as traffic coming from the east which is bound for Parkmore Industrial Estate and Ballybrit Industrial Estate remains on the proposed road development until the proposed exit at Parkmore Link Road
- Improves the capacity of the existing N6/N83 Tuam Road Junction as traffic is retained on the proposed road development
- Frees road space on the existing N6 between the N6/N83 Tuam Road Junction and the proposed Coolagh Junction

4.8.7 Parkmore Link Road Ch. 14+400

The alignment of the Parkmore Link Road has been moved slightly east in order to protect the historical Parkmore mass path and facilitate the future expansion of Boston Scientific’s existing facility.

The eastern link road within the Ballybrit Business Park has been removed and an at-grade signalised junction connection to the existing N6 has been incorporated into the design at this location for the following reasons:

- Eliminates duplication of road provision as minimal demand on this eastern link road
- Avoids impact on the track and boundary drain at Galway Racecourse at a particularly tight area where the emerging preferred route corridor was close to the racetrack
- The GTS recommends a primary cycle route network along the existing N6 at this location. The junction provides improved connectivity to the existing N6 at this location for all traffic modes especially for vulnerable road users as currently there is no provision for the desire line to the large employment centres at the eastern end of Ballybrit Business Park

The current alignment of Parkmore Link Road ties-in at grade to the north of the existing IDA owned cul-de-sac road. The current design provides safe passage for all modes of transport as it consists of 2m cycle lanes and 2m pedestrian footways on the proposed new alignment.

Within the Galway Transport Strategy, *"specific emphasis is also placed on improving connectivity and permeability, within and to the industrial sites to the east of the city, including to, from and between Ballybrit and Parkmore Industrial Parks"*. In this context, the proposed 'Parkmore Link Road' forms part of the Galway Transport Strategy 'Primary Cycle Network', providing a new direct connection to and through Ballybrit Business Park and onwards to Parkmore Industrial Estate. The overall aspiration of the proposed cycle network is *"to provide a safe and comfortable environment for cyclists in the city and surrounding areas, in turn supporting an increase in the number of cyclists and encouraging a greater mode shift from the private car to cycling"*.

The strategic cycling aim of the Galway Transport Strategy primary cycle network is to "*provide a convenient and safe route for medium-distance radial commuter / leisure journeys"*. The primary cycle network through Ballybrit Business Park and along the proposed Parkmore Link Road will therefore have dedicated, segregated cycle facilities and make provision for new or improved pedestrian facilities.

Specifically, it is the intention of the Galway Transport Strategy to *"ensure that the needs of pedestrians, including the mobility impaired and disabled, are fully considered in the design of all new facilities and upgrades of existing facilities….Permeability is a key constraint for cyclists and pedestrians in Galway. Links between residential areas and workplaces alike will be continuously improved as part of a structured, prioritised implementation programme based on the above principles"*.

The Galway Transport Strategy recognises that the integration of land-use and transportation is essential in creating sustainable living. The Galway Transport Strategy states that *"the primary goals of land-use and transport integration in responding to the need to travel may be summarised as follows:*

- **Reducing** the need to travel;
- **Reducing** the distance travelled;
- **Reducing** the time taken to travel;
- **Promoting** walking and cycling; and
- **Promoting** public transport use."

The Galway Transport Strategy therefore incorporates specific land use principles to guide development in Galway, including:

- *New development areas should be fully permeable for walking and cycling and the retrofit of walking and cycling facilities should be undertaken where practicable in existing neighbourhoods, in order to give a competitive advantage to these modes;*
- *Where possible, developments should provide for filtered permeability. These would provide for walking, cycling and public transport and private vehicle access but at the same time would discourage through trips by private car;*
- *To the extent practicable, proposals for right of way extinguishments or other requirements should only be considered where these do not result in more*

circuitous walking and cycling trips for local residents accessing public transport or local destinations; and

- *In urban areas, including the numerous towns, villages and settlements, the Design Manual for Urban Roads and Streets (DMURS) will guide localised proposals with a view to reaffirming walking, cycling and public transport modes over the private car.*

The current design of the Parkmore Link Road is in compliance with the design basis set out in the Galway Transport Strategy and this is reflected in the bus routes and cycle network therein, refer to **Plate 4.16** and **4.17**. It serves as the most efficient and shortest public transport route and is along the pedestrian and cyclist desire line. With the advancement of the Parkmore Link Road, pedestrian and cycle access to this employment area is improved significantly.

Plate 4.16: Proposed Bus Routes per Galway Transport Strategy

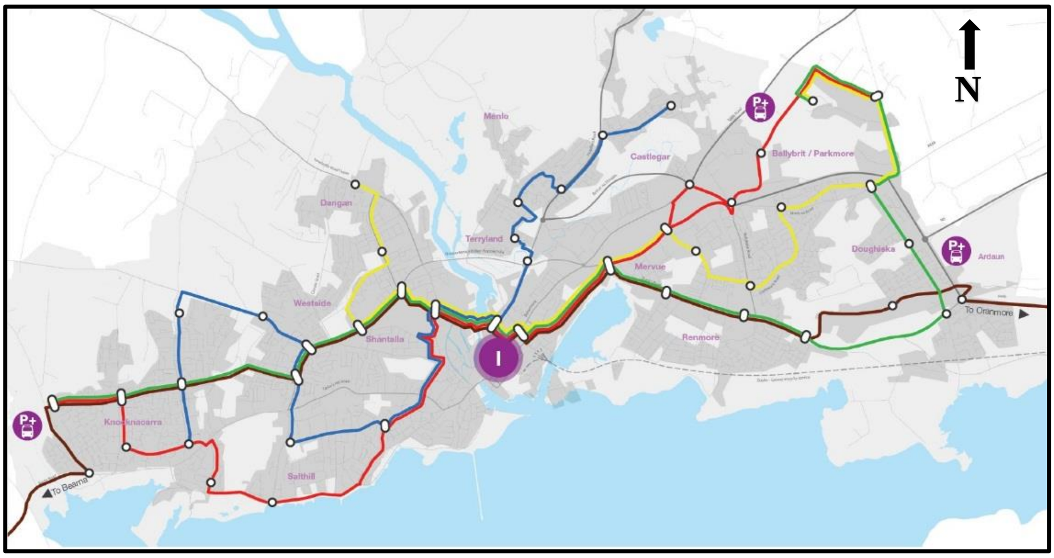

Plate 4.17: Proposed Cycle Network per Galway Transport Strategy

As can be seen above, the linking of the industrial estates via the Parkmore Link Road provides a more direct route from the city centre and western suburbs to the employment areas in the north east quadrant.

4.8.8 Galway Racecourse Tunnel Ch. 14+000 to 15+150

A design change to the proposed Galway Racecourse Tunnel was adopted following a peer review with the Transport Infrastructure Ireland (TII) tunnel operations team. This review considered the long-term operational and maintenance requirements associated with an 850m cut and cover tunnel in addition to the capital cost of its construction. Following this review an exercise was carried out to assess the viability of shortening the overall tunnel length and moving the alignment north to facilitate an open cut section. Following this assessment, it was concluded that a shorter, 240m long tunnel and realignment to the north was preferable to the previous longer design in terms of overall safety and long term operational requirements of the proposed Galway Racecourse Tunnel. This is in addition to the cost savings provided by the shorter tunnel.

In summary the short tunnel option provided the following benefits:

- Reduced operation and maintenance costs
- Reduced construction costs
- Reduced construction programme
- Reduced construction risks
- Reduced interface with Galway Racecourse operations, most notably during construction
- Reduced risks to Galway Racecourse operations due to reduction of overlap between construction and racecourse operations
- Due to the limitation of a nine-month construction window which is required to accommodate the racecourse operations there is a significant increase in time available to excavate rock in the open section of the proposed road development which is no longer within a tunnel or Galway Racecourse lands
- No mechanical tunnel ventilation system required
- No requirement for a deluge system for fixed fire suppression
- Water supply storage and water retention sumps are significantly reduced due to extent of tunnel and absence of deluge fire suppression system
- Removal of 85km/h reduced design speed through shorter tunnel section as alignment allows 100km/h design speed in area
- Significant reduction in carbon footprint due to shorter tunnel and reduced maintenance requirements
- More economical solution over the life time of the proposed road development
- It has been observed that there is a higher rate of accidents at tunnel portal locations. The redesign removes the conflict of the eastbound merge and westbound diverge with the western tunnel portal

- Slip ramps on revised N83 Junction do not require a departure from design standards thereby enhancing safety, operational performance and junction consistency. Standard slip road geometry presents road users with clear unambiguous decision points allowing smooth and safe merge and diverge movements. Consistent merge and diverge layouts across the scheme eliminate driver confusion and aid driver interpretation of junction layouts. The proposed layout is more amenable to future modification, if required, than the original design for the most part as a result of the relocation of the tunnel portal away from the junction

4.8.9 Monivea Road - Coolagh Ch. 15+150 to 17+450

Following the Phase 3 on site geotechnical investigations, the vertical alignment of the proposed road development was altered to cross over the R339 Monivea Road and Briarhill Business Park Road. This is due to the discovery of a high water table in the area and the consequential impacts associated with being in cut in this area.

The layout of the Coolagh Junction has been amended approaching the existing N6. This revised layout has been incorporated into the design for the following reasons:

- Simplifies the proposed junction and the connection to existing N6
- Clearly segregates bypass traffic from traffic accessing the eastern suburbs
- Prioritises national route traffic movements over local route traffic movements
- Provides route continuity for the N6 around Galway City
- Incorporates shorter and more direct links
- Capacity can be increased via upgrade to free flow if demand requires
- Has reduced construction costs and construction complexity

4.9 N6 GCRR – The Optimum Transport Solution

The emerging preferred route corridor for the proposed road development was selected following an extensive evaluation of potential physical and environmental constraints. Route Corridors were analysed through early screening processes to reduce the number of feasible options. The assessment of these options included extensive public consultation exercises and project team workshops. The options were also subject to assessment by an appraisal team independent of the project team. Finally, through further optimisation and avoidance of impacts, the final design corridor was determined.

This preferred route commences in An Baile Nua west of Bearna Village at the R336 and proceeds in a north east direction crossing over the River Corrib in Dangan and connects to the existing N6 at Coolagh. A full overview of the route of the proposed road development is provided in **Chapter 5, Description of Proposed Road Development**.

The proposed road development avoids the greatest number of known and immovable constraints, and utilises the available fabric to greatest extent. It also meets with the requirements of modern road design and of current policy needs.

The design changes made to the proposed road development following the selection of the EPRC further reduce the overall potential environmental impacts on the area and the community without in any way affecting and or altering the selection process carried out. The solution proffered in the proposed road development is the optimum transport solution while also being the preferred option from an environmental perspective, both from a human environment and natural habitat perspective. It incorporates the responses received as part of the extensive public consultation carried out in respect of the project and delivers all of the following:

- Provides a strategic route, forming part of the TEN-T comprehensive network, across the River Corrib without the need to go through the city
- Provides the necessary connectivity to all the national roads and the Western Region and for those living within Galway and the rest of the country
- Provides for strategic traffic accessing Galway City and connectivity with zones of traffic generators and attractors
- It meets the functionality of the road component of the overall intermodal transport solution
- Enables the reallocation of existing road space within the city to public transport and smart mobility measures and is part of a sustainable holistic transport solution
- Alleviates congestion within Galway City which would result in reduced air and noise pollution
- Facilitates a more efficient public transport system
- Facilitates the provision of a multi-modal choice of travel
- Improves safety levels for all public road users
- Minimises property demolition and acquisition as far as possible
- Improves the quality of life of those living within Galway City with a reduction in traffic congestion and hence reduced pollution and an increase in opportunities for physical activity
- The proposed development will deliver the additional crossing of the River Corrib and the new link road as proposed by the GTS. Therefore, the proposed road development forms an essential part of the GTS, it delivers the road component of the overall transport solution for Galway City and its environs, provides benefit to the local and the larger regional population of Galway and the western region and is cognisant of the sensitive environment into which it is interwoven

The proposed road development is going to have negative impacts on the receiving environment including, unfortunately, a significant level of property acquisitions or demolitions that are unavoidable. However, the proposed road development provides the very significant and very much needed benefits to the EU transport network, the Western Region and County Galway as well as the built-up environment of Galway City and environs and the location required for the road infrastructure.

- The routing of thousands of vehicles per day through the city centre brings with it associated and unmitigated impacts on businesses, public facilities, homes and non-motorised road users. These impacts include noise and air pollution. The stop/start nature of urban driving and platooning of vehicles behind slow moving vehicles adds to the levels of pollution experienced by locals and visitors
- The need for the proposed road development from an environmental sustainability perspective is to deliver an integrated, sustainable transport solution that aligns transport investment with settlement patterns, travel movements and also supports a sustainable use of land
- The proposed road development as part of the GTS will reduce car dependency through facilitating a reallocation of road space to improve capacity and reliability of public transport and to facilitate cycling and walking within the city centre core area, with a resultant 16% increase in public transport trips in 2039 when compared to the scenario of not progressing the scheme
- The overall transport solution promotes the reduction of greenhouse gas emissions as it facilitates the advancement of a low-carbon and more energy efficient transport system, whilst also providing accessibility and connections to the city
- This also reduces the level of pollution within the city centre
- It will also bring an additional positive impact on air quality where traffic is diverted away from the receptors along the existing road network within the city centre
- The provision of improved walking and cycling facilities will also have the added benefit of increased physical activity for the city population, which is now of national importance as national policy includes a requirement to include physical activity as one of the criteria against which all projects incurring public funds must be assessed
- Existing impacts on the receiving environment at present include severance effects of traffic congestion in urban areas and traffic speeds on minor roads in rural areas as local roads are used to avoid the congested national road network. This severance will be reduced by the transfer of traffic to the proposed road development

The benefits which the proposed road development facilitate far outweigh the potential negative impacts on the receiving environment and the current design is a proportionate response to the significant transport issues outlined in **Chapter 3, Need for the Proposed Road Development** and summarised above in **Section 4.2**.

5 Description of Proposed Road Development

5.1 Introduction

The proposed N6 Galway City Ring Road (GCRR), hereafter referred to as the proposed road development, comprises the construction of approximately 5.6km of a single carriageway from the western side of Bearna as far as the Ballymoneen Road and approximately 11.9km of dual carriageway from Ballymoneen Road to the eastern tie in with the existing N6 at Coolagh, Briarhill, and associated link roads, side roads, junctions, structures and localised works to the existing electricity transmission and distribution networks (specifically comprising of the diversion of the 110kV and 38kV services). The section of the proposed road development from the tie-in with the R336 Coast Road to the N59 Letteragh Junction is a protected road[1] and the section from this junction to the tie-in with the existing N6 at Coolagh, Briarhill is a motorway.

The total area within the footprint of the development boundary is approximately 280ha. Of this total area, an area of approximately 180ha is required for the proposed road development construction works.

5.2 Background

As discussed in **Chapter 4, Alternatives Considered** there are a number of constraints within which to work and the evolution of the proposed road development took cognisance of and recognised the constraints existing in a city environment, such as Galway City, that includes Lough Corrib, the River Corrib, Galway Bay and the surrounding natural environment, the presence of designated sites as well as the constraints of the built environment of the city itself. Elements were included in the design, which allowed the proposed road development to avoid or reduce direct and indirect impacts on sensitive environmental receptors including persons and businesses potentially affected.

These avoidance measures which are incorporated as part of the design include the following:

- A bridge over the River Corrib with no instream piers and the piers located in areas of non-Annex I habitat
- A viaduct structure extending from the River Corrib Bridge to traverse NUIG Sporting Campus
- A viaduct over non-designated priority Annex I habitat at Menlough

[1] A protected road means a public road or proposed public road specified to be a protected road in a protected road scheme approved by the An Bord Pleanála. A protected road scheme approved by An Bord Pleanála may provide for the prohibition, closure, stopping up, removal, alteration, diversion or restriction of any specified or all means of direct access to the protected road from specified land or from specified land used for a specified purpose or to such land from the protected road.

- A tunnel beneath a narrow section of the Lough Corrib cSAC in Menlough at Lackagh Quarry
- A retaining wall on the southern side of the proposed road development at approximately Ch. 9+880 to Ch. 10+050 and on both sides of the proposed road development at approximately Ch. 10+850 to Ch. 11+150 to avoid the encroachment on Annex I habitat within the Lough Corrib cSAC
- A retaining wall on the southern side of the proposed road development at approximately Ch. 8+340 to Ch. 8+380 to reduce the potential impact on a private property
- Galway Racecourse Tunnel structure under the racecourse
- Lowering of the proposed road development from an overbridge to at-grade junction at Cappagh Road and changing from an overbridge at Hynes' Bóithrín in Castlegar from being in a cutting to at-grade to reduce the potential impacts on private properties
- Movement of the N59 Letteragh Junction further west and revision of the Coolagh Junction to avoid private dwellings

The provision of the above structures in the proposed road development have facilitated the avoidance of more densely populated areas of Galway City and avoided the acquisition of additional properties.

5.3 Proposed Road Development Description

5.3.1 Overview

The proposed road development is located in Galway as shown on **Figure 1.1** with the proposed plan layout shown on **Figures 5.1.01** to **5.1.15** and the plan and profile of mainline and side roads shown on **Figures 5.2.01** to **5.2.15** and **Figures 5.3.01** to **5.3.21**, respectively.

The proposed road development ties into the existing R336 Coast Road in An Baile Nua with an at-grade roundabout junction approximately 2km to the west of Bearna Village and then proceeds north and east as a single carriageway to the north of Bearna Village and onwards towards Ballymoneen. Local connectivity is maintained via the Troscaigh/Na Foraí Maola Overbridge Link whilst an at-grade roundabout is proposed at the Bearna to Moycullen (Maigh Cuilinn) Road L1321. At-grade signalised junctions are proposed at Cappagh Road and Ballymoneen Road.

To the east of the Ballymoneen Road Junction, the proposed road development is a dual carriageway and continues east to the grade separated N59 Letteragh Junction located in Letteragh. The junction connects to the N59 Moycullen Road via the proposed N59 Link Road North, and to the Letteragh Road and Rahoon Road via the proposed N59 Link Road South. The proposed road development continues eastwards to cross the existing N59 Moycullen Road at Dangan and travels on a viaduct over the NUIG Sporting Campus before crossing the River Corrib on a bridge structure. The total length of the structure through the NUIG Sporting Campus and over the River Corrib Bridge is 620m.

It is proposed to construct an all-weather full size GAA pitch and a training pitch at the location of the existing GAA pitches at the NUIG Sporting Campus. The NUIG Sports Pavilion will be modified and will continue to function as a sports facility post construction.

East of the River Corrib the proposed road development continues east on embankment toward the Menlough Viaduct. Additional lands to the north of Menlo Castle are included as part of the proposed development to provide lands for the enhancement of the core foraging habitat for the Lesser horseshoe bat known to roost at Menlo Castle and to mitigate against potential impacts to this species. These lands will be planted with additional hedgerows, maintained as agricultural lands by the local authority and will remain in their ownership.

Continuing east the proposed road development crosses over Bóthar Nua in the townland of Menlough and remains on a viaduct section, Menlough Viaduct (length 320m), towards Seanbóthar before entering a section of cut preceding Lackagh Tunnel (length 250m) immediately west of Lackagh Quarry, and exits the tunnel in the quarry. There is a tunnel maintenance building located adjacent to Lackagh Tunnel.

The proposed road development continues east with a grade separated junction located at the N84 Headford Road Junction at Ballinfoyle and continues east through the townland of Castlegar to the grade separated junction at N83 Tuam Road[2]. This junction provides access to both the N83 Tuam Road and the proposed Parkmore Link Road between the Ballybrit Business Park and the Parkmore Industrial Estate via the proposed City North Business Park Link road to provide full connectivity at this location.

The proposed road development then continues eastwards entering the Galway Racecourse Tunnel (length 230m) at Ballybrit to the north of the racetrack. There is a tunnel maintenance building located adjacent to the Galway Racecourse Tunnel and new stables provided for the Galway Racecourse. On emerging from the tunnel, the proposed road development continues south, crossing over the R339 Monivea Road on embankment and continuing south to enter a cutting as it reaches its junction with the existing N6 at Coolagh Junction. The proposed Coolagh Junction will be a fully grade separated junction with partial free flow on the major movements.

The proposed road development will also include extensive landscape planting for screening and the creation of specific habitat areas to compensate for loss of habitat elsewhere. To mitigate noise impacts across the proposed road development, a low noise road surface (LNRS) will be incorporated to reduce noise at source. In addition, an extensive scheme of noise barriers has also been incorporated into the design to further reduce noise levels along the proposed road development.

[2] Formally known as the N17 Tuam Road.

The proposed road development has been designed to a sufficient level of detail for a full environmental impact assessment of all potential direct and indirect impacts.

5.4 Design Standards

The design of the mainline, junctions, link and connector roads and non-motorised user facilities for the proposed road development have been completed in accordance with the TII current design standards available on the TII Publication's website, the TII Manual of Contract Documents for Road Works (MCDRW), the Department of Transport's Design Manual for Urban Roads and Streets (DMURS) and the National Transport Authority's National Cycling Manual. As the proposed road development is spread between urban and rural environment consideration has been given to allow for safe provision of non-motorised users within the proposed development boundary using the above standards. The following TII Publications are particularly relevant to the design:

- DN-GEO-03031 – Road Link Design
- DN-GEO-03060 – Geometric Design of Junctions (priority junctions, direct accesses, roundabouts, grade separated and compact grade separated junctions)
- DN-GEO-03036 – Cross-Sections and Headroom
- Design Manual for Urban Roads and Streets
- National Transport Authority, National Cycling Manual

In addition to the above design documents further guidance was drawn as necessary from relevant published data.

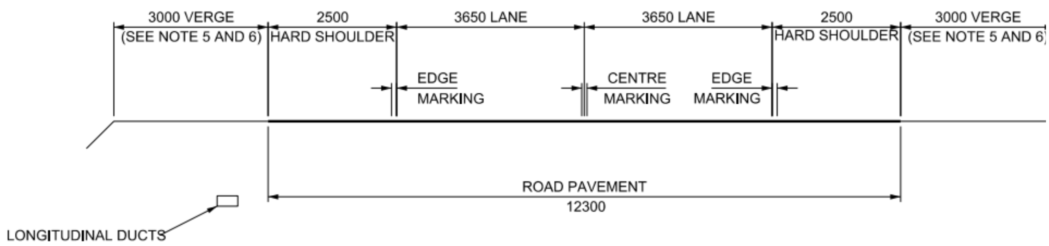
5.5 Proposed Road Type and Cross-Section

5.5.1 Mainline

From the R336 Coast Road to Ballymoneen, the mainline of the proposed road development is a Type 1 Single Carriageway in accordance with TII Publication DN-GEO-03036 (Cross Sections and Headroom). This section of mainline will be designated as a protected national road. The design speed of the mainline over this area is 85km/h. The cross section, shown in **Plate 5.1**, is as follows:

Western Verge Width (minimum):	3.0m
Western Hard Shoulder:	2.5m
Carriageway Width:	7.3m (2 x 3.65m lanes)
Eastern Hard Shoulder:	2.5m
Eastern Verge Width (minimum):	3.0m
Total Width (minimum):	**18.3m**

Plate 5.1: Typical cross section of the Type 1 Single Carriageway Link from the R336 to Ballymoneen



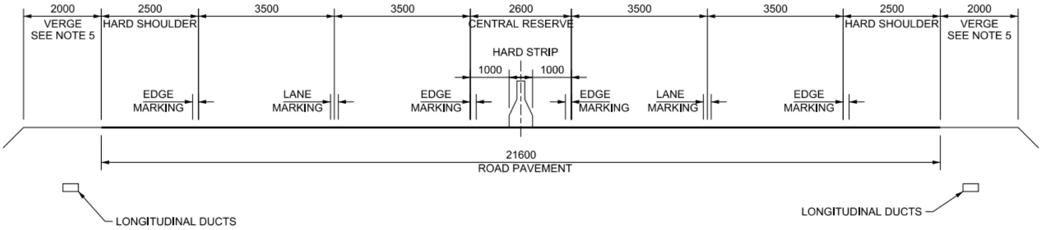
Climbing lanes are incorporated on the single carriageway at two locations, one in the eastbound direction and one in the westbound direction. These are designed in accordance with DN-GEO-03031.

From Ballymoneen Road to the eastern tie in with the existing N6 at Coolagh, Briarhill the mainline of the proposed road development is a Standard Dual Carriageway Urban Motorway (D2UM) in accordance with DN-GEO-03036. The mainline from Ballymoneen Road to the N59 Letteragh Junction will be designated as a Protected National Road and the mainline from the N59 Letteragh Junction to the N6 Coolagh Junction will be designated as a motorway, however, the cross sections remain the same. The design speed of the mainline over this area is 100km/h. The cross section, illustrated by **Plate 5.2**, is as follows:

Western Verge Width (minimum):	3.0m
Western Hard Shoulder Width (minimum):	2.5m
Western Carriageway Width:	7.0m (2 x 3.5m lanes)

Central Reserve Width (minimum):	2.6m (including 2 x 1.0m offside hardstrip)
Eastern Carriageway Width:	7.0m (2 x 3.5m lanes)
Eastern Hard Shoulder Width (minimum):	2.5m
Eastern Verge Width (minimum):	3.0m
Total Width (minimum):	**27.6m**

Plate 5.2: Typical cross section of the Dual Carriageway Urban Motorway Link from Ballymoneen to Coolagh



Between the N84 Headford Road Junction and the N83 Tuam Road Junction the mainline cross section will widen to 34.6m to accommodate a third lane in each direction (3 x 3.5m lane). This is to cater for the forecasted traffic between these junctions.

The cross sections at the River Corrib Bridge and Menlough Viaduct consist of the same as described above with the exception of the hard shoulder width which is reduced to 0.5m and a raised verge of 0.6m (excluding widening requirements for visibility).

The cross sections of the Lackagh Tunnel and the Galway Racecourse Tunnel differ from that required for a Standard Dual Carriageway Urban Motorway in accordance with DN-GEO-03036. These cross sections are dictated by national and international best practice with respect to tunnel layouts, geometric parameters such as stopping sight distance, the provision of space for operational equipment and the provision of safe access and egress in cases of emergency. Cross sections of both tunnels consist of 2 x 3.75m lanes in both directions, minimum nearside and offside 0.5m hard strip (excluding widening requirements for visibility) and 1.2m walkways nearside and offside. A minimum maintained headroom of 5.3m is provided in both tunnels.

5.5.2 Link Roads

There are four main link roads included as part of the proposed road development:

- N59 Link Road North
- N59 Link Road South
- Parkmore Link Road
- City North Business Park Link

A signalised grade separated junction at Letteragh connects the proposed road development to the N59 Moycullen Road via the N59 Link Road North and to the Rahoon and Letteragh Roads to the south via the N59 Link Road South.

The Parkmore Link Road forms part of the N83 Tuam Road Junction. The Link Road connects the Parkmore Industrial Estate to Ballybrit and City East Business Parks, providing a new access/egress to these estates as well as to the N83 Tuam Road. Access to the N83 Tuam Road is facilitated via City North Business Park Link. All link roads described above consist of a footpath in either direction with a minimum width of 1.8m in accordance with DN-GEO-03036. These link roads are detailed below in **Table 5.1**.

Table 5.1: Link Roads

Road Name	Lane Width	Footpath	Cycle Lane	Length	Chainage
N59 Link Road North & South	2 x 3.5m	Min 1.8m	2.0m (Ch. 1+500 – 2+220)	2200m	Ch. 7+575
City North Business Park Link	2 x 3.5m	Min 1.8m	2.0m	420m	Ch. 14+000
Parkmore Link Road	2 x 3.5m	Min 1.8m	2.0m	1350m	Ch. 14+375

5.5.3 Side Roads

Side roads which require redesign and realignment for the proposed road development have been designed in accordance with the standards noted in **Section 5.4**. **Table 5.2** details all side roads, both online and offline.

Table 5.2: Side Roads

Road Name	Lane Width	Length	Approx. Chainage	Comment
R336 Coast Road West	2 x 3m	245m	Ch. 0+030	Realignment of R336 Coast Road west to proposed roundabout, Bearna West Roundabout, at Baile Nua.
R336 Coast Road East	2 x 3m	90m	Ch. 0+030	Realignment of R336 Coast Road east to proposed roundabout, Bearna West Roundabout, at Baile Nua.
Na Foraí Maola to Troscaigh Link Road North	2 x 3m	500m	Ch. 1+400	Link road to connect existing local roads north and south of the proposed mainline via overbridge.
Na Foraí Maola to Troscaigh Link Road South	2 x 3m	730m	Ch. 1+400	Link road to connect existing local roads north and south of the proposed mainline via overbridge.
Na Foraí Maola to Troscaigh Overbridge Link	2 x 3m	200m	Ch. 0+190	Link road connecting Na Foraí Maola to Troscaigh Link Road North and Na Foraí Maola to

Road Name	Lane Width	Length	Approx. Chainage	Comment
				Troscaigh Link Road South.
L1321 Bearna to Moycullen Road North	2 x 3m	170m	Ch. 2+800	Realignment and tie into proposed Bearna East Roundabout.
L1321 Bearna to Moycullen Road South	2 x 3m	170m	Ch. 2+800	Realignment and tie into proposed Bearna East Roundabout.
L5384 Aille Road	2 x 3m	270m	Ch. 3+310	Realignment of L5384 Aille Road for proposed mainline underbridge.
Cappagh Road North	2 x 3m	140m	Ch. 4+450	Realignment and tie into proposed signalised junction.
Cappagh Road South	2 x 3m	230m	Ch. 4+450	Realignment and tie into proposed signalised junction.
Ballymoneen Road North	2 x 3m	230m	Ch. 5+650	Realignment and tie into proposed signalised junction.
Ballymoneen Road South	2 x 3m	130m	Ch. 5+650	Realignment and tie into proposed signalised junction.
Rahoon Road	2 x 3m	290m	Ch. 6+350	Redesign of Rahoon Road at Mincloon to accommodate mainline overbridge.
Clybaun Road	2 x 3m	410m	Ch. 6+350 to Ch. 6+650	Redesign of Clybaun Road at Mincloon to accommodate mainline overbridge and staggered junction.
Rahoon Road	2 x 3m	290	N59 Link Road Ch. 2+200	Redesign Rahoon Road at Gort na Bro to tie to proposed signalised junction with Letteragh Link Road South.

Ballybrit Crescent	2 x 3.5m	200m	Ch. 15+850	Redesign of Ballybrit Crescent Road

Note: *N59 LRN = N59 Link Road North
+N59 LRS = N59 Link Road South

5.5.4 Other Design Aspects

This section describes the design of other aspects of the proposed road development. Reference is made to the relevant guidance on which the design is based.

5.5.4.1 Traffic Signs

Signage will be provided along the proposed road development to ensure that clear directional and regulatory messages are transmitted to drivers and other road users and has been included in the design. The design of the signs and road marking is based on the 2010 Traffic Signs Manual issued by the Department of Transport and complemented by series 1200 of TII MCDRW, the National Cycle Manual by the National Transport Authority, and the Design Manual for Urban and Streets (DMURS) also compiled by the Department of Transport. There are 29 gantries signs, which will support advanced directional signage, proposed as part of the proposed road development.

5.5.4.2 Pedestrian and Cyclist Provision

As outlined in previous chapters of this EIAR, the proposed road development is a key element of a wider transportation strategy for Galway City and its environs, the Galway Transport Strategy (GTS). The GTS examines and provides for the needs of all modes of transport including but not limited to cyclists, pedestrians, public transport users, private motorists etc. Information on this strategy can be obtained by visiting the Galway City Council website (http://www.galwaycity.ie/galway-transport-strategy/).

The proposed road development interacts with the existing road network at numerous locations along its extent. The existing networks at these locations act as multi modal corridors and as a result required particular attention and care when designing suitable provisions. An overview of the interactions along the extent of the proposed road development along with the provisions at each location is detailed below.

Bearna West Roundabout

The Bearna West Roundabout is located on the R336 Coast Road west of Bearna Village. Footpaths are provided on each arm of the junction which facilitates pedestrian crossings away from the flaring of the approaches.

Na Foraí Maola to Troscaigh Overbridge

An overbridge with footpaths on both sides is provided in this area. These footpaths extend from the structure along the upgraded overbridge link road to maintain connectivity north and south of the proposed road development to the Na Foraí Maola and Troscaigh area.

Bearna East Roundabout

The Bearna East Roundabout is located on the Bearna to Moycullen Road (L1321) north of Bearna Village. Footpaths are provided on each arm of the junction which facilitates pedestrian crossing away from the flaring of the approaches. The area is remote from amenities and services and there is low pedestrian activity in the area.

An Chloch Scoilte

An overbridge is provided in this area. There is no direct connection provided to the mainline of the proposed road development. Footpaths are provided on the overbridge. These footpaths extend from the structure along the upgraded Aille Road (L5384) and connect into the An Chloch Scoilte Road (L5385).

Cappagh Road Junction

A signalised junction is provided in order to enhance operational safety and performance and to facilitate the efficient movement of all road users. Footpaths are provided on each arm of the junction. These footpaths connect into the existing networks in the area.

Ballymoneen Road Junction

A signalised junction is provided in order to enhance operational safety and performance and to facilitate the efficient movement of all road users. Footpaths are provided on each arm of the junction. These footpaths connect into the existing networks in the area.

Rahoon Road

An underbridge is provided in this area. There is no direct connection provided to the mainline of the proposed road development. Footpaths are provided on the Rahoon Road. These footpaths extend from the structure along the upgraded Rahoon Road and connect into the existing road network.

Letteragh Road

A signalised junction is provided in order to enhance operational safety and performance and to facilitate the efficient movement of all road users. Footpaths are provided on each arm of the junction. Dedicated footways are provided through the junction on the N59 Link Road South, a dedicated cycleway is provided on the southern arm of this junction to Rahoon Road as per the GTS. These cycleways and footways connect into the existing networks in the area.

N59 Letteragh Junction

Signalised junctions are provided in order to enhance operational safety and performance and to facilitate the efficient movement of all road users. Dedicated crossing points are provided on each arm of the junction. Dedicated footways are provided through the junction on the N59 Link Road South as per the GTS. These footways connect into the existing networks in the area.

Bushypark Junction

A signalised junction is provided in order to enhance operational safety and performance and to facilitate the efficient movement of all road users. Footpaths are provided on each arm of the junction. Dedicated footways are provided on the N59 Link Road North. The need for this provision arose from the GTS. These footways connect into the existing networks in the area.

Rahoon Road Junction

A signalised junction is provided in order to enhance operational safety and performance and to facilitate the efficient movement of all road users. Footpaths are provided on each arm of the junction. Dedicated cycleways and footways are provided on the N59 Link Road South and footways on the Gort Na Bró Link Road as per the GTS. These cycleways and footways connect into the existing networks in the area.

Gateway Retail Junction

Gateway Retail Junction is a simple junction providing connectivity to the Gort na Bró Road from existing residential areas. The existing network provides dedicated footways and these are maintained in the design.

N59 Moycullen Road Area

An overbridge is provided in the area where the mainline of the proposed road development crosses the N59 Moycullen Road. There is no direct connection provided to the mainline of the proposed road development. Footpaths are provided in the area. These footpaths extend from the location of the structure along the upgraded N59 Moycullen Road and connect into the existing networks.

Bóthar Nua (Coolough Road)

An underbridge is provided in the area where the mainline of the proposed road development crosses Bóthar Nua. There is no direct connection provided to the mainline of the proposed road development. The existing road serves all modes. There are no footpaths or dedicated cycleways in the area. It is not proposed to provide isolated footpaths/cycleways in the area.

Seanbóthar (Menlo)

An underbridge is provided in the area where the mainline of the proposed road development crosses Seanbóthar. There is no direct connection provided to the mainline of the proposed road development. However, there is a diverge from the mainline to Seanbóthar to accommodate the egress of over height and emergency vehicles from Lackagh Tunnel. Seanbóthar is an existing access road which primarily serves agricultural traffic. Footpaths are provided along the section of road beneath the structure.

N84 Headford Road

Dedicated crossing points are provided on each arm of the junction. Dedicated footways are provided through the junction. These footways connect into the existing networks in the area.

School Road Castlegar

An overbridge is provided in this area. There is no direct connection provided to the mainline of the proposed road development. Footpaths are provided on the overbridge. These footpaths extend from the structure along the upgraded School Road (L2134) and connect into the existing road network.

N83 Tuam Road Junction and Parkmore Link Road

Signalised junctions are proposed where diverge and merge arms interact with the existing N83 Tuam Road. Signalised junctions are provided in order to enhance operational safety and performance and to facilitate the efficient movement of all road users. Dedicated crossing points for pedestrians and cyclists are provided on each arm of the junction. Dedicated cycleways and footways are provided through the junction in line with the GTS. These cycleways and footways will connect into the existing and proposed networks in the area. A dedicated inward bus only lane, as per the GTS, is also accommodated within the design.

The Parkmore Link Road is proposed to connect major industrial areas of Galway City. This is an urban street and dedicated cycleways and footways are provided along its length. The Parkmore Link Road is a key component of the GTS which has been identified as being one of the infrastructure measures to cater for public transport between the Ballybrit and Parkmore industrial estates. It facilitates the interchange of bus routes servicing these industrial estates thus increasing the level of provision of public transport into the whole of the north eastern quarter of the city. It also provides a shorter direct route with full provision of appropriate infrastructure along the desire line for both pedestrians and cyclists to the industrial estates of Parkmore and Ballybrit. City North Business Park Link provides connectivity between the proposed Parkmore Link Road and the existing N83 Tuam

Road. This link has dedicated cycleways and footways as per the GTS thereby linking the networks for all modes in the area. All of this culminates in the encouragement of a modal shift to sustainable transport measures.

Signalised junctions are proposed for each junction along the length of the Parkmore Link Road with the exception of Business Park Junctions 1 and 2. Signalised junctions are provided in order to enhance operational safety and performance and to facilitate the efficient movement of all road users. Dedicated crossing points for pedestrians and cyclists are provided at each junction location.

Ballybrit Crescent Junction

Ballybrit Crescent Junction is an existing signalised junction. The upgrade of this junction as part of the proposed road development caters for the requirements of the GTS which includes a dedicated bus lane and dedicated cycle facilities. Footpaths are maintained in the area at the current level of provision.

Lynch Junction

Lynch Junction is an existing signalised junction. This junction was previously upgraded to signalisation to enhance operational safety and performance and to facilitate the efficient movement of all road users. No works are proposed to be undertaken on the Lynch Junction at Briarhill as part of the proposed road development. The proposed road development will connect to the junction only.

City East Business Park Junction

There is currently a merge lane from City East Business Park to the existing N6 at this location. As part of the proposed road development it is proposed to provide a signalised junction. Footpaths are proposed on the City East Business Park Road. Footpaths are not proposed on the N6 Bóthar na dTreabh.

Coolagh Junction

The eastern terminus of the proposed road development connects to the existing N6 at Coolagh, Briarhill. The provision of a full movement, high quality junction at the intersection of the proposed road development and the existing N6 terminus is necessary due to the fact that the N6 is the primary access to Galway from the east and has become the primary access to Galway from the south since the opening of the M17/M18.

The existing road serves all modes. There are no footpaths or dedicated cycleways in the area. It is not proposed to provide isolated footpaths/cycleways in the area as safer alternatives are available. From the signalised junction to the east, motorway restrictions will apply.

The proposed pedestrian and cyclist provisions are shown on **Figures 5.1.01** to **5.1.15**.

5.5.4.3 Fencing and Barriers

At the beginning of the construction phase the land to be acquired as per the proposed development boundary will be fenced and access across it restricted. Temporary construction fencing or hoarding may be required during construction prior to the installation of permanent fencing to secure the site and prevent unauthorised access. Fencing will be erected from the proposed road side of the fence. In areas where the proposed development boundary includes Annex I habitat within Lough Corrib cSAC the permanent fencing will be located between the proposed road and the Annex I habitat and will not be located within the habitat areas.

Fence types will vary across the proposed road development depending on the different requirements and maybe temporary in nature. Fence types will include timber post and rail fencing, masonry walls, steel palisade fencing, noise barriers, parapets etc. Fencing, safety barriers and parapets on the proposed road development will be provided to meet the requirements of the current TII Publications and guidance documents.

Standard detailed fencing typically used on schemes of this nature will be used however site specific requirements may differ between rural and urban environments across the proposed road development. Existing residential and commercial boundary walls impacted by the proposed road development will be replaced.

A vehicle restraint system design has been completed in accordance with DN-REQ-03034 Safety Barriers and DN-STR-03011 (The Design of Vehicle and Pedestrian Parapets). All hazards located within the clear zone have been addressed as per hazard definitions, classifications, and ranking. Fencing within the defined clear zone of vehicular traffic will need to be installed as timber post and tension mesh fencing in accordance with TII Publication DN-REQ-03034. See also **Chapter 8, Biodiversity** for the location of mammal proof fencing and **Chapter 17, Noise and Vibration** for noise mitigation and their associated figures for their locations.

5.5.4.4 Lighting

The road lighting design shall meet the requirements of BS5489-1, IS EN 13201 and the UK DMRB TD 34-07 and TII addendum (DN-LHT-03038). This will ensure that light pollution is kept to a minimum.

The proposed road lighting installation has been considered and designed with limiting light trespass as a key priority.

Multiple measures have been taken to ensure that light is applied only where it is required. In addition to traditional good practice design approaches, modern and emerging technologies have been applied to limit the light spill. For the road lighting, these generally include:

- The use of LED lanterns with well-defined and controlled light beam distributions, mounted on columns with a maximum height of 10m. When compared with traditional discharge lamps and lantern technologies, this will provide a significant reduction in light trespass to surrounding areas and properties

- The lanterns are mounted on bracket arms with a 0° tilt to the horizontal, where a 5° tilt would have been typical with older technologies or in less sensitive areas of application
- The LED lanterns emit 0% of their light above the horizontal, meaning no light is directly emitted into the night-sky. The lanterns have been selected to ensure that light directed behind the lantern is minimised

All of the above factors combine to produce a design that is compliant with the relevant standards previously quoted, but also a design that has paid due attention to the sensitive nature of the surrounding areas. It is proposed to provide public lighting at roundabouts on the proposed road development for reasons of safety. Lighting is also provided at Cappagh Road, Ballymoneen Road, N59 Letteragh, N84 Headford Road, N83 Tuam Road and the Coolagh Junctions and associated slip roads in accordance with TII Guidelines. There will also be lighting provided at the entrances to both the Lackagh Tunnel and Galway Racecourse Tunnel.

The City North Business Park Link, Parkmore Link and N59 Link Road North and South will also be lit as they are urban roads. Lighting will be provided at the car parks for the tunnel maintenance buildings at Lackagh Quarry and Galway Racecourse and the stables at Galway Racecourse. Flood lighting will also be provided at the proposed 3G pitch and training pitch at NUIG.

There is currently lighting on the Ballybrit Crescent Junction, the southern section of the existing N83 Tuam Road (Ch. 14+000), the N59 Moycullen Road and the southern portion of the Rahoon Road at the proposed Rahoon Road Junction. The lighting provision in these areas shall be extended to tie into that of the proposed road development.

The road lighting column heights and their proposed locations along with the potential light spill are shown on **Figures 5.4.01** to **5.4.15**. The proposed lighting for NUIG and the carparks are included in **Appendix A.5.1, A.15.1** and **A.15.2**. The potential direct and indirect impacts of the proposed lighting on ecology is assessed in **Chapter 8, Biodiversity** and on human beings in **Chapter 12, Landscape and Visual** and **Chapter 18, Human Beings, Population and Health**.

5.5.4.5 Earthworks and Road Surfaces

The aspects relating to earthworks such as quantities, proposed site compounds and haul routes are discussed in **Chapter 7, Construction Activities** and **Chapter 9, Soils and Geology**.

The pavement design for all roads has been carried out considering the appropriate design life and axle loading in accordance with current TII document PE-SMG-02002 addendum to HD 24/06 Traffic Assessment and DN–PAV-03021 Pavement and Foundation Design. Low noise surfacing will be used for the full length of the mainline of the proposed road development and at junctions.

5.5.4.6 Structures

The proposed road development includes a total of 164 structures. **Table 5.3** below gives a summary of the 164 structures included in the proposed road development.

Table 5.3: Structures Overview

Structure Group		Overview
Major Structures	River Corrib Bridge	The River Corrib Bridge crosses the River Corrib and through the Lough Corrib cSAC. It is in close proximity to Menlo Castle and traverses the NUIG Sporting Campus. The width of the river at the crossing is approximately 153m.
	Menlough Viaduct	In the vicinity of the Menlough area, the proposed road development will be carried on a viaduct to reduce the potential impacts on Limestone pavement which is immediately adjacent to the Lough Corrib cSAC boundary and a Turlough.
	Lackagh Tunnel	The proposed road development will tunnel under the Lough Corrib cSAC immediately west of Lackagh Quarry with is primary function to avoid direct impacts on Annex I habitats at the surface, namely Limestone pavement and Calcareous grasslands. This tunnel will be constructed in such a way to avoid any deformations to the Annex I habitat at the surface. This tunnel is expected to be constructed using mined tunnels methods (drill and blast). See **Chapter 7, Construction Activities** for further details.
	Galway Racecourse Tunnel	The proposed road development will be accommodated in a 240m cut and cover tunnel in the Ballybrit area to reduce the residual impact on the Galway Racecourse. This tunnel is expected to be constructed using the cut and cover method. See **Chapter 7, Construction Activities** for further details.
Standard Overbridges		This family of structures consists of 7 standard overbridges carrying side roads over the proposed road development. These bridges will typically be 2 or 3 span bridges with clear open spans.
Standard Underbridges		This family of structures consists of 10 standard underbridges carrying the proposed road development over local and regional roads. At local roads, typically a single span portal frame arrangement will be adopted; at regional road crossings configuration with clear open span(s) will be chosen.
Other Structures	Retaining Structures	15 retaining structures are currently identified. These are expected to be of reinforced earth and/or reinforced concrete retaining wall configuration.

Structure Group		Overview
	Culverts & Minor Watercourse crossings	Currently there are approximately 43 culvert type structures, of which 28 are structural, to accommodate drainage and watercourses and wildlife under the proposed road development.
	Sign Gantries	29 sign gantries are to be constructed in accordance with DN-STR-03010 and TII Standard Construction Details for sign gantries.
	Environmental Noise Barriers	56 noise barriers are to be constructed. The location, form and type of the environmental noise barriers are shown on **Figures 17.1.01** to **17.1.14**.

The following is a summary of the main structures to be constructed for the proposed road development:

River Corrib Bridge

The proposed road development crosses the River Corrib on a bridge structure (S08/04) from Ch. 8+850 to Ch. 9+500 (650m in length). The proposed structure comprises of an eight span bridge carrying the proposed road development over the River Corrib adjacent to a retained embankment with five culvert openings on the eastern approach. The proposed structure is a variable depth single concrete box without supports in the river. The proposed structure is a variable depth (between 3m and 7m) single concrete box without supports in the river with the main span over the river being 153m. The adjacent spans consist a variable depth single concrete box increasing in depth from 3m to 7m on approach to the main span. The remaining western approach spans consists of 3m constant depth single concrete box while the remaining eastern approach links into a retaining embankment with five culvert openings to facilitate the passage of wildlife. The superstructure will be supported on reinforced concrete piers. For aesthetic reasons, inclined webs instead of vertical webs are proposed.

Menlough Viaduct

A viaduct structure, Menlough Viaduct (S10/01) is proposed from Ch. 10+100 to Ch. 10+420 is located outside but adjacent to the Lough Corrib cSAC. The total length of the bridge is dictated by the area of priority Annex I habitat over which it crosses, namely Limestone pavement and a Turlough (all of which fall outside of the Lough Corrib cSAC boundary) and this will reduce the potential impact on these habitats. The viaduct has a total length of approximately 320m, and the proposed road development is on embankment on both approaches to it. The viaduct contains eight spans of a similar 40m span length. The span lengths have been adjusted to reduce the impact of the substructure and foundations on the Limestone pavement and Turlough.

The minimum distance between the soffit of the superstructure and the ground level is approximately 1.5m at one pinch point at the location of the high point in the rock outcropping on the western side. The bridge deck superstructure will consist of prefabricated precast post-tensioned beams supporting a cast in-situ concrete bridge deck. The substructure will consist of conventional reinforced concrete piers at intermediate supports while the reinforced concrete bankseats at the abutments will be supported on a reinforced earthworks system. No substructure supports are proposed within the extents of the Turlough.

Lackagh Tunnel

Lackagh Tunnel (S11/01) is 270m long and is located at Ch. 11+150 to Ch. 11+420. The eastern portal of Lackagh Tunnel is located within the inactive Lackagh Quarry, a limestone quarry. The central section of the tunnel will pass under the Lough Corrib cSAC, while the western portal is proposed to be located in agricultural fields, outside of Lough Corrib cSAC.

The primary function of the Lackagh Tunnel and its Western Approach is to transverse the Lough Corrib candidate Special Area of Conservation (cSAC) between Lackagh Quarry and Menlough without directly impacting on the Limestone pavement and Calcareous grass within the Lough Corrib cSAC. This requires a safe method of excavation and construction of the tunnel such that there will be no impact on the Lough Corrib cSAC during the construction or operation of the tunnel, as discussed in **Chapter 7, Construction Activities** and **Appendix A.7.3**.

Galway Racecourse Tunnel

The proposed Galway Racecourse Tunnel (S14/02) consists of a 240m twin tube reinforced concrete cut and cover tunnel with central wall. The purpose of the Galway Racecourse Tunnel is to avoid by design adverse impacts, namely disruption to operations and functioning, on the Galway Racecourse. The proposed mainline passes through the north western corner of Galway Racecourse property and necessitates a cut and cover tunnel from Ch. 14+950 to Ch. 15+190, resulting in a tunnel length of approximately 240m.

Underbridges

There are 10 underbridges identified in the current design, which will carry the proposed road development over local, regional and national roads. All underbridges are single span. Three main types of underbridges are proposed:

- Type 1: Buried reinforced concrete box structure
- Type 2: Bridge deck with reinforced earth wall abutment
- Type 3: Concrete deck with side slopes

The underbridges over National Roads will incorporate open clear spans as appropriate, in recognition of the fact that higher volumes of traffic on these National Roads will make these bridges highly visible.

The proposed standard underbridges are located at chainages stated in **Table 5.4** below, along the proposed road development.

Table 5.4: Standard underbridge mainline chainages

Name of Structure	Approx. Chainage
S06/01 - Rahoon Road Underbridge	Ch. 6+335
S07/01 - Letteragh Road Underbridge	Ch. 7+290
S07/02 - N59 Link Road Underbridge	Ch. 7+570
S08/02 - N59 Moycullen Road Underbridge	Ch. 8+540
S09/01 - Menlo Castle Bóithrín Underbridge	Ch. 9+730
S10/02 – Seanbóthar Underbridge	Ch. 10+520
S12/01 - N84 Headford Road Underbridge	Ch. 12+150
S13/02 - N83 Tuam Road Underbridge	Ch. 13+975
S15/01 - Briarhill Business Park Underbridge	Ch. 15+725
S15/02 – Monivea Road R339 Underbridge	Ch. 15+880

Overbridges

There are seven overbridges proposed and the function of these are:

- Structure S01/01, S03/01, S13/01, and S14/01 are overbridges required to carry local roads over the proposed road development
- Structure S12/02 is required as a mammal crossing (green bridge) over proposed road development
- Structures S16/01 and S16/02 are required at Coolagh Junction to provide free flow access between the R446 and the proposed road development

The proposed standard overbridges are located at chainages stated in **Table 5.5** below, along the proposed road development.

Table 5.5: Standard overbridge mainline chainages

Name of Structure	Approx. Chainage
S01/01 - Na Foraí Maola to Troscaigh Overbridge	Ch. 1+375
S03/01 - Barr Aille Overbridge	Ch. 3+300
S12/02 - Castlegar Wildlife Overbridge	Ch. 12+700
S13/01 - School Road Overbridge	Ch. 13+185
S14/01 - Parkmore Link Road Overbridge	Ch. 14+375
S16/01 - Coolagh Junction Overbridge (EB diverge to R446)	Ch. 16+410
S16/02 - Coolagh Junction Overbridge (EB merge from R446)	Ch. 16+830

Culverts and Underpasses

Hydraulic culverts have been designed to minimise impact on both upstream and downstream flood risk. In addition to the hydraulic requirements for the proposed road development crossings, consideration has also been given to the passage of mammals at some ecologically sensitive areas. Some of the hydraulic culverts have been increased in size to allow passage for a range of mammal species; for example, otters, badgers and bats.

A full list of the culverts and underpasses is provided in **Table 5.6**.

Table 5.6: Culverts and Underpasses

Name of Structure	Approx. Chainage	Function	Other Requirements

Other Structures

There are a number of other structures incorporated into the proposed road development. These include retaining structures, sign gantries and noise barriers.

The proposed retaining structures are located at chainages stated in **Table 5.7** below, along the proposed road development.

Table 5.7: Retaining structures location

Name of Structure	Approx. Chainage

R15/01	Ch. 15+630
R15/02	Ch. 15+750

Note: *N59 LRN = N59 Link Road North

It should be noted that there are other retaining structures proposed elsewhere on the proposed road development, for example at the western approach to Lackagh Tunnel, at Structure S11/01, as abutments to overbridges and underbridges, etc. These retaining structures are included with the associated structure.

The proposed sign gantries are located at chainages stated in **5.8** below, along the mainline of the proposed road development.

Table 5.8: Sign Gantries location

Name of Structure	Approx. Chainage	Gantry type	Lateral siting / span	Comments
G06/01	Ch. 6+260	Cantilever	Eastbound verge	Variable Message Sign

5.5.4.7 Landscaping

The aspects relating to landscaping are discussed in **Chapter 12, Landscape and Visual**.

5.5.4.8 Drainage

The proposed road development involves the construction of a new drainage system which includes the provision of a surface water collection system, earthworks drainage, sub-surface drainage, attenuation and pollution control, and the culverting of existing streams. The proposed road development has been designed such that surface water drainage and sub-surface drainage will be provided for the proposed mainline carriageway, junctions, link roads and all new sections of local roads.

Due to the contrasting geological features across the extents of the proposed road development, the type of natural drainage can be split into two different broad categories west and east of the N59 Moycullen Road.

The natural discharge of rainfall and surface water drainage west of the N59 Moycullen Road is overland to low points in the topography where shallow ditches and streams are present. The underlying bedrock is granite. This is a low importance, poor aquifer where the bedrock is generally unproductive except for local zones (ref **Chapter 10, Hydrogeology**). In general, the water table is quite close to the surface.

The natural discharge of rainfall and surface water drainage east of the N59 Moycullen Road is directly to ground, with extreme events accumulating at low points and seasonal lakes within the topography. The underlying bedrock is limestone. The aquifer is a regionally important karstified aquifer which is dominated by conduit flow (ref **Chapter 10, Hydrogeology**). Except for the River Corrib, Terryland River, Ballindooley Lough and Coolagh Lakes, there are no other significant watercourses in the area east of the N59 Moycullen Road.

The two different categories of natural drainage inform the approach to drainage design for the proposed road development. As well as the efficient removal of water from the road surface and pavement, the drainage design aims to minimise the impact of runoff from the proposed road development on the receiving environment by replicating, as much as possible, the natural water flows across the proposed road development. This is achieved using a variety of sustainable drainage measures.

All surface water collected by the proposed carriageway drainage system will be discharged to watercourses or existing storm sewers crossed by or adjacent to the proposed road development if present, or will be discharged to ground via infiltration. Flow control measures will be provided at all outfalls and discharge points along the length of the proposed road development to ensure discharge does not cause any adverse effects upstream or downstream of the receiving watercourse or sewer. Infiltration basins have been sized to allow sufficient time for infiltration to discharge to the ground. Pollution control measures will be provided on all mainline road drainage networks prior to outfalling/discharging to ensure that receiving water bodies are not contaminated by runoff from the proposed road development.

In summary, the design basis for the drainage strategy is as follows:

- West of the N59 Moycullen Road the surface water collected by the carriageway drainage system will be discharged into watercourses crossed by, or adjacent to, the proposed road development that eventually outfall to Galway Bay
- East of the N59 Moycullen Road the surface water collected by the carriageway drainage system will be discharged to ground via infiltration, with the exception of two drainage networks (S18A and S18B refer **Figure 11.6.107**) which will discharge directly to the River Corrib and three networks (S14A, S14B and S15 refer to **Figure 11.6.106**) which discharge to tributaries which eventually outfall to the River Corrib

The procedures below have been adopted for the drainage design of the proposed road development in accordance with current TII Publications, guidance documents and best practice methods.

Watercourses

The proposed road development crosses a number of existing watercourses which includes the Bearna Stream and its tributaries, the River Corrib and a number of smaller streams. Streams and rivers will be crossed using culverts or bridge structures.

There is one major river bridge required to cross the River Corrib as outlined in **Section 5.5.4.6**.

As noted in **Section 5.5.4.6**, culverts have been designed to minimise impact on both upstream and downstream flood risk. In addition to the hydraulic requirements for the proposed road development crossings, consideration has also been given for the passage of mammals at some ecologically sensitive areas. Some of the hydraulic culverts have been increased in size to cater for a range of mammal passages for example otters, badgers and bats. **Section 5.5.4.6** summarises the proposed hydraulic culverts and bridge structures.

All of the proposed structures over existing watercourses have been submitted to the OPW for approval under Section 50 of the Arterial Drainage Act and have been approved. Details of required stream realignments in the vicinity of the structures have also been submitted and approved.

There are a small number of Salmonid rivers interacting with the proposed road development. Inland Fisheries Ireland have been consulted regarding the requirements, for fish passage at these locations. The design of all culverts conveying watercourses provides a minimum embedment depth of 150mm on circular culverts or 300mm on rectangular box culverts below stream bed or to the minimum level as requested by Inland Fisheries Ireland. This is to encourage the re-establishment of stream bed ecology. The bed of the channel both upstream and downstream of the culvert should be reinstated with material similar to that removed during construction. This is similar to a “natural” bed contiguous with the existing stream bed, upstream and downstream of the proposed culvert. Proposed culverts encroaching on fish habitats shall be designed to ensure that the velocity of flow will be less than the swimming speed to allow passage of migrating fish. Culverts will be designed such that the velocity in the barrel will not be significantly increased from the velocity of the existing watercourse.

Gradients of proposed culverts will aim to recreate the gradient of the existing watercourse where possible. Where relevant, the culvert design shall accommodate invert baffles to facilitate fish passage upstream and downstream. Suitable measures are to be employed to ensure that livestock are prevented from entering culverts.

Interceptor Ditches

Interceptor ditches are required to intercept the overland flow from the natural catchment adjacent to the proposed road development (both during construction and the operational phases) and to prevent ponding of water adjacent to embankments. The use of interceptor ditches is to prevent drainage from the road curtilage running onto adjacent lands and vice-versa.

The interceptor ditches are provided at the top of the cutting or the base of the embankment where land falls towards the proposed road development to collect overland flow. The ditches have been sized to cater for a 1 in 75 year return period as per DN-DNG-03064 – Drainage of Runoff from Natural Catchments (HD 106). All land drains that are intercepted by the proposed works will be discharged into an interceptor ditch. Scour protection shall be provided where velocities exceed 2.5m/s in the interceptor ditches.

To the west of the N59 Moycullen Road, interceptor ditches will discharge to existing streams, rivers and storm sewers. Due to the undulating nature of the natural topography of the land along the route of the proposed road development, there are some considerable areas of cutting required for earthworks drainage. To the east of the River Corrib, interceptor ditches will discharge to stone filled infiltration trenches located adjacent to the proposed road development. Cross-drains will be provided to convey flow from the interceptor ditches beneath the proposed road development to the outfall/discharge locations where required.

Carriageway Drainage

A surface water collection system will be provided so as to comply with the design requirements of DN-DNG-03022 – Drainage Systems for National Roads (HD33/15). This includes providing suitably sized longitudinal carrier drains to accommodate a 1 year return period storm in-bore without surcharging, with no flooding of the proposed carriageway for a 1 in 5 year return period for filter drains. Where combined surface and ground water drains are proposed, a 1 in 5 year return period storm will not rise above the formation level, or sub-formation level where a capping layer is present. The drainage networks are designed to include an increase of 20% in rainfall depth to cater for the impact of climate change.

In the western section of the proposed road development from the R336 Coast Road to the N59 Moycullen Road, the drainage network is in accordance with Figure 3.1 of DN-DNG-03022 (HD33/15). However, in the eastern section of the proposed road development from the N59 Moycullen Road to the connection point with the existing N6 at Coolagh, Briarhill, due to the karstic nature of the underlying bedrock and the vulnerability of the underlying aquifers, there is a requirement for a fully sealed system to accept the proposed carriageway runoff. Therefore, the network collecting the drainage from the proposed carriageway will be kept separate to the groundwater and sub-surface drainage network. This will be achieved by using either a kerb, gully and carrier pipe system or a surface water channel and carrier pipe system. This allows for controlled treatment of surface waters prior to discharge to the ground thereby reducing the risk to the underlying aquifer. For cuttings and low embankments, a separate filter drain will be provided for sub surface flows **Table 5.9** summarises the proposed mainline drainage networks.

Table 5.9: Summary of Mainline and Junction Drainage Networks

Drainage Network Ref. No.	Mainline / Junction	Chainage	Approx. Total Drainage Area (ha)	Outfalling to	Drainage System Type (Sealed / Non-Sealed)
S1	Mainline	Ch. 0+000 to Ch. 0+700	2.05	Watercourse	Non-Sealed

S29	Junction	Ch. 16+500 Coolagh Junction south to tie-in with R446	2.73	Existing Sewer	Sealed

Suitably sized and located outfalls have been designed in accordance with DN-DNG-03071 – Design of Outfall and Culvert Details (HD 107).

Sub-Surface Drainage

A sub-surface drainage system of the road pavement will be provided in order to control groundwater levels in the vicinity of the proposed road development and to drain the road foundation. This is required in areas of cuttings and low embankments (<1.5m). In general, this is achieved using a network of filter drains or narrow filter drains.

Due to the karstic nature of the catchments to the east of the N59 Moycullen Road a hydrogeological risk assessment for each surface water drainage network catchment has been carried out at the location of each infiltration basin. This assessment is included in **Chapter 10, Hydrogeology**.

Structure Drainage

A separate isolated sealed drainage system will be utilised for the Lackagh Tunnel and the Galway Racecourse Tunnel structures. The drainage system will be designed in accordance DN-STR-03015 – Design of Road Tunnel (BD78). The sealed system of slot drains and carrier pipes will be used in both tunnels to pick up groundwater ingress, surface water from wheels, fire flows and tunnel wash down, all of which will be drained to sumps and pumped to the closest foul sewer. This system mitigates against the potential for pollution of groundwater and also minimises the risk to the Lough Corrib cSAC surface water bodies.

A watertight seal will be installed on the underside of the road base and cuttings on the western approach to the Lackagh Tunnel and on the eastern approach to the Galway Racecourse Tunnel up to the known high winter groundwater level. This is to protect against groundwater inflow and prevent contamination of groundwater and no dewatering is permitted in the operational phase of the proposed road development at these locations (see **Chapter 10, Hydrogeology**).

Drainage of the proposed bridge structures will be managed so as to achieve the requirements set out in DN-DNG-03022 – Drainage Systems for National Roads (HD33/15). For the long lengths of the Menlough Viaduct and the River Corrib Bridge a specialised sealed drainage system will capture the runoff on the bridge deck, transport it beneath the structure in a network of slung sealed carrier drains, before descending into the ground at suitable pier locations and discharging to a wetland and attenuation treatment area. This is required due to the sensitivity of the areas which the bridges are crossing above i.e. Limestone pavement and Turlough (Priority Annex 1 habitats) and the River Corrib (Lough Corrib cSAC).

Link Road and Side Road Drainage

The side roads and proposed link roads where drainage is proposed include the R336 Coast Road, L5386 Na Foraí Maola Road, L5387 Troscaigh Road, Na Foraí Maola to Troscaigh Link Road North, South and Overbridge Link, L1321 Bearna to Moycullen Road, L5384 Aille Road, Cappagh Road, Ballymoneen Road, Rahoon Road, Clybaun Road, L1323 Letteragh Road, N59 Link Road North and South, Seanbóthar, N84 Headford Road, L2134 School Road, N83 Tuam Road, Parkmore Link Road, Briarhill Business Park Road, Ballybrit Crescent and R339 Monivea Road. These roads require kerbs at locations including at bridge or junction locations or where footways are required and will therefore be drained using gullies with carrier drains or combined filter/carrier drains. Piped drains will discharge to an outfall, a sealed drain or to the mainline drainage system. **Table 5.10** summarises the proposed link road drainage networks.

Table 5.10: Summary of Link Road and Side Road Drainage Networks

Drainage Network Ref. No.	Link Road/Side Road	Road Name and Chainage	Approx. Total Drainage Area (ha)	Outfalling to	Drainage System Type (Sealed/Non-Sealed)

S41	Side Road	School Road - Ch. 13+150	0.24	Existing Sewer	Sealed

Side roads that do not require kerbs will be drained using either over-the edge drainage or combined filter drains where appropriate in accordance with the principles described above. The drains will discharge to an outfall, a sealed drain or to the mainline drainage system.

Outfalls, Attenuation Ponds and Infiltration Basins

West of the N59 Moycullen Road the surface water collected by the carriageway drainage system will be discharged to watercourses crossed by, or adjacent to, the proposed road development. In order to prevent discharge from the road increasing the peak flow rate of water within many of the watercourses, which may compound any flooding downstream of the proposed road development, flow restriction and attenuation storage is proposed. Attenuation ponds have been selected as the main attenuation facility provided along the proposed road development. Attenuation ponds will not be lined to the west of the N59 Moycullen Road and can become a feature of the landscape in time and is in line with current best practice guidelines. The proposed outfalls, with proposed attenuation ponds, have been chosen at appropriate locations along the route of the proposed road development typically as close as possible to an existing watercourse. **Table 5.11** details the drainage networks that discharge to watercourses and the associated volumes of storage required to attenuate peak flows up to the 1 in 100 year return period storm event.

Table 5.11: Proposed Mainline and Link Road Drainage Networks Discharging to Surface Waterbodies

S4B	0.12	0.07	21	4.2
S15	1.89	0.73	692	7.5

Where the drainage system outfalls to a watercourse the final outfall level (after the attenuation and treatment measures) shall be set above the 1 in 5 year flood level of the watercourse where possible. Furthermore, an assessment of the impact of the outfall from the pond on the hydraulic regime of the watercourse has been undertaken (**Chapter 11, Hydrology**).

A flow control device (Hydro-Break or similar) will be installed at the outfall location of all attenuation ponds to restrict the flow rate from the pond to the receiving watercourse. The discharge rate for each drainage catchment is set to the Q_{bar} greenfield runoff rate to replicate the existing environment or to a minimum of 5 l/s to minimise the risk of blockage from debris within the network.

There are a number of outfalls to existing sewers along the proposed road development. The surface water sewers are generally located in the more urbanised areas adjacent to the proposed road development, where existing streams and ditches have already been previously culverted to facilitate development. **Table 5.12** details the drainage networks that discharge to existing storm sewers.

Table 5.12: Proposed Mainline & Link Road Drainage Networks Discharging to Storm Sewers

Drainage Network Ref. No.	Approx. Total Drainage Area (ha)	Approx. Pavement Area (ha)	Network Discharge Q100 (l/s)	Receiving Storm Sewer Diameter (mm)

S22C1	1.46	1.36	5.0	900

To the east of the N59 Moycullen Road the surface water collected by the carriageway drainage system will be discharged to ground via an infiltration basin where a positive outfall to a watercourse is not available. Ground investigations have been undertaken at the proposed locations of the infiltration basins to determine the permeability of the existing soil and bedrock and inform the design of the infiltration basins. Where the infiltration rate is outside the range of the permissible flow rates (e.g. discharge directly to karst limestone bedrock) then the base layer of the infiltration basin will be created synthetically to reduce the infiltration rate artificially. The design infiltration rate for the proposed road development is 0.036m/hr. The infiltration basins have been sized so as to drain down to half volume in a 24-hour period. The infiltration basins will not be lined so as to allow for infiltration to ground. **Table 5.13** details the proposed drainage networks that discharge to ground via infiltration basin.

Table 5.13: Proposed Mainline and Link Road Drainage Networks Discharging to Ground via Infiltration Basins

S22C2	0.55	0.52	290	38.64

To the East of the N59 Moycullen Road, where attenuation ponds and discharge to watercourses or public sewers are proposed in the karst limestone area, the base of the attenuation ponds will be lined to prevent infiltration to groundwater using a synthetic or suitable clay liner.

All attenuation ponds and infiltration basins will cater for return period up to a 1 in 100 year storm event minimising any increase in flood risk to adjacent properties as set out in Clause 7.5 of DN-DNG-03022 (HD33/15). A minimum freeboard of 300mm is provided between the maximum water level in the attenuation pond or infiltration basin and the top level of the pond/basin or the pond/basin protection bund. Peak discharge rates from the proposed road development will not exceed the peak discharge rates in the greenfield scenario for the critical storm return period. The pond/basin will be bunded to a level 500mm above any adjacent 1 in 100 year flood levels in rivers or streams. To reduce the risk of receiving water and groundwater being contaminated by runoff from the proposed road development, pollution control measures will be provided as detailed in the following section.

Pollution Control

Pollution control measures are proposed prior to each outfall/discharge point from the carriageway to reduce the risk of watercourses or groundwater being contaminated by runoff from the proposed road development. A range of pollution control measures have been adopted along the length of the proposed road development which includes combined filter drains, attenuation ponds, grassed surface water channels, petrol and oil interceptors, emergency spill containment areas, surface flow wetlands and infiltration basins.

Sustainable drainage systems (SuDS) have been considered in the first instance. Only where there is insufficient space or the road geometry precludes their inclusion (e.g. on embankments higher than 1.5m or in cuttings with groundwater drainage problems) were other conventional methods used. In general, where the risk to groundwater is low combined filter drains form the first treatment against pollutants making their way into surrounding water bodies as combined filter drains can reduce the release of pollutants. The filter material will trap suspended solids and other contaminants thus reducing the downstream pollution risk. Where the proposed road development carriageway runoff will drain into grassed surface water channels, the slow moving flow through the wide shallow grassed channels will allow for the processes of sedimentation and adsorption to take place while carrying the runoff to the outfall.

Where the groundwater is highly vulnerable, typically in the karstic area to the east of the River Corrib, a sealed drainage system will collect and distribute surface water runoff to a suitable outfall location/discharge point (e.g. carrier pipe with gullies, concrete surface water channels, slot drains etc.) Sub surface flow will be collected in a series of narrow filter drains.

At each mainline and link road drainage network across the proposed road development, a SuDS surface flow (SF) treatment wetland will also be provided upstream of each attenuation pond or infiltration basin to further treat runoff. The surface flow wetlands have been sized to store the 'First Flush' runoff from their associated road pavement catchments in the permanent pool. This comprises a volume equal to a 15mm depth of rainfall on the road catchment. This 'First Flush' runoff carries the highest load of pollutants, compared to runoff discharged later in the rainfall event. The minimum depth of the permanent pool is 600mm which will further encourage settlement of suspended solids and will be lined to reduce the risk of watercourses or groundwater being contaminated by runoff from the proposed road development. Suitable planting and additional measures will be employed to encourage the settlement of silt and absorption of any remaining pollutants i.e. silt traps, reed beds. The increased retention time provided by the wetland will provide additional time for further adsorption and sedimentation to take place and will also allow for a range of natural biological processes (including biodegradation, microbial action and plant uptake) to further remove waterborne pollutants.

Oil and petrol interceptors will be provided upstream of the wetland and attenuation pond/infiltration basin to prevent any contamination from hydrocarbons, such as oil or petrol spillages, from entering the receiving water or groundwater. The interceptors will be sized for each drainage catchment according to the inflow. Along the mainline of the proposed road development a minimum emergency spill containment volume area equal to $25m^3$ will be provided at all outfall locations as set out in the TII Drainage Standards.

The outfalls of each drainage network have been assessed individually for potential impacts to the water environment as part of the HD45 assessments and appropriate methods of treatment applied in accordance with TII requirements, the assessments are detailed in the **Chapter 10, Hydrogeology** and **Chapter 11, Hydrology**. The adopted pollution control measures are listed in **Table 5.14**.

Table 5.14: Proposed Pollution Control Measures for Mainline, Link Road and Side Road Drainage Networks

Drainage Network Ref. No.	Discharging to	Pollution Control Measure
S1	Watercourse	Spillage Containment Pipe, Oil and Petrol Interceptor, Wetland, Attenuation Pond

S31A	Watercourse	None Required, overlay of existing local road
S31B	Watercourse	None Required, overlay of existing local road
S31C	Existing Sewer	Online Attenuation - Flow Control and Oversized Pipes
S32	Existing Sewer	Attenuation Pond

Drainage Network Ref. No.	Discharging to	Pollution Control Measure
S33	Existing Sewer	Attenuation Tank
S36A	Watercourse	None Required, upgrade of existing local road
S36B	Existing Ditch	None Required, overlay of existing local road
S37	Existing Sewer	Online Attenuation - Oversized Pipes
S38	Existing Sewer	None Required, overlay of existing local road
S39	Existing Sewer	None Required, overlay of existing local road
S40	Infiltration Basin	Spillage Containment Area, Oil and Petrol Interceptor, Infiltration Basin
S41	Existing Sewer	None Required, overlay of existing local road

The regular inspection and maintenance of drainage systems is essential for continued protection of the natural water regime into which the road runoff discharges and must take priority. Maintenance procedures are to be undertaken as set out in TII Publications, guidance documents and best practice methods.

5.5.4.9 Utilities

The infrastructure of a number of service providers is impacted by the proposed road development. The provision of the proposed road development shall ensure there are no permanent disruptions to services provided by these bodies and that all temporary disruptions must be kept to a minimum. Where services diversions are required all design works and construction works must be carried out in coordination with the relevant statutory bodies and services providers.

Furthermore, these services are being developed and expanded on an on-going basis. In order to avoid trenching in the new road for services after completion, provision must be made at construction stage for future crossing by services where agreed with local authority.

The following statutory bodies and service providers were consulted to identify conflict areas between their services and the proposed road development:

- Galway County Council – Watermain, Surface Water Drainage, Foul Sewer
- Galway City Council – Watermain Surface Water Drainage, Foul Sewer
- Irish Water – Watermain, Foul Sewer
- Eir
- ESB Networks – Low to Medium Voltage
- ESB Networks as the Transmission system Owner and EirGrid as the Transmission System Operator ESB International (ESBI), – High Voltage
- Gas Network Ireland – Transmission and Distribution
- E-Net
- Virgin Media

- BT Ireland
- SSE Airtricity
- Three Networks Ireland

All works required for the diversion or protection of any of the above services in conflict with the proposed road development have been confirmed with each of the service providers. Further details on the locations, potential utility impacts and proposed measures are included in **Chapter 15, Material Assets Non-Agriculture**.

5.5.4.10 Noise Barriers

The aspects relating to noise barriers are discussed in **Chapter 17, Noise and Vibration**.

5.5.4.11 Biodiversity measures

Four new artificial bat roosts and the modification of one existing building to become a bat roost are proposed as part of the proposed road development. Full details of these roosts are discussed in **Chapter 8, Biodiversity**.

5.5.4.12 Permanent Maintenance Facilities

There are two permanent maintenance facilities proposed as part of the proposed road development. These tunnel services, monitoring and maintenance buildings (TSB) will house operations personal and tunnel plant and equipment and will include an office area, control room, technical equipment room(s) (TER(s)), staff welfare facilities, stores and plant rooms to assist with the monitoring and control of traffic and systems both leading up to and within the tunnel.

Both are located in close proximity to the proposed tunnel structures. These permanent maintenance facilities will serve as tunnel services, monitoring and maintenance buildings. One facility is located in Lackagh Quarry on the south side of the eastern portal of Lackagh Tunnel and the other is located at Galway Racecourse adjacent to the western portal of the Galway Racecourse Tunnel as shown on **Figure 5.1.8** and **5.1.10** respectively.

These buildings will be serviced with electrical services, surface water drainage, potable water supply and foul water drainage. Heating, ventilation and air conditioning will be required to the TSB.

The surface water drainage design for the Lackagh TSB and Galway Racecourse Tunnel TSB site compounds are designed in accordance with best practice and BS EN-752 – Drain and Sewer Systems outside buildings. Roof runoff is collected from the rainwater down pipes and discharged to a system of carrier pipes located within the site compound. Runoff from the service yard and car parking areas will be collected using road gullies. Discharge from the service yard area will be routed through a Class 1 full retention forecourt oil and petrol interceptor located within the TSB site compound. The outfall discharge from the Lackagh TSB site is to ground via an infiltration basin which is provided as part of the mainline road drainage system. The outfall discharge from the Galway Racecourse Tunnel TSB site is to the existing trunk storm sewer located to the north of the eastern Racecourse Tunnel portal. The flow will be attenuated in an underground attenuation tank and released at a design discharge flow of 5l/s.

The water demand for the potable water supply is based on 10 staff per building with an assumed usage of 60 litres per person per day. The water connections will

also be utilised as needed to fill the tunnel fire water storage tanks. A pre connection enquiry form has been approved in principle by Irish Water for the connection to the existing public watermains. The watermain connection for the Lackagh Tunnel TSB is to the existing 150mm diameter public watermain located in Coolough Road. The proposed new watermain connection for the Racecourse Tunnel TSB is to the proposed new 100mm watermain diversion, located in the realigned racecourse avenue.

Pre-Connection Enquiries have been approved in principle by Irish Water for the proposed foul connections required for the TSBs. The foul wastewater discharge for the Lackagh Quarry TSB will be pumped to the public foul sewer at the Barr na Coille (Crestwood) housing estate adjacent to the Coolough Road. The foul wastewater discharge for the Galway Racecourse Tunnel TSB will be by gravity to the realigned IDA foul sewer west of the eastern Galway Racecourse Tunnel portal.

The main access for Lackagh Quarry TSB will be from the existing main entrance of Lackagh Quarry on Coolough Road. The main access to the Racecourse Tunnel TSB will be from the realigned Racecourse Avenue. Emergency access is also provided from the proposed road development to both buildings. Car parking will also be provided at both sites.

Drawings of the details on these tunnel services, monitoring and maintenance buildings are included in **Appendix A.5.1**.

5.5.4.13 Land and Property Requirements

Galway County Council, together with Arup, undertook a series of meetings with affected landowners.

The findings of these meetings have been combined with land registry records to produce a comprehensive landownership mosaic for the proposed road development (ref **Figures 14.01** to **14.15**).

This landownership mosaic together with information gained during individual meetings was used to establish access requirements and to evaluate side road and mainline realignments. Requests made by the impacted landowners and the general public were evaluated and included to the extent that this was reasonably possible having regard to the objectives of the proposed road development.

The accommodation works proposed will be introduced to serve the landowners in the following ways:

- To ensure landowners are given access to the local road network in the area, and that access can be gained between the local road and primary road networks
- To provide access between severed and separated land parcels

The accommodation works include access roads to allow access to land severed by the proposed road development. These access roads are 4.0m wide with 1.0m grass verges on either side and shall be designed in accordance with TII Standard Construction Details (SCDs) CC-SCD-02754 and CC-SCD-00706.

The following is a list of access roads identified. These access roads will be private roads with a private right of way provided to those parties listed in the **Table 5.15** below under the reference number.

Table 5.15: Access Roads

Location		Plot ID / Landowner Reference	Comments
Approx. Chainage	Description		
Ch. 0+000	80m access road AR0/01	102, 103	Provides access to houses and land parcels both via single field gates as current access is onto the existing R336
Ch. 0+000 to Ch. 0+250	320m access road AR0/02	106, 107, 108, 109, 112	Provides access to attenuation ponds and land parcels via single field gates as current access is severed by the proposed road development
Ch. 0+650 to Ch. 0+700	65m access road AR0/03	-	Provides access to attenuation ponds.
Ch. 0+850 to Ch. 0+950	160m access road AR0/04	114, 117	Provides access to land parcels
Ch. 0+990	30m access road AR0/05	-	Provides access to attenuation ponds only
Ch. 1+100 (Troscaigh Road L5387)	35m access road AR1/01	130, 131, 7891	Re-graded entrance to a house and land parcels as current access via Foraí Maola Road is severed by the proposed road development
Ch. 1+300 (Troscaigh Road L5387)	30m access road AR1/03	144, 145	Provides access (via the proposed Na Foraí Maola to Troscaigh link road) to land parcels as current access arrangement is impacted by the proposed road development
Ch. 1+500	15m access road AR1/04	156, 157	Proposed access to tie-in to existing access to houses. Current access arrangement via Troscaigh Road L5387 is impacted by the proposed road development
Ch. 1+550	25m access road AR1/05	154	Provides access to land parcel as current access arrangement via Troscaigh Road L5387 is severed by the proposed road development
Ch. 1+550 to Ch. 1+675 (Troscaigh Road L5387)	215m access road AR1/06	149, 150, 151, 152, 153	Access to houses and land parcels but also provides access to attenuation ponds

Location		Plot ID / Landowner Reference	Comments
Approx. Chainage	Description		
Ch. 1+750 to Ch. 2+550	830m access road AR2/02	197, 171, 147, 174, 173, 172, 170, 169, 167, 166, 146, 165,	Provides access to houses and land parcels as current access via Ann Gibbons Road L13215 is severed by the proposed road development
Ch. 2+475 to Ch. 2+550	65m access road AR2/01	176	Provides access to land parcel via Ann Gibbons Road L13215 as land parcel is being severed by proposed development
Ch. 3+275	10m access road AR3/01	199	Provides access to land as current access via Aille road is altered by the proposed road development (located north of proposed Aille Overbridge S03/01)
Ch. 3+325 to Ch. 3+900	620m access road AR3/02	197, 205, 208, 209, 210	Provides access to land parcels via Aille Road L5384 as current access is severed by the proposed road development. Also provides access to attenuation ponds
Ch. 4+025 to Ch. 4+050	75m access road AR4/01	-	Provides access to attenuation ponds
Ch. 4+240 to Ch. 4+360	140m access road AR4/02	-	Provides access to attenuation ponds
Ch. 4+450 (South of Cappagh Road Junction)	20m access road AR4/03	213	Access re-alignment required due to the proximity with the proposed Cappagh Road signalised Junction
Ch. 4+450 (North of Cappagh Road Junction)	10m access road AR4/04	215	Access re-alignment required due to the proximity with the proposed Cappagh Road signalised Junction
Ch. 4+450 to Ch. 4+675 (North of Cappagh Road Junction)	185m access road AR4/05	216, 223, 226	Provides access onto land parcels as current access via Boleybeg Bóthrín is severed by the proposed road development
Ch. 4+525 to Ch. 4+650	145m access road AR4/06	223, 224, 226, 227	Re-alignment of Boleybeg Bóthrín as currently being severed by the proposed road development. Provides access onto land parcels

Location		Plot ID / Landowner Reference	Comments
Approx. Chainage	**Description**		
Ch. 4+950 to Ch. 4+990	60m access road AR4/07	-	Provide access to attenuation ponds. Pond access gate to be provided
Ch. 5+360 to Ch. 5+660 North of Ballymoneen Road Junction	345m access road AR5/01	223, 232, 230	Provide access to farmyard and land parcels as current access is directly onto the existing Ballymoneen Road
Ch. 5+600 to Ch. 5+625 South of Ballymoneen Road Junction	30m access road AR5/02	232	Access already provided to houses located directly onto Ballymoneen Road, but re-alignment needed due to the proximity with the proposed signalised Junction
Ch. 6+375 to Ch. 6+475	110m access road AR6/01	243	Provide access to land parcel as existing access via Clybaun Road is severed by the proposed road development
Ch. 6+525 to Ch. 6+560	45m access road AR6/02	312	Provides access to farmyard. Access provided as part of Clybaun Road re-alignment
Ch. 6+600 to Ch. 6+960	370m access road AR6/03	241, 239, 247	Provide access to land parcels as being severed by the proposed road development
Gort na Bró Link Road	25m access road AR6/06	479	Access provided to tie the proposed road development in to the existing access road which eventually provides access to Gateway Retail Park
Gort na Bró road	100m Gateway Retail Park Link Road AR6/04	-	Realignment of access to Gateway Retail Park Link Road including roundabout
Gort na Bró road	30m access road AR6/05	-	Access provided to tie the proposed road development in to the existing access road to Gort na Bró housing estate
Gort na Bró road - North	15m access road AR6/06	-	Provides access to Gateway Retail Park
N59 Link Road South Ch. 1+900	50m access road AR7/01	481	Provides access to land parcels as part of the proposed road development
N59 Link Road South Ch. 1+900	60m access road AR7/02	-	Provides access to Bun a’ Chnoc and Culgharraí housing developments as part of the proposed road development
N59 Link Road South Ch. 1+900	55m access road AR7/03	-	Provides access to Bun a’ Chnoc and Culgharraí housing developments as part of the proposed road development. Ties-in to AR7/02
Ch. 7+225 to Ch. 7+300	60m access road AR7/04	250	Located just off Letteragh Road L1323. Provides access to land parcel as current access is severed by the proposed road development

Location		Plot ID / Landowner Reference	Comments
Approx. Chainage	**Description**		
Ch. 7+260 to Ch. 7+450	200m access road AR7/05	272	Located just off Letteragh Road L1323. Provides access to land parcel as current access is severed by the proposed road development. Also access to attenuation ponds
N59 Link Road South Ch. 1+500	60m access road AR7/06	486	Located just off Letteragh Road L1323, near the at-grade Letteragh Road junction. Provides access to house as current access is impacted by the provision of the junction
N59 Link Road South Ch. 1+350 to Ch. 1+400	80m access road AR7/07	486, 272	Provide access to land parcels as current access is severed by the proposed road development
N59 Link Road South Ch. 1+140 to Ch. 1+190	70m access road AR7/08	289	Provides access to house as current access is provided via a private access road
N59 Link Road Ch. 0+700 to Ch. 0+860	210m access road AR7/09	289, 502, 505, 501	Provides access to land parcels as current access is severed by the proposed road development
Ch. 7+800 to Ch. 7+850. Access from local road network	160m access road AR7/10	506 504	Provides access to land parcel as current access is severed by the proposed road development. Access via The Heath housing development
N59 Link Road South Ch. 1+760	10m access road AR7/11	484	Provides access to land parcel as current access is severed by the proposed road development
Ch. 8+360 to Ch. 8+500	115m access road AR8/01	518, 517	Located just off the N59. Provides access to house and ties-in to existing housing development access (517). Current access is severed by the proposed road development. Also provides access to attenuation ponds
Ch. 8+375 to Ch. 8+450	165m access road AR8/02	515	Provides access to house as current access is severed by the proposed road development. Access connected to Circular Road L1020
Ch. 8+525 to Ch. 8+625	115m access road AR8/03	-	Located just off the N59. Provides access to Aughnacurra Estate (houses and land parcels) as current access is severed by the proposed road development. Access is to tie-in with the remainder of the existing access
Ch. 8+450	30m access road AR08/04	-	Located just off the N59 (northern part of the proposed road development). Ties-in to existing access road
Ch. 8+500	640m access road AR8/05	-	Provides access to attenuation ponds

Location		Plot ID / Landowner Reference	Comments
Approx. Chainage	Description		
Ch. 9+090 to Ch. 9+160	110m access road AR9/01	-	Provides access to NUIG Sporting Campus as current access is severed by the proposed road development. Also provides access to an attenuation pond located near-by
Ch. 9+710	120m access road AR9/02	559, 553	Underbridge that maintains and provides a link to land parcels to the south of Menlo Castle Bóithrín severed by the proposed road development. Also provides access to AR9/03 & AR9/04
Ch. 9+560 to Ch. 9+710	145m access road AR9/03	-	Provides access to attenuation ponds. Accessed from AR9/02
Ch. 9+710 to Ch. 9+850	160m access road AR9/04	565	Provides access to land parcel as current access is severed by the proposed road development. Accessed from AR9/02
Ch. 9+550	120m access road AR9/05	-	Provides access to land parcel as current access is severed by the proposed road development
Ch. 9+500	120m access road AR9/06	549	Provides access to land parcel as current access is severed by the proposed road development
Ch. 10+050 to Ch. 10+140	85m access road AR10/01	563, 568, 564	Located off Bóthar Nua, provides access to land parcels as current access is severed by the proposed road development
Ch. 10+475 to Ch. 10+890	420m access road AR10/02	581	Provides access to land parcels as current access is severed by the proposed road development; but also provides access to attenuation ponds - via AR10/03, AR10/04, AR10/05, AR10/06, or AR10/07
Ch. 10+625	100m access road AR10/03	563	Provides access to land parcel as current access is severed by the proposed road development. Also provides access to attenuation pond. Ties-in to AR10/02 & AR10/04
Ch. 10+625 to Ch. 10+670	65m access road AR10/04	553	Provides access to land. Ties-in to AR 10/03 & AR10/05
Ch. 10+625 to Ch. 10+725	125m access road AR10/05	-	Ties-in to AR 10/02 and AR 10/03. Loop around attenuation pond to allow the Over Height Vehicles coming from the emergency slip road (prior the Lackagh tunnel) exit the AR network
Ch. 10+825	20m access road AR10/06	-	Allow for turning movement of the Over Height Vehicles coming from the emergency slip road (prior the Lackagh tunnel) exit the AR network. Access road accessed from AR10/02
Ch. 10+620 to Ch. 10+700	70m access road AR10/07	-	Provides the last exit point for Over Height Vehicles travelling east-bound on the N6 GCRR before to enter the Lackagh tunnel. Connects to AR10/02
Ch. 11+075 to Ch. 11+575	615m access road AR11/01	-	Provides re-routing for Over Height Vehicles engaged on the N6 GCRR prior entering the Lackagh Tunnel when travelling west-bound.

Location		Plot ID / Landowner Reference	Comments
Approx. Chainage	Description		
			Also provides access to attenuation ponds, and Tunnel services building
Ch. 11+990 to Ch. 12+125	245m access road AR11/02	583, 603	Provides access to farmyards and land parcels along the existing Ballindooley Bóithrín as current access is severed by the proposed road development
Ch. 12+110 to Ch. 12+240	130m access road AR12/01	602	Provides access to commercial premises. Slight Re-alignment of the existing access as located in close proximity with the proposed N84 grade separated junction
Ch. 12+290 to Ch. 13+090	100m access road AR12/03	602	Provides access to land parcel of the commercial premises. Work required to realign existing access as it is located in close proximity with a proposed retaining wall
Ch. 12+540 to Ch. 13+100	630m access road AR12/04	626, 627	Provides access to land parcels via School Road, as current access is severed by the proposed road development. Also provides access to attenuation ponds. Maintains access to the northern portion of Hynes' Bóithrín
Ch. 13+140 to Ch. 13+180	70m access road AR13/01	631, 635, 7103	Re-alignment of the existing Spellman's Bóithrín access road due to the close proximity with the Overbridge S13/01. Provides access to houses and land parcels via School Road
Ch. 13+140 to Ch. 13+290	180m access road AR13/02	625, 651, 627	Provides access via School Road to land parcels as current access is severed by the proposed road development
Ch. 13+390 to Ch. 13+425	45m access road AR13/03	625, 658	Provides access to land parcels as current access is severed by the proposed road development. Located on an existing access road that connects with School Road
City North Business Park Link	145m access road AR13/04	690,	Provides access to City North Business Park commercial premises as existing access (from the N83 Tuam Road) is severed by the proposed road development. Access to be re-located onto the proposed City North Park Link. Also provides access to attenuation ponds
Ch. 13+725 (Off the N83 Tuam Road)	25m access road AR13/05	-	Provides access to attenuation ponds
Ch. 13+825 to Ch. 14+175 (Off the N83 Tuam Road)	470m access road AR13/06	683, 682, 681, 680, 679, 678, 677, 676,	Provides a new access to individual houses and land parcels which are currently accessed directly from the N83 Tuam Road. Access road will be segregated from N83 Tuam Road

Location		**Plot ID / Landowner Reference**	**Comments**

		675, 674, 673, 658,	
Parkmore Link Road	50m access road AR13/07	695, 696	Re-alignment of the existing access to commercial premises (Ballybrit Business Park) so as to accommodate the proposed Parkmore Link Road
Parkmore Link Road	35m access road AR13/08	695	Re-alignment of the existing access to commercial premises (Ballybrit Business Park) so as to accommodate the proposed Parkmore Link Road
Parkmore Link Road	50m access road AR13/09	695	Re-alignment of the existing access to commercial premises (Ballybrit Business Park) so as to accommodate the proposed Parkmore Link Road
Parkmore Link Road	20m access road AR14/04	701	Provides access to land parcel as current access is severed by the proposed road development
Parkmore Link Road	45m access road AR14/05	696	Connects the proposed Parkmore Link Road with the existing Parkmore Industrial Estate internal road
Parkmore Link Road	75m access road AR14/07	691	Provides access to Galway Racecourse
Parkmore Link Road	20m access road AR14/08	691	Provides access to Galway Racecourse
Ch. 14+790 to Ch. 15+000	235m access road AR14/09	-	Provides the last exit point for Over Height Vehicles travelling east-bound on the proposed road development before to enter the Galway Racecourse Tunnel. Connects to AR15/01
Ch. 15+125	470m access road AR15/01	691, 707, 713	Re-alignment of the Racecourse Avenue which provides access to commercial premises, as current access is severed by the proposed road development. Also provides access to proposed Galway Racecourse Tunnel services building. Ties-in to AR14/09 but also AR 15/06
Ch. 15+200 to Ch. 15+725	545m access road AR15/02	691, 716, 701, 718, 719	Provides access to land parcels as current access is severed by the proposed road development. Also provides access to attenuation ponds. Ties-in to AR15/03 to the south, and to AR15/06 to the north; also provides access to AR15/07 users (Over Height Vehicle re-routing option)
Ch. 15+700 to Ch. 15+725	185m access road AR15/03	719, 721, 733	Provides access to Briarhill Business Park commercial premises (from Parkmore Road) as current access is severed by the proposed road development. The access road is proposed to pass

Location		Plot ID / Landowner Reference	Comments
Approx. Chainage	Description		
			under S15/02 bridge. Provides access to AR15/04 and to AR15/02
Ch. 15+690 to Ch. 15+720	30 m access road AR15/04	720, 719	Slight re-alignment of the current access to a commercial premise (from proposed AR 15/03) as it is in close proximity with the proposed S15/02 Underbridge
City East Business Park Junction	55m access road AR15/05	691	Re-alignment of the existing access road to the Galway Racecourse as part of the near-by junction's upgrade
Ch. 15+150 to Ch. 15+200	120m access road AR15/06	-	Provides connection (over the Galway Racecourse Tunnel) to AR15/01 and AR15/02 to facilitate the re-routing of Over Height Vehicles
Ch. 15+425 to Ch. 15+475	50m access road AR15/07	-	Provides re-routing for Over Height Vehicles engaged on the proposed road development prior entering the Galway Racecourse Tunnel when travelling west bound. Connects to AR15/02
Briarhill Link	55m access road AR16/01	724	Provides access to land parcel as current access is severed by the proposed road development
Ch. 16+800 to Ch. 16+830	30m access road AR16/02	756, 757	Upgrade/slight re-alignment of an existing access road to serve land parcel severed by proposed development boundary
Ch. 16+950 to Ch. 17+475	560m access road AR17/01	754, 753, 752	Provides access to land parcels as current access is severed by the proposed road development. Connects to existing access road

Alternative pitch facilities will be provided at NUIG to replace the existing pitches directly impacted by the proposed road development. The facilities include a floodlit 3G GAA pitch and a floodlit 3G training area and associated site infrastructure for the drainage of these pitches and furniture such as ball-stop netting. The proposed road development also intercepts the existing sports pavilion resulting in direct impacts to its western end and the building will be modified as follows:

- the existing western plant room, 1 no. changing room, 1 no. storage area, 1 no. weights area and associated access hallways on both ground floor and upper levels will be demolished
- the western plant room and its associated plant will be relocated
- Construction and reconfiguration of the internal and external walls, roof, windows and door locations

Refer also to **Chapter 15, Material Assets Non-Agriculture** and **Appendix A.15.1**.

Temporary stables will be provided for Galway Racecourse during the construction of the proposed road development until such time as the Galway Racecourse Tunnel is complete and the permanent stables are constructed. This is further discussed in **Chapter 15, Material Assets Non-Agriculture** and **Appendix A.15.2**.

5.5.4.14 Demolitions and Acquisitions

One of the project objectives for the proposed road development was "to seek to preserve existing well established communities". Therefore, from the outset of the design of the proposed road development every effort was made to avoid property demolitions where possible. However, there are still unfortunately and unavoidably a number of property demolitions that are necessary for the construction of the proposed road development and to secure the many benefits the proposed road development offers as follows:

- 44 residential properties
- 2 industrial properties (one property includes four buildings)
- 2 commercial properties

In addition to the demolition of 44 residential properties, an additional 10 residential properties require full acquisition.

In addition to the demolition of 44 residential properties, an additional 10 residential properties, one commercial property and one landholding that has a full residential planning permission require full acquisition.

It is proposed that 17 farm buildings will be acquired to accommodate the proposed road development.

These properties and structures are also discussed in more detail in the following chapters of the EIAR:

- Chapter 12, Landscape and Visual
- Chapter 13, Architectural Heritage
- Chapter 14, Material Assets Agriculture
- Chapter 15, Material Assets Non-Agriculture
- Chapter 18, Human Beings, Population and Health

5.5.4.15 Planning Permission Modifications

The proposed road development will require the acquisition of lands from five properties upon which there is currently full planning permission for residential development or commercial development. These acquisitions will result in either the revocation or the need for modification of the planning permission. These properties are listed below in **Table 5.16** and set out in the Seventh Schedule of the Protected Road Scheme and Motorway Scheme.

Table 5.16: Non-Agricultural Planning Permissions affected by the proposed road development

PRS / MS Ref. Number	Townland	Description	Area of Property (Ha)	Description of Landtake/ Modification	Land to be Acquired (ha)
124	Na Foraí Maola	House and garden	0.47	Acquisition of whole site	0.47
149	Troscaigh Thiar	Planning permission for roadside boundary wall and existing access point as constructed with all associated works and ancillary services.	0.20	Boundary Wall relocation, Road Bed acquisition	0.01
229	Ballyburke	Planning permission granted for the demolition of two existing houses shed and outbuildings, construction of crèche, 3 no retail units, 3 no office units, bar/restaurant and 299 residential units in varying design and form, in two and three storey blocks, bin storage, ESB substation, surface and basement car parking and all associated external and site development works including 3 vehicular access points and road widening along Ballymoneen Rd. (1454) (Extension of time to 18/07/2019)	9.2	Severance of site	1.45
528_543	Dangan Lower	Permission for new all-weather sports pitch on the site of existing training pitch (including floodlighting)(14104)	95.896	Partial acquisition of property	6.293
528_543	Dangan Lower	Permission for flood lighting of existing GAA pitches adjacent to the river. (17159)	95.896	Partial acquisition of property	6.293

5.6 Functionality of N6 GCRR

The function of the N6 GCRR is to facilitate the reduction of existing traffic congestion and future proof the effectiveness of this part of the national road network. To achieve this dual functionality, the proposed road development design sought to:

1. provide for the strategic need of the TEN-T comprehensive road network and connectivity of Galway City and the West Region to the national road network
2. provide an additional crossing of the River Corrib, thus facilitating the reduction of congestion on city centre roads, and allow the reallocation of road space in the city network to non-motorised modes of transport, thereby facilitating the effective implementation of all the elements contained in the GTS, namely the improvement of public transport, cycling and walking measures

The transport strategy for Galway (i.e. the GTS) has been developed to segregate and direct people to the most appropriate mode, which allows the road component of this strategy to serve the function for which it is designed. The N6 GCRR will serve the strategic traffic currently trying to cross the city via the existing N6 as well as the strategic traffic that is currently trying to rat-run through the city using the existing city street network due to the congestion levels on the national road network. The N6 GCRR will free up road space in the city centre that can be used by other modes of transport. The city at its heart serves a strategic function as the economic engine for the West Region and must be free of congestion to enable it to do so.

The grade separated junctions on the N59 Moycullen Road, N84 Headford Road, N83 Tuam Road and Coolagh Junction provide the necessary connections to distribute traffic in accordance with demand, whilst also being of a standard to comply with TEN-T regulations (ref **Chapter 2, Planning and Policy Context**) which require that all roads that form part of the TEN-T Comprehensive network, as a minimum, be a high quality road. Regulation (EU) No 1315/2013 sets out the requirements for high quality roads that shall form part of the network, both Core and Comprehensive.

The N59 Letteragh Junction is a standard grade separated junction, but is offset from the N59 Moycullen Road. The purpose of this offset from the N59 Moycullen Road is two-fold, firstly to minimise the direct impact on residential property at the N59 Moycullen Road bridge crossing and secondly to provide better connectivity and traffic distribution from the proposed road development to Knocknacarra and the crossing of the N59 Moycullen Road area. The N59 Link Road South connects to the Letteragh Road and Rahoon Road which effectively distributes traffic accessing National University of Ireland, Galway (NUIG) South (south of the Quincentary Bridge), Knocknacarra and University Hospital Galway (UHG), whilst the N59 Link Road North facilitates traffic accessing NUIG North (Sporting Campus), N59 Moycullen Road and Connemara.

The N84 Headford Road Junction is a standard grade separated junction located on the N84 Headford Road to connect with the N84 Headford Road national road traffic. The layout as shown on **Figures 5.1.08** and **5.1.09** is the minimum footprint achievable. However, this junction does directly impact on residential property in this area due to the presence of ribbon development along the N84 Headford Road (ref **Chapter 15, Material Assets Non-Agriculture**).

The N83 Tuam Road Junction is a combined junction to serve the demand arising from the N83Tuam Road and the demand arising from the business parks in the Parkmore and Ballybrit area. As the forecast volume of movements in the N83Tuam Road area could not be accommodated via single junction slips, alternative layouts had to be considered. The solution determined as most suitable and capable of delivering suitable capacity was a merge / diverge arrangement split between the N83Tuam Road and Parkmore Link Road. The key features of this layout are as follows:

- Eastbound diverge from the proposed road development to the existing N83Tuam Road and westbound merge from the existing N83Tuam Road to the proposed road development
- No direct connection from the existing N83Tuam Road to the proposed road development travelling eastbound or no direct connection from the proposed Parkmore Link Road to the proposed road development travelling westbound. However, the forecast volume of such movements was minimal and they were therefore accommodated via the provision of a connection from the proposed Parkmore Link Road to the existing N83Tuam Road, the City North Business Park Link Road

The proposed N83Tuam Road Junction arrangement facilitates the efficient movement of all road users (motor vehicles, buses, trucks, bicycles, and pedestrians). The layout has the benefit of minimising the number of traffic conflicts by segregating the major movements and by providing connections between the proposed and existing road networks as appropriate.

The grade separated junction at the eastern terminus of the N6 at Coolagh provides an efficient partial free-flow transfer of traffic from the existing N6 to the proposed road development. Traffic destined for the eastern part of the city diverges from the existing N6 to an at-grade junction in the vicinity of the existing N6 Coolagh Roundabout. Clear signage at this signalised junction, together with appropriate gantry signage in advance of the split for the proposed road development will enable drivers to make the appropriate choice to arrive at their destination.

6 Traffic Assessment and Route Cross-Section

6.1 Introduction

This chapter presents the potential traffic and transport impacts that may arise from the proposed N6 Galway City Ring Road (N6 GCRR), hereafter referred to as the proposed road development.

The strategic and local traffic and transport impacts associated with the proposed road development are discussed, assessed and evaluated in this chapter which is set out as follows:

- Transportation Assessment Methodology (**Section 6.2**)
- Receiving Environment (**Section 6.3**)
- Future Environment / Proposed Road Development (**Section 6.4**)
- Assessment of proposed road development using Traffic Model (**Section 6.5**)
- Traffic Impact Assessment (**Section 6.6**)
- Mitigation Measures (**Section 6.7**)
- Residual Impacts (**Section 6.8**)
- Summary (**Section 6.9**)
- References (**Section 6.9**)

6.1.1 Guidelines Utilised

This traffic and transport assessment has been prepared with reference to the following documents:

- Project Appraisal Guidelines for National Roads – Transport Infrastructure Ireland (2016)
- EPA: Revised Guidelines on the Information to be contained in Environmental Impact Statements, (2002 and Draft, September 2015)
- EPA: Advice Notes for Preparing Environmental Impact Statements, (2003 and Draft, September 2015)
- Guidelines on the information to be contained in Environmental Impact Assessment Reports – Environmental Protection Agency (Draft 2017) (referred to as EPA guidelines in this chapter)
- Spatial Planning and National Roads – Guidelines for Planning Authorities - DECLG (2012)
- Traffic and Transport Assessment Guidelines – NRA (2007)

- Traffic Management Guidelines – DEHLG, Department of Transport (DOT), Dublin Transportation Office (DTO) (2003)

6.1.2 Key Assessment Terminology

Presented below are some of the key terms that are used throughout this chapter to describe the traffic situation and potential impacts associated with the proposed road development.

- **Heavy Goods Vehicles (HGVs)** are classified as Articulated / Rigid Trucks and Buses with 2 or 3 more axles and vehicles pulling
- **Light Vehicles (LVs)** are classified as Cars, 4 Wheel Drive, Utility and Light Vans
- **Passenger Car Unit (PCU)** is a unit of traffic volume, with 1 LV = 1 PCU and 1 HGV = Approximately 2 PCUs
- **Annual Average Daily Traffic (AADT)** is an estimate of the average daily traffic volume at a location over the course of a year. Calculation of AADT involves dividing the total traffic volume in the year by the number of days in the year. The AADT is a measure of the total traffic over a road and thus is useful for indicating the cumulative impact of traffic on a road pavement. The AADT thus informs road pavement design and maintenance
- **Peak Hour** is the time of the day that travel demand is at its highest, e.g. where there is a lot of commuter traffic, typically 8am to 9am in the morning when commuters are travelling to work and school with a corresponding peak in the evening, usually from 5pm to 6pm. The PM peak is usually less pronounced than the AM Peak period because commuters return home over a wider spread of time in the evening on the return leg of the commute and school related travel typically occurs outside the evening peak
- **Ratio of Flow to Capacity (RFC)** also referred to as **Volume over Capacity (V/C)** is a means to describe the capacity of each approach road to a junction. An RFC below 0.85 (or 0.90 for a signalised junction) implies an approach road is operating satisfactorily within capacity; between 0.85 (or 0.90 for signalised junctions) and 1.0 RFC implies the approach road is operating within capacity but at less than optimal efficiency; above 1.0 RFC the approach road is deemed to be above capacity, therefore, when a road is at capacity a slight increase in traffic volumes can have a disproportionate impact on the length of queuing and delays
- **Transport Infrastructure Ireland (TII) Project Appraisal Guidelines (PAG)** are a set of "how to" appraisal guidelines to ensure consistency of approach across TII projects and compliance with Department of Transport, Tourism and Sport (DTTAS) requirements. The PAG suite of documents include detailed guidance on Transport Modelling, Economic Appraisal and Multi-Criteria Analysis

- **Model Periods** for which transport demand is extracted are as follows:
  - AM peak (07:00 - 10:00)
  - Inter peak 1 (IP1) (10:00 - 13:00)
  - Inter peak 2 (IP2) (13:00 - 16:00)
  - PM peak (16:00 - 19:00)
  - Off peak (19:00 - 07:00)

6.2 Transportation Assessment Methodology

6.2.1 Introduction

The methodology for the traffic and transportation assessment can be summarised as follows:

- Undertake a **baseline review** in relation to the existing traffic situation, including consultation with Galway City and County Councils, Transport Infrastructure Ireland (TII), National Transport Authority (NTA), etc.
- Undertake **traffic modelling** to assess future year scenarios, with the proposed road development ('Do-Something' [1]) and without the proposed road development ('Do-Minimum'[2]) in place
- **Evaluate the traffic modelling results** which forecast the impact of existing and future traffic on the road network
- **Identify any traffic impacts**, develop and test proposed **mitigation measures** to remove and/or reduce any identified negative traffic impacts of major significance
- **Determine any residual impacts** arising from the forecast traffic combined with the proposed mitigation measures

6.2.2 Baseline Review

As a first step, a Baseline Review was produced to determine the existing traffic conditions in Galway City and surrounding areas.

The baseline review, contained within chapters 1 and 2 of the Traffic Modelling Report (included in **Appendix A.6.1**) and summarised in **Section 6.3** and **6.6**, includes a review of the existing road network and the operating transport conditions for vehicular traffic, walking and cycling infrastructure and public transport services. A number of site visits were carried out and traffic surveys were commissioned to determine the existing traffic levels and conditions. The Baseline Review also included a review of demographic information and latest Census data to understand existing levels of travel demand and traffic patterns on the

[1] 'Do-Something' relates to a situation where the proposed road development is approved and proceeds as expected.
2 'Do-Minimum' relates to a situation where the proposed road development does not proceed.

surrounding road infrastructure. Policy documents relating to the area and other relevant background documentation were also reviewed.

As part of the Baseline Review, extensive consultations were held with many key stakeholders including liaising with TII, Galway County Council and Galway City Council to discuss any planned infrastructure and land use changes in the area. Meetings were also held with the NTA to agree the detailed methodologies for traffic modelling since this authority is now responsible for the development and maintenance of the new regional transport model for the West Regional Model (WRM), centred on Galway, which was used as part of this traffic assessment.

6.2.3 Traffic Modelling

6.2.3.1 Traffic Model Development

West Regional Model

The West Regional Model (WRM) is a strategic transport multi-modal model for the counties Galway, Mayo, Roscommon, Sligo, Leitrim and Donegal, with a focus on the city of Galway. It is part of a hierarchical multi-modal transport modelling system for Ireland (known as the 'Regional Modelling System' RMS) that allows the appraisal of a wide range of potential future transport and land use options. The regional models are focussed on the travel-to-work areas of major population centres (e.g. Dublin, Cork, Galway, Limerick, and Waterford).

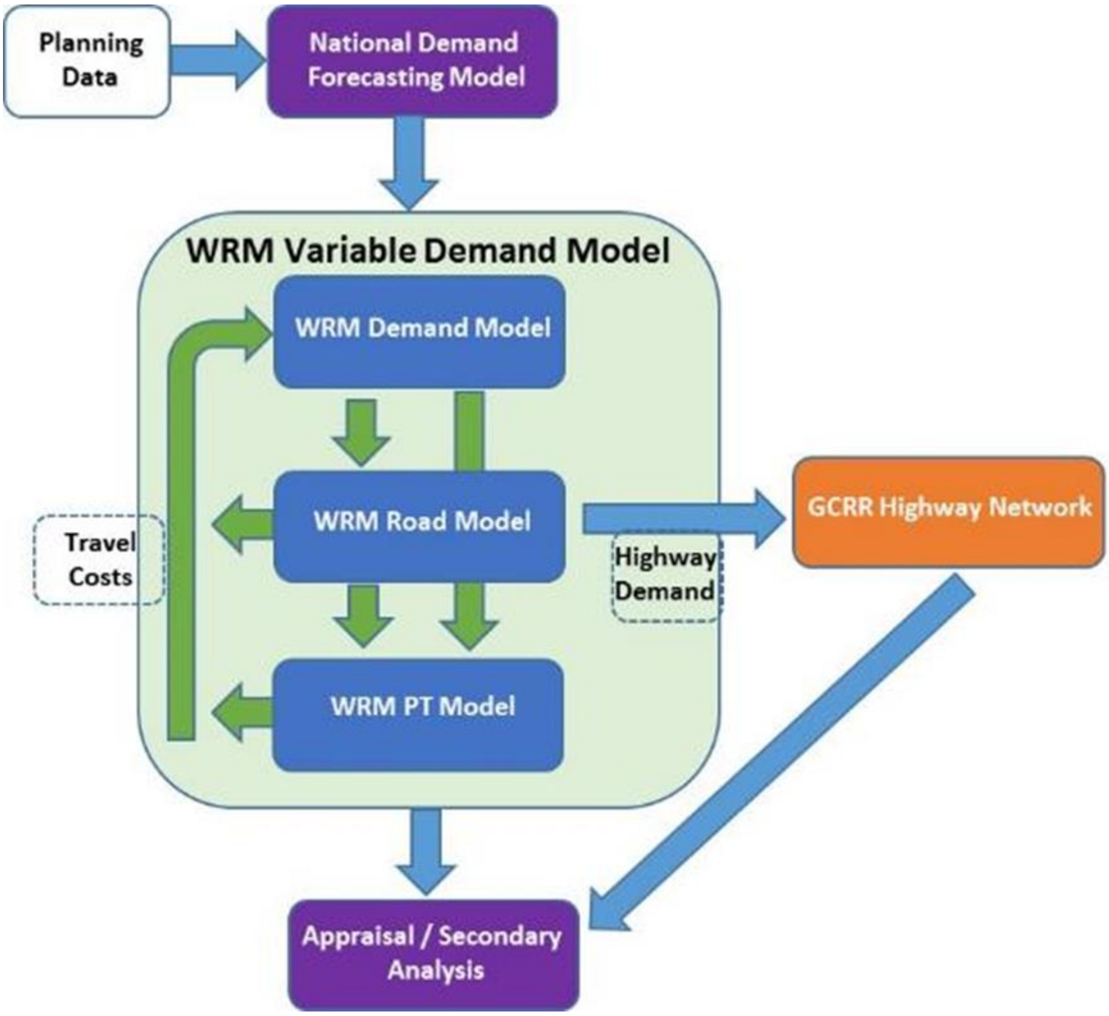
N6 Galway City Ring Road Model

In order to progress the modelling for the design stage (Phase 3 of TII PAG) of the proposed road development it was necessary to improve aspects of the WRM so that the proposed road development model met the required TII PAG model criteria.

To achieve this, the WRM highway models for each time-period (AM, IP1, IP2 and PM) were refined in the area of influence of the proposed road development to provide the base models for the proposed road development assessment (further details of this process are contained within the Traffic Modelling Report, contained in **Appendix A.6.1**).

The completion of the refinement process, resulted in AM, IP1, IP2 and PM highway models of the area of influence of the proposed road development which meet the TII PAG criteria for model development. These highway models are referred to as the **N6 Galway City Ring Road (GCRR) Model**. The demand for these models is derived from the WRM Demand Model and has been used to test the various scenarios required for the proposed road development. The model structure is illustrated in **Plate 6.1** below.

Plate 6.1: N6 GCRR Model Structure



The objective in developing the N6 GCRR Model was to develop a traffic model that accurately reflects existing traffic conditions in the study area at a sufficient level of detail to allow for an accurate traffic assessment. The model software used for the highway assignment element of the model is the SATURN (Simulation Assignment of Traffic to Urban Road Networks) suite of transportation modelling programs. Two peak hour, and two inter-peak hour, models were developed for the purposes of this study to represent the following time periods:

- AM Morning peak period (07:00 – 10:00)
- Average Morning Inter-peak period (10:00 – 13:00)
- Average Afternoon Inter-peak period (13:00 – 16:00)
- PM Evening peak period (16:00 – 19:00)

6.2.3.2 Future Year Model Development

In order to assess the traffic impacts of the proposed road development, two future year models were developed to represent the proposed road development Opening Year (2024) and Design Year (2039).

The future year ‘Do-Minimum’ networks include the base year network plus all schemes (road and public transport) that are already built, are committed to be built or likely to be built by 2024 and 2039. The list of schemes to be included was developed in coordination with Galway City Council, Galway County Council, TII and NTA.

The future year ‘Do-Something’ network includes the ‘Do-Minimum’ schemes plus the proposed road development.

A detailed approach to forecasting travel demand has been developed in order to capture the planned growth in population and employment at a local level in Galway. This approach required input from key stakeholders of the NTA, TII, Galway County Council and Galway City Council.

The following forecast scenarios (and associated demographic forecasts) have been used on this project in order to create future year travel demand:

- **Low Growth Scenario:** NTA Reference Case - These are based on M2F2 Traditional (Scenario 1). The traditional scenario follows the Central Statistics Office (CSO) moderate path of seeing a return towards the 1996 patterns of inter-regional migration (specifically). The population in the West increases at a moderate pace of natural growth in line with the measured outflow of migrants (net) elsewhere
- **Medium Growth Scenario:** TII National Model Medium Growth Scenario
- **High Growth Scenario:** TII National Model High Growth Scenario

In addition to the Core Future Year Scenarios tested (listed above) a further sensitivity test has also been carried out to assess the performance of the proposed road development in conjunction with all the active travel, public transport and road infrastructure proposals included in the **Galway Transport Strategy (GTS)**. As the GTS is a 20-year strategy, this sensitivity test has only been carried out in 2039, Design Year.

Model Application

The models and scenarios described above were used to determine and assess the traffic impacts of the proposed road development.

For further information on model development and application, please refer to the Traffic Modelling Report in **Appendix A.6.1** which contains a full description of the model development and traffic impact analysis process.

6.2.4 Evaluation of traffic modelling results

The traffic model is used to inform various aspects of the EIAR including but not limited to air quality and climate, noise, human beings, population and health and material assets as well as being used to determine traffic impacts associated with the proposed road development (which is the main focus of this chapter).

The AADT flows within the study area were supplied to the design team including environmental experts and used to assess the potential environmental impact of the traffic from the proposed road development. (i.e. air quality and climate, noise, etc.)

The potential traffic impact of the proposed road development is assessed using the N6 GCRR Traffic Model and considers the time periods when traffic congestion is at its most critical in the Galway City area. Key Performance Indicators (KPI) have been identified to assist in the assessment and evaluation of the proposed road development on peak period traffic. Each of the KPIs is quantifiable to allow the scenarios tested to be easily compared against one another to determine traffic related impacts.

The following KPIs have been used to determine traffic impacts:

- Journey Times on Key Routes
- Ratio of Flow (of Traffic) to Capacity ratio at Key Junctions (i.e. a measure of congestion levels)
- Network Statistics

Journey times on key routes have been considered to determine the traffic impact of the proposed road development on the strategic road network. Ratio of Flow to capacity (or degree of saturation ratios) at key junctions have been considered to take account of local traffic impacts. Finally, model network statistics give an overall, general, assessment of the performance of the entire model network (which covers Galway City and its environs) for a given scenario.

All three KPIs are used for the traffic impact assessment as one KPI may reveal a traffic impact that is not picked up by another KPI. For this reason all three KPIs are used to inform the full range of potential traffic impacts.

The impacts of the proposed road development, both at the strategic and at local levels, are rated as positive, negligible, minor, moderate or major, as appropriate and these categories are described as follows:

- **Positive:** effects improve conditions
- **Negligible:** effects that are of such low importance that they are not material to decision-making
- **Minor Significance:** effects that are of low importance in the decision-making process
- **Moderate Significance:** effects of the proposed road development that may be judged to be important at a local scale (i.e. in the planning context) only
- **Major Significance:** effects of the proposed road development which are of greater than local scale importance (i.e. strategic significance)

The likelihood (low, medium or high) and duration (short, medium or long term) of the predicted impacts is also assessed and noted. As per EPA guidelines, short-term equates to 1-7 years, medium term is between 7 and 15 years and long term is between 15 and 60 years. This method of rating impacts allows the traffic modelling scenarios to be compared in a clear, concise and measurable way.

Mitigation measures of traffic impacts of major significance identified are developed and are further evaluated if required.

The remaining residual impacts are also considered.

6.3 Receiving Environment

6.3.1 Existing Road Network

The existing road network is shown on **Plate 6.2**. The existing N6 is a four lane carriageway between Coolagh, Briarhill and the N59 Moycullen Road, with varying median width, and a number of at-grade roundabouts and signalised junctions. There are various forms of at-grade junctions including roundabouts, signals and priority junctions on the R338 from its junction with the N59 Moycullen Road to the R336 Coast Road.

The M6 motorway becomes the N6 National Road to the east of Galway City and is the primary access to Galway from the east. The existing N6 connects to the local road network at Coolagh Roundabout, an at-grade junction which experiences congestion during the morning peak hour. The existing N6 then turns north to Briarhill Junction, an at-grade signalised junction, which connects to R339 Monivea Road and onto Parkmore Road. This junction experiences capacity problems (refer to **Section 6.3.5** below) during both the morning and evening peak hour due to the volume of traffic trying to access/egress the Industrial Estates at Parkmore, Ballybrit and Briarhill.

The existing N6 continues as a dual carriageway to the at-grade signalised junction at the Ballybane Junction and onto the N83 Tuam Road[3], again a signalised junction. This particular junction experiences delays at peak hours due to the traffic volumes on the N83 Tuam Road being equivalent to the volumes on the existing N6. The dual carriageway continues to the Kirwan Roundabout, i.e. the junction of the existing N6 and the N84 Headford Road. This five arm at-grade roundabout experiences delays at peak hour due to the strongest demand controlling the flows onto the roundabout (refer to **Section 6.3.5** below). Again, the traffic volumes on the N84 Headford Road are of the same order as the traffic volumes on the existing N6 at this point.

The N6 Headford Road between the Kirwan Roundabout and the Bodkin Junction is one of the busiest roads in the city carrying approximately 32,000 vehicles per day. This short section also has two additional traffic signals to facilitate access to retail and residential areas. The existing N6 over the Quincentenary Bridge, to the west of the Bodkin Junction, carries approximately 34,600 vehicles per day (as per 2012 traffic count data). This volume decreases on the west of the river as traffic

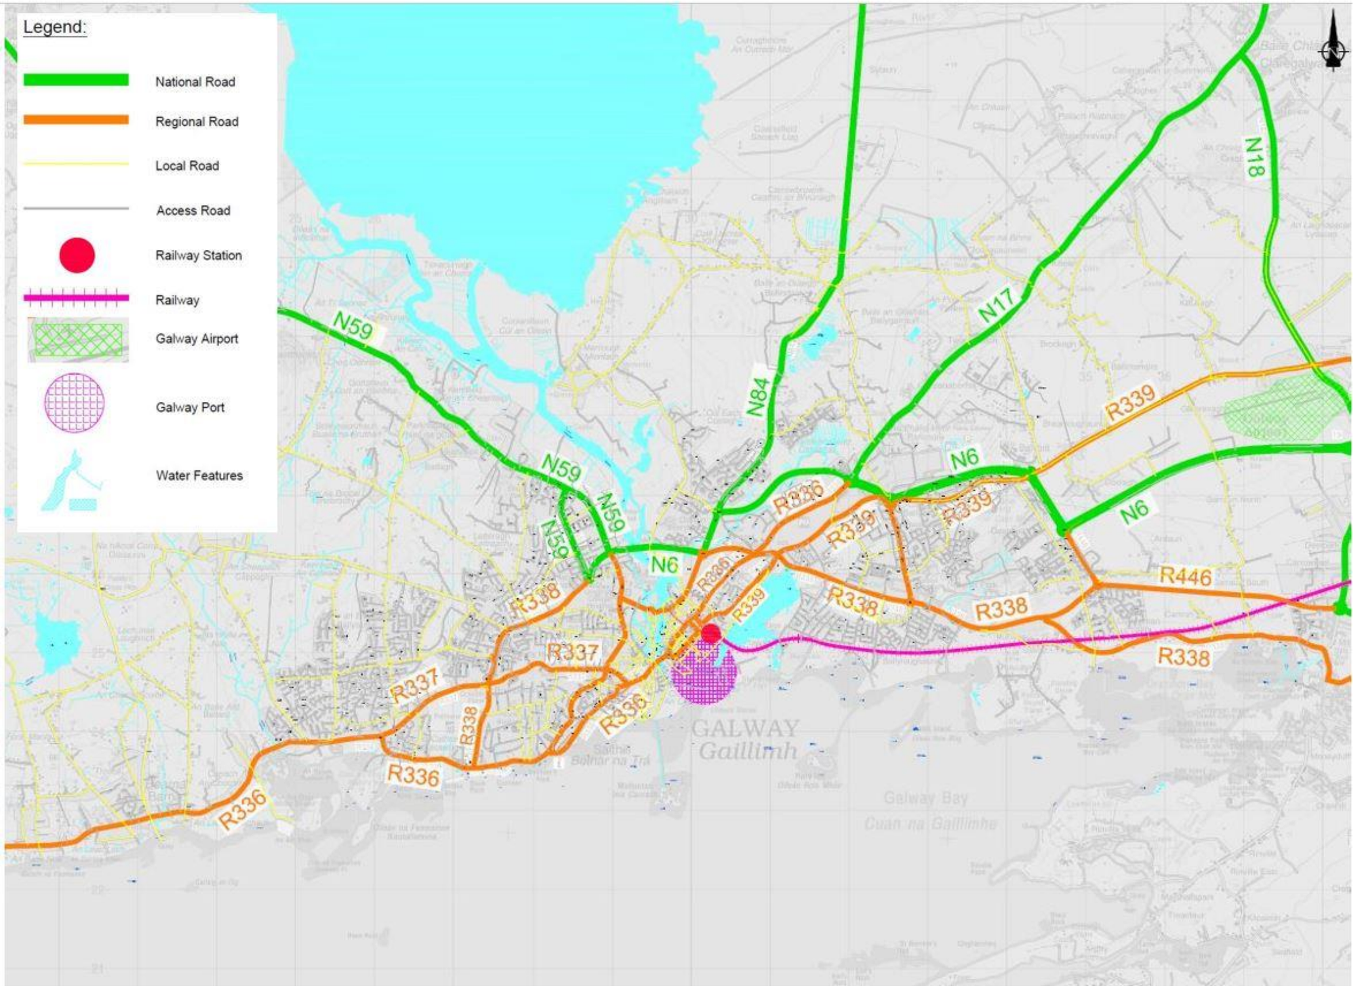
[3] Formally known as the N17 Tuam Road

accesses the university and the hospital at the existing N6/Newcastle Road and existing N6/N59 Browne Roundabout Junctions, However, the R338 Seamus Quirke Road to the west of Browne Roundabout, which is a single carriageway plus bus lanes, carries approximately 24,000 vehicles per day along a busy street with frontage, retail accesses, cyclists and high pedestrian usage.

The R338 then connects to the R336 Coast Road by continuing south along Threadneedle Road. There are two major secondary schools, and three primary schools in the vicinity of Threadneedle Road, all of which contribute to delay.

Therefore, the existing N6 weaves a route through many at-grade junctions from east to west around Galway City. The proximity of the junctions and the frequency of these junctions does not facilitate movement of vehicles in a timely manner or in a reliable manner. It also hinders and discourages modal shift as the public transport vehicles are also experiencing similar delays and such congested streets are perceived as dangerous for cyclists and pedestrians.

Plate 6.2: Existing Road Network



6.3.2 Existing Travel Patterns

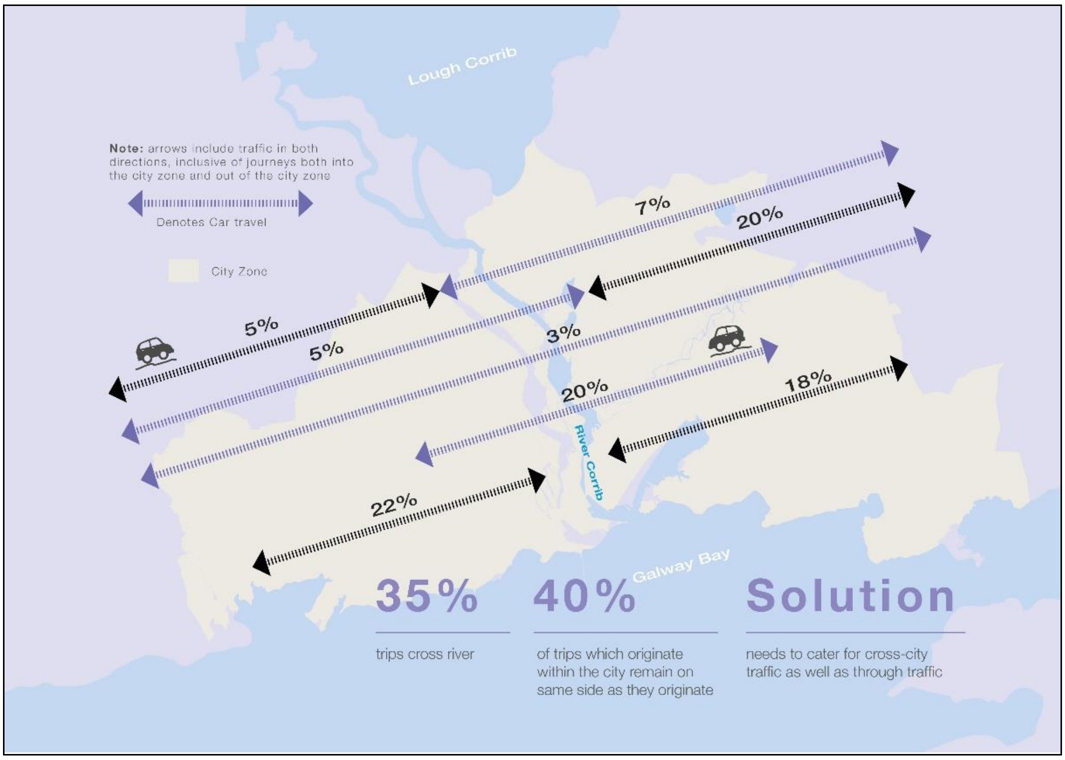
An analysis of desire lines for travel in Galway City and its environs has been undertaken using the West Regional Model to gain an understanding of travel patterns in the proposed road development study area. This has been developed using the extensive information on trip origins and destinations incorporated into the base year transport model. The model is divided up into approximately 300 zones, which have been aggregated to 16 sectors for the purposes of establishing the desire lines or demand between the sectors. The desire line analysis can be further aggregated into a broad representation of strategic travel patterns in Galway City and its environs focusing on trips that cross the River Corrib and that either travel into Galway City or travel through the city.

Plate 6.3 below is a schematic diagram to illustrate the travel patterns for private car trips to, from or through Galway City in the 2012 Base Year morning peak hour (extracted from the traffic model). Red arrows show movements that cross the River Corrib and green arrows show movements that do not cross the River Corrib.

As discussed in **Chapter 3, Need for the Proposed Road Development**, in total 35% of total car trips into and around Galway City cross the River Corrib. Of this total number of cross-river trips, approximately 3% are bypass traffic. Some 40% of all trips remain on the same side of the city as where they started i.e. that is to say the trip commences in the city and terminates in the city but does not cross the river.

One of the strongest movements is from the west side of Galway City to the east side of Galway City and vice versa which represents 20% of all trips. This analysis implies that any proposed development must cater for movements from one side of the city to the other in addition to through traffic, rather than a conventional bypass of the city which would mainly cater for through traffic. This analysis also demonstrates the importance of an integrated solution which supports modal shift for shorter commutes.

Plate 6.3: Travel Patterns 2012 Base Year Morning Peak Hour



6.3.3 Existing AADT on key links

The following Average Annual Daily Traffic (AADT) flows were estimated based on traffic counts undertaken by Galway City Council November 2012 and 2013 along the existing N6:

- N6 between Coolagh Roundabout and Monivea Road – 21,400 AADT
- N6 at Galway Racecourse – 19,900 AADT
- N6 between Tuam Road and Kirwan Roundabout – 22,400 AADT
- N6 River Corrib Crossing – 34,600 AADT

These volumes are significant volumes given the fact that these roads are also part of the street network serving Galway City.

Existing Peak Hour Flows and Level of Service

Average weekday peak hour traffic flows on the existing N6, within the Galway urban area have been derived from the November 2012 traffic surveys and are presented in **Table 6.1**.

Table 6.1: N6 Peak Hour Traffic Volumes (November 2012)

Road	Location	C'way	Direction	AM Peak (08:00 - 09:00)	PM Peak (17:00 - 18:00)
N6	Quincentenary Bridge	Single	Eastbound	1,614	1,357
			Westbound	1,466	1,520
N6	North of Bodkin Roundabout	Single	Northbound	1,315	1,132
			Southbound	1,286	1,052
N6	Terryland	Single	Eastbound	925	885
			Westbound	1,000	1,000
N6	Galway Racecourse	Dual	Eastbound	881	1,178
			Westbound	905	1,357
N6	Coolagh	Dual	Northbound	1,274	731
			Southbound	490	1,201
N6	Ardaun	Dual	Eastbound	601	1,183
			Westbound	930	603

TA 79/99 of the UK DMRB is used to determine the capacity of urban roads. This standard is not formally implemented in Ireland but is considered as background reading which indicates good practice. Within this standard, classifications such as Urban Motorways or Urban All Purpose roads are used, with further sub-classification of Urban All Purpose Roads as UAP1 to UAP4. The existing N6 in Galway can be defined as a UAP2 which refers to a "good standard single/dual carriageway road with frontage access and two side roads per km". From TA 79/99, a 2 lane UAP2 road has a capacity of approximately 1,470 vehicles per hour for a 7.3m wide 2 lane single carriageway. This capacity increases to 3,200 vehicles per hour for a 7.3m wide 2 lane dual carriageway. This does not account for capacity issues at the junctions.

When the existing volumes are compared against the theoretical capacity, the 4 lane single carriageway section of the existing N6 between the Quincentenary Bridge and Terryland are frequently at or above the capacity threshold defined in TA 79/99, which results in congestion on the route and a reduced level of service. Lower traffic volumes are carried on the dualled eastern section of the N6 Bóthar na dTreabh, however congestion is still experienced along this section, due to capacity restrictions at junctions, of which there are many as this also forms part of the street network serving Galway City.

6.3.4 Journey Time Reliability Assessment

Peak hour congestion on the road network in Galway, predominantly caused by junction capacity issues, results in increased journey times in peak periods in Galway. This leads to a reduction in journey time reliability in the city during these periods.

An analysis of observed journey times on three key routes around Galway and its environs was carried out to show the variance in journey times between the peak and off-peak periods in the base year. The three key routes are shown on **Plate 6.4**. The difference between the peak and off-peak journey times is a measure of the level of congestion during the peak, and increasing congestion results in worsening journey time reliability.

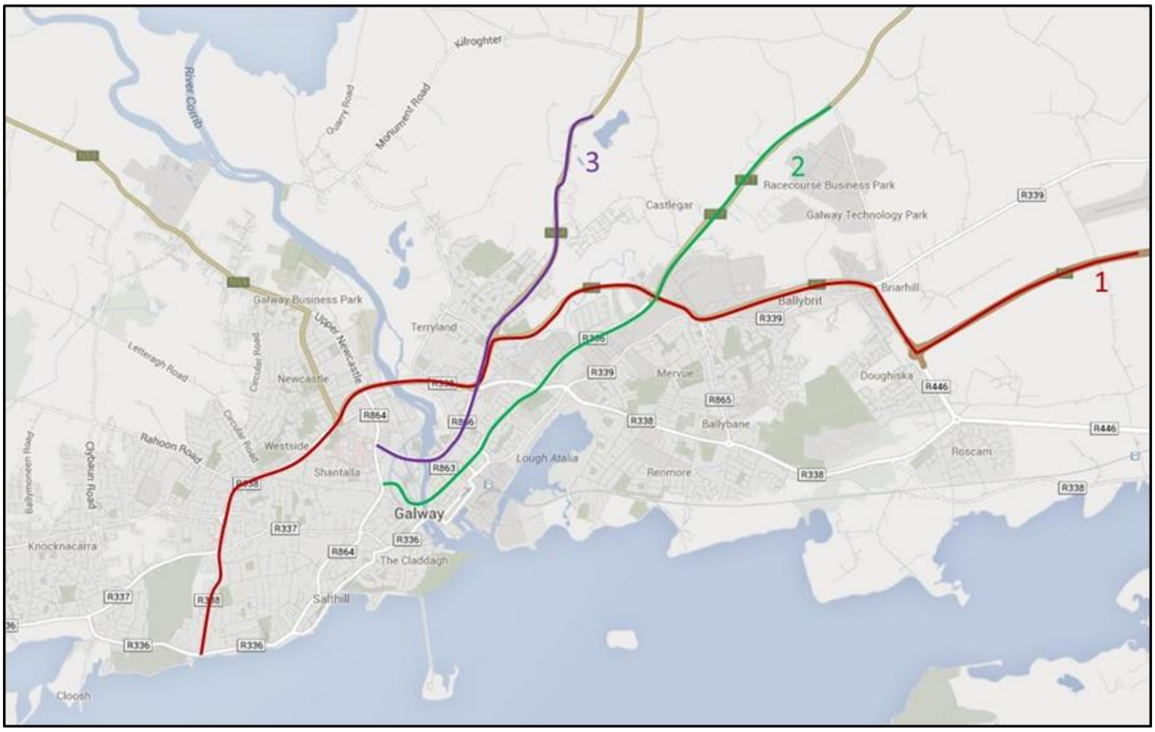
Observed travel times in 2012 Base Year on each of the routes in the inbound direction in the morning peak period versus the off-peak period are tabulated in **Table 6.2** below.

This assessment of journey time shows that the travel times on these three key routes in the morning peak hour are on average more than double the off-peak travel times.

Table 6.2: Journey Time Reliability

		2012 Observed Journey Times (minutes)			
		Off-peak average hour	**Morning peak hour**	**Difference**	**% Difference**
Inbound	Route 1 IN	14	28	14	100%
	Route 2 IN	14	25	11	79%
	Route 3 IN	8	19	11	138%
	Average	12	24	12	105%

Plate 6.4: Journey Time Reliability Routes



6.3.5 Junction Capacity Assessment

In the urban area, junction capacity is the key contributor to road congestion, over and above link capacity. Therefore, an assessment of the ratio of flow to capacity was undertaken at signalised junctions and roundabouts, plus other key junctions in the study area as shown on **Plate 6.5**. Data was extracted from the 2012 AM Peak Base Year traffic model to show the maximum volume-to-capacity ratio for the turns at each junction. The volume to capacity ratios are then related to level of delay and congestion at the junctions.

Plate 6.5: Volume/Capacity Ratios at Junctions (2012)

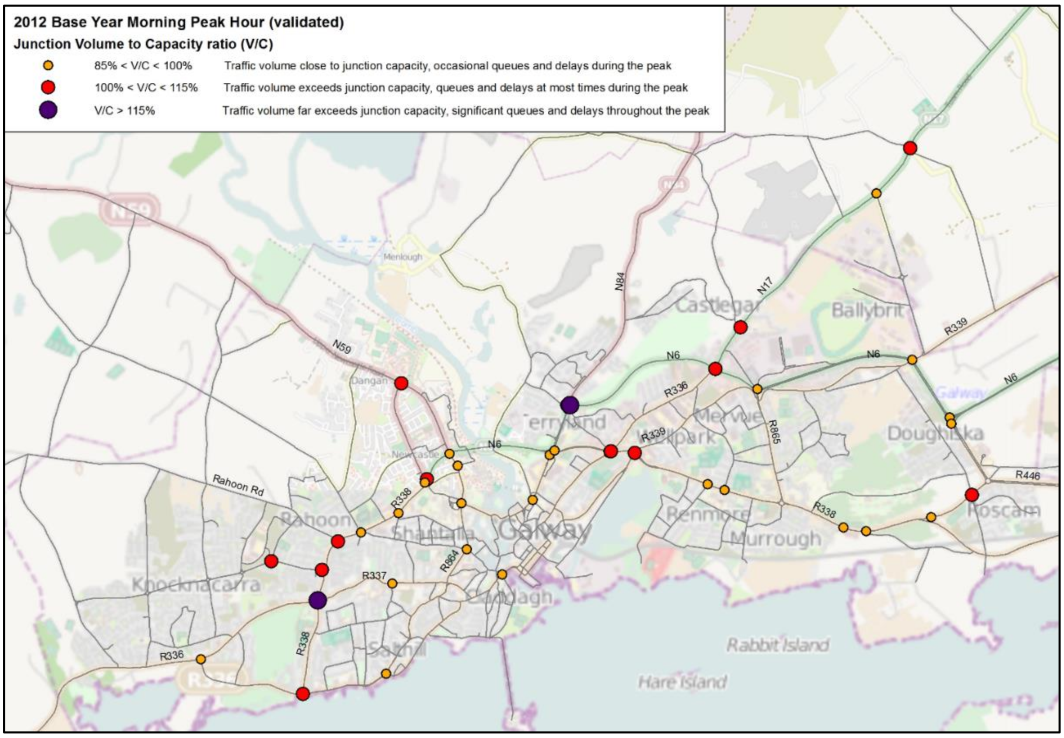


Table 6.3 summarises the number of junctions with a max turn RFC within standard ranges of 0.85-1.00, 1.00-1.15 and >1.15. Junctions with a RFC greater than 1 are over capacity. Ideally junctions should operate at a RFC ratio of < 0.85 (or 0.90 for signalised junctions), which would allow 15% spare capacity in the junction to cope with an unexpected event or natural growth.

This analysis demonstrates that the existing network is restricted by junction capacity. The junctions on the critical corridors accessing the city, namely the junctions of the N84 Headford Road, N83 Tuam Road and N59 Moycullen Road junctions with the existing N6, currently have no spare capacity at peak hour as shown on **Plate 6.5** above. These junctions are operating at greater than 100% of their capacity, which in turn leads to delays at these junctions. As these junctions are the main arteries into the city and the main junctions on the circumferential route around the city, this is a significant issue for the Gateway of Galway.

In addition, approximately 40% of all junctions on the key access routes across the study area are operating above 85% capacity during peak periods. This demonstrates that the network is finely balanced with minimal spare capacity to allow for any unforeseen event or natural growth.

Table 6.3: Junction Volume/Capacity Ratio (2012)

Sector	Sector Name	0.85 – 1.00	1.00 – 1.15	> 1.15
1	City Centre	2	0	0
2	City West	2	0	0
3	City East	3	1	0
4	R338 West	5	1	0
5	R338 East	1	2	0
6	N6	8	4	1
7	Western Distributor	0	0	0
8	R336	4	0	0
9	N59/Newcastle Road	0	1	0
10	N84	0	0	1
11	N83	2	1	0
12	R339	0	0	0
13	N6 from M6	0	0	0
Total	-	27	10	2

6.3.6 Alternative Modes

6.3.6.1 Existing Bus Network Conditions

Galway City is served by Bus Éireann and a small number of private operators. The city bus infrastructure is very much discontinuous, with priority measures only provided along sections of key corridors and not continuous over any significant portion of the network. As such the city bus network is subject to delay, impacting the attractiveness of the bus as a mode of choice.

In addition to the city bus network, a number of regional bus service providers operate to and from the city. Regional, intercity and private tourist coach services are subject to delays due to infrastructural deficiencies approaching and within the city centre, where the principal destinations are located at Ceannt Station, Fairgreen Coach Station, Eyre Square/Merchants Road and Galway Cathedral. These delays, along with multiple centralised destinations in the city centre and a lack of cohesion with the city bus routes and ticketing systems, discourage use of regional bus services for commuters from surrounding towns and villages which are served directly by regional buses.

National coach services benefit from high-quality road connectivity from the east and south, increasingly of motorway standard with the relatively recent construction of the M6 and the current development of the M17/M18, which will also improve connectivity to the north-east. Similar to the regional services, there are numerous operators providing intercity services to and from the city, with a resultant high number of arrivals and departures daily from Ceannt Station and Fairgreen Station.

These services are also subject to delays due to infrastructural deficiencies approaching and within the city centre, which discourages use of public transport between cities, and may impact on tourism in Galway City if accessibility of the city is not improved.

6.3.6.2 Existing Rail Network

Galway City is served by the existing single-track heavy commuter rail line from the east, terminating in the city centre at Ceannt Station. The rail line connects to Oranmore/Garraun and Athenry to the east. From Athenry there is a connection to the Western Rail Corridor service from Limerick and Ennis, and the main line continues east to Dublin.

There are 10 daily services scheduled from Ceannt Station to Heuston, and 9 scheduled return services from Heuston to Ceannt, with journey time being as short as 130 minutes.

There are eight scheduled daily services between Ceannt Station and Colbert Station in Limerick, and eight scheduled return services, with journey time being as short as 90 minutes.

6.3.6.3 Existing Pedestrian Network

The majority of the study area is provided with pedestrian facilities of varying quality. Within the city centre, there are pedestrian-only streets which are a key asset to the local economy, in particular the tourism/shopping thoroughfare of William Street, Shop Street and Quay Street. Other pedestrian facilities of note include the city canal network and the promenade at Salthill.

There have also been major junction improvement schemes in recent years which have considerably improved the pedestrian offering across the city and suburbs.

However, numerous locations throughout the study area remain where the quality of the pedestrian facilities is poor. At certain locations in the city centre, private and public vehicular traffic impacts on the safety and comfort of pedestrians. There are streets throughout the city with substandard or missing footpaths, limited or no crossing facilities, and permeability issues resulting from the manner in which residential areas have been developed. Some suburban residential areas are accessible by direct routes, but these are substandard and not suitable for use by mobility impaired pedestrians, while others have no footpaths provided for pedestrian access to main thoroughfares. The absence of permeability within housing areas often leads to excessively circuitous trips for pedestrians to walk a relatively short distance. All of these factors discourage walking as a mode for short trips.

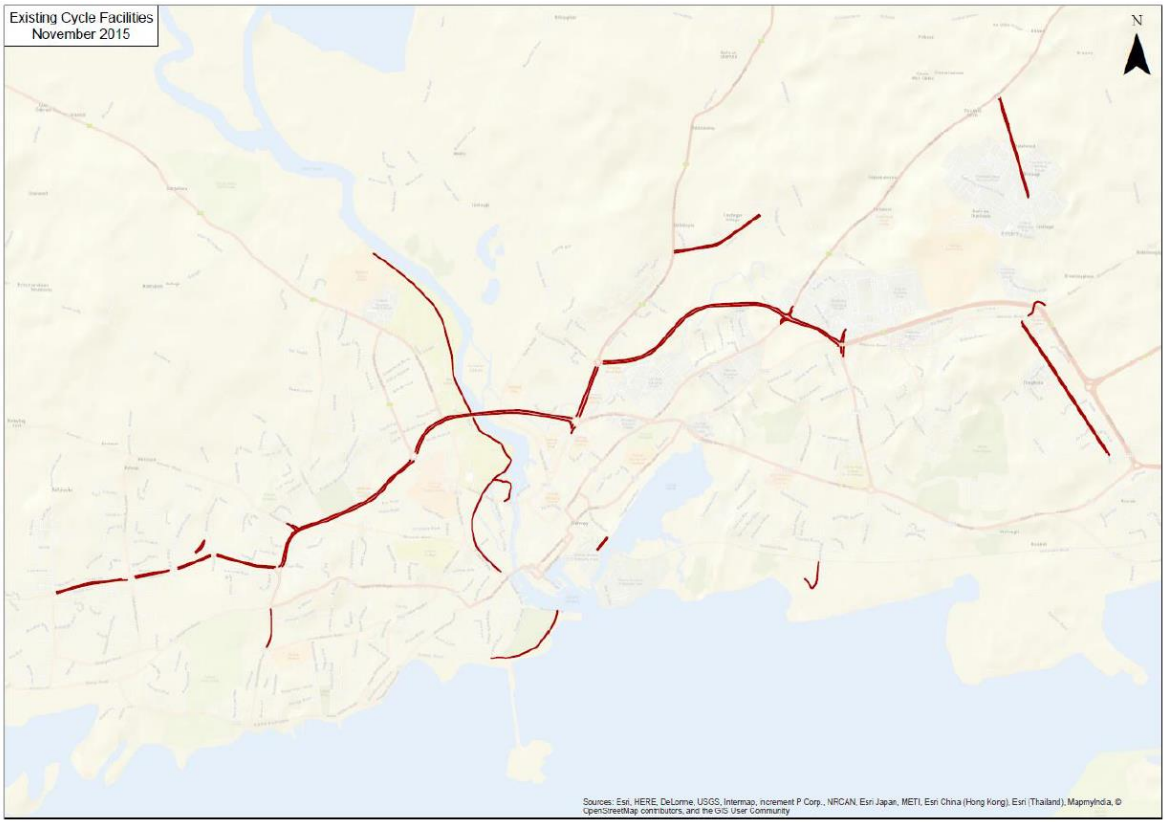
6.3.6.4 Existing Cycle Network

Although the city's generally flat topography is conducive to cycling as a suitable mode of travel, the current mode share of 5% is relatively low. Similar to the bus network, the existing network of cycle infrastructure is limited and discontinuous.

Plate 6.6 below shows the extent of the current cycle network.

The volume of vehicular traffic on the narrow city centre streets of Galway City also contributes to an environment that is neither appealing nor perceived as particularly safe for cycling. While there have been numerous improvements in recent years to the cycle network, not least the roll-out of the Bike Share Scheme, and several schemes in development aimed at enhancing the network, the cycling environment remains limited. This is particularly true in areas outside the city, where many towns and villages are within cycling distance of the city and each other, such as Bearna, Oranmore, Moycullen and Claregalway.

Plate 6.6: Extent of Existing Cycle Network Infrastructure



6.4 Future Environment / Proposed Road Development

6.4.1 Characteristics of the Proposed Road Development

The proposed road development, as described in detail in **Chapter 5, Description of the Proposed Road Development**, comprises the construction of a single carriageway from the western side of Bearna as far as the Ballymoneen Road and a dual carriageway from Ballymoneen Road to the eastern tie in with the existing N6 at Coolagh, Briarhill, and associated link roads, side roads, junctions and structures. The proposed road development also incorporates some facilities for non-motorised users which have been identified as part of the Galway Transport Strategy.

The design of the proposed road development is shown on **Figures 5.1** to **5.14** of this EIAR.

6.4.1.1 Proposed Road Type and Cross-Section

From the R336 Coast Road to Ballymoneen the mainline carriageway of the proposed road development is a Type 1 Single Carriageway in accordance with TII DMRB DN-GEO-03036 (Cross Sections and Headroom). The design speed of the mainline over this area is 85km/h, and the cross section is as outlined within **Chapter 5, Description of the Proposed Road Development**.

From Ballymoneen Road to the eastern tie in with the existing N6 at Coolagh, Briarhill, the mainline of the proposed road development is a Standard Dual Carriageway Urban Motorway (D2UM) in accordance with TII DMRB DN-GEO-03036. The design speed of the mainline over this area is 100km/h and cross section is as outlined within **Chapter 5, Description of the Proposed Road Development**.

The section of the proposed road development between the N83 Tuam Road and N84 Headford Road Junctions is a 3 lane dual carriageway. The total length of this section is approximately 1,850m.

6.4.2 Selection of Road Type

The appropriate cross section/road type of the proposed road development was determined based on a number of influencing factors which are discussed below.

6.4.2.1 TEN-T Network

As discussed in **Chapter 2, Planning and Policy Context** and **Chapter 3, Need for the Proposed Road Development**, the proposed road development forms part of the Trans European Transport Network (TEN-T) Comprehensive Network which has implications on the choice of cross-section as set out below.

The TEN-T requires that all roads that form part of the network, as a minimum, be a high quality road. Regulation (EU) No 1315/2013 sets out the requirements for high quality roads that shall form part of the network, both Core and Comprehensive, and states under Article 17(3), the following:

"High-quality roads shall be specially designed and built for motor traffic, and shall be either motorways, express roads or conventional strategic roads."

6.4.3 Incremental Assessment

An incremental assessment was undertaken to determine the carriageway cross section, design speed and the extent of the proposed road development. The objective of this assessment was to examine the alternative cross sections available, alternative design speeds and alternative scheme extents in order to determine the most suitable combination.

The incremental assessment identified the following as the most suitable combination for the proposed road development:

- Single carriageway with a design speed of 85km/h from the R336 to Ballymoneen Road
- Type 1 dual carriageway with a design speed of 100km/h from Ballymoneen Road to the N59 Junction
- Urban motorway with a design speed of 100km/h from N59 Junction to the existing N6. It has been determined that the section of the proposed road development between the N84 Headford Road and N83 Tuam Road is to be 3 lanes in each direction, the remaining sections are 2 lanes in each direction

This combination was selected as the most suitable for the following reasons:

- It provides a high level of provision for the transportation infrastructure in Galway City and environs
- The combination complies with the TEN-T regulations noted as it allows access to be restricted to junctions only
- The combination can accommodate the forecast traffic volumes for the Design Year

6.4.3.1 Junction Strategy

The objectives considered in determining the junction strategy include the following:

- Restriction of access to junctions as the proposed road development is of strategic importance and part of the TEN-T Comprehensive Network
- Connectivity to National and Regional road network
- Serve existing travel demand by all modes
- Junctions located so as to relieve traffic congestion
- Sufficient junctions to provide a minimum level of accessibility to the region to support further economic, social and territorial development
- Junction form to deliver capacity as experience has shown that the network breaks down due to junction failure due to capacity problems

- Promote a mobility that is efficient and safe

The junction strategy of the proposed road development has been designed to meet these objectives. The strategy meets the objectives for the following reasons:

- Provides a high quality road with limited access in accordance with TEN-T designation
- Provides connectivity to the national roads via junctions to maximise the transfer of cross-city movements to the new road infrastructure, thus releasing and freeing the existing city centre zone from congestion caused by traffic trying to access a city centre bridge to cross the River Corrib
- Improves connectivity to the Western Region i.e. the county areas and hinterland beyond the city zone
- Caters for the strong demand between zones on either side of the city
- Facilitates crossing the River Corrib without negotiating the city centre
- Provides this additional river crossing with connectivity back to the city either side of the River Corrib Bridge and provides essential city street links to better distribute traffic
- Attracts traffic from the city centre zone thus facilitating reallocation of road space to public transport leading to improve journey time reliability for public transport, supporting a mobility that is efficient and safer environment for active modes
- Facilitates improved city centre environment for all due to reduced congestion, thus encouraging walking and cycling as safe transport modes

6.4.4 Future Transportation Network

6.4.4.1 Future Highway Network

The future year highway networks include the 2012 base network plus all of the schemes that are already built, are committed, or are likely to be built by 2024 and 2039 (Opening and Design Years). The list of schemes to be included was developed in coordination with Galway City Council, Galway County Council, the NTA and TII.

The complete list of road schemes included in the future year networks is available in the Traffic Modelling Report (**Appendix A.6.1**). Some of the key network upgrades included are:

- Kirwan Roundabout Upgrade
- Browne Roundabout Upgrade
- M17/M18 Gort to Tuam Motorway
- Various other junction improvements and reconfigurations throughout Galway City

6.4.4.2 Future Alternative Modes

As mentioned previously, Galway County Council, Galway City Council, and the National Transport Authority (NTA) worked collaboratively in developing an integrated transport strategy to resolve the existing transportation issues in Galway City and its environs. The transportation solution developed includes a smart mobility component, public transport and active mode component and a road component and is known as the Galway Transport Strategy. The Galway Transport Strategy (GTS) aims to address the current and future transport requirements of the city and its connectivity to surrounding towns and villages, including Bearna, Oranmore, Moycullen and Claregalway.

The GTS, which has been adopted by both Galway City and County Councils, sets out a series of actions and measures, covering infrastructural, operational and policy elements to be implemented in Galway over the next 20 years and sets out a framework to deliver the projects in a phased manner. It identifies that Galway has a transport problem due to its reliance on the private car, which has been influenced by the existing public transport network, limited cycling facilities, a large rural hinterland and being the key gateway in and out of Connemara. Combined with this, it has a road and street network which is ill-suited to the high traffic flows currently prevalent and contributing to increased congestion and delay, affecting quality of life and impacting on the functionality of the city. To address this, a fundamental shift is needed towards sustainable travel, reducing the dependency on the private car and taking action to make Galway more accessible and connected, enhancing quality of life within the city for all. Galway City Council are seeking to make Galway an exemplar of Smarter Travel in Ireland. The proposed road development forms part of the GTS as the main road component of the overall transport solution for Galway City and its environs.

The GTS outlines a host of proposed measures for active travel, public transport and general traffic in Galway, to be implemented over a 20-year period. Some of the key proposals included in the Strategy are listed below:

- A Public Transport Corridor through the City Centre with Public Transport Only allowed on the Salmon Weir Bridge, Eglington Street and College Road
- Localised City Centre Traffic Management Proposals
- An outer orbital route (proposed road development) to enhance resilience of the GTS
- Rationalise Bus Route network and increase service frequencies
- Provision for Park and Ride

A full list of the proposals is contained within the GTS Report, “Galway Transport Strategy, An Integrated Transport Management Programme for Galway City and Environs, September 2016”.

6.5 Assessment of Proposed Road Development using Traffic Model

6.5.1 Travel Demand Forecasts

As mentioned previously, the future year traffic forecasts for the proposed road development were developed in accordance with TII project appraisal guidelines and use demographic forecasts from the National Traffic Model (NTM), the National Transport Authority planning unit and Galway City and County Councils.

The following forecast scenarios were agreed, with TII and Galway City and County Council, for use on this project:

- Low: NTA Reference Case - These are based on M2F2 Traditional (Scenario 1). The traditional scenario follows the Central Statistics Office (CSO) moderate path of seeing a return towards the 1996 patterns of inter-regional migration (specifically). The population in the West increases at a moderate pace of natural growth in line with the measured outflow of migrants (net) elsewhere
- Medium: TII National Model Medium Growth Scenario
- High: TII National Model High Growth Scenario

For the medium and high growth scenarios, TII population and employment forecasts were taken at an Electoral Division (ED) level (smallest available) and distributed among the Census Small Areas and model zones based on a combination of the existing distribution and NTAs forecast distributions.

In the case of the Low Growth Scenario, the NTA applied a top-down approach to distribute the population forecasts across the census small areas (CSAs) within the WRM.

An assumption was made that the overall growth in employment would be in line with the population growth. This methodology is consistent with the approach adopted in the demographic forecasts for the TII National Transport Model.

6.5.2 Assessment Years

In addition to the Base Year (2012), two assessment years were modelled, these were 2024 and 2039. 2024 was chosen as the proposed Opening Year of the proposed road development. As per TII Traffic and Transport Guidelines, the proposed road development must also be assessed for a future year of 15 years after the first year of operation, and therefore 2039 is chosen on this basis.

For each of the modelled years, the road network and travel demand included in the traffic model reflects the projected infrastructure and population growth scheduled to be in place at that particular stage.

Two business as usual scenarios (i.e. ‘no road development’) entitled Do Minimum 2024 and Do Minimum 2039 are used to represent the base situation against which other scenarios are compared. This comparison demonstrates the impact of the proposed road development, when compared to a scenario without the proposed development in place. The two ‘development’ scenarios are entitled Do Something 2024 and Do Something 2039.

6.5.3 Scenarios Tested

6.5.3.1 Modelled Scenarios

Core Tests

As previously described, the future year ‘Do-Minimum’ network includes the 2012 base network plus all of the schemes (road and public transport) that are already built, or are committed, or likely to be built by 2024 and 2039.

The future year ‘Do-Something’ networks include the Do-Minimum schemes plus the proposed road development. In addition to the validated 2012 Base Year network, the following future year networks have been developed and tested using the Medium Growth Travel Demand Forecasts:

- 2024 Opening Year Do-Minimum
- 2024 Opening Year Do-Something
- 2039 Design Year Do-Minimum
- 2039 Design Year Do-Something

Galway Transport Strategy

In addition to the Core Scenarios tested (listed above) a further test has also been carried out to assess the performance of the proposed road development in conjunction with all of the active travel, public transport and road infrastructure proposals included in the Galway Transport Strategy. As the GTS is a 20-year strategy, this sensitivity test has only been carried out in 2039, Design Year.

6.5.3.2 Low and High Growth Sensitivity Tests

Each of the scenarios listed above have been assessed further utilising the Low and High growth travel demand forecasts which have been described in **Section 6.5.1**.

6.6 Traffic Impact Assessment

6.6.1 Identification and Scale of impacts

The impact assessment process introduced in **Section 6.2.3** is used to identify and measure potential traffic impacts generated by the proposed road development. 'Do Minimum' scenarios, i.e. without the proposed road development, are compared to 'Do Something' scenarios, i.e. with the proposed road development in place. Construction impacts associated with constructing the proposed road development etc. will also be assessed.

The 'Do Minimum' and 'Do Something' scenarios are compared for the same year, i.e. 2024 or 2039, and therefore, other than the proposed road development, the same infrastructure is assumed for the scenarios which are being compared.

To recap, and as discussed previously in **Section 6.2.3**, three Key Performance Indicators (KPI) have been identified which will assist in the assessment and evaluation process which will determine the traffic impact of the proposed road development on these roads during peak hours. The three KPIs are:

- **Journey times** on key routes – to understand strategic impacts
- **Network Statistics** – Network wide indicators of congestion and delay
- **Ratio of Flow to Capacity (RFC)** at Key Junctions – to understand local impacts, congestion and queues

Using these KPIs, the traffic impacts of the proposed road development is assessed at both a strategic and local level.

6.6.1.1 Journey Times

To develop an understanding of the potential impact of the proposed road development on key routes serving Galway City and its environs, the projected change in vehicular journey times were assessed. Journey times represent a good basis for strategic traffic impact assessment as they provide a mechanism to quantify the traffic impact along a full route. This KPI is based on a comparison between the 'Do-Minimum' journey times (i.e. without the proposed road development) and the 'Do-Something' journey times (i.e. with the proposed road development). Both the percentage change and absolute change in journey times (seconds) is considered in order to determine the impact, as shown in **Table 6.4** below.

The journey time routes used for the assessment of impact are shown in **Plate 6.7**. This KPI, therefore, assesses the strategic traffic impact of the proposed road development.

The impact scale used for journey times has been developed using the 2011 Census travel statistics for Galway and locally based traffic survey information. These CSO Census 2011 statistics state that the majority of journeys to work (62%) in Galway County took under 30 minutes and only 15% of workers faced a commuting time in excess of 45 minutes.

Table 6.4: Representation of Negative Impact on Vehicle Journey Times

		Absolute Difference (seconds)			
		<60	60-120	120-240	>240
% Change	<5%	Negligible	Negligible	Minor	Moderate
	5-10%	Negligible	Minor	Moderate	Moderate
	10-20%	Minor	Minor	Moderate	Major
	>20%	Minor	Moderate	Major	Major

A Green Box would indicate a positive impact between the Do-Minimum and Do-Something Scenario

Plate 6.7: Journey Time Routes

Table 6.4 is interpreted as follows - the impact is considered “Major” if the change in journey time, when comparing the ‘Do-Minimum’ and ‘Do-Something’ scenarios, is greater than 240 seconds and the percentage change is greater than 10% or the time increase is between 120 – 240 seconds and percentage change is greater than 20%.

In situations where the journey times decrease, i.e. the change in journeys time when comparing the ‘Do-Minimum’ to the ‘Do-Something’ scenarios is negative, this impact is described as ‘Positive’.

Journey times on key routes have been considered in order to determine the traffic impacts on the strategic road network.

The results from this analysis are presented in **Section 6.6.3**.

6.6.1.2 Network Statistics

To further quantify the impact of the proposed road development on the strategic road network the model network statistics are assessed. These statistics provide information on the following parameters (averaged across the entire city network):

- Average Speed – Measured in kilometres per hour (kph)
- Average Delay – Measured in total delay for all vehicles
- Total Network Travel Time – Measures in total travel time for all vehicles
- Total Vehicle Distance Travelled – Measured in total kilometres for all vehicles

This KPI therefore presents an indication of the overall performance of the model network for a given scenario.

As there are several related parameters to consider for this criterion, and in order to avoid confusion, this KPI is measured in absolute terms. i.e. there is either a positive or negative impact on overall network statistics.

This analysis is presented at **Section 6.6.3**.

6.6.1.3 Ratio of Flow to Capacity at Key Junctions

To further understand the potential impact on junction operations of the proposed road development, the Ratio (of traffic flow) over capacity (RFC) at key junctions along the existing N6 corridor have been analysed and compared across scenarios.

RFC is a standard reference for measuring traffic congestion at a junction. It is standard practice to consider that a junction is congested when traffic flows are at 85% of the estimated capacity of a priority junction, or 90% of a signalised junction. At traffic flows above 90% of capacity the delays at a junction become erratic and are difficult to control. A value of 100% means that demand and capacity are equal and no further traffic can progress through the junction without experiencing delays.

A Ratio of Flow to Capacity analysis has been undertaken using information from the proposed road development Highway Network models for each modelling scenario. This analysis considered all approaches to key junctions along the N6/R338 corridor, illustrated in **Plate 6.8** below.

The models were also used to produce an overall summary of the number of links, in the entire network, operating at 90% capacity or above in each scenario.

Plate 6.8: N6/R338 Key Junctions

The scale of the impact is based on the threshold values described above and it is the change in these values arising from the impact of the proposed road development (Do Something) which indicates the extent of localised impact at the junctions assessed. – **Table 6.5**, below, refers to roundabouts and other priority junctions and **Table 6.6** refers to signalised junctions and summarises how the change in the value of these parameters indicates the performance impact.

Table 6.5: Impact on RFC at Key Junctions (Roundabout)

RFC	**Do Something**			
Do Minimum	<75%	75-85%	85-90%	>90%
<75%	Negligible	Moderate	Major	Major
75-85%	Positive	Minor	Moderate	Major
85-90%	Positive	Positive	Minor	Major
>90%	Positive	Positive	Positive	Minor

It is assumed that if a roundabout is currently operating well within capacity (e.g. <75%) and the additional traffic associated with the proposed road development causes the junction to be congested (i.e. over 85%) there is a traffic impact of major significance. Conversely if the junction currently has congestion issues (e.g. 85-90%) and the traffic from the proposed road development causes an increase in congestion, but within the same parameter value band (i.e. 85-90%) the impact of the proposed road development is considered to be of minor significance.

Table 6.6: Impact on RFC at Key Junctions (Signalised)

RFC	Do Something			
Do Minimum	<80%	80-90%	90-95%	>95%
<80%	Negligible	Moderate	Major	Major
80-90%	Positive	Minor	Moderate	Major
90-95%	Positive	Positive	Minor	Major
>95%	Positive	Positive	Positive	Minor

It is assumed that if a signalised junction is currently operating well within capacity (e.g. <80%) and the additional traffic associated with the proposed road development causes the junction to be congested (i.e. over 90%) the traffic impact is of major significance. However, if the junction currently has congestion issues (e.g. 90-95%) and the traffic from the proposed road development causes an increase in congestion, but within the same parameter value band (i.e. 90-95%) the impact on junction performance is considered to be minor significance, i.e. little change – still congested.

6.6.2 Rating Impacts

The impact of the proposed road development under each scenario is rated using the assessment KPI framework detailed above as follows:

- **Step 1:** The relative changes between the 'Do-Minimum' and 'Do-Something' scenarios are categorised as positive, negligible, minor, moderate or major (as above)
- **Step 2:** The likelihood of the negative impacts occurring are rated as either low, medium or high
- **Step 3:** The duration of negative impacts is rated as short, medium or long term. As per EPA guidelines, short-term equates to 1-7 years, medium term is between 7 and 15 years and long term is between 15 and 60 years

This method of rating impacts allows the 'Do-Minimum' and 'Do-Something' scenarios to be compared in a clear, concise and measurable way.

6.6.3 Significance of Impact Assessment

The results of the strategic and local traffic impacts for each scenario are described under each KPI below. In summary, the scenarios compared are:

- 2024 Opening Year Do-Minimum
- 2024 Opening Year Do-Something
- 2039 Design Year Do-Minimum
- 2039 Design Year Do-Something
- 2039 Design Year – Do GTS

The results presented in this section refer to the Medium Growth Forecasts only. The evaluation of Low and High growth sensitivity tests are summarised within **Section 6.7**.

6.6.3.1 Journey Time Analysis

Core Scenarios

The tables below detail the results of the journey time comparison as extracted from the 2024 and 2039 traffic models for the Core Scenarios. **Plate 6.7**, above illustrates each of the journey time routes which have been analysed.

Table 6.7: 2024 AM Peak Journey Time Results

Route Description	2024 DM Seconds	2024 DM Minutes	2024 DS Seconds	2024 DS Minutes	Diff (Seconds)	% Difference
Route 1 – Inbound	1050	17.5	778	13.0	-272	-25.9%

Route 11 – Outbound	1325	22.1	1023	17.1	-302	-22.8%

The 2024 AM Peak results above show that, in general, the opening of the proposed road development has a significant positive impact on the majority of Journey Time routes analysed.

A number of routes (2, 3, 6) show negligible impacts, with increases in journey times of less than 60 seconds across the entire route. Route 6 inbound experiences a minor impact, where the journey time has increased by 100 seconds across the entire route. These increases are caused by the addition of signalised junctions, for example the N59 Link Road Junctions, which require traffic to slow down where previously it was not necessary.

In this regard it should be noted that the impact of the proposed road development is hugely beneficial for reducing traffic congestion in Galway City in the AM Peak and for reducing journey times.

The 2024 PM Peak results show that, similar to the AM peak, the opening of the proposed road development has a significantly positive impact on the majority of Journey Time routes analysed.

As with the AM peak number of routes show negligible or minor impacts, with relatively small (less than 2 minute) increases across the entire route. These increases are as a result of new signalised junctions, related to the proposed road development, requiring traffic to slow down where previously it was not necessary.

The introduction of the proposed road development reduces traffic congestion and average journey times in Galway City in the PM Peak.

Journey time results for the inter peak periods demonstrate the same pattern as the AM and PM peaks, with positive impacts seen across the majority of routes analysed. Any increases in journey times are negligible in nature.

Table 6.11: 2039 AM Peak Journey Time Results

The 2039 results show a similar pattern to the 2024 results discussed previously. In general, the opening of the proposed road development has a significantly positive impact on the majority of Journey Time routes analysed in all 2039 modelled periods for the Core Scenarios.

A small number of routes show negligible or minor impacts, with increases in journey times of less than 120 seconds across the entire route. These increases are caused by the addition of new signalised junctions, requiring traffic to slow down where previously it was not necessary.

GTS Sensitivity Test

The tables below outline the results of the journey time comparison as extracted from the traffic model for the 2039 Galway Transport Strategy Sensitivity Test.

These results show a similar pattern to the Core Scenario tests discussed above. In general, the opening of the proposed road development, in conjunction with the other measures proposed in the GTS, has a positive impact on the majority of Journey Time routes analysed, particularly in the AM and PM peak periods.

The results below show more negative impacts on journey times than the DS Core Scenario tests. The reason for this is that the GTS contains a number of proposals which limit vehicular capacity on the city centre network, as a result of increased active mode and public transport priority measures in the city centre, and therefore adds delay to certain sections of the network. Also, traffic management arrangements proposed in the GTS result in the lengthening of some journey time routes which in turn adds to the total journey times.

6.6.3.2 Network Statistics (2024 and 2039)

The tables below present Network Statistics from each modelled time-period for all medium growth scenarios.

Table 6.19: Network Performance Indicators – Morning Peak Hour

Scenario	Total Vehicle Distance (pcu. Kms)	Total Network Travel Time (pcu. Hrs)	Total Network Delay (pcu. Hrs)	Average Vehicle Speed (kph)	Impact
2024 Do-Minimum	223,666	7,576	2,274	29.5	-
2024 Do-Something	258,719	6,798	1,505	38.1	Positive
2039 Do-Minimum	247,788	8,619	2,812	28.7	-
2039 Do-Something	294,178	7,611	1,738	38.7	Positive
2039 Galway Strategy	294,497	7,756	1,810	38	Positive

Table 6.20: Network Performance Indicators – IP 1

Scenario	Total Vehicle Distance (pcu. Kms)	Total Network Travel Time (pcu. Hrs)	Total Network Delay (pcu. Hrs)	Average Vehicle Speed (kph)	Impact
2024 Do-Minimum	148,147	4,321	920	34.3	-
2024 Do-Something	163,308	4,144	767	39.4	Positive
2039 Do-Minimum	171,081	5,039	1,171	33.9	-
2039 Do-Something	190,786	4,750	916	40.2	Positive
2039 Galway Strategy	192,388	4,932	1,009	39	Positive

Table 6.21: Network Performance Indicators – IP 2

Scenario	Total Vehicle Distance (pcu. Kms)	Total Network Travel Time (pcu. Hrs)	Total Network Delay (pcu. Hrs)	Average Vehicle Speed (kph)	Impact
2024 Do-Minimum	173,045	5,164	1,124	33.5	-
2024 Do-Something	192,752	5,023	980	38.4	Positive
2039 Do-Minimum	196,764	5,929	1,403	33.2	-
2039 Do-Something	223,715	5,731	1,189	39	Positive
2039 Galway Strategy	224,131	5,910	1,292	37.9	Positive

Table 6.22: Network Performance Indicators – Evening peak Hour

Scenario	Total Vehicle Distance (pcu. Kms)	Total Network Travel Time (pcu. Hrs)	Total Network Delay (pcu. Hrs)	Average Vehicle Speed (kph)	Impact
2024 Do-Minimum	206,659	6,669	1,824	31	-
2024 Do-Something	233,756	6,135	1,318	38.1	Positive
2039 Do-Minimum	230,010	7,774	2,453	29.6	-
2039 Do-Something	264,746	6,919	1,593	38.3	Positive
2039 Galway Strategy	266,632	7,128	1,720	37.4	Positive

The tables above demonstrate that the Do-Something (with proposed road development) option reduces the network delay considerably relative to the Do-Minimum, and provides a higher average speed in all time periods in both the Opening and Design Year. The reduction in delay allows traffic to travel further in a shorter period of time, which is illustrated in the increase in vehicle Km's and decrease in Total Travel time in all Do-Something Scenarios.

Analysis of the Galway Transport Strategy (GTS) scenario results indicate an increased level of delay and slightly lower average speeds compared to the "Do-Something" scenario of the same year. This increase in vehicular delay is caused by the proposed implementation of a number of active mode and public transport priority proposals contained within the GTS (e.g. converting the Salmon Weir Bridge to Public Transport Only) which result in decreased highway capacity for general vehicular traffic in Galway City Centre, which is in line with the objectives of the GTS. The level of network delay observed in this scenario is much lower than in the Do-Minimum Scenario of the same year. As with the Core Scenarios this is a result of the proposed road development relieving congestion in the City Centre.

This analysis indicates that the proposed road development will have a significantly positive impact in both Opening and Design Years.

Core Scenarios

The tables below summarise the junction evaluations for the 2024 and 2039 - Medium Growth Scenarios.

Table 6.23: Number of Junction approaches at or over capacity - AM Peak

		2024			2039		
		DM	**DS**	**Impact**	**DM**	**DS**	**Impact**
Key Junctions (N6 / R338)	RFC > 90%	15	9	Positive	18	12	Positive
Entire Network	RFC > 90%	151	78	Positive	200	115	Positive

Table 6.24: Number of Junction approaches at or over capacity - IP 1

		2024			2039		
		DM	**DS**	**Impact**	**DM**	**DS**	**Impact**
Key Junctions (N6 / R338)	RFC > 90%	6	2	Positive	9	5	Positive
Entire Network	RFC > 90%	28	12	Positive	60	26	Positive

Table 6.25: Number of Junction approaches at or over capacity - IP 2

		2024			2039		
		DM	**DS**	**Impact**	**DM**	**DS**	**Impact**
Key Junctions (N6 / R338)	RFC > 90%	8	4	Positive	11	5	Positive
Entire Network	RFC > 90%	53	29	Positive	81	49	Positive

Table 6.26: Number of Junction approaches at or over capacity - PM Peak

		2024			2039		
		DM	**DS**	**Impact**	**DM**	**DS**	**Impact**
Key Junctions (N6 / R338)	RFC > 90%	17	4	Positive	20	6	Positive
Entire Network	RFC > 90%	139	62	Positive	193	100	Positive

The above tables show that with the introduction of the proposed road development there is a large decrease in the number of links in the network which have an RFC of over 90%. This is particularly evident in the PM peak period where the number of over-capacity links, at key junctions along the N6/ R338 Corridor, reduces by over 70% in both 2024 and 2039. Similarly, the number of over-capacity links on the entire city network is reduced by 55% and 48% in 2024 and 2039, respectively, as a result of the introduction of the proposed road development.

GTS Sensitivity Test

The tables below summarise the junction evaluations for the 2039 - Medium Growth – Galway Transport Strategy (GTS).

Table 6.27: Number of Junction approaches at or over capacity - AM Peak

		2024			2039		
		DM	GTS	Impact	DM	GTS	Impact
Key Junctions (N6 / R338)	RFC > 90%	N/A	N/A	Positive	18	8	Positive
Entire Network	RFC > 90%	N/A	N/A	Positive	200	131	Positive

Table 6.28: Number of Junction approaches at or over capacity - IP 1

		2024			2039		
		DM	GTS	Impact	DM	GTS	Impact
Key Junctions (N6 / R338)	RFC > 90%	N/A	N/A	Positive	9	2	Positive
Entire Network	RFC > 90%	N/A	N/A	Positive	60	32	Positive

Table 6.29: Number of Junction approaches at or over capacity - IP 2

		2024			**2039**		
		DM	GTS	Impact	DM	GTS	Impact
Key Junctions (N6 / R338)	RFC > 90%	N/A	N/A	Positive	11	3	Positive
Entire Network	RFC > 90%	N/A	N/A	Positive	81	52	Positive

Table 6.30: Number of Junction approaches at or over capacity - PM Peak

		2024			**2039**		
		DM	GTS	Impact	DM	GTS	Impact
Key Junctions (N6 / R338)	RFC > 90%	N/A	N/A	Positive	20	6	Positive
Entire Network	RFC > 90%	N/A	N/A	Positive	193	123	Positive

The above tables show that, as with the Core Scenarios, the introduction of the Galway Transport Strategy proposals results in a decrease in the number of junctions operating above capacity within the entire city area and along the N6/R338 corridor.

In summary, the RFC analysis has shown that the introduction of the proposed road development will have a considerably positive impact on the key junctions in Galway City.

6.6.4 Assessment of Impact Significance

6.6.4.1 Impact Significance 2024

In 2024 the proposed road development does not result in any traffic impacts of major significance. In terms of the three key performance indicators used, the impact of the proposed road development is rated as having a positive impact.

6.6.4.2 Impact Significance 2039

In 2024 the proposed road development does not result in any traffic impacts of major significance. In terms of the three key performance indicators used, the impact of the proposed road development is rated as having a positive impact.

6.6.5 Construction Impacts

Construction traffic impacts, and associated mitigation measures, of the proposed road development are considered in detail in **Chapter 7, Construction Activities**.

Construction of the proposed road development will add additional traffic to the local networks for the duration of the construction works, as a result of materials supply and disposal, movement of site equipment and travel demand from site workers and visitors. The likelihood of these impacts are high but will be short-term in nature. Dedicated haulage routes were identified and are outlined in **Chapter 7, Construction Activities**.

Existing traffic movements on the local and regional road network will generally not be restricted by the proposed construction works. The proposed road development will ensure the minimum possible disturbance to local residents and existing traffic.

Night time working will be generally avoided, however, it will be necessary to work night shifts during certain critical stages during the project, such as for bridge works and road tie-in points. It is anticipated that, over the expected 36 month construction phase, there will be 10 weeks of night time working.

Existing cyclist and pedestrian movements will be facilitated throughout the construction period.

During construction, detailed traffic management plans in accordance with the mitigation measures and environmental measures set out in the EIAR and incorporating any specific additional requirements of statutory authorities and any conditions imposed by An Bord Pleanála, will clearly set out any temporary traffic restrictions.

6.6.6 Cumulative Impacts

6.6.6.1 Transport Schemes

As detailed in **Sections 6.4**, all core modelling scenarios (Do-Minimum and Do-Something) have taken into account committed transport schemes for Galway City and its environs and those likely to be completed for the various years assessed. The Galway Transport Strategy (GTS) sensitivity test, further analyses the cumulative impacts of complementary transport schemes by assessing the impacts of the proposed road development in conjunction with all of the Public Transport and Active Mode proposals contained within the GTS.

6.6.6.2 Transport Demand

Cumulative traffic volumes have been included in the analysis contained within this chapter through the use of travel demand forecasting. The proposed road development has been assessed in conjunction with three different travel demand scenarios (Low, Medium and High) designed to allow for a robust assessment of traffic growth in Galway over time resulting from increases in population and economic activity.

Further details on the cumulative impacts of traffic flows are detailed within **Chapter 16, Air Quality and Climate**, **Chapter 17, Noise and Vibration**, **Chapter 18, Human Beings, Population and Human Health** and **Chapter 19, Inter Relationships, Interactions, Cumulative Impacts and Other Impacts**.

6.6.6.3 Growth Forecast Sensitivity Tests

This section considers the potential implications on traffic impacts and mitigation requirements of variations in Growth Forecasts (i.e. from those assumed in the Core tests described above). This is done by way of sensitivity testing using the WRM and proposed road development Highway Network Models.

The sensitivity tests are listed below, whilst noting the definition of the basis of the Low and High growth is set out in **Section 6.2.3.2**:

- **Sensitivity Test 1:** 2024 & 2039 Low Growth Forecasts
- **Sensitivity Test 2:** 2024 & 2039 High Growth Forecasts

Sensitivity Test Impact Summary

In summary, there are no traffic impacts of major significance in either of the Low or High Growth Scenarios tested. As with the medium growth scenarios (discussed above) the proposed road development results in some negligible and minor impacts in terms of journey times due to the introduction of signalised junctions. However, the traffic impacts are positive and no mitigation measures are required.

6.7 Mitigation Measures

6.7.1 Construction Phase

As noted, the construction of the proposed road development will cause temporary short term traffic impacts on the local road network. The Construction Environmental Management Plan, included in **Appendix A.7.5** of this report, shall ensure that construction traffic impacts are minimised through the control of site access/ egress routes and site access locations.

6.7.2 Operational Phase

In summary, the traffic modelling indicates that for the Opening (2024) and Design (2039) Years there are no traffic impacts of major significance and therefore no mitigation measures are required.

However, as the proposed road development is a TEN-T route, which is required to cater for strategically important trips at an appropriate level of service, it will be important to protect the operating capacity of the proposed road development well into the future. To do this, measures to manage demand on the transport infrastructure, such as the integration of transport and land use planning, are considered within the development of the Galway Transport Strategy.

6.8 Residual Impacts

6.8.1 Construction Phase

With the implementation of the mitigation measures that have been identified, there will be no major impacts during the construction phase of the proposed road development.

6.8.2 Operational Phase

The proposed road development will see changes to the local, regional and national road network and traffic flows. The modelling work undertaken to assess the traffic impacts of the proposed road development indicates that there will be an overall positive traffic benefit associated with the proposed road development. Further, the proposed road development will provide benefits to existing and new public transport services and walking and cycling routes on the adjoining local and regional road network and other measures proposed by the Galway Transport Strategy.

Therefore, there are no residual negative traffic impacts anticipated.

6.8.3 Forecast Traffic Flows

6.8.3.1 AADT Forecasts

AADT estimates have been calculated using the N6 GCRR Traffic Model and in accordance with TII PAG Guidelines. To further demonstrate the benefits of the proposed road development and to help quantify the level of traffic redistribution which will occur as a result of the proposed road development, forecast traffic flows for the medium growth scenario are presented in this section.

Plate 6.9 illustrates the location of AADT points with corresponding AADT values shown in **Table 6.31**. A complete set of AADT data, including forecast flows for all sensitivity tests (Low, Medium, High) and further details on the methodology used to calculate AADTs, is available in the Traffic Modelling Report contained within **Appendix A.6.1**.

Table 6.31 illustrates that, in the 2039 medium growth scenario, there is significant demand for the proposed road development with AADTs in excess of 49,000 forecast for certain sections. This table also shows that traffic in the city centre is reduced as a result of the introduction of the proposed road development, as evidenced by the reduction in AADTs on Quincentenary Bridge (29% reduction).

Plate 6.9: Proposed Road Development AADT Locations

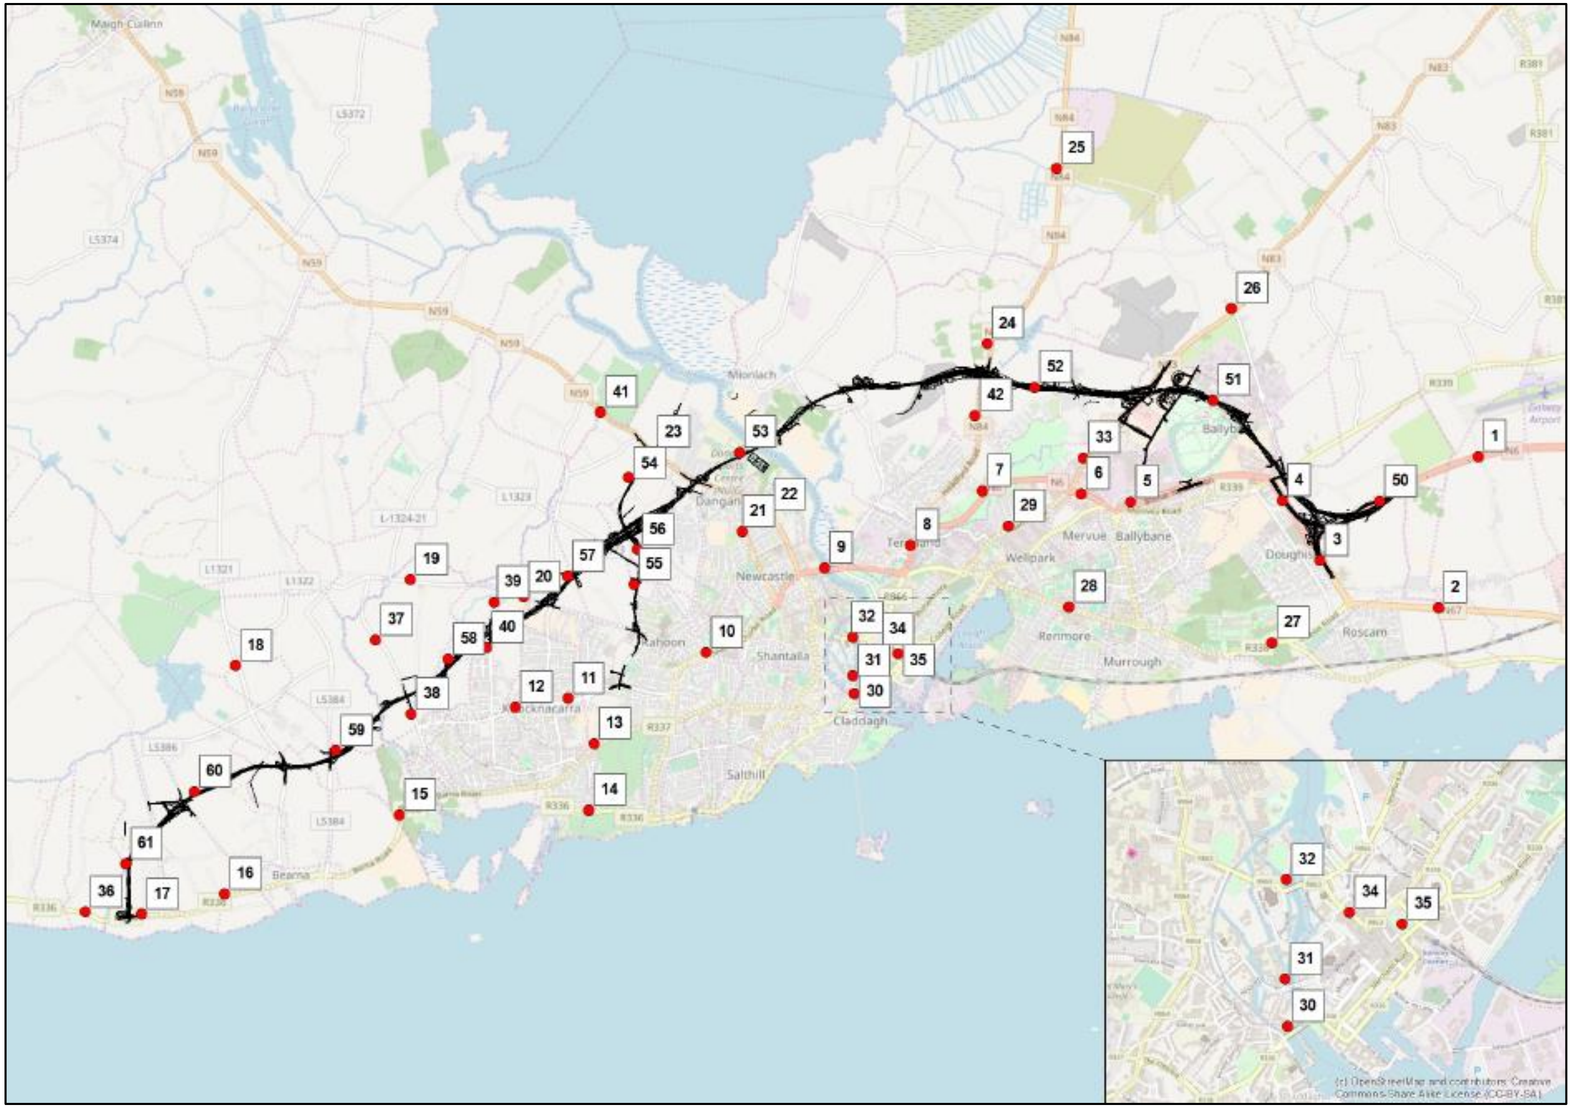

Table 6.31: Proposed Road Development AADT 2039 Design Year – Medium Growth

AADT Point	Location	2039 Do-Minimum Medium Growth		2039 GTS Medium Growth	
		AADT	%HGV	AADT	%HGV
1	N6 South of Galway Airport	23,382	8%	36,008	6%

6.8.3.2 Trip Redistribution and Overcapacity Demand

Induced traffic is the concept that car traffic grows to fill the available capacity of a road network.

The traffic modelling undertaken takes account of induced travel demand to varying degrees. The modelling results consider the redistribution effect of trips due to the introduction of new infrastructure and services (i.e. trip patterns changing because of lower costs of travel). It also takes account of re-routing of trips as a result of the provision of additional capacity on the network. The mode shift of trips from active modes and public transport to car (and vice versa) is also taken into account in the modelling results.

Induced development, is the phenomenon whereby new development is concentrated in the vicinity of high capacity transport corridors. The modelling undertaken for the proposed road development, takes account of forecast growth in the region as set out in local and regional plans (for low, medium and high growth scenarios), but does not include for the redistribution of growth that may occur along the corridor of the proposed road development.

It has been assumed that the forecast population and employment figures, and hence overall travel demand, will be the same in both the Do-Minimum and Do-Something Scenarios. These demographic forecasts have been agreed by Galway City and County Council and are based on the development plans for these areas which will not change with the opening of the proposed road development.

It is the role of the Planning Authorities to ensure that any development which could undermine the strategic function of the proposed road development will be appropriately mitigated. This may include the implementation of demand management measures to maintain the capacity and strategic function of the proposed road development.

Examination of the Do-Minimum and Do-Something traffic totals on the crossings of the River Corrib indicate that the proposed road development will lead to an increase of circa 19,000 AADT in 2039. It is important to highlight the fact that this increase is caused primarily by two factors:

1. The **redistribution of trips** with the opening of the proposed road development
2. **Release of overcapacity demand**[4] caused by congestion on the existing River Corrib crossings in the Do-Minimum network

Trip Redistribution

The introduction of the proposed road development reduces congestion on the River Corrib crossings leading to decreases in journey times from east to west across Galway City. The decrease in travel costs for these movements will result in a change in peoples living and working patterns in the city and its environs (e.g.

[4] Overcapacity demand refers to the difference between the desired trips and the actual trips undertaken.

potentially longer commuting patterns). This redistribution of trips contributes to the increase in cross city traffic described above.

Overcapacity Demand

In the Do-Minimum scenario, traffic congestion is at such a level that not all the trips which desire to cross the city (i.e. demand flow) can reach the River Corrib crossings in the assigned model periods. As actual flows (i.e. actual flows on the River Corrib crossing) are used to calculate the forecast AADT figures, the difference between demand flow and actual flow (which is known as the overcapacity demand) is not accounted for in the Do-minimum AADT figures. In the Do-something scenarios, demand flow and actual flows are closely aligned and therefore no overcapacity demand exists.

6.8.3.3 Galway Transport Strategy Forecasts

As outlined in **Section 6.4.3.2**, Galway County Council, Galway City Council, and the National Transport Authority have worked collaboratively in developing a multi-modal integrated transport strategy to resolve the existing transportation issues in Galway City and its environs. As a critical component of the overall transport solution for Galway, the proposed road development releases capacity in the city centre transport network and facilitates the implementation of key public transport and active mode proposals such as:

- A public transport corridor through the city centre with public transport only allowed on the Salmon Weir Bridge, Eglington Street, College Road and Eyre Square
- Localised City Centre Traffic Management proposals
- Rationalised Bus Route network with increase services and bus priority
- Improved Cycle Network

These measures in turn will result in an increase in sustainable travel and improvements to pedestrian safety throughout the city centre.

Table 6.32 below presents the mode share between private vehicle, public transport, walking and cycling for the 2012 Base Year, 2024 Opening Year and 2039 Design Year, extracted from the traffic model for the 24-hour period.

The mode share analysis shows that there is a low public transport mode share of just 4% in the Base Year. As can be seen below, the impact of the Do-Something options on mode share is minimal, with Car Mode share increasing by circa 1% in both 2024 and 2039 as a result of the opening of the proposed road development.

The GTS test increases Public Transport mode share to 5.0%, which is a 16% increase in Public Transport trips relative to the Do-Minimum Scenario.

Table 6.32: Mode Share Percentages

Option	% Car	% PT	% Walk	% Cycle
2012 Base Year	66.7%	3.9%	26.3%	3.1%
2024 Do-Minimum	67.4%	4.2%	25.4%	3.0%
2024 Do-Something	68.4%	4.0%	24.9%	2.7%
2039 Do-Minimum	67.4%	4.3%	25.2%	3.1%
2039 Do-Something	68.6%	4.1%	24.5%	2.8%
2039 GTS	67.3%	5.0%	24.9%	2.8%

Due to the fact that the proposed road development forms a constituent element of the wider reaching Galway Transport Strategy, it is appropriate that the forecast flows in the future year network should be reviewed in the context of the full implementation of the GTS. These flows are outlined in **Table 6.33**. Analysis of these figures indicate that the full implementation of the GTS leads to a smaller increase in traffic crossing the River Corrib in 2039, with total bridge crossings of circa 13,000 higher than the Do-Minimum Scenario. As outlined above, this increase is related to changes in trip distribution and the release of overcapacity demand linked to the opening of the proposed road development.

61	GCRR – North of Terminus			10,566	3%

6.9 Summary

There will be no traffic negative impacts of major significance as a result of the introduction of the proposed road development. The traffic impact analysis carried out in **Section 6.6** shows that the introduction of the proposed road development results in significant benefits in terms of junction operation, network performance and journey time savings. By providing an alternative route around the city, the proposed road development will result in reduced traffic levels and congestion in the City Centre.

The RFC analysis in the peak travel periods shows that the proposed road development leads to almost a 50% reduction in the number of junctions operating at or close to capacity. Similarly, journey times on key routes around, and into, the city are reduced during peak periods because of the introduction of the proposed road development. For example, the existing N6, following the opening of the proposed road development experiences journey time savings of between 40% - 50% during peak periods.

As a constituent element of the Galway Transport Strategy the proposed road development will tackle the city's congestion issues, the proposed road development will provide a better quality of life for the city's inhabitants and provide a much safer environment in which to live. By reducing the number of cars on the roads within the city centre and improving streetscapes, workers and school children are facilitated to commute using active modes and on the public transport system. As a result, more sustainable travel will be supported and encouraged.

In the absence of the proposed road development, traffic conditions in the city centre will continue to deteriorate resulting in a situation whereby crossing the city becomes increasingly difficult. This restricted movement of people will lead to changes to where people live and work over time, with people choosing to live and work on one side of the city or another as the delay experienced travelling across the city becomes too great. This change in travel behaviour, or suppression of trip making, will constrain the economic development of Galway City and its environs. The proposed road development will provide the required capacity for all modes of transport in Galway to support economic growth into the future. Further economic benefits of the proposed road development are detailed within the Phase 3 Cost Benefit Analysis Report (included in **Appendix A.6.2**) which estimates that the Net Present Value of the proposed road development to the local and national economy will be in the region of €1.04bn - €1.46bn, with a benefit to cost ratio of approximately 4:1, over the 30-year assessment period.

7 Construction Activities

7.1 Introduction

This chapter of the EIAR describes the construction activities associated with the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development. It considers how the proposed road development will be constructed, including construction fencing, site clearance, any necessary investigations, import and disposal of materials, drainage and general construction activities for road infrastructure.

This chapter initially sets out the methodology followed in preparing this chapter (**Section 7.2**), describes the receiving environment (**Section 7.3**) and describes the construction activities associated with the proposed road development (**Section 7.4**). The potential construction impacts of the proposed road development are described (**Section 7.5**) and proposed mitigation (**Section 7.6**) and residual impacts are described (**Section 7.7**). The chapter concludes with a summary (**Section 7.8**) and reference section (**Section 7.9**).

This chapter has utilised the information gathered during the constraints and route selection studies for the proposed road development and other assessments made under the headings of soils and geology, material assets non-agriculture, noise and vibration, air quality and climate, human beings, population and health, hydrogeology, hydrology, archaeology, architectural and cultural heritage, landscape and visual for this EIAR. This chapter should be read in conjunction with **Figures 7.001** to **7.002**; **7.101** to **7.124**; **7.201** to **7.202** and **7.301** to **7.302**.

7.2 Methodology

The preparation of this chapter is based on a desk study, site walkovers, ground investigations and on information gathered during consultations with landowners and homeowners, utility and service providers and the public.

A construction workshop was held on 17 November 2016 in the Project Design Office. The purpose of the workshop was to review and assess how the proposed road development would be constructed for the associated environmental assessments. The workshop was attended by various environmental specialists interacting with the design team. The specialists from various different disciplines included ecology, noise & vibration, air quality & climate, landscape & visual, geotechnical and hydrology. An overview of the design of the proposed road development and the key constraints to be considered during construction was presented by the design team. A collaborative discussion was held between the various disciplines to highlight any additional potential constraints and impacts associated with the construction. Further follow up collaboration continued between the various specialists and the design team following this workshop. This ongoing interactive process informed the assessments included in this chapter and other relevant chapters of this report.

The main guidelines used in preparing this chapter are:

- Environmental Protection Agency (EPA) Draft Guidelines on the Information to be contained in Environmental Impact Assessment Reports (EPA, 2017)
- Environmental Protection Agency (EPA) Draft Revised Guidelines on Information to be contained in Environmental Impact Statements (EPA, 2015)
- Environmental Protection Agency (EPA) Draft Advice Notes for Preparing Environmental Impact Statements (EPA, 2015)
- Environmental Protection Agency (EPA) Guidelines on the information to be contained in Environmental Impact Statements (EPA, 2002)
- Environmental Protection Agency (EPA) Advice Notes on current practice in the preparation of EISs (EPA 2003)
- Transport Infrastructure Ireland (TII) guidelines on procedures for assessment and treatment of geology, hydrology and hydrogeology for National Road Schemes (TII, 2009)
- TII Environmental Impact Assessment of National Road Schemes – A Practical Guide (TII, 2008)

7.3 Receiving Environment

The receiving environment is represented by rural lands mixed with the urban fringe of Galway City and includes some built-up suburban development such as that along the N59 Moycullen Road and the N83[1] Tuam Road. The area to the west of the N59 Moycullen Road is underlain with granite and to the east of the N59 Moycullen Road with limestone which needs to be taken into consideration in the reuse of materials during construction. The existing road network which could be used as haulage routes is made up of the National, Regional and Local roads. A description of the proposed haul route network is provided below in **Table 7.4** and shown on **Figures 7.001** and **7.002** and **7.101** to **7.123**. Locations of potential blasting for excavations during construction are shown on **Figures 7.201** and **7.202** and areas proposed for material deposition areas are shown on **Figures 7.301** and **7.302**. A full description of the receiving environment is provided in **Chapter 5, Description of the Proposed Road Development**.

7.4 Construction Activities

7.4.1 Overview

This Section outlines the construction phasing (**Section 7.4.2**), enabling works (**Section 7.4.3**), site preparation and clearance works (**Section 7.4.4**), proposed road closures and diversions (**Section 7.4.5**), potential form of contract **(Section 7.4.6)** main construction activities which for the purposes of this report are divided into sections (**Section 7.4.7**), proposed construction methodologies (**Section 7.4.8**), material sources and transportation including, earthworks quantities, proposed haul routes and construction compounds (**Section 7.4.9**), service and utility diversions (**Section 7.4.10**), employment and welfare (**Section 7.4.8**), construction health and

[1] Formerly known as the N17 Tuam Road

safety (**Section 7.4.12**), commissioning and decommissioning of the construction phase of the proposed road development (**Sections 7.4.13** and **14**).

It is estimated that the overall construction period will last for approximately 36 months. A variety of construction activities will occur simultaneously at a number of locations along the route of the proposed road development, but will be in a phased manner. Construction will be undertaken using internationally accepted methods. Construction of the proposed road development will include activities such as excavation, embankment and structural construction, tunnelling, piling, rock breaking and movement of materials within the fenced off working area. This will generate noise, dust and movement of machinery which will potentially impact on the surrounding environment. A series of best practice mitigation measures described in the relevant chapters of this EIAR will be incorporated during the construction phase to ensure that strict limit values set to avoid significant impacts will not be exceeded at sensitive locations.

A strategy for construction has been developed with the aim of minimising potential environmental impacts at each subsequent phase of the project. Major construction activity such as excavation work, requires the use of powerful and often large and heavy equipment. These works take a significant time period to complete and progressive phases of construction entail different activities and require the use of various types of equipment. Overall, however, construction is a temporary activity. Modern machinery and techniques are sophisticated and are designed to be operated to minimise the impact on their surroundings. Any residual impact, which may arise as a result, is for a limited period of time. The works required to construct the proposed road development are essentially similar to other major construction projects in Ireland and across the world.

The general activities and potential impacts associated with the construction of the proposed road development include:

- Site clearance including demolitions and vegetation clearance
- Fencing
- Site access
- Construction compounds
- Site investigations and archaeological testing
- Quarrying and processing of aggregates
- Material requirement and source of material
- Temporary road closures and diversions
- Water management/treatment
- Temporary storage of materials, surplus materials or wastes arising

The above activities are discussed in the following sections which should be read in conjunction with **Chapter 5, Description of Proposed Road Development**. In addition to the above list the following are also discussed:

- Construction form and duration of works

- Construction constraints
- General construction methods
- Construction programme, staging and working hours

Associated construction activities considered in other chapters of this EIAR are as follows:

- Earthworks and management of excavated material (ref. **Chapter 9, Soils and Geology**)
- Site drainage (ref. **Chapter 5, Description of Proposed Road Development, Chapter 10, Hydrogeology** and **Chapter 11, Hydrology**)
- Construction traffic and access (ref. **Chapter 6, Traffic Assessment and Route Cross-Section**)
- Landscaping (ref. **Chapter 12, Landscape and Visual**)
- Diversion of utilities (ref. **Section 7.4.4.3** below and **Chapter 15, Material Assets Non-agriculture**)

7.4.1.1 Construction Environment Management Plan (CEMP)

A Construction Environmental Management Plan (CEMP) for the proposed road development is provided in **Appendix A.7.5** of this EIAR. The CEMP documents the overall environmental management strategy that will be adopted and implemented during the construction phase of the proposed road development. The purpose of the CEMP is to demonstrate how the proposed construction works can be delivered in a logical, sensible and safe sequence with the incorporation of specific environmental control measures relevant to construction works of this nature. The CEMP sets out the mechanism by which environmental protection is to be achieved during the construction phase of the proposed road development. Implementation of the CEMP will ensure disruption and nuisance are kept to a minimum. The following is included in the CEMP:

- General Project Details
- Contact Sheets
- Reference Documents
- Organisational Structure/Duties and Responsibilities
- Environmental Commitments and Environmental Control Measures
- Site Specific Method Statements/Management Plans
  - Construction and Demolition Waste Management Plan
  - Sediment, Erosion and Pollution Control Plan
  - Non-native Invasive Species Management Plan
  - Incident Response Plan
  - Construction Traffic Management Plan
- Environmental Awareness Training Strategy
- Communications Strategy

- Inspections, Auditing and Monitoring Compliance Strategy
- Final Handover

The CEMP as provided in **Appendix A.7.5** must be read in conjunction with the construction details already provided in the EIAR. Refer also to **Section 7.6.1** of this chapter for further details on the CEMP.

7.4.2 Construction Phasing

An east to west build sequence is likely to be adopted and construction may be completed in two concurrent phases or a single overall contract:

- Phase 1 – N6 Coolagh to N59 Letteragh Junction – 9.9km (Including the N59 Link Road North and South.)
- Phase 2 – N59 Letteragh Junction to R336 Coast Road west of Bearna - 7.5km

Completion of Phase 1 would provide the benefit of a new river crossing and also provide a new connection to the N59 Moycullen Road and greater Knocknacarra area. The N59 Link Road North and South and Parkmore Link Road could also potentially be constructed as part of an advance works contract however these will be assessed as part of the main contract for the purpose of this EIAR as the associated environmental impacts would be the same.

Completion of Phase 2 would enable a full connection from the west of Bearna Village and to the east in Coolagh, Briarhill with various at-grade and grade separated connections.

7.4.3 Enabling Works

Enabling works are those generally undertaken to existing facilities in order to provide space or access for the permanent works and or construction. By their nature, these works must be complete before the main works can start. The timing of enabling works depends on the programmed start of the phase of main works that they are designed to enable. Some may start well in advance of the main construction activities. The potential environmental impacts associated with the enabling works have been considered in this EIAR.

Before the start of the main construction works, there will be elements of enabling and preparatory works, such as utility diversions, ground investigation, treatment of non-native invasive species and archaeological investigations, which are designed essentially to clear the ground for the main activities. These activities have been considered at this stage to ensure all necessary land and access is included within the proposed development boundary.

Some examples of main enabling works are as follows:

- Diversion of 110kV ESB overhead lines at Coolagh, Briarhill, and Ballybrit
- Diversion of the Gas distribution network at Rahoon and Gas transmission network at School Road

- Racecourse Avenue diversion and the realignment of the northern access to Galway Racecourse, construction of temporary stables and replacement of two wells for Galway Racecourse

7.4.4 Site Clearance and Preparation Works

Site clearance including demolitions, vegetation clearance and treatment of non-native invasive species will be undertaken within the proposed development boundary. The clearance of vegetation and treatment of non-native invasive species will be done in accordance with the Construction Environmental Management Plan (CEMP) (**Appendix A.7.5**). There are restrictions for site clearance and construction at locations of breeding birds. Where feasible, vegetation (e.g. hedgerows, trees, scrub and grassland) will not be removed, between the 1 March and the 31 August, to avoid direct impacts on nesting birds. Where the construction programme does not allow this seasonal restriction to be observed, then these areas will be inspected by a suitably qualified ecologist for the presence of breeding birds prior to clearance. Areas found not to contain nests will be cleared within 3 days of the nest survey, otherwise repeat surveys will be required, (*ref* ***Chapter 8, Biodiversity***).

All areas of the site required for the construction of the proposed road development will need to be cleared down to ground level, with in some cases demolition of existing structures including residential dwellings and commercial properties, ref **Chapter 15, Material Assets Non Agriculture**. Trees will be protected where practicable when construction accesses are formed. The presence and nature of items of heritage significance will be recorded and preserved where possible. Archaeological monitoring and investigations will also be undertaken in order to record and preserve any buried findings using the appropriate methods.

Access for additional ground investigation work and archaeological testing have been considered as part of this EIAR and are included within the proposed development boundary.

Surplus materials will be reused within the works for the proposed road development where feasible and subject to appropriate testing to ensure it is suitable for its end use. Unavoidable wastes generated will be managed as outlined in **Section 7.6.8 Waste Management**.

7.4.4.1 Fencing

At the beginning of the construction phase the land to be acquired as per the proposed development boundary will be fenced and access across it restricted. Temporary construction fencing or hoarding may be required during construction prior to the installation of permanent fencing to secure the site and prevent unauthorised access. Fencing in accordance with TII Publications will be used.

Fence types will vary across the proposed road development depending on different circumstances which may require, timber post and rail fencing, timber post and mesh fencing, masonry walls, steel palisade fencing, noise barriers, parapets and may be temporary in nature. The method for erecting the fence will also vary depending on the location of sensitive receptors such as the presence of Annex I habitats. For example, the fencing at the Menlough Viaduct will be erected without in any way impacting on the Annex 1 habitat, namely Limestone pavement (ref **Appendix A.7.2**). The contractor will be required to prepare a method statement in order to demonstrate this. In certain situations, temporary crossing points for livestock and machinery will be allowed until accommodation roads are constructed. Fencing will also be erected from the proposed road side of the fence. In areas where the proposed development boundary includes Annex I habitat within Lough Corrib cSAC the permanent fencing will be located between the proposed road and the Annex I habitat and will not be located within the habitat areas.

7.4.4.2 Water Management

Site drainage will be provided to collect surface water runoff, which will be directed into a site water treatment facility before being discharged to the local drainage network. Pre-earthwork drains will need to be constructed in advance of main earthworks to prevent flooding of adjacent lands or vice versa.

Drainage ponds and interceptor ditches will also need to be constructed in advance of main earthworks to collect, treat and discharge all surface water run off during construction. Silt traps will be required for any construction in proximity to sensitive watercourses.

As detailed in the CEMP (**Appendix A.7.5**) (such as the sediment, erosion and pollution control plan) specific controls/mitigation measures will be put in place to manage runoff and minimise pollution to receiving waterbodies during the construction phase. Further details on same are also provided in **Chapter 10, Hydrogeology** and **Chapter 11, Hydrology**.

Construction dewatering will be required and managed at the following locations:

- Interception of groundwater for cuttings in the Galway Granite Aquifer, with groundwater discharged to surface watercourses
- The cutting west of the N83 Tuam Road Ch. 13+050 to Ch. 13+650 (EW27) may encounter groundwater seasonally during peak groundwater levels in the Visean Undifferentiated Limestone. The design includes drainage to intercept and carry groundwater away from the construction for discharge in the same groundwater body
- The Galway Racecourse Tunnel and its approaches will include dewatering of the Visean Undifferentiated Limestone. The construction drainage will intercept and carry groundwater away from the construction for discharge in the same groundwater body

Further details on same are also provided in **Chapter 10, Hydrogeology**.

7.4.4.3 Utilities Diversion

All utility diversion work such as electrical, telecommunications, gas and water are assessed in **Chapter 15, Material Assets Non Agriculture**. The key main diversions include four 110kV overhead line diversions at Ballybrit and Coolagh, one gas main diversion at Rahoon, one temporary gas main and foul sewer diversion at School Road Castlegar, and two foul main sewer diversion at Ballybrit and Ballymoneen Road.

7.4.4.4 Demolitions

Demolition of existing buildings is required at a number of areas and these demolitions are considered and assessed in **Section 14.5.3** of **Chapter 14, Material Assets Agriculture** and **Section 15.5.2.1** of **Chapter 15, Material Assets Non-agriculture** and shown on **Figures 14.1.1** to **14.1.15**.

The demolition work will be carried out by a specialist demolition contractor who will operate in accordance with the method statement and Health and Safety legalisation (refer to **Section 7.4.12** below). The method statement will outline how the contractor proposes to undertake the demolition works in accordance with the CEMP in order to demonstrate that the work will be carried out safely and to ensure that significant environmental impacts will not arise. This method statement will be approved by the Employer in advance of any works.

As detailed in the CEMP (**Appendix A.7.5**), the Contractor will put in place a Public Communications Strategy which will provide a two-way mechanism for members of the public to communicate with a designated member of the Contractor's staff and for the Contractor to communicate important information on various aspects of the proposed road development to the public. This will include a communications strategy for notifying neighbouring residences of proposed demolitions in the area. Warning signs will be erected notifying people of dangers of moving plant/demolition works.

In addition, a suite of mitigation measures and specific controls that the contractor is obliged to put in place in relation to construction works (including demolition works) is specifically detailed and set out in the CEMP in **Appendix A.7.5** and **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration** (refer to **Section 7.4.1** and **Section 7.6** for further details).

Prior to the commencement of any demolition works, security fencing will be erected around the area to be demolished and regularly checked to see that it is in a satisfactory condition. Potential impacts to neighbouring properties during construction will be mitigated by the implementation of the measures outlined in **Section 7.6** below.

Prior to any demolition, asbestos surveys will be carried out on all structures to determine if there are any asbestos materials present. Demolition work will not take place unless the structure has been safely cleared of asbestos. Properties will be surveyed for asbestos containing materials by a competent person and the asbestos materials will be removed by trained personnel and placed into appropriate packaging ready for removal off site in accordance with Health and Safety legalisation (refer to **Section 7.4.12** below) thereby ensuring significant environmental impacts will not arise.

Prior to the heavy demolition works taking place, all rubbish and debris surrounding the property will be removed and placed into skips for recycling/disposal. These materials will include all the domestic waste, furniture and kitchen appliances dumped on, in or around the properties. These materials will be removed using mechanical techniques and segregated and stockpiled for removal off-site.

Before the commencement of demolition works, all existing services will be identified, located and turned off. This includes ESB, water, gas and telecommunications. The contractor will ensure all services to properties are off before demolition works commence.

A bat survey is to be completed at all properties prior to being demolished. This will involve the ecologist using a cherry picker to access the roof tiles and removing several tiles. Once the ecologist confirms the roof space is clear the demolition can take place.

The demolition process will include the mechanical demolition of buildings and the removal of the materials from site. The works will be carried out as swiftly as possible and in an efficient and safe manner. Demolition works will be carried out under strict supervision at all times. Demolition of buildings will be well supervised with the area around the building closed off to unauthorised personnel.

Demolition of the larger structures will commence from the roof structure working downwards. The contractor will use a large tracked excavator for the demolition works which will provide extra reach and extra power for the task at hand. A water bowser will be used to suppress dust from the demolition works should the need arise. Dust suppression units will be provided to disc cutting machines, to dampen down dust.

The properties affected will be demolished and all rubble stockpiled for removal. Demolition shall be completed in a controlled manner with no operatives allowed near the structure until the building is completely levelled. All material will be removed off site to a licenced facility. No buildings will to be left in an unstable or unsafe condition.

In general, excavators or other suitable equipment will be utilised to peel off the front walls of the properties first to enable access to remove the floors and their contents. The materials will be pulled clear of the structure to a suitable area for further processing, segregation and loading. The remaining concrete structures will then be demolished and temporarily stockpiled where they fall. The excavator may crunch the structure on a bay by bay basis into small sections which will allow the structure to be progressively demolished in a safe manner. This will minimise the dropping of large sections of concrete to the ground in an uncontrolled manner.

When demolition operations allow materials such as timber, steel and concrete will be gathered to a central location, where it will be sorted and segregated for removal off site. On completion of the removal of the property internal structures, the remaining external walls will be pulled down and stockpiled. Removal of waste materials will be carried out during all stages of the mechanical works to create a safe and workable site for both the excavator and the operatives on site. When enough material has been accumulated the segregated stockpiles will be removed for disposal and or recycling.

Temporary disruption to services in the locality may arise during the course of the work but these will be re-instated. In liaison with the local service providers, all services will be disconnected prior to demolition works.

A designated point man will be present to allow safe manoeuvring of machinery/hauliers. Construction traffic will be managed safely and in accordance with the overall construction traffic management plan (**Appendix A.7.5**).

No operatives will work under areas of demolition and all equipment operated by the employees will be maintained in good working order and inspected in accordance with manufacturers recommended intervals. All work will be carried out in accordance with the method statement and under fulltime supervision.

Construction waste will vary significantly from site to site but typically would include the following non-hazardous fractions:

- Soil and stone
- Concrete, brick, tiles and ceramics
- Asphalt
- Metals
- Wood
- Other

The hazardous waste streams which could arise from construction activities may include the following:

- Waste electrical and electronic components
- Batteries
- Asbestos
- Wood preservatives
- Liquid fuels
- Contaminated soil

Any metals that can be salvaged for recycling will be removed and stored separately. All glass in the property such as windows and doors, will have been removed prior to demolition works to remove the dangers associated with broken glass in the rubble or during demolition works.

In all cases where demolition and site clearance is being undertaken, the relevant archaeological and architectural heritage mitigation measures will be implemented. Refer to Section 7 Construction & Demolition Waste Management Plan of the CEMP included in **Appendix A.7.5**.

All potential impacts associated with the demolition works are fully assessed within the relevant chapters of this EIAR.

7.4.4.5 Site Offices and Compounds

Site preparation works will also include the facilities for the contractor and the construction management team.

These will include the following:

- Setting up of access control to the site
- Site offices
- Site facilities (canteen, toilets, drying rooms, etc.)
- Offices for construction management team
- Secure compound for the storage of all on-site machinery and materials
- Temporary car parking facilities
- Permanent and temporary fencing
- Site security

See **Section 7.4.9.4** for more information on site compounds.

7.4.4.6 Concrete Batching and Rock Crushing Plants

Locations for concrete batching and rock crushing plants within the proposed development boundary have been considered as part of this EIAR. It is proposed to include a concrete batching and rock crushing plant at Lackagh Quarry (Site Compound SC 11/01). Lackagh Quarry site compound will be one of the principal site compounds across the proposed road development, given its size and location in relation to the overall proposed road development. It is also proposed to include a rock crushing and grading plant at site compounds in close proximity to the major cuttings across the proposed road development in order to minimise the distance for haulage of excavated material. It may also be necessary to utilise a mobile rock crushing unit to minimise haulage of excavated material. See **Table 7.5** below for a summary of potential site compounds and possible locations identified for concrete batching and rock crushing plants. The appropriate authorisation for crushing plants such as waste facility permits will be obtained by the operator prior to commencement of the activity.

7.4.5 Road Closures and Diversions

The proposed road development will be constructed in a manner which will minimise, as much as possible, any disturbance to the local residents and road users. Requirements for temporary traffic management during the construction of the proposed road development will be explicitly written into the Employer's Requirements for the construction contract documents and tenderers will have to demonstrate compliance with these requirements during the tender process.

There are two locations where temporary road diversions will be in place in order to construct bridge structures at Ch. 3+300 Aille Road L5384 and Ch. 13+150 School Road, Castlegar L2134. A plan outline of these proposed temporary diversions is presented in **Figures 7.001** and **7.002** and described below in **Section 7.4.5**.

Temporary night-time closure of existing roads may be required where overbridges are to be constructed at locations such as the Rahoon Road, Letteragh Road, N59 Moycullen Road, Menlo Castle Bóithrín, Bóthar Nua, An Seanbóthar, N84 Headford Road, N83 Tuam Road, Briarhill Business Park Road and R339 Monivea Road.

As detailed in the CEMP (**Appendix A.7.5**), the Contractor will put in place a Public Communications Strategy which will include procedures to inform members of the community who may be directly affected by the construction phase on schedules for any activity of a particularly disruptive nature which is likely to impinge on their property such as blasting, demolition, road closures and diversions, pile driving and any mitigating actions that are being taken (shielding, restriction on work hours, etc.) to minimise such disruption.

There are two permanent road closures proposed along the proposed road development. The Ann Gibbons Road (L13215) at Ch. 2+500 in Troscaigh will be severed by the proposed road development and a permanent diversion for local traffic will be required via the existing Bearna to Moycullen Road L1321. The existing link road from the Western Distributor Road Roundabout at Gort na Bró to the Knocknacarra Shopping Centre will be closed and replaced with a new link road connecting to the Gort na Bró Road. Details of these road closures are shown on **Figures 7.102** and **7.113**.

In order to minimise the impact on local residents, landowners and the public, access to existing residential areas, business premises and public facilities will be maintained during construction.

7.4.6 Potential Form of Contract

Whilst a decision on the exact contractual arrangements for the construction of the proposed road development has not yet been made, the proposed road development is suitable for development as a Design and Build (D&B) Scheme or a Public Private Partnership (PPP) contract.

Regardless of the form of contract, the Contractor for the works will be contractually bound within the contract by any conditions arising from the site constraints, the commitments and mitigation measures set out in the EIAR, the employers requirements for the project, any modifications that may be imposed on the proposed road development by An Bord Pleanála and any conditions imposed by An Bord Pleanála and or other Statutory Regulations. This may incorporate alternative details provided it can be demonstrated that it provides the same performance criteria (or higher) than those outlined in the CEMP. Prior to construction the CEMP will be finalised by the Contractor and approved by the Employer. The CEMP is included in **Appendix A.7.5** and summarises the overall environmental management strategy that will be adopted and implemented during the construction phases of the proposed road development. The purpose of the CEMP is to demonstrate how the proposed construction works can be delivered in a logical, sensible and safe sequence with the incorporation of specific environmental control measures relevant to construction works of this nature.

7.4.7 Main Construction Works

The main construction works will involve the excavation and placement of material for the construction of cuttings and embankments as well as the hauling of materials and importation/exportation of materials to complete the road formation. Materials for the road construction will include materials that need to be brought to site including gravels and bituminous pavement and surfacing materials. In addition to the earthworks construction the main activities will involve the following:

- Road Works — sub-base and base construction, bituminous pavement, surfacing
- Drainage — the installation of pipe culverts, filter drains, linear grassed channels and wetlands
- Structures — the construction of retaining walls, piling works, construction of bridges and viaducts including their foundations, piers, abutments and the installation of large beams and other reinforced concrete works
- Tunnels – the construction of a mined tunnel and a cut and cover tunnel
- Blasting – excavation of rock for cuttings and tunnels. (See also **Chapter 9, Soils and Geology**)
- The diversion and construction of utilities and services
- Ancillary roadworks including the installation of safety barriers, signage and road marking
- Accommodation works for landowners such as access roads, entrances, fences, gates, walls, ducting and reconnection of severed services
- Temporary traffic management

The main construction work for the proposed road development will be split up into different sections along the route of the proposed road development. The proposed phasing of construction is discussed above in **Section 7.4.2**.

Table 7.1 below provides a summary of these sub divided construction sections (going from west to east) and includes the estimated duration of construction for each section. Sections may be completed simultaneously and combined in certain areas. Some sections will be constrained to certain times of the year and some require enabling works. A likely sequence of construction is presented as part of this EIAR, this is based on a worst-case scenario so that all potential impacts are considered. It is likely that the contractor will construct the proposed road development in a sequence which gives rise to lesser impacts than those described. All construction will be employed using best practice methods and in accordance with the relevant standards.

Table 7.1: Construction Sections

Section No.	Phase	Location	Chainage (m)		Length (m)	Time Constraint	Estimated Construction Time (months)
			From	To			
S1	2	R336 to Aille	0+000	3+300	3300	No	6-9
S2	2	Aille to Ballymoneen Road	3+300	5+650	2350	No	6-9
S3	2	Ballymoneen Road to N59 Letteragh Junction	5+650	7+550	1900	No	9-12
S4	1	N59 Link Road South (LRS)	LRS 1+050	2+020	970	No	9-12
S5	1	N59 Link Road North (LRN)	LRN 0+000	0+950	950	No	9-12
S6	1	Letteragh Junction to River Corrib	7+550	8+850	1300	No	6-9
S7	1	River Corrib Bridge	8+850	9+500	650	No	18-24
S8	1	River Corrib Bridge to Menlough Viaduct	9+500	10+100	600	No	9-12
S9	1	Menlough Viaduct	10+100	10+430	330	No	18 - 24
S10	1	Menlough Viaduct to Lackagh Tunnel	10+430	11+150	720	Yes – Construction to be completed without any groundwater dewatering. Construction may cease when groundwater levels are too high to allow dry working. However, works above this level may continue.	24-36

Section No.	Phase	Location	Chainage (m)		Length (m)	Time Constraint	Estimated Construction Time (months)
			From	To			
S11	1	Lackagh Tunnel	11+150	11+400	250	Yes – To be constructed without groundwater dewatering and as such works may need to cease during the winter groundwater high. However, works above this level may continue. Start before mid-February (Peregrine Breeding Season)	24-36
S12	1	Lackagh Tunnel to School Road	11+450	13+150	1700	No	12-18
S13	1	School Road to Galway Racecourse Tunnel	13+150	14+950	1800	No	12-18
S14	1	Galway Racecourse Tunnel	14+300	15+150	240	Yes. Construction sequence plan in accordance with Galway Racecourse Festivals and Activities	24-36
S15	1	Galway Racecourse Tunnel to Coolagh Junction	15+150	17+450	2300	No	12-18

An overview of each section and its associated construction activities are discussed in the following sections which should be read in conjunction with **Chapter 5, Description of Proposed Road Development** which includes a full description of the proposed road development and **Figures 7.001** to **7.002** and **7.101** to **7.123** which show the locations of the proposed sections, site compounds and haul routes. **Figures 7.201** and **7.201** show potential locations of blasting for excavation during construction.

7.4.7.1 Section S1 – R336 Baile Nua to Aille

This section consists of 3,300m of single carriageway and includes two roundabouts, 11 accommodation roads and eight structures. The main structures along this section include an overbridge at Na Foraí Maola at Ch. 1+375 and an overbridge at Aille Road L5384 Ch. 3+300 and seven culvert crossings. There are six proposed drainage networks located on this section each consisting of an oil and petrol interceptor, a constructed wetland and an attenuation pond.

The proposed level of the proposed road development in this section is largely at-grade or in slight fill to maintain connectivity to the local network via an overbridge and roundabouts. The Aille Road L5384 will be raised by c. 4m as the mainline will cross under the local road and will be in a cutting. The main access to this site will be from the R336 at Baile Nua and L-1321 Bearna to Moycullen Road. A site compound (SC 00/01) is proposed on the west of this section at the R336 Baile Nua.

The Aille Road L5384 will be temporarily realigned to the east to accommodate the construction of the overbridge. Traffic disruption will be kept to a minimum during construction of this section. For the construction of the roundabout at the R336 in Baile Nua and the Bearna to Moycullen Road Roundabout traffic will be diverted through one half of the roundabout once complete until the other half is constructed. Similarly, access will be maintained north and south of the proposed road development during the construction of the Foraí Maola to Troscaigh overbridge and associated link roads. Temporary traffic management may be required at certain times to maintain safe access.

The Ann Gibbons Road (L-13215) will be severed by the proposed road development therefore access will be diverted via the L-1321 Bearna to Moycullen Road. It is also proposed to overlay a portion of the Ann Gibbons Road due to its current poor condition.

7.4.7.2 Section S2 – Aille to Ballymoneen Road

This section consists of 2,350m of single carriageway and includes two at-grade signalised junctions, and ten accommodation roads. The mainline of the proposed road development is largely in cut on the western end of this section as it crosses under the Aille Road L5384 and rises back to at-grade at approximately Ch. 3+900. Substantial material excavation will be required here to remove the overburden and underlying granite rock. **Section 7.4.9** below gives a summary of earthworks quantities. Groundwater seepages from the cutting are expected to be low and will be accommodated in interceptor drains. Excavation for this cutting will likely require blasting and material excavated will be tested for suitability for use along the fill sections west of the River Corrib, (ref. **Chapter, 9 Soils and Geology**).

There are four drainage networks proposed and five culverts. Site compounds (SC 04/01 & SC 05/01) are proposed at Ch. 4+000 and Ch. 5+250 west of Ballymoneen Road. Access to the site will be from the L-1321 Bearna to Moycullen Road and Cappagh Road.

Similarly, to Section S1, minimal traffic disruption is expected to local traffic with the construction of the Cappagh Road and Ballymoneen Road signalised junctions. Temporary traffic management may be required during diversion phases.

7.4.7.3 Section S3 – Ballymoneen Road to Letteragh Junction

This section consists of 1,900m of dual carriageway, two slip lanes for the N59 Letteragh Junction and five accommodation roads. A substantial volume of engineering fill is required here which will potentially be sourced locally from a proposed cutting at Letteragh (if the material extracted is acceptable after crushing and grading), otherwise it will be imported to site from a certified source. **Section 7.4.9** below gives a summary of earthworks quantities.

The main structures consist of three underbridges and four culverts. There are three drainage networks located in this section. The nearest site compound (SC 07/01) is proposed at Ch. 7+550. To minimise traffic disruption temporary night time closures of Rahoon and Letteragh Roads may be required during the construction of the underbridges which will require lifting of beams from either side once supporting structures and embankments have been constructed. The Clybaun Road Junction at Mincloon will be realigned in advance of the underbridge construction to redirect traffic safely. Temporary traffic management may be required also during this phase. Access for haul route traffic across Rahoon and Letteragh Road will be manned by stop/go personnel.

7.4.7.4 Section S4 – Letteragh Junction to Rahoon Road (N59 Link Road South & Gort na Bró Upgrade)

This section consists of 930m of the N59 Link Road South which consists of 7m wide single carriageway with 2m footpaths in both directions. Due to undulating landscape in the area the lengths of cut and fill vary. The section going from north to south is largely in cut for c.300m and rises to an at-grade signalised junction at Letteragh Road, then continues on embankment for c.200m and lowers to at-grade again to join with the Rahoon Road.

There are two proposed drainage networks to be constructed in this section and one combined hydraulic culvert and mammal underpass. Groundwater seepages from the cutting are expected to be low and will be accommodated in interceptor drains. There are six access roads to be constructed in this section including a realigned entrance to the Rosán Glas housing estate. Temporary traffic management may also be required during the road closure and diversion stage. There is also a diversion of a gas distribution network at the Rahoon Junction. The nearest site compound is located in Letteragh (SC07/01). There will be minimal interference with local traffic as the majority of this section is offline. Access across Letteragh and Rahoon Road will be manned by stop/go personnel to ensure safety of access/egress. Letteragh and Rahoon Road will require upgrade work including widening at the proposed signal crossings for turn lanes, realignment of vertical curvature to improve visibility and a pavement overlay of the existing network as shown in **Figures 5.001** to **5.015**.

The Gort na Bró Roundabout on the Western Distributor Road is to be converted to a signal controlled junction. A new link road and entrance to the Gateway Retail Park in Knocknacarra is to be constructed to replace the fifth arm off the existing roundabout. The Western Distributor road will widen to allow for two-way bus lanes on approach to the junction and provide for future connectivity of the public transport network. Temporary traffic diversions may be required during this construction phase. The contractor will ensure to minimise any traffic disruption during this phase.

7.4.7.5 Section S5 – N59 Letteragh Junction to N59 Moycullen Road (N59 Link Road North)

This section consists of 1,050m of 7m wide single carriageway with 2.0m footpaths in both directions. This link road connects the Letteragh Junction to the existing N59 Moycullen Road at Bushypark. A deep excavation (9-12m for c.300m) is required to connect this link road at-grade to the N59 Moycullen Road, therefore a substantial volume of soil and rock excavation will be required. Noise and vibration levels will be monitored carefully during excavation due to the proximity of residential properties (ref. **Chapter 17, Noise and Vibration**).

All material excavated will be tested for suitability for use in fill sections to the west of Letteragh. Site compound (SC 07/01) located nearby will be used for temporary stockpiling of excavated material. The N59 Moycullen Road will require some upgrade work to widen at the location of the proposed signalised junction. Temporary traffic management may be required during this phase.

One drainage network is to be constructed north of the N59 Moycullen Road to treat surface water runoff from this section before discharging to the River Corrib. This network consists of a hydrocarbon interceptor, constructed wetland and attenuation pond connected via an underground pipe. Groundwater seepages from the cutting are expected to be low and will be accommodated in interceptor drains.

7.4.7.6 Section S6 – N59 Letteragh Junction to River Corrib

This section includes 1,300m of dual carriageway and two slip lanes for the N59 Letteragh Junction and consists of one of the largest cuttings in the proposed road development (>14m) for the N59 Letteragh Junction which will likely require drill and blasting excavation, refer to **Chapter 9, Soils and Geology** of this EIAR for the quantities and types of soil and rock excavation at this location. Groundwater seepages from the cutting are expected to be low and will be accommodated in interceptor drains. A large site compound SC 07/01 (2.93ha) is proposed in close proximity to this cutting to allow for crushing, regrading and temporary stockpiling of excavated material and storage of plant machinery. This site can be accessed from the east via N59 Moycullen Road or from the north once the N59 Link Road is constructed.

There is one underbridge proposed in this section, spanning over the N59 Moycullen Road. Night time closures of the N59 Moycullen Road may be required to construct the bridge and temporary traffic management will be in place for diversions.

Also included in this section are five accommodation roads, one culvert, four retaining walls, and four mammal underpasses. Material for the fill sections will be sourced locally from the excavated section of the N59 Letteragh Junction where possible. Site compound (SC 08/01) is the located at Ch. 8+700 and access will be from the N59 Moycullen Road. This will be a storage only compound.

There are three drainage networks which discharge directly to the Lough Corrib cSAC, namely S15, which drains the proposed N59 Link Road North and outfalls to an existing drainage ditch which ultimately outfalls to the River Corrib, S18A and S18B which both directly discharge to the River Corrib as shown on **Figures 11.6.106** and **11.6.107**.

Additionally, there are two drainage networks (S14A and S14B) which outfall indirectly to the Lough Corrib cSAC via an existing stream which flows to the west of Aughnacurra residential estate as shown on **Figures 11.6.106**.

A working width of 15m is available for the construction of the above drainage networks to allow room for the necessary machinery and equipment to operate. The extent of the proposed development boundary does not include any Annex I habitat within the Lough Corrib cSAC in these areas.

The headwall at the outfalls in to the Lough Corrib cSAC will be constructed flush with the existing drainage bank. The headwall can be constructed using either a precast headwall or by casting the headwall in-situ. For either method, the construction process will be undertaken using standard best practices. Where the headwall will be constructed using a precast headwall, a temporary cofferdam structure can be constructed if necessary to allow the precast concrete headwall to be lowered into position. Where the headwall is to be cast in-situ, a temporary cofferdam will be constructed to allow the necessary ground works to be completed and to cast the headwall. This cofferdam is used to prevent any potential impact to the water quality of the river/stream/drainage ditch. Where any pumping of water is required, this water will go through environmental treatment to remove all pollutants before being reintroduced to the local surface water drainage network. Once the headwall has been constructed the temporary cofferdam is removed.

7.4.7.7 Section S7 – River Corrib Bridge

The River Corrib Bridge clear spans the river (i.e. with no piers in the river) and as such a balanced cantilever construction is proposed over the river section and the spans over the river banks. Due to the larger span, the superstructure structural depth is significantly larger at the pier locations and varies in depth along the span. This increases the construction complexity of the deck. Post-tensioned in-situ concrete deck can be built using travelling formwork over the river and side spans; and using falsework or travelling formwork on approach spans. For full details of the proposed construction of the River Corrib Bridge see **Appendix A.7.1**.

The bridge continues on a viaduct west of the River Corrib to maintain access for the NUIG Sporting Campus, therefore, management of construction traffic and material delivery is required to minimise disruption and interaction with activities in the sports campus at peak times.

There are two drainage networks proposed west and east of the River Corrib in Section S7. There are two site compounds located in close proximity to the structure on the west (SC-08/01 (storage compound only)) and east (SC-09/01) of the River Corrib.

7.4.7.8 Section S8 – River Corrib Bridge to Menlough Viaduct

This section consists of 600m of dual carriageway and is mainly on embankment. There is one underbridge structure over Menlo Castle Bóithrín, a mammal underpass and a retaining wall to be constructed along this section. Three accommodation roads will be constructed, and three mammal underpasses/culverts. It is proposed to realign An Bóthar Nua to accommodate the underbridge and improve overall safety of this road. Temporary traffic management may be required during this work.

A retaining structure, reinforced soil embankment, between Ch. 9+850 to Ch. 10+050 will retain the proposed road development from encroachment on the Annex I habitat of the Lough Corrib cSAC. The construction of the retaining structure will be undertaken within the proposed development boundary and outside the areas of Annex I habitat. The reinforced soil embankment will be constructed using heavy plant machinery with the height of the retaining structure increasing at the same rate as the embankment height increases.

A site compound (SC-09/01) is proposed east of the River Corrib off the Menlo Castle Bóithrín and access to this site will be from Bóthar Nua in Coolough once site clearance and haul routes have been completed. There is an infiltration basin located east of the River Corrib and south of the proposed road development. Material for the fill sections will be sourced from nearby cuttings where feasible such as the western approach for Lackagh Tunnel, otherwise it will be imported to site from a certified source. Material can be transported from stockpiles, once crushed and re-graded, along haul routes identified in **Figure 7.107**.

7.4.7.9 Section S9 – Menlough Viaduct

The Menlough Viaduct is required to span over Annex I habitat, namely Limestone Pavement and a Turlough adjacent to the Lough Corrib cSAC. There are three alternative construction methods possible for constructing Menlough Viaduct to reduce the potential impacts to the Annex I habitats. Construction Method 1 includes the construction of a protection system over the Limestone pavement and using this as a construction platform and Construction Method 2 utilises the balanced cantilever system in conjunction with a protection system over the Limestone pavement. Construction Method 3 is a prestressed precast beam superstructure construction method. This method is similar to Method 1 and a protection system the Limestone pavement will be provided.

The stages of the construction under the proposed methodologies are as follows:

- Stage 1 - Site access and enabling works
- Stage 2 - Construction of the Limestone pavement protection system
- Stage 3 - Viaduct construction

All of the construction methodologies are described in full in **Appendix A.7.2** and incorporate the need to protect the Annex I habitats. There is some scope to integrate the methodologies to incorporate aspects of the cantilever method and to add false work if required.

The potential environmental impacts of each of these three construction methodologies are the same and have been fully assessed in this EIAR. All such construction methodologies ensure that there will be no effect on Annex I habitats with the exception of the removal of Limestone pavement for one of the pier locations.

A specialised sealed drainage system will capture the runoff on the bridge deck, transport it beneath the structure in a network of sealed carrier drains, before discharging to a wetland and infiltration basin at a suitable location located east of the viaduct. This specialised sealed drainage system is required due to the sensitivity of the areas which the viaduct is crossing above i.e. Annex I habitat.

7.4.7.10 Section S10 – Menlough Viaduct to Lackagh Tunnel

This section consists of 720m of dual carriageway commencing on embankment after the Menlough Viaduct before entering a deep cutting of 7-12m for a length of c.300m as it approaches Lackagh Tunnel. There are three accommodation roads to be constructed to maintain farm land access as well as to facilitate an emergency exit road. Seanbóthar will require upgrading, overlay and verge widening at the underbridge.

Two drainage networks are proposed in this section which consists of an oil and petrol interceptor, a constructed wetland and infiltration basin. A culvert structure is proposed at Ch. 10+735 for a stream diversion. Retaining walls on the approach to Lackagh Tunnel will be constructed to retain the embankment of the proposed road development from encroachment on the Annex I habitat of the Lough Corrib cSAC. The construction of the retaining wall will be undertaken within the proposed development boundary and outside the areas of Annex I habitat. The construction process for the retaining wall will be undertaken in tandem with the construction of the embankment. The embankment will be constructed using heavy plant machinery with the height of the retaining wall increasing at the same rate as the embankment height increases.

A combination of retaining systems will be implemented along the Western Approach and above the western tunnel portal at Lackagh Tunnel (Ch. 10+850 to Ch. 11+150) where the use of unsupported slopes is not used as they would encroach on areas of Annex I habitats. The retaining system type is governed by the ground conditions encountered at that particular location. Within this area the rock head level changes significantly, requiring retaining system solutions for shallow and deep rock ground conditions which can be constructed outside the Annex I habitat within the Lough Corrib cSAC.

The retaining systems constructed in this area include the following construction methodologies:

- In areas of shallow rock:

    The overburden will be removed followed by rock excavation which will be progressed in levels in a cyclic manner including drilling, blasting, rock mapping by a geotechnical expert and mucking out. A composite rock stability support system in the form of rock bolts, rock dowels, steel mesh and sprayed concrete will be implemented where required for stability on the rock face prior to excavation to the next excavation level based on the rock mapping results. A watertight reinforced concrete retaining structure will be constructed within the rock excavation cutting, generally at the base of the excavation (where the excavation is below +17.7mOD).

    Prior to undertaking this excavation, a detailed ground investigation, including down the hole geophysical survey to determine the rock mass geometry will be completed to inform the detailed design and ensure that this method is feasible. In the event that this method is not feasible a piled solution from surface level will be implemented, which is described below.

    A trial blast, as per the Schedule of Commitments and will be carried out as part of a blast assessment. The monitored trial blast will be undertaken in the same bedrock formation by the blasting contractor in a controlled location, not exceeding the vibration limitations of the local sensitive receptors, posing no risk to sensitive receptors including Annex I habitat in Lough Corrib cSAC. The trial blast will calibrate the blast design to a site specific design.

- In areas of deep rock (overburden only) or a combination of overburden and rock:

    Piled retaining walls, with ground anchors will be implemented in these areas. The piled wall will be either a contiguous or secant piled wall. Both of these wall types are installed using the same rig and construction methods. A contiguous piled wall is not watertight as it is a linear series of individual piles whilst a secant piled wall can be designed to be watertight as it is a linear series of interconnected/overlapping piles. A watertight system is only required below +17.7mOD, therefore contiguous piled walls will be implemented with a watertight structure constructed within the excavation.

    The piles will be installed from the existing ground level prior to excavation works or from a reduced excavation level where potential impacts to the Annex I habitat in Lough Corrib cSAC can be avoided. The piling rig will be set up outside of the footprint of the Annex I habitat. Once the piles have been installed, the excavation of the overburden and bedrock will be completed. The bedrock will be broken using a hydraulic hammer or by blasting with the piled wall acting as an additional buffer to the rock blast.

    A watertight reinforced concrete retaining structure will be constructed within the excavation footprint where required.

Prior to undertaking the piling works, a detailed ground investigation, will be completed to inform the detailed design and ensure it is site specific.

These retaining solutions are considered and assessed throughout the assessment for this EIAR.

Access to Section S10 will be primarily from Seanbóthar in Menlough. Acceptable material excavated for the Lackagh Tunnel approach will be used for the embankment section. Excess excavated material can be hauled back to Lackagh Quarry site compound (SC 11/01) for temporary stockpiling after crushing and re-grading and used elsewhere on the proposed road development.

7.4.7.11 Section S11 – Lackagh Tunnel

The construction activities for Lackagh Tunnel is split into three sections:

Section 1:	Stabilisation of the Lackagh Quarry Face
Section 2:	Construction of the eastern entry portal
	Construction of tunnel (from east to west) – Mined (drill and blast)
	Stabilisation of the connection to Section 3 (Western Approach)
Section 3:	Installation of retaining wall structures where required
	Excavation of overburden
	Installation of retaining wall temporary/permanent support
	Construction of western approach road

The following construction sequence is envisaged. It is possible for Section 3 to be constructed in parallel with the construction of Sections 1 and 2.

Stage 1:

- Site enabling and preparation works

Stage 2:

- Stabilisation of the Lackagh Quarry western face (Section 1)
- Construction of the tunnel entry portal (Sections 1 and 2)
- Installation of a retaining wall from existing ground level in Section 3

Stage 3:

- Construction of the proposed tunnel (Section 2)
- Ongoing installation of retaining wall from existing ground level in Section 3 and commencement of the excavation works (Section 3)

Stage 4:

- Excavation ongoing for Section 3

- Stabilisation of the rock along the Section 2/Section 3 boundary (if/where required)
- Completion of the proposed tunnel (Section 2)
- Construction of the proposed road (Section 3)

A detailed report of the constructability of Lackagh Tunnel and the Western Approach and its potential impacts are assessed and included in **Appendix A.7.3**. This report concludes that due to the sensitivity of nearby groundwater receptors that construction will be undertaken without dewatering. Peak groundwater levels may lead to construction ceasing during part of the winter. When the groundwater rise occurs all construction activities within the zone below the high water groundwater level for the tunnel will cease and the operation made safe until groundwater levels drop, which may include the installation of berms to prevent groundwater entering or exiting the tunnel from the tunnel portal. Construction shall start before the Peregrine breeding season (before mid-February) rather than after nesting takes place.

Access to the eastern side of this section of the proposed road development will be from Lackagh Quarry which is accessed via Coolough Road and access to the western side will be from Seanbóthar. Lackagh Quarry (SC 11/01) will be the main site compound for this section. It is proposed to construct a tunnel services, monitoring and maintenance building within Lackagh Quarry which will serve the function of maintenance facility for the proposed tunnel. An emergency exit road for westbound traffic will be constructed to allow egress from the proposed road development in advance of the eastern tunnel portal if required. This will exit onto Coolough Road at the existing entrance to Lackagh Quarry. Similarly, an emergency exit road for eastbound traffic will be constructed to allow egress from the proposed road development in advance of the western tunnel portal. This emergency exit road forms part of a loop which exits onto Seanbóthar and then crosses under the mainline and connects back to Bóthar Nua in Coolough. These emergency exit roads will primarily serve as access for emergency service vehicles with gated barrier controlled entry and exit. These will also be used in the event of an over-height vehicle detection to safely remove the vehicle in advance of the tunnel.

7.4.7.12 Section S12 - N84 Headford Road Junction/Lackagh Quarry to School Road

This section consists of 1,700m of dual carriageway with one grade separated junction at the N84 Headford Road. The mainline of the proposed road development will span the N84 Headford Road, therefore temporary night time road closures may be required when constructing the overbridge once supporting structures and embankments have been built up on either side. A temporary diversion of School Road, Castlegar will also be required. The road will be realigned west of the existing road and this will also require a temporary diversion of a gas transmission network and foul sewer which currently runs along School Road. Once the cutting has been excavated from the east and the overbridge structure put in place the gas main and foul sewer can be relocated to the bridge structure.

Site access will be from the N84 Headford Road. The nearest site compound on the west of this section will be Lackagh Quarry (SC 11/01) and on the east will be at Twomileditch (SC 14/01) within the area of the proposed N83 Junction. There will be a large cutting into the eastern face of Lackagh Quarry. Material excavated will be stored at Lackagh Quarry site compound and tested for suitability for use in fill sections of the proposed road development.

The main structures in this section include one underbridge, two overbridges, four mammal underpasses and three retaining walls. There are six accommodation roads to be constructed and three drainage networks included in this section.

The material excavated from the cutting at School Road, Castlegar will be drawn back to either site compound SC 11/01 or SC 14/01. Vibration and noise monitoring will be required due to the proximity of residential and commercial properties (ref. **Chapter 17, Noise and Vibration**).

7.4.7.13 Section S13 School Road to Galway Racecourse Tunnel

This section consists of 1,800m of dual carriageway with one grade separated junction at the N83 Tuam Road. The mainline of the proposed road development will span over the N83 Tuam Road therefore temporary night time road closures may be required when constructing the overbridge once supporting structures and embankments have been built up on either side. Site access will be from the N83 Tuam Road. The nearest site compound is at Twomileditch (SC 14/01, SC 14/02 and SC 14/03) within the area of the N83 Tuam Road Junction.

At the N83 Tuam Road Junction the mainline will cut into a hill and remain in cut until the portal of the proposed Galway Racecourse Tunnel, therefore substantial material excavation will be required here. This excavated material can be reused if deemed suitable for the embankments on the mainline and slip lanes connecting to the Parkmore Link Road. The Parkmore Link Road and the City North Business Park Link will be constructed in advance of removing the existing access from the N83 Tuam Road to Galway Racecourse in order to maintain access.

The main structures in this section include one underbridge, one overbridge, one mammal underpass and one retaining wall. There are nine accommodation roads to be constructed and three drainage networks included in this section.

During the construction phase noise monitoring will be undertaken at the nearest sensitive locations to ensure construction noise limits (outlined in **Table 17.1** of **Chapter 17, Noise and Vibration**) are not exceeded.

Vibration monitoring will be undertaken at identified sensitive buildings, where proposed works have the potential to be at or exceed the vibration limit values. Baseline vibration monitoring will also be undertaken at potentially vibration sensitive activities for manufacturing facilities within the Parkmore and Racecourse Business Parks (ref. **Chapter 17, Noise and Vibration**).

7.4.7.14 Section S14 - Galway Racecourse Tunnel

A construction programme of works has been compiled in conjunction with Galway Racecourse to minimise the disruption to the commercial practice of the business throughout the year, not only for the racing festivals. An advance works schedule is included in this programme which includes two well relocations and associated infrastructure, water, telecoms, E-net and electrical utility diversions, access road realignments and replacement link roads. A 240m cut and cover tunnel will be constructed in phases over a three-year period with nine-month construction windows per year. Blasting of material will be required to remove shallow rock head which has been established from ground investigation work. Noise and vibration monitoring will be implemented due to the proximity of commercial and residential buildings in the area. A diversion of the main IDA surface water and foul sewer is required at the eastern portal of the tunnel. Material excavated will be tested for suitability for use in fill sections such as the Coolagh Junction.

Refer to **Appendix A.7.4** for further information regarding this construction sequence programme.

7.4.7.15 Section S15 - Galway Racecourse Tunnel to Coolagh Junction

There is a large amount of engineering fill required in this section due to the proposed overbridges and raised junction at Coolagh, Briarhill (ref. **Section 7.4.9** below). There are two underbridges, two overbridges, and two retaining walls included in this section. Two of the underbridge structures will be constructed over existing public roads (R336 Monivea Road and Briarhill Business Park Road) therefore it is envisaged that night time road closures will be required to construct beams once embankments and supporting structures have been constructed on either side.

Both retaining walls are in close proximity to two commercial properties therefore care will be required in construction of the walls to minimise disruption to the businesses as a result of the construction. Site compounds (SC 15/01 & SC 16/01) will be the main depots serving Section S14. See **Table 7.3** below for more information regarding the site compound locations. Access to the southern section will be provided from the R339 Monivea Road and access to the northern section will be from the Briarhill Business Park Road. Access to the north will be over R339 Monivea Road once the bridge has been constructed. Racecourse Avenue will be used as a haul route but will have restricted use. It will be used for delivery of materials only and will not be permitted for hauling excavated materials.

Traffic congestion at AM and PM peak times is a major issue at this location therefore contractors must ensure to minimise construction traffic movements at these times.

The main cuttings in this section include the eastern approach to the Galway Racecourse Tunnel and the connection with the existing N6 at Coolagh, Briarhill. Hard ripping using a hydraulic hammer or blasting will be required at these excavation locations due to the presence of shallow rock (ref. **Chapter 9, Soils and Geology**). There is also a risk of encountering a high water table in this area therefore, if encountered on site pumping will be implemented (ref. **Chapter 10, Hydrogeology**). There are six drainage networks in this section. (ref. **Chapter 5, Proposed Road Development** for description of drainage networks).

A Construction Traffic Management Plan is included in the CEMP in **Appendix A.7.5** and will be finalised and updated by the Contractor prior to construction. This plan will be complied with throughout construction for the sequencing of Coolagh Junction to ensure there is no major disruption to existing traffic.

7.4.8 Construction Methods

7.4.8.1 General

This section outlines the main construction activities and the associated methodologies that will be employed for the proposed road development. The following table is a high level summary of these methodologies which will use best practice methods in accordance with the relevant standards.

Table 7.2: Construction Activity Methodologies

Construction Activity	Construction Methodologies
Bulk Earthworks	Excavation works Drill and blast Rock crushing Fill
Cut and Cover Tunnel	Excavation Drill and blast Bottom up construction In-situ/precast Waterproofing Backfilling Mechanical & Electrical Ventilation Fire safety
Retaining Walls	Sheet Piling Anchors Rock Bolts Pins/Straps/Ties In situ casting
Mined Tunnel	Drill and blast Excavation Backfilling Supporting In-situ casting Waterproofing Mechanical & Electrical Ventilation Fire safety

Construction Activity	Construction Methodologies
Menlough Viaduct Construction	Limestone pavement protection system Pier construction (in-situ) Geotextile grid layer Floating beams
Bridge Construction	Pier construction (in-situ) Balanced cantilever beams

Detailed description of methodologies proposed for the construction of significant structures such as the River Corrib Bridge, Menlough Viaduct, Lackagh Tunnel and Galway Racecourse Tunnel are included in **Appendices A.7.1** to **A.7.4**.

7.4.8.2 Earthworks

Topsoil and subsoil will be excavated and replaced with road construction. Stripped topsoil and subsoil will be stored within the site boundary and reused within the construction of the proposed road development where feasible subject to testing to ensure it is suitable for its proposed end use. Where off-site storage is required for any period the contractor will ensure that these storage facilities have the appropriate waste licences or waste facility permits in place. All earthworks shall be managed having regard to the TII Guidelines for the Management of Waste from National Road Construction Projects.

Materials will be transported to and from the site using the existing road network. Excavation and filling will be carried out using mechanical plant.

Road embankments will be constructed using excavated material or, where necessary, imported fill material and will generally be compacted using static and vibrating rollers or similar equipment.

The embankments will be constructed for the majority from self-supporting fill material. Where during the detailed design, the requirement for soil retention is identified it shall be provided by using steepened earthworks which shall have a vegetated finish or reinforced soil or reinforced concrete retaining walls with a specified range of acceptable finishes to the exposed faces. The requirements for the aesthetic appearance of the exposed faces will be specified in the contract documents.

7.4.8.3 Pavement Works

Bituminous paving will be undertaken throughout the extent of the proposed road development. The thickness of the road pavement will be determined at detailed design stage but on this type of road, a new blacktop thickness of 350mm could be anticipated.

All new blacktop material will be transported to site in trucks designed for the transportation of materials at high temperatures. The material shall be transferred directly to paving machines, which spreads the blacktop onto the road in layers. The spread material is then compacted using rollers.

7.4.8.4 Environmental Management

Every reasonable effort will be made to ensure that any damaging environmental effects will be minimised during the construction phase of the proposed road development. The construction planning will be geared towards keeping disruption and nuisance to a minimum.

Environmental impacts during construction will be mitigated or reduced where possible (refer to the individual chapters in this EIAR for specific mitigation measures).

In this regard, prior to the commencing any works on site, the CEMP included in **Appendix A.7.5** of this EIAR will be finalised by the main contractor (Refer to **Section 7.4.1.1** above). Adherence to this plan will be a contract requirement and this will ensure good working practices are followed so as to minimise and manage any environmental impacts arising from construction.

7.4.9 Material Sources and Transportation

7.4.9.1 Overview

The earthworks operations will be a major activity on site and will include excavation, stockpiling, processing, deposition, blasting, material reuse, import and transportation from site for recovery/disposal. The construction of the proposed road development will require considerable movements of materials to, from and around the site. Most of the materials leaving the site will consist of hazardous material from the excavation works.

The current design of the proposed road development has an overall surplus of excavation material west of the River Corrib and an overall deficit of fill material east of the River Corrib, see below for details. All excavated material deemed to meet the required standards will be reused as part of the fill sections subject to testing to ensure it is suitable for its proposed end use.

If the proposed road development is to be constructed in phases as per **Section 7.4.2** above, then there will an overall surplus of 597,000m^3 in Phase 1 and overall deficit of 258,000 m^3 in Phase 2. Therefore, there will be a requirement to store excavated acceptable material from Phase 1 to balance the deficit in Phase 2. (Ref. **Section 7.4.9.2**). This material will be stored within the proposed development boundary in identified material deposition areas shown on **Figures 7.301** and **7.302**. All wastes which are not suitable for reuse within the proposed road development will be transported by authorised waste collectors in accordance with the Waste Management (Collection Permit) Regulations, 2007 as amended.

All wastes from the development will be delivered to authorised waste facilities in accordance with the Waste Management Acts 1996-2016. By only using facilities with the appropriate waste permits/licence, Galway County Council will condition the Contractor that he/she must comply with the objectives of the Waste Management Act and that any environmental emissions (noise, dust, water) are managed at the destination site and therefore are legally the responsibility of the owner/operator of the destination site. In this manner Galway County Council can be satisfied that the off-site spoil management aspect of the development is legally compliant with environmental and waste management legislation.

All traffic movements associated with the import or export of materials have been included in the construction traffic impact assessment. Materials required for the construction works will be sourced locally where possible. Materials required from quarries will only be sourced from quarries which are listed on the register maintained by the local authority. All material reused on site will be subject to testing to ensure it is suitable for its proposed end use.

There are operational quarries located in close proximity to the proposed road development. There is potential to import bituminous material for paving from one of these quarries. Haul routes have been identified to these quarries and any potential impacts associated with these haul routes have been assessed in this EIAR.

Rock crushing may be undertaken on site in order to make the excavated rock suitable for reuse as general fill. Otherwise it will be necessary to import crushed stone to site.

7.4.9.2 General Earthwork Quantities

In line with the principles of sustainable development, the proposed road development will seek to minimise the amount of materials brought into the construction site. This will be achieved by re-using as much of the materials generated during construction as possible subject to further testing to determine if materials meet the specific engineering standards for their proposed end-use.

Over 99% of excavated material generated by the proposed road development will be used to satisfy the necessary engineering, landscape and safety quantities required on the proposed road development.

The anticipated material which will be encountered along the proposed road development is provided below:

- **Acceptable Earthwork Material:** These can be categorised in accordance with TII Series 600 Table 6/1 Classes 1, 2, 6 and 8. They comprise the greater part of materials likely to be encountered, with their prescribed use provided in Table 6/1
- **Marginal Material:** Requires treatment such as addition of lime or air drying in order to meet acceptability requirements of TII Series 600. In terms of material being incorporated into the Works, the Contractor shall ensure, in advance, that the material is tested to ensure suitability for its proposed end use and that all pertinent legislation and guidelines are complied with. In addition, use of this material must be discussed with the Employers Representative in advance of any works
- **Topsoil:** Topsoil shall comply with requirements for Class 5 material as outlined in TII Series 600 Table 6/1
- **Peat:** In accordance with TII Series 600 Cl 601.2, non-hazardous peat shall be categorised as Unacceptable U1 material

- **U1 Soil:** Non-hazardous soil which does not comply with the requirements outlined in TII Series 600 Cl 601.1, shall be categorised as Unacceptable U1 material
- **U1 Rock:** Non-hazardous rock which does not comply with the requirements outlined in TII Series 600 Cl. 601.1, shall be categorised as Unacceptable U1 material
- **Hazardous Material:** Hazardous material, as defined in TII Series 600 Cl 601.3 shall be categorised as Unacceptable U2 material

Further information regarding the excavated material and general geology of the proposed road development can be found in **Chapter 9, Soils and Geology**.

A summary of the estimated quantities associated with the material requiring placement on-site and removal off-site are provided in **Table 7.3**. In addition to the material described in **Table 7.3** some services will be removed during excavation works including disused sewers, drains, cables, ducts, pipelines, disused basements, cellars and gullies.

A summary of the estimated quantities associated with the material requiring placement on-site and removal off-site are provided in **Table 7.3**.

Table 7.3: Estimated Excavation Material Volumes generated by Tunnelling and Road Construction

	Category (note 1)	**Estimated excavated material (m^3)**	**Estimated re-use within the proposed road development (m^3)**	**Estimated surplus excavated material requiring recovery/ disposal off site (m^3)**
Acceptable Earthworks Material	Classes 1, 2, 6 and 8	2,602,350	2,602,350	0
Marginal Material	Requires treatment in order to meet acceptability requirements	168,500	168,500	0
Topsoil	Class 5	151,450	151,450	0
Peat	Unacceptable category U1	76,000	76,000	
U1 Soil: Non-peat	Unacceptable Category U1	147,500	191,300	0
U1 Rock: Non-peat	Unacceptable Category U1	43,800		0
Landscaping and habitat creation	Class 4 (Note 2)	0		
Hazardous Material	Unacceptable Category U2	7,600	0	7,600
Total		**3,197,200**	**3,189,600**	**7,600**

Note 1: TII Series 600 including Table 6/1: Acceptable Earthworks Materials: Classification and Compaction Requirements.
Note 2: Landscape Fill in accordance with Class 4 of TII Series 600 including Table 6/1: Acceptable Earthworks Materials: Classification and Compaction Requirements.

In addition to the above excavation materials some services will be removed during excavation works including disused sewers, drains, cables, ducts, pipelines, disused basements, cellars and gullies.

A review has been undertaken of capacity at waste permitted and licenced facilities and this indicates that there is expected to be sufficient capacity within operational and planned waste management facilities to accept wastes generated by the proposed road development.

7.4.9.3 Potential Haul Routes

Potential haul routes have been identified across the proposed road development with aim of minimising interaction with the general public and creating as little disruption to the receiving environment as possible. Where possible haul routes will remain within the proposed development boundary with local road crossing points. However, there will be unavoidable periods where haul routes will require the use of public roads.

Haul routes along public roads have been identified taking cognisance of their current use, Average Annual Daily Traffic (AADT), non-motorised users (NMUS) such as pedestrians and cyclist and the current condition, width and alignment, in addition to their proximity to sensitive receptors. Where necessary flag men will operate at crossing points of junctions along haul routes to ensure safety of access and egress from the site of the proposed road development and site compounds. All haul routes along public roads will undergo a pre-structural assessment and any remediation works required will be put in place in advance of construction. Haul routes along public roads will be monitored for deterioration throughout construction and a structural assessment will be carried out to determine any sites requiring remediation work post construction. This arrangement has been successful in similar road schemes in the west such as the M17/M18 motorway scheme. A summary of the main haul routes are listed in **Table 7.4** below. Refer **Figures 7.101** to **124** for haul route locations.

Table 7.4: Haul Routes

Haul Route ID	Location & Chainage		Road Name(s)	Approximate Width	Road Description
	From	To			
HR 00/01	0+000 R336	1+150 Troscaigh Thiar	R336 and Bearna to Moycullen Road	6m within the proposed development boundary, 6m on Bearna/Moycullen Road and 9m on R336	The R336 is a regional road which runs through the village of Bearna. The road is in moderate-good condition and includes a footpath to the south for the length of the haul route and one footpath to the north in the village. The haul route identified along the R336 will then join the L-1321 Bearna to Moycullen Road at the signalised junction in Bearna Village. The L-1321 Bearna to Moycullen Road is a local road in moderate condition and includes footpaths within the Bearna Village environs.
HR 01/01	1+550 Troscaigh Thiar	4+440 Cappagh Road	Bearna/Moycullen Road, R336 and Cappagh Road	6m within the proposed development boundary, 6m on Bearna/Moycullen Road, 9m on R336 and 4.7-7.3m on Cappagh Road	The L-1321 Bearna to Moycullen Road is a local road in moderate condition and includes footpaths within the Bearna Village environs. The haul route along the L-1321 will join the R336 at the signalised junction in Bearna Village. The haul route continues along the R336, a regional road which runs through the village of Bearna, passing Bearna National School, towards Galway City. The road is in good condition and includes a footpath to the south for the length of the haul route and one footpath to the north in the village. The haul

Haul Route ID	Location & Chainage		Road Name(s)	Approximate Width	Road Description
	From	To			
					route joins Cappagh Road at the T-junction between Cappagh Road and the R336. Cappagh Road is a local road which is 7.3m wide and in good condition up to the Cappagh Road/Western Distributor Road Roundabout. From 100m north of the roundabout the road narrows to 4.3m and the road condition worsens. The southern section of Cappagh Road runs through a residential area and includes footpaths on either side. The northern section has footpaths on either side for the first 100m.
HR 04/01	4+450 Cappagh Road	8+500 N59 Dangan	Crossing Cappagh Road, Ballymoneen Road, Rahoon Road, Letteragh Road and access to N59	6m	To be constructed within the proposed development boundary.
HR 04/02	4+450 Cappagh Road	11+450 Kirwan Roundabout	R336, R337, R338 Bishop O'Donnell Road, R338 Seamus Quirke Road and N6	6m on R336 and R337. 9m on R338 Bishop O'Donnell Road. 15m on R338 Seamus Quirke Road. 15m on N6	This haul route links all haul routes to the west of the River Corrib with the haul routes on the east. The R336 is a regional road which runs towards Galway City. The road is in moderate-good condition and includes a footpath to the north for the length of the haul route. The R336 links into the R337 on Kingston Road. The R337 is a regional road which runs towards Galway City. The road is in moderate-good condition and includes a

Haul Route ID	Location & Chainage		Road Name(s)	Approximate Width	Road Description
	From	To			
					footpath to the north for the length of the haul route. The R337 links into the R338 Bishop O'Donnell Road at the signalised junction at the top of Threadneedle Road. The R338 Bishop O'Donnell Road is a regional road which runs towards the existing N6 national primary road. The road is in good condition and includes footpaths and cycle lanes on either side for the duration of the haul route. The R338 Bishop O'Donnell Road links into the R338 Seamus Quirke Road at the signalised junction with Circular Road. The R338 Seamus Quirke Road is a regional road which runs towards the existing N6 national primary road. The road is in good condition and includes footpaths, bus lanes and cycle lanes on either side for the duration of the haul route. The R338 Seamus Quirke Road ties into the N6 at Browne Roundabout. The existing N6 is a national primary route which includes two traffic lanes, raised cycle lanes and footpaths in either direction. The route is in good condition and links into the eastern haul routes at the Kirwan Roundabout.

Haul Route ID	Location & Chainage		Road Name(s)	Approximate Width	Road Description
	From	To			
HR 06/01	0+350 N59 Link	2+100 N59 Link	Crossing Letteragh Road and on Rahoon Road. Links into Bishop O'Donnell Road	6m inside development boundary. 9m on Rahoon Road	To be constructed within the proposed development boundary. Rahoon Road is a local road with footpaths on both sides for the length of the haul route. The road is in good condition for the length of the haul route.
HR 08/01	0+300 N59 Northern Link	9+250 Dangan	N59	9.2m on N59 6m inside the proposed development boundary	The N59 is a national secondary route with footpaths on either side of the identified haul route. The road is in good condition for the length of the haul route.
HR 09/01	9+400 Menlough & River Corrib Crossing	11+750 Coolough & Lackagh Quarry	Coolough Road	4.26 - 5.045m	Coolough Road is a local road which narrows north of Lackagh Quarry. The road is in poor condition with restricted views.
HR 11/01	11+450 Lackagh Quarry	12+550 N84 Junction	Coolough Road and N84	Coolough Road – 7.8m N84 - 8.5m	Coolough Road is a local road with footpaths on either side. The road was previously used by HGVs from Lackagh Quarry as a link to the national road network. The road is in moderate condition from Lackagh Quarry to the Kirwan Roundabout. The N84 is a national secondary route with footpaths on both sides for the majority of the identified haul route. The road is in good condition for the length of the haul route.

Haul Route ID	Location & Chainage		Road Name(s)	Approximate Width	Road Description
	From	To			
HR 11/02	11+850 Headford Road	13+150 School Road, Castlegar	Crossing N84	6m	To be constructed within the proposed development boundary.
HR 11/03	11+450 Lackagh Quarry	13+900 N83 Tuam Road	Coolough Road, N6 Bóthar Na dTreabh and N83 Tuam Road	Coolough Road – 7.8m, N6 Bóthar Na dTreabh – 14.2m N83 Tuam Road – 11.6m	Coolough Road is a local road with footpaths on either side. The road was previously used by HGVs from Lackagh Quarry as a link to the national road network. The road is in moderate condition from Lackagh Quarry to the Kirwan Roundabout. The existing N6 is a national primary route which includes two traffic lanes, raised cycle lanes and footpaths in either direction. The route is in good condition. The N83 is a national secondary route with footpaths on both sides for the majority of the identified haul route. The road is in good condition for the length of the haul route.
HR 13/01	13+150 School Road, Castlegar	14+950 N83 Junction & Racecourse Tunnel	Crossing, N83	6m	To be constructed within the proposed development boundary.
HR 14/01	14+000 N83 Tuam Road	17+450 Coolagh Junction	N6 Bóthar Na dTreabh – 14.2m	N6 Bóthar Na dTreabh – 14.2m	The existing N6 is a national primary route which includes two traffic lanes in each direction. There are raised cycle lanes and footpaths in either direction up to the Morris Junction. The route is in good condition.

Haul Route ID	Location & Chainage		Road Name(s)	Approximate Width	Road Description
	From	To			
HR 15/01	15+000 Ballybrit	17+450 Coolagh Junction	Crossing R339	6m	To be constructed within the proposed development boundary.
HR 15/02	15+500 Briarhill	15+950 Coolagh	Briarhill Business Park Road, Ballybrit Crescent and crossing R339	Briarhill Business Park Road - 7.1m Ballybrit Crescent -10.6m	The Briarhill Business Park Road is a commercial road which includes footpaths on either side. The road is in good condition and connects to Ballybrit Crescent at a T-junction. Ballybrit Crescent is a local road which includes footpaths on either side. The road is in good condition and terminates at the signalised junction at its intersection with the R339. Access along this route will be restricted to deliveries only.

7.4.9.4 Potential Site Compounds and Depots

There are thirteen sites identified as potential site compounds across the proposed road development. They have been identified at strategic locations across the proposed road development to minimise the distance for site construction traffic and personnel to travel. Sites identified have been chosen taking cognisance of proximity to major structures, excavations and embankments, proximity to residential properties, environmental constraints and current land use and ownership. Where possible site compound locations have been identified within the permanent proposed development boundary, there is one location which has been identified as a temporary acquisition for the purposes of construction and with ownership returned to the landowner post construction (SC 07/01). Larger area compounds have the potential for material stockpiling, crushing, regrading and delivery in tandem with site offices. No excavation works will be undertaken in site compounds in the granite area. Refer to **Table 7.5** below and **Figures 7.101** to **7.124** for potential site compound locations.

Table 7.5: Potential Site Compound Locations

Site No.	Location	Service Range (Chainage)		Approx. Site Area (ha)	Access	Main Construction Activities
		From	To			
SC 00/01	R336 Baile Nua	Ch. 0+000	Ch. 2+750	0.6	R336	Western tie-in for proposed road development
SC 04/01	Aille	Ch. 2+750	Ch. 4+100	0.4	Aille/ Cappagh Road	Aille Cutting, Rock Crushing Plant
SC 05/01	Ballymoneen	Ch. 5+250	Ch. 6+300	1.0	Cappagh Road	Aille Cutting, Letteragh and Rahoon Road Overbridges
SC 07/01	Letteragh	Ch. 6+300	Ch. 9+350	3.3	N59 Moycullen Road	Major cut at Letteragh Junction and River Corrib Bridge (western section) Rock Crushing & Regrading Plant

SC 15/01	Coolagh / Briarhill	Ch. 15+200	Ch. 16+100	0.5	R338 Monivea Road	Galway Racecourse Tunnel (eastern section)
SC 16/01	Coolagh	Ch. 16+100	Ch. 17+500	1.3	R338 Monivea Road	Coolagh Junction

7.4.9.5 Construction Traffic

An investigation of the construction traffic was carried out to determine the estimated vehicular movements required to transport the materials to and from construction zones. It should be noted that only registered vehicles will be allowed on public roads. **Table 7.6** below gives a summary of this assessment.

For the purposes of this assessment volumes were divided into seven zones:

- Zone 1 Ch. 0+000 - 3+900
- Zone 2 Ch. 3+900 - 7+750
- Zone 3 Ch. 7+750 - 9+300
- Zone 4 Ch. 9+300 - 11+140
- Zone 5 Ch. 11+140 - 14+140
- Zone 6 Ch. 14+140 - 16+200
- Zone 7 Ch. 16+200 - 17+550

In calculating this the following assumptions were made:

- 8 wheeler lorry for all road movements (capacity of 20 Tonne)
- 38 Tonne dumper for bulk earthworks
- No programme of works estimated – i.e. the number of estimated movements would be distributed over the construction period
- Import of non-site won material included e.g. concrete, pavement, Information Communication Technology (ICT)
- The construction period for Zones 1 to 3 is one year and for Zones 4 to 7 is three years

Table 7.6: Increase in HGV Percentage by Zone

Zone Reference	Location Reference	Existing Daily HGV's	Additional daily HGV's over construction period	Daily construction related AADT over construction period
Zone 1	R336	282	7	131
Zone 1	Bearna to Moycullen Road L1321	9	7	131
Zone 2	Cappagh Road	2	10	133
Zone 2	Seamus Quirke Road	480	16	264
Zone 2	Kingston Road	310	16	264
Zone 3	N59 at Hazel Park	103	10	59
Zone 3	N59 at Chestnut Lane	309	10	59
Summary of West	Quincentenary Bridge	1658	26	324
Zone 4	Bóthar Nua	17	51	110
Zone 5	N84 Headford Road at Ballinfoyle	501	10	58
Zone 5	N83 Tuam Road at City North Business Park	758	10	58
Zone 5	N6 Bóthar na dTreabh between N83 Tuam Road Junction and Morris Junction	1098	97	550
Zone 5	N6 Bóthar na dTreabh between N84 Headford Road Junction and N83 Tuam Road Junction	794	87	540
Zone 6	Parkmore Link Road at Business Park Junction 2	178	22	88
Zone 6	N6 Bóthar na dTreabh between Morris Junction and Lynch Junction	1364	119	638
Zone 7	N6 Bóthar na dTreabh at Ardaun	1350	124	684

Note: the above AADT figures include all construction related traffic such as demolition works, construction activities, delivery of goods and construction workers.

7.4.9.6 Traffic Safety

All construction works will be undertaken in a clearly delineated site area which will have specific entry and exit points for construction related traffic onto the public road network. Boundary treatment in the form of a fence will be erected prior to the commencement of construction and will define the extent of the construction site.

Where works are to be undertaken adjacent to the existing roads, temporary traffic barriers will be erected to separate the construction works from the public, to create a safe working space for the contractor and to clearly define the areas within which construction will be undertaken.

As has been stated above, traffic management will be required on the existing road networks during the construction of roads and structures. The contractor will be required to ensure safe operation of traffic at all times during the construction phase. Refer to Construction Traffic Management Plan Section 11 of the CEMP in **Appendix A.7.5**.

7.4.10 Services and Utility Requirements for Construction

7.4.10.1 Electricity

In liaison with the ESB Networks, a temporary transformer served from local supplies will be installed to provide the necessary power required at the various site compounds identified.

7.4.10.2 Water Supply

The construction activities requiring water during the construction phase will vary depending on the activity type. The initial estimate of demand is approximately $15m^3$ per day, primarily based on the demand requirement for the construction workers and the associated support facilities. However additional demand of water supply will be required for wheel washing facilities and requirements for construction activities such as drill and blast. In agreement with Irish Water, water will be sourced from the existing watermains at the most convenient point.

7.4.10.3 Storm Water and Foul Water Disposal

Storm water will be treated and managed carefully during construction. Storm water east of the River Corrib will be infiltrated to ground via silt traps and managed soakaways in the absence of public storm sewers. Storm water west of the River Corrib will be treated before being discharged to existing watercourses. The laydown areas will be suitably drained and any areas which will involve the storage of fuel and refuelling will be paved and bunded and hydrocarbon interceptors will be installed to ensure that no spillages will get into the surface water or groundwater (ref. **Chapter 10, Hydrogeology** and **Chapter 11, Hydrology**).

Prior to commencement of the main construction activities, a dedicated holding tank for storage of construction foul effluent will be constructed at compounds where welfare facilities are provided. This holding tank will be sealed to avoid any potential risk of spillage and contamination of the groundwater within this area. The effluent will be regularly disposed of off-site by tanker by a licensed contractor to an approved licenced facility (ref. Section 8 the CEMP in **Appendix A.7.5**).

7.4.11 Employment and Welfare

Through the construction phase there will be some variation in the numbers of staff working on site. It is anticipated there will be 250-270 staff directly employed on site across the proposed road development, rising to 300 staff at peak construction. Temporary office accommodation and other construction facilities will be installed on site for the construction phase. All temporary units will be of a high standard in accordance with statutory regulations, as a minimum. The co-ordination of people and materials on-site will be one of the key activities throughout the construction phases. The Construction Traffic Management Plan included in the CEMP in **Appendix A.7.5** includes designated traffic routes, timings and parking arrangements to be updated by the contractor prior to the commencement of construction.

The site start time will ensure that construction workers arrive to site prior to the morning peak hour for traffic on the local network.

Typical working hours during the construction phase will be:

Start	Finish	
0700	1900	Monday – Friday
0700	1600	Saturday (if required)

It will be necessary to work overtime (including weekends) and night shifts at certain critical stages during the project. There may be some periods where 24hr work and supervision is required. Consideration of safety, weather or sub-contractor availability is likely to necessitate working outside normal hours. Over the expected 36-month construction phase there will be up to 10 weeks of night time working. Heavy or noisy construction activities will be avoided outside normal hours and the amount of work outside normal hours will be strictly controlled.

7.4.12 Construction Health and Safety

7.4.12.1 Health and Safety

The requirements of the Safety, Health and Welfare at Work Act 2005, the Safety, Health and Welfare at Work (Construction) Regulations, 2013 and other relevant Irish and EU safety legislation will be complied with at all times.

As required by the Regulations, a Health and Safety Plan will be formulated which will address health and safety issues from the design stages through to the completions of the construction and maintenance phases. This plan will be reviewed as the development progresses. The contents of the Health and Safety Plan will follow the requirements of the Regulations.

In accordance with the Regulations, a "Project Supervisor Design Process" has been appointed and "Project Supervisor Construction Stage" will be appointed as appropriate.

The Project Supervisor Construction Stage will assemble the Safety File as the project progresses. The safety file will be incorporated into the overall technical record system at the end of project.

7.4.12.2 Fire Safety and Egress Design Strategy

The fire safety objectives adopted in the design will achieve compliance with the Building Regulations, particularly reference to Part B (Fire).

7.4.12.3 Construction Site Management and Security

There will be a contract management team on site for the duration of the construction phase. The team will supervise the construction of the works including monitoring the contractor's performance to ensure that the proposed construction phase mitigation measures are implemented and that construction impacts and nuisance are minimised.

7.4.12.4 Incident & Emergency Response Provisions

Appropriate site personnel will be trained as first aiders and fire marshals. In addition, appropriate staff will be trained in environmental issues and spill response procedures. Tanks and drums of potentially polluting materials will be stored in secure containers or compounds which will be locked when not in use. Secure valves will be provided on oil and fuel storage facilities. Equipment and vehicles will be locked, have keys removed and be stored in secure compounds.

The contractor will maintain an incident and emergency response action plan which will cover all foreseeable risks, i.e. fire, flood, collapse etc. An Incident Response Plan (IRP) is located in Section 10 of the CEMP in **Appendix A.7.5**.

The objective of this IRP is to:

- Ensure the health and safety of workers and visitors along the site
- Minimise any impacts to the environment and ensure protection of the water quality and the aquatic species dependent on it
- Minimise any impacts on properties, services etc.
- Establish procedures that enable personnel to respond to incidents with an integrated multi-departmental effort and in a manner that minimises the possibility of loss and reduces the potential for affecting health, property, and the environment

7.4.12.5 Site Security

The primary function of the sites security team will be to ensure that no unauthorised entry to site occurs. There will be fencing around the sites to minimise the risk of vandalism and unauthorised access. This process will be made easier by all operatives possessing and ID card. ID Cards will only be issued to operatives that have attended the site induction and (if relevant) a medical examination.

7.4.13 Commissioning Phase

If an east to west build is adopted, then it is likely that partial sections will be commissioned in phases e.g. N6 Coolagh Junction to N59 Letteragh Junction as part of Phase 1 and N59 Letteragh Junction to R336 west of Bearna as part of Phase 2 (Refer **Section 7.4.2** above).

Some sections could also be commissioned as part of an advance works contract e.g. Parkmore Link Road or the N59 Link Road North and South to alleviate existing traffic congestion problems. However, it is noted that if Parkmore Link Road were to be constructed separately as an advanced contract the cutting and overbridge structure for the mainline will need to be completed at the same time as it would be difficult to implement post construction with live traffic on the link road.

7.4.14 Construction Site Decommissioning

On completion of construction, all construction facilities and equipment such as plant, materials, signage, contractors' offices and laydown areas, etc. will be removed from site. All ground will be reinstated to an appropriate standard.

7.5 Potential Construction Impacts

The potential impacts identified in this section represent the "worst case" scenario predicted in the absence of any mitigation.

Potential construction impacts include emissions to air such as dust, noise and vibration, construction traffic (including oversized deliveries), surface water runoff from the site, leaks or spills from construction plant and equipment, construction waste and disruption to road users during the road upgrade. Additional traffic on the road network will be generated by the construction works. These potential impacts are assessed in the relevant chapters of this EIAR as outlined below.

There is also the potential for impacts on major existing services during construction such as the gas distribution main at Rahoon, gas transmission main at School Road, Castlegar, the 110kV overhead cables at Ballybrit and Coolagh, Briarhill, the IDA sewer at Parkmore and other services that are in conflict with the proposed road development. There will be temporary outages and disruption to the services as new connections are made and/or services are relocated. Refer to **Chapter 15, Material Assets (Non-agricultural)** for further information in relation to these potential impacts.

Potential impacts associated with the construction activities outlined above and in **Section 7.4** are also considered in other chapters of this EIAR as follows:

- Construction traffic (refer **Chapter 6, Traffic Assessment and Route Cross Section**)
- Flora and fauna (ref. **Chapter 8, Biodiversity**)
- Soils and geology (ref. **Chapter 9, Soils and Geology**)
- Hydrogeology (ref. **Chapter 10, Hydrogeology**)
- Hydrology (ref. **Chapter 11, Hydrology**)
- Visual impacts (ref. **Chapter 12, Landscape and Visual**)
- Archaeological, architectural and cultural heritage (ref. **Chapter 13, Archaeological, Architectural & Cultural Heritage**)
- Material Assets (ref. **Chapter 14, Material Assets Agriculture** and **Chapter 15, Material Assets Non-Agriculture**)
- Air quality and climate (ref. **Chapter 16, Air Quality and Climate**)
- Noise and vibration (ref. **Chapter 17, Noise and Vibration**)
- Human beings and health (ref. **Chapter 18, Human Beings, Population and Health**)

Specific construction mitigation measures are described in the individual chapters and general mitigation measures are described below.

7.6 Mitigation Measures

7.6.1 Construction Environmental Management Plan

Every effort will be made to ensure that any negative environmental effects will be avoided, prevented or reduced during the construction phase.

A Construction Environmental Management Plan (CEMP) has been prepared and is included in **Appendix A.7.5** which will be updated and finalised by the Contractor prior to construction commencing. The CEMP comprises all of the construction mitigation measures, which are set out in this EIAR, and will be updated with any additional measures which are required by the conditions attached to An Bord Pleanála’s decision. Implementation of the CEMP will ensure disruption and nuisance are kept to a minimum. The plan has regard to the guidance contained in the handbook published by Construction Industry Research and Information Association (CIRIA) in the UK, *Environmental Good Practice on Site Guide, 4th Edition* (CIRIA 2015). The plan also has regard to the TII Guidelines for the Creation, Implementation and Maintenance of an Environmental Operating Plan.

A construction management team shall be appointed for the duration of the construction phase. This team will supervise the construction of the proposed road development, including monitoring the performance of the contractors to ensure that the proposed construction phase mitigation measures are implemented and that construction impacts and nuisance are minimised. The construction management team will liaise with neighbours and the general community during the construction phase to ensure that any disturbance is kept to a minimum.

The CEMP summarises the overall environmental management strategy that will be adopted and implemented during the construction phase of the proposed road development. The purpose of the CEMP is to demonstrate how the proposed construction works can be delivered in a logical, sensible and safe sequence with the incorporation of specific environmental control measures relevant to construction works of this nature. The CEMP sets out the mechanism by which environmental protection is to be achieved during the construction phase of the proposed road development. Implementation of the CEMP will ensure disruption and nuisance are kept to a minimum.

The CEMP has been prepared in conjunction with the Environmental Impact Assessment (EIA) Report and Natura Impact Statement (NIS), having regard to consultations with a range of specialists and environmental organisations, in particular, the National Parks and Wildlife Service (NPWS) and Inland Fisheries Ireland (IFI). The CEMP supports the information already provided in this EIAR and must be read in conjunction with the information already provided in this EIAR.

The information included in the CEMP are presented below:

- General Project Details
- Contact Sheets
- Reference Documents
- Organisational Structure/Duties and Responsibilities
- Environmental Commitments and Environmental Control Measures
- Site Specific Method Statements/Management Plans
  - Construction and Demolition Waste Management Plan
  - Sediment, Erosion and Pollution Control Plan
  - Non-native Invasive Species Management Plan
  - Incident Response Plan
  - Construction Traffic Management Plan
  - Environmental Awareness Training Strategy
  - Communications Strategy
  - Inspections, Auditing and Monitoring Compliance Strategy
  - Final Handover

The CEMP is a working document and will be finalised by the Contractor following appointment and prior to commencing works on site. All of the content provided in this CEMP will be implemented in full by the Contractor and its finalisation by the Contractor will not affect the robustness and adequacy of the information presented and relied upon in this EIAR. Some information (such as project details and the schedule of environmental commitments from the EIAR) has already been provided in this EIAR and is not repeated in the version of the CEMP in **Appendix A.7.5**. However, it will be included in the CEMP which is finalised by the Contractor.

In addition to the items listed above, the following information will also be provided by the Contractor when finalising the CEMP:

- Planning Consent - If planning approval is granted for the proposed road development, the entire contents of the planning consent will be included in the CEMP
- Comprehensively incorporate all Environmental Commitments set out in the Contract documents (in particular the Works Requirements), those presented in this EIAR and any additional commitments which may arise as part of the development consent process up to and including the Oral Hearing. The CEMP will include the complete suite of Environmental Commitments together with the relative specification, evidence and responsibilities of how each commitment will be met
- Relevant Environmental Performance Criteria prescribed in environmental legislation and in Contract documents
- Register of all applicable legislation, including relevant standards, Codes of Practice and Guidelines
- Description of the Environmental Management System of the proposed road development, which shall be devised according to the criteria of ISO 14001:2004 – Environmental Management Systems. The CEMP will be complemented by General Procedures, Work Procedures and Operations Instructions. These documents will be in place within the site administration offices and appropriate site locations during works

The CEMP is a dynamic document and the Contractor will ensure that it remains up to date for the duration of the construction period. The CEMP may need to be altered during the lifecycle of the construction period to take account of monitoring results, legislative changes, outcomes of third-party consultations etc. Additional appendices may be added to the CEMP to accommodate monitoring results, permits etc. However, the finalisation of the CEMP by the Contractor will not affect the robustness and adequacy of the information presented here and relied upon in this EIAR.

In order to help ensure the successful development, implementation and maintenance of the CEMP, the Contractor will be obliged to appoint a Site Environmental Manager (SEM). The SEM will possess sufficient training, experience and knowledge appropriate to the nature of the task to be undertaken, a Level Eight qualification recognised by the Higher Education and Training Awards Council (HETAC), or a University equivalent, or other qualifications acceptable to the Employer, in Environmental Science or Environmental Management, or other subjects acceptable to the Employer. In particular, the SEM will require suitably qualified ecological experts to oversee ecologically sensitive elements of the construction works, ecological derogation licensing requirements and ecological monitoring. Further details on the roles and responsibilities of the SEM are provided throughout the CEMP in **Appendix A.7.5**.

The key Site Specific Method Statements/Management Plans of relevance to this EIAR are described below.

A **Construction & Demolition (C&D) Waste Management Plan (WMP)** has been prepared as part of the CEMP to ensure that waste arising during the construction and demolition phase of the proposed road development on site will be managed and disposed of in a way that ensures compliance with the provisions of the Waste Management (Amendment) Act, 1996- 2011 and associated Regulations (1996-2011) to ensure that optimum levels of reduction, re-use and recycling are achieved and to ensure that waste management does not impact on any European sites.

The **Sediment, Erosion and Pollution Control Plan (SEPCP**) summarises the procedures and technical practices for implementing effective sediment, erosion and pollution control through a variety of delivery methods for the construction phase of the proposed road development. The purpose of this SEPCP is to demonstrate at this stage, how the proposed construction works can be delivered in a logical, sensible and safe sequence with the incorporation of specific sediment, erosion and pollution control measures relevant to construction works of this nature.

A **Non-native Invasive Species Management Plan (NISMP)** has been prepared to outline the strategy that will be adopted during the construction and operation of the proposed road development in order to manage and prevent the spread of the non-native alien invasive plant species to any European sites. Refer to **Section 7.6.6** for further details.

The focus of including all of the stringent measures in this CEMP is on prevention of the incident arising in the first place. However, an Incident Response Plan (IRP) has been prepared to ensure that in the unlikely event of an incident, response efforts are prompt, efficient, and suitable for particular circumstances. The IRP describes the procedures, lines of authority and processes that will be followed to ensure that incident response efforts are prompt, efficient, and suitable for particular circumstances. The IRP details the procedures to be undertaken in the event of the release of any sediment into a watercourse, serious spillage of chemical, fuel or other hazardous wastes (e.g. concrete), non-compliance incident with any permit or license, or other such risks that could lead to a pollution incident, including flood risks.

All of the Contractor’s site staff will receive relevant and appropriate training to ensure that they have the appropriate knowledge to successfully implement the CEMP.

The CEMP also outlines the communications strategy which will be adopted during the construction phase which ensures that awareness, education and information sharing procedures are adopted and implemented. Finally, the CEMP outlines the inspections, auditing and monitoring compliance strategy that will be adopted by the Contractor.

7.6.2 Dust

Emissions to air during earthmoving and construction will occur, although the prevailing weather, the size of the site and its distance from sensitive receptors will assist in facilitating the management of any effects. The focus of the control procedures will therefore be to reduce the generation of airborne material.

The assessment of potential construction impacts includes for the implementation of ‘standard dust control measures’, as stated in the TII guidance. This shall include the following measures:

- Spraying of exposed earthwork activities and site haul roads during dry weather
- Provision of wheel washes at exit points
- Control of vehicle speeds and speed restrictions. It is proposed that site traffic is restricted to 20km/hr. This will help to minimise the occurrence of dust re-suspension
- Sweeping of hard surface roads

Additional measures, including dust screens will be implemented at locations where there is the potential for air quality impacts during the construction phase. Ref **Chapter 16, Air Quality and Climate, Section 16.5.3**. Employee awareness is also a most important way that dust may be controlled on any site. Staff training and the vigilant management of operations ensure that all dust suppression methods are implemented and continuously inspected.

Dust deposition monitoring will be conducted at a number of locations in the vicinity of the proposed road development. At least one month of dust deposition monitoring will be carried out in advance of the commencement of works to determine a baseline.

Refer to **Chapter 16, Air Quality and Climate** and Section 8 Sediment, Erosion and Pollution Control Plan of the CEMP in **Appendix A.7.5**, of this EIAR.

7.6.3 Debris

The following are some of the measures that will be taken to ensure that the construction site and surroundings are maintained to a high standard of cleanliness:

- Daily inspections will be undertaken to monitor tidiness
- A regular program of site tidying will be established to ensure a safe and orderly site
- If necessary, scaffolding will have debris netting attached to prevent materials and equipment being scattered by the wind
- Food waste will be strictly controlled on all parts of the site
- Wheel wash facilities will be provided for vehicles exiting the construction site. Wheel wash run off will be stored in an onsite storage tank and will be disposed of by permitted waste haulage company at a permitted or licensed facility
- In the unlikely event that mud is carried from the construction site to the public road, it will be cleaned as required and will not be allowed to accumulate
- Loaded lorries and skips will be covered if required
- Surrounding roads used by trucks for access to and egress from the site will be inspected regularly and cleaned, using an approved mechanical road sweeper, when required

- In the event of any fugitive solid waste escaping the site, it will be collected immediately and removed to storage on site, and subsequently disposed of in the normal manner

7.6.4 Noise and Vibration

Construction noise will be kept to a minimum in accordance with BS 5228 (2009). Potential construction noise impacts are addressed in **Chapter 17, Noise and Vibration** of this EIAR.

The contract documents will clearly specify that the contractor, undertaking the construction of the works, will be obliged to comply with the construction noise and vibration limits included in the EIAR. This will require specific noise abatement measures in line with the best practice measures outlined in British Standard BS 5228 – 1: 2009 +A1 2014: *Code of practice for noise and vibration control on construction and open sites – Noise* and the NRA (now TII) guidelines *Good Practice Guideline for the Treatment of Noise during the planning of National Road Schemes* (NRA 2014).

There will be areas of potential impacts due to construction noise on neighbouring residences. Prior to the construction works commencing on site, environmental noise monitors will be installed at the selected locations. Refer to **Chapter 17, Noise and Vibration** of this EIAR for further details.

It is anticipated that potential vibration will be generated during the construction phases of the proposed road development in areas of excavation which require drill and blasting. Prior to the construction works commencing on site, environmental vibration monitors will be installed at the selected locations. Refer to **Chapter 17, Noise and Vibration** of this EIAR for further details.

Piling is also likely to be required during the construction of the proposed road development. It will utilise methods that will minimise the risk of vibration being generated and will only be undertaken in daytime. Rock breaking, where required will use methods that will minimise noise and vibration. It will be necessary to conduct monitored trial blasts in the same bedrock formation as the proposed blast locations as part of the blast design assessment. The trial blasts will calibrate the blast design to site specific designs and will refine and validate the blast design properties. Trial blasts will not exceed the limitations of the local sensitive receptors. A liaison officer will be appointed by the contractor to notify residents and business in proximity to all blast sites in advance of this work. Locations of potential blasting are included on **Figures 7.201** to **7.202**.

7.6.5 Existing Services

The existing services running within and adjacent to the site and the proposed road development will be carefully located, identified and suitable working methods will be employed to ensure that these services are protected. Diversion or relocation of services will be undertaken in consultation with the owners of the services and in accordance with the relevant standards and codes of practice. Some protection measures such as cover slabs may be used for the services which will be left in place. Refer to **Chapter 15, Material Assets Non-Agricultural** for further details.

Service users will be notified in advance of any temporary disruption or outages necessitated by the construction works. The disruption to services or outages will be carefully planned so the duration is minimised.

7.6.6 Non-native Invasive Plant Species

Ecological surveys undertaken for this EIAR recorded 13 locations of invasive plant species at various locations along the route of the proposed road development (ref. **Chapter 8, Biodiversity**).

- Himalayan knotweed - *Persicaria wallichii* – 2 No. locations
- Japanese knotweed - *Fallopia japonica* – 8 No. locations
- Rhododendron - *Rhododendron ponticum* – 3 No locations

Refer to **Figure 8.15.1** to **8.15.14** for location details.

Japanese knotweed and Himalayan knotweed dispersal typically occurs through rhizome fragments being transported in soil by humans or to a lesser extent, through passive mechanical means such as in floodwaters. Dispersal is also achieved through vegetative reproduction from plant fragments. The plant typically occurs along roadsides, riverbanks and waste ground in Ireland where it forms dense, monotypic stands. During the winter, the brown stalks remain standing even though the plant dies back to the rootstock. Japanese knotweed causes a range of problems due to its prolific and dense growth habit including blocking sightlines on roads, damage to paving and structures, erosion of riverbanks and flood defence structures, damage to archaeological sites, loss and displacement of native habitats and species. Japanese knotweed is widespread throughout Ireland and is spreading rapidly.

Rhododendron ponticum is invasive in Ireland. It can spread via seed or can also occur by vegetative means where plants sucker or throw up new sprouts from roots as well as branches. It can withstand considerable shade and thrives as an understorey species in woodland, though it also tolerates open conditions in suitable acid soils. Its dense tangle of stems can block pathways, smother watercourses and encroach on roadways thereby impinging on sight-lines. The foliage of rhododendron contains various compounds that appear to have an allelopathic action on other species (inhibiting their growth) which may further inhibit plants from growing within close proximity.

At present, there are no specific legislative provisions that directly govern Japanese knotweed control or removal in Ireland. Every effort shall be made by the Local Authority to eradicate the non-native invasive species prior to award of the construction contract.

The contractor will have to put in place a management plan to treat/remove any invasive plant species which may require resurveying prior to construction in accordance with the CEMP in **Appendix A.7.5**. There is also the potential for non-native invasive plant species to be inadvertently brought onsite in imported fill or on the wheels/tracks of construction vehicles. The supplier of fill will be required to provide a guarantee that the fill to be imported does not contain non-native invasive plant species. In addition, the fill will be inspected for signs of non-native invasive plant species, prior to importation to site. The UK Environmental

Agency's publication *Managing Japanese knotweed on development sites - The Knotweed Code of Practice* (EA 2013), states that inspection of topsoil brought into the site, should be carried out using the guidance in appendix I-IV of the code BS 3882:2007 *The British Standard Specification for topsoil and requirements for use*. This Standard was replaced subsequently by BS3882:2015 *Specification for Topsoil*. The inspection of fill will be carried out according to this Standard.

The contractor will be required to inspect vehicles before using them on site, and will pay particular attention to caterpillar tracks and where trucks and dumpers are stowed.

A management plan for the control of non-native invasive plant species on the site during construction is included in the CEMP in **Appendix A.7.5** and was developed with reference to the following codes of practice and guidelines:

- Best Practice Management Guidelines Japanese knotweed Fallopia japonica (2008) - prepared for NIEA and NPWS as part of Invasive Species Ireland
- NRA Guidelines on The Management of Noxious Weeds and Non-Native Invasive Plant Species on National Roads (2008)
- Managing Japanese knotweed on development sites - The Knotweed Code of Practice produced by the Environmental Agency

The implementation of the above measures will minimise the risk of Japanese Knotweed being spread within the site or to lands outside the site during the construction phase of the proposed road development.

A Non-native Invasive Species Management Plan is included in the CEMP in **Appendix A.7.5**.

7.6.7 Biodiversity

Potential impacts of the construction phase on biodiversity are addressed in **Chapter 8, Biodiversity** of this EIAR. Air and water pollution control measures are addressed in **Chapter 10, Hydrogeology**, **Chapter 11, Hydrology** and **Chapter 16, Air Quality and Climate**.

7.6.8 Waste Management

7.6.8.1 General

Waste generated during the construction phase will be carefully managed according to the accepted waste hierarchy which gives precedence to prevention, minimisation, reuse and recycling over disposal with energy recovery and finally disposal to landfill.

This hierarchy will be implemented by identifying opportunities to firstly prevent waste from being produced, and secondly minimise the amount of waste produced. Where prevention and minimisation will not be feasible, ways to reuse or recycle waste will be sought, preferably on-site to avoid the impacts arising from transportation. If this is not feasible, opportunities to reuse or recycle the waste off-site will be investigated or waste will be sent to an energy recovery facility, and only where there is no alternative, will waste be disposed of to landfill.

All waste removed from the site will be collected only by contractors with valid waste collection permits, under the Waste Management (Facility Permit and Registration) Regulations 2007 and (Amendment) Regulations 2008, 2014, 2015. All facilities to which waste will be taken will have appropriate waste licences or permits, under the Waste Management Act 1996, as amended, and the regulations thereunder, allowing them to accept the type of waste that is to be sent there. Hazardous waste generation will be minimised, and such waste will be recovered where feasible, and only disposed of if recovery is not feasible. Hazardous waste will be managed in accordance with the relevant legislation.

7.6.8.2 Resource and Waste Management

Surplus materials are likely to be generated as a result of demolition, excavation, construction and operation of the proposed road development.

Surplus materials generated during the following phases are addressed in this section:

- demolition phase
- excavation phase
- construction phase

There will also be operational waste from the proposed road development and it is likely to consist of road surface maintenance and landscaping wastes. Small quantities of operational waste are likely to be generated from the proposed road development. Contractors will be required to removed waste generated during works and deliver wastes to authorised waste facilities, for example waste permitted or EPA licenced facilities.

All wastes from the proposed road development will be delivered to authorised waste facilities in accordance with the Waste Management Acts 1996-2016. By only using facilities with the appropriate waste permits/licence, Galway County Council will be satisfied that the Contractor will comply with the objectives of the Waste Management Act and that any environmental emissions (noise, dust, water) are managed at the destination site and therefore are legally the responsibility of the owner/operator of the destination site. In this manner Galway County Council can be satisfied that the off-site spoil management aspect of the development is legally compliant with environmental and waste management legislation.

Demolition

An estimated 47,400 tonnes surplus demolition materials will be generated as a result of the proposed road development.

Excavation

An estimated 3,189,600m^3 excavated material will be reused within the proposed road development.

An estimated 15,200 tonnes (7,600m^3) waste will be generated as a result of the proposed road development.

Construction

In general, construction waste materials may include general construction debris, scrap timber and steel, machinery oils and chemical cleaning solutions. The practice of excessive purchase of materials and equipment to allow for anticipated wastage will be avoided.

The Building Research Establishment has published benchmark waste generation data from new build construction projects completed in the UK. Up to November 2009 a rate of 26.07m^3 waste / £100k was recorded in relation to civil engineering projects. Therefore, based on the estimated construction cost for the proposed road development an estimated 25,300 tonnes of construction waste will be generated.

7.6.8.3 Construction and Demolition Waste Management Plan for the Construction Phase

A Construction and Demolition Waste Management Plan is included in the CEMP in **Appendix A.7.5** to this report. This plan meets the requirements of the *Best Practice Guidelines for the Preparation of Waste Management Plans for Construction and Demolition Projects* (Department of Environment, Heritage & Local Government. 2006) and *TII Guidelines for the Management of Waste from National Road Construction Projects*. The contractor will be obliged to implement the Construction and Demolition Waste Management Plan.

7.6.9 Soil, Surface Water and Groundwater

There are several watercourses located along the route of proposed road development. The employment of good construction management practices will minimise the risk of pollution of soil, storm water run-off or groundwater. The Construction Industry Research and Information Association (CIRIA) in the UK has issued a guidance note on the control and management of water pollution from construction sites, *Control of Water Pollution from Construction Sites, guidance for consultants and contractors* (Masters-Williams et al 2001). Additional guidance is provided in the CIRIA technical guidance on *Control of Water Pollution from Linear Construction Projects* (Murnane *et al* 2006) and *TII Guidelines for the Crossing of Watercourses during the Construction of National Road Schemes*.

Site activities considered in the guidance include the following:

- excavation
- earthmoving
- concreting operations
- spreading of topsoil
- road surfacing
- site drainage, and the control and discharge of surface water runoff from the site

- oil and fuel delivery and storage
- plant maintenance

Measures, as recommended in the guidance above, that will be implemented to minimise the risk of spills and contamination of soils and waters, include:

- Training of site managers, foremen and workforce, including all subcontractors, in pollution risks and preventative measures
- Careful consideration will be given to the location of any fuel storage facilities. These will be designed in accordance with guidelines produced by CIRIA, and will be fully bunded
- All vehicles and plant will be regularly inspected for fuel, oil and hydraulic fluid leaks. Suitable equipment to deal with spills will be maintained on site
- Where feasible, soil excavation will be completed during dry periods and undertaken with excavators and dump trucks. Topsoil and subsoil will not be mixed together
- Ensure that all areas where liquids are stored or cleaning is carried out are in a designated impermeable area that is isolated from the surrounding area, e.g. by a roll-over bund, raised kerb, ramps or stepped access
- Use collection systems to prevent any contaminated drainage entering surface water drains, watercourses or groundwater, or draining onto the land
- Minimise the use of cleaning chemicals
- Use trigger-operated spray guns, with automatic water-supply cut-off
- Use settlement lagoons or suitable absorbent material such as flocculent to remove suspended solids such as mud and silt
- Ensure that all staff are trained and follow vehicle cleaning procedures. Post details of the procedures in the work area for easy reference

Refer also to the Sediment, Erosion and Pollution Control Plan included in the CEMP in **Appendix A.7.5**, **Chapter 10, Hydrogeology** and **Chapter 11, Hydrology**.

7.7 Residual Impacts

There will be little or no residual impacts as a result of the proposed construction activities. As described above the main impacts will be during the construction period. Any residual impacts to the existing environment such as deterioration of public roads used as haul routes will be repaired. Any structural damage caused to buildings/structures/wells as a result of the construction will undergo a full stabilisation and rehabilitation works. The residual impacts of the other construction related activities of the proposed road development are assessed in the relevant chapters of this EIAR.

7.8 Summary

An overall construction period of 36 months is anticipated for the construction of this proposed road development. It is envisaged that the construction will be phased and potentially in an east to west build with the sections outlined in **Section 7.4.7**. These sections can run concurrently and combined where feasible. Potential haul routes and site compound locations have been identified taking cognisance of potential impacts to existing environment and proximity to major structures along the proposed road development. Construction methods employed will be in accordance with best practice standards and guidelines. All necessary precautions and mitigation measures to reduce the potential impacts of the construction activities to the environment will be implemented. Management plans will be put in place to mitigate impacts such as dust, debris, noise and vibration, service diversions, non-native invasive plant species and waste.

8 Biodiversity

8.0 Executive Summary

This chapter presents an assessment of the likely significant effects of the proposed road development on the receiving biodiversity environment. Given the considerable level of detail contained in this assessment, a summary is first presented to give an overview and assist in an understanding of this chapter. Alongside the term "biodiversity", the terms "ecology" and "ecological" are also used throughout this chapter as a broader term to refer to the relationships of biodiversity receptors to one another and to their environment.

The collation of the biodiversity baseline data and the preparation of this chapter has had regard to current legislation relating to biodiversity protection and current best practice guidance documents on valuing biodiversity receptors and impact assessment - both for the purposes of EIA and AA.

A desktop study was carried out to inform the initial scope of the ecological surveys required for the environmental impact assessment. The desktop study involved collection and review of relevant published and unpublished sources of data, collation of existing information on the ecological environment and consultation with relevant statutory bodies (e.g. National Parks & Wildlife Service (NPWS) and Inland Fisheries Ireland (IFI)).

A comprehensive range of field surveys were carried out between 2013 and 2018 to inform the impact assessment. These included habitat surveys, surveys for protected plant species, mammal surveys (including dedicated surveys for Otter, Badger and bats), White-clawed crayfish surveys, molluscan surveys (including Freshwater pearl mussel and *Vertigo* snail species surveys), Marsh fritillary butterfly surveys, breeding and wintering bird surveys (including dedicated Barn owl, Peregrine falcon, Red grouse and Woodcock surveys), amphibian surveys, Common lizard surveys and fish surveys (including assessment of biological water quality status).

Each of the sections below provides a summary for each of the key ecological receptors (KERs[1]) in the receiving environment. These summaries include an overview of the baseline, the likely impacts of the proposed road development and the mitigation measures proposed to avoid or minimise the predicted impacts, including a monitoring[2] programme where relevant, the residual impacts remaining, and (where relevant) any compensation measures proposed to further address those residual impacts. Where used below, the term Zone of Influence (ZoI) refers to the area within which the proposed road development could affect the receiving biodiversity environment as a consequence of a particular potential impact.

[1]KERs are those biodiversity receptors within the ZoI of the proposed road development which are "both of sufficient value to be material in decision making and likely to be affected significantly" i.e. with an ecological value of local importance (higher value) or greater.

[2] In accordance with the requirement for monitoring set out in the EIA Directive 2014/52/EU to monitor significant effects on the environment

The KER summaries are divided into the following headings for ease of reading:

- Designed areas for nature conservation:
    - European sites (cSAC & SPA)
    - Natural Heritage Areas (NHA)
    - Proposed Natural Heritage Areas (pNHA)
- Habitats
- Rare and protected species
- Otter
- Bats
- Badger
- Other Mammal Species
- Mollusc species
- Marsh fritillary butterfly
- Breeding birds
- Wintering birds
- Amphibians
- Reptiles
- Fish

Local biodiversity areas, as defined in the *Galway City Development Plan 2017–2023* and the most recent draft of the *Galway City Biodiversity Action Plan 2014–2024* are also considered. Local biodiversity areas provide habitat for a range of species with the River Corrib corridor providing an important link between Galway Bay and the mosaic of habitats surrounding the city, which includes the wetland complex associated with Lough Corrib. The local biodivsersity areas that lie within the zone of influence of the proposed road development are:

- Rusheen Bay – Barna Woods – Illaunafamona
- Cappagh – Ballymoneen
- Ballagh – Barnacranny Hill
- River Corrib and adjoining wetlands
- Menlough to Coolough Hill
- Ballindooley – Castlegar (which is linked to the River Corrib by the Terryland River)
- Galway Racecourse, Ballybrit
- Doughiska
- Mutton Island and nearby shoreline

8.0.1 Designed areas for nature conservation

8.0.1.1 European sites – (candidate) Special Areas of Conservation ((c)SACs) and Special Protection Areas (SPAs)

There are four European sites within the ZoI of the proposed road development: Lough Corrib cSAC is traversed by the proposed road development, with Lough Corrib SPA located upstream and Galway Bay Complex cSAC and Inner Galway Bay SPA downstream of the proposed road development. There are no other European sites at risk of impacts from the proposed road development.

The potential impacts associated with the proposed road development, how these might affect the European sites' conservation objectives, and the mitigation measures that will be implemented to ensure that adverse effects on site integrity do not arise, are considered and assessed in full detail in the Natura Impact Statement (NIS). The conclusion of the NIS assessment was that the proposed road development will not adversely affect the integrity of any European site, either alone or in combination with other plans or projects.

The proposed road development will, however, have a residual biodiversity effect on Lough Corrib cSAC locally, as there will be permanent habitat losses and long-term effects on local bat populations[3] that use habitats within the European site. None of these impacts will affect the site's conservation objectives or adversely affect the integrity of Lough Corrib cSAC and therefore, the proposed road development will not result in a likely significant residual effect on any European sites.

The European sites are discussed in detail below with the receiving environment in **Section 8.3.3**; evaluation of impacts in **Section 8.5.3**; proposed mitigation measures in **Section 8.6.1** and residual impacts in **Section 8.7.1**.

8.0.1.2 Natural Heritage Areas (NHAs) and proposed Natural Heritage Areas (pNHAs)

Moycullen Bogs NHA lies immediately adjacent to the proposed road development at Tonabrocky and is the only NHA site within the ZoI of the proposed road development.

The potential impacts associated with the proposed road development on Moycullen Bogs NHA include the deposition of dust during construction, the introduction of non-native invasive plant species and surface water impacts during construction. Moycullen Bogs NHA is beyond the ZoI of any hydrogeological effects from the proposed road development. Mitigation measures will be implemented to ensure that the proposed road development does not affect habitats

---

[3] The Menlough Lesser horseshoe bat population is not connected to the Eborhall Lesser horseshoe bat population, which is the qualifying interest (QI) population for Lough Corrib cSAC. Any predicted impacts on Lesser horseshoe bats associated with the proposed road development will not affect the conservation objectives of the Lough Corrib cSACs QI Lesser horseshoe bat population.

and species in Moycullen Bogs NHA via these impacts. Therefore, the proposed road development will not result in likely significant residual effects on the NHA.

There are only two pNHA sites within the ZoI of the proposed road development: Lough Corrib pNHA and Galway bay Complex pNHA.

Lough Corrib pNHA is traversed by the proposed road development at the River Corrib Bridge crossing. The potential impacts associated with the proposed road development on this pNHA site are generally as per those discussed in the NIS in relation to Lough Corrib cSAC and Lough Corrib SPA – habitat loss, surface water impacts during construction, deposition of dust during construction, the introduction of non-native invasive plant species, hydrogeological impacts and mortality risk to aquatic species. However, the zone within which the proposed road development directly interacts with Lough Corrib pNHA is much smaller than that directly affected within Lough Corrib cSAC, and is limited to the River Corrib channel and banks at the proposed River Corrib Bridge. Mitigation measures will be implemented to avoid and minimise effects on biodiversity receptors in the receiving environment. As with Lough Corrib cSAC, although there will be some level of residual impact in the vicinity of the River Corrib this is not likely to affect the integrity of Lough Corrib pNHA.

Galway Bay Complex pNHA lies downstream of the proposed road development where it crosses the Bearna Stream catchment, the Knocknacarra Stream catchment and the River Corrib. The potential impacts associated with the proposed road development on this pNHA site are generally as per those discussed in the NIS in relation to Galway Bay Complex cSAC and Inner Galway Bay SPA - surface water impacts during construction, the introduction of non-native invasive plant species, barrier effect and mortality risk to aquatic species, affecting groundwater and disturbing wintering birds at important wetland sites (e.g. Ballindooley Lough). Mitigation measures will be implemented to ensure that the proposed road development will not result in likely significant residual effects on the pNHA via these impacts.

Therefore, the proposed road development will not result in likely significant residual effects on pNHAs.

The NHA and pNHA sites are discussed in detail below with the receiving environment in **Section 8.3.3**; evaluation of impacts in **Section 8.5.3**; proposed mitigation measures in **Section 8.6.1** and residual impacts in **Section 8.7.1**.

8.0.2 Habitats

West of the River Corrib, outside of the built environment, habitats recorded during the surveys generally consisted of a mosaic of agricultural fields, peatland/heath habitats, and scrub; separated into distinct habitat blocks of varying sizes by the local road network and the associated linear residential development. The peatland habitat blocks consisted of predominantly wet heath, dry heath and bog habitat mosaics.

The area from the River Corrib to the N84 Headford Road comprised of a patchwork of semi-natural woodland, limestone pavement, scrub and calcareous grassland fields. East of the N84 Headford Road, habitats comprised of predominantly improved agricultural grasslands surrounded by residential and industrial development in Parkmore, Ballybrit, Briarhill and Doughiska, although there were some isolated patches of semi-natural habitats – calcareous grassland and limestone pavement – in the Coolagh/Doughiska area. There were also two wetland complexes of note: at the Coolagh Lakes and at Ballindooley Lough.

Non-native invasive plant species (Japanese knotweed, Himalayan knotweed and Rhododendron) were recorded in dispersed locations across the study area.

The following Annex I habitats were recorded within, or adjacent to, the proposed development boundary: Hard water lakes [3140], Turloughs [*3180], Petrifying springs [*7220], Residual alluvial forests [*91E0], Limestone pavement [*8240], Wet heath [4010], Dry heath [4030], Calcareous grassland [*6210/6210], *Molinia* meadow [6410], Blanket bog (active) [*7130], *Cladium* fen [*7210], and Alkaline fen [7230].

The potential impacts of the proposed road development are loss of habitat, habitat fragmentation, and habitat degradation through effects on surface water quality, groundwater, deposition of dust during construction, the introduction of non-native invasive plant species and the structural stability of rock around tunnels and deep excavations/cuttings.

Mitigation measures will be implemented to protect surface water quality and groundwater in the receiving environment, control dust emissions from the construction site, control and prevent the spread of non-native invasive plant species, ensure that tunnelling and deep excavations do not affect the structural integrity of the surrounding rock mass, and to minimise habitat losses within the proposed development boundary.

However, the permanent losses of the following habitats will result in a likely significant negative residual effect at geographic scales ranging from local to international: a Petrifying spring feature at Lackagh Quarry, c.0.1ha of Residual alluvial forest habitat, c.0.54ha of Limestone pavement habitat, c.2.06ha of Wet heath habitat, c.1.85ha of Dry heath habitat, c.0.87ha of Wet heath/Dry heath/*Molinia* habitat mosaic, c.0.7ha of Calcareous grassland habitat (non-priority), c.0.28ha of *Molinia* meadow habitat, fifteen calcareous spring features (FP1), c.7.81ha of dry-humid acid grassland habitat, c.0.13ha of poor fen and flush (PF2) habitat, c.2.62ha of (mixed) broadleaved woodland (WD1), c.7.8km of hedgerows (WL1) and c.4km of treelines.

Compensatory habitat will be provided to replace the areas of Residual alluvial forest (c.0.18ha), Dry heath (c.7.06ha), Calcareous grassland (c.7.14ha), *Molinia* meadow (0.49ha), (mixed) broadleaved woodland (> 2.62ha), hedgerows (> 7.8km) and treelines (> 4km) by providing a greater area to that being permanently lost to the proposed road development.

However, some of the Annex I habitat types that are being lost, outside of any European sites, cannot be directly compensated. Therefore, there will be a likely significant residual negative effect at the international geographic scale for the permanent loss of c.0.54ha of Limestone pavement, at the national geographic scale for the permanent loss of c.2.93ha of Wet heath and wet heath mosaic habitat, at the county geographic scale for the loss of a Petrifying spring feature at Lackagh

Quarry, and at the local geographic scale for the permanent loss of 15 calcareous springs at Lackagh Quarry, c.7.81ha of dry-humid acid grassland and c.0.13ha of poor fen and flush habitat. The Annex I habitat impacts are summarised in **Table 8.0** below.

Table 8.0: Summary of Annex I Habitat Impacts

Annex I habitat type	**Area Potentially Impacted**	**Area to be Retained**	**Permanent area of habitat loss**	**Area of Compensatory Habitat**	**Residual Habitat Loss**
Turlough [*3180]	c.0.04ha within proposed development boundary[4]	All	None	n/a	None
Petrifying springs [*7220]	Two Petrifying spring features at Lackagh Quarry	One feature to be retained	One Petrifying spring feature	n/a	One Petrifying spring feature
Residual alluvial forest [*91E0]	c.0.1ha	None	c.0.1ha	c.0.18ha	None
Limestone pavement [*8240]	c.2.18ha	c.1.64ha	c.0.54ha	n/a	c.0.54ha
Limestone pavement/Calcareous grassland [*8240/6210] Above Lackagh Tunnel	c.0.12ha	All	None	n/a	None
Wet heath [4010]	c.2.06ha	None	c.2.06ha	n/a	c.2.06ha
Dry heath [4030]	c.1.96ha	c.0.11ha	c.1.85ha	c.7.06ha	None
Wet heath/Dry heath/*Molinia* mosaic [4010/4030/6410]	c.1.13ha	c.0.26ha	c.0.87ha	n/a	c.0.87ha
Calcareous grassland [6210]	c.1.14ha	c.0.44ha	c.0.7ha	c.7.14ha	None
Molinia meadow [6410]	c.1.02ha	c.0.74ha	c.0.28ha	c.0.49ha	None

Habitats are discussed in detail below with the receiving environment in **Section 8.3.4** and **8.3.6** (for non-native invasive plants); evaluation of impacts in **Section 8.5.4**; proposed mitigation measures in **Section 8.6.2** to **8.6.6**; residual impacts in **Section 8.7.2** and proposed compensatory measures in **Section 8.9.1**.

[4] Total area of Turlough is c.0.1ha

8.0.3 Rare and protected plant species

There are no rare or legally protected plant species present within the proposed development boundary or known from areas within the ZoI of the proposed road development. Therefore, the proposed road development will not result in likely significant residual effects on rare or legally protected plant species.

Rare and protected plant species are discussed in detail below with the receiving environment in **Section 8.3.5**; evaluation of impacts in **Section 8.5.5** and residual impacts in **Section 8.7.3**.

8.0.4 Otter

Otter, and their breeding and resting places, are protected under the Wildlife Acts. Otter are also listed on Annex II and Annex IV of the EU Habitats Directive. Evidence of Otter activity was abundant and widespread along the River Corrib corridor and the south-eastern shore of Lough Corrib. Otter were also recorded in the catchment of the Bearna Stream and the Tonabrocky Stream. There were no Otter holt or couch sites within the ZoI of the proposed road development.

The proposed road development will result in the loss of a small area of Otter habitat, it may pose a temporary habitat severance/barrier effect, and will result in some level of disturbance to Otter during construction and operation. However, this will not result in any long-term effects on the local Otter population. During operation, the combination of the network of wildlife passage facilities, culverts, bridges and viaduct structures (e.g. the proposed River Corrib Bridge and the Menlough Viaduct), and the mammal fencing, will reduce any long-term severance or barrier effects and the mortality risk associated with the proposed road development, such that the local Otter population will not be negatively affected. The effectiveness of the mitigation measures will be monitored post-construction.

Therefore, the proposed road development will not result in likely significant residual effects on the local Otter population.

Otter are discussed in detail below with the receiving environment in **Section 8.3.7.1**; evaluation of impacts in **Section 8.5.6.1**; proposed mitigation measures in **Section 8.6.7.1** and residual impacts in **Section 8.7.4.1**.

8.0.5 Bats

Bats, and their breeding and resting places, are protected under the Wildlife Acts. All bat species are also listed on Annex IV of the Habitats Directive; with the Lesser horseshoe bat also listed on Annex II. The following bat species were recorded locally during the field surveys: the Lesser horseshoe bat, Leisler’s bat, the Common pipistrelle bat, the Soprano pipistrelle bat, Nathusius’ pipistrelle bat, the Brown long-eared bat, Daubenton’s bat, Natterer’s bat and the Whiskered bat. A total of 88 roost sites were recorded within the local area during the field surveys.

The local Lesser horseshoe population is of particular importance given its Annex II status and the importance of the local area as a stepping-stone for the species between Lesser horseshoe bat populations in north Galway/south Mayo and south

Galway/Clare [5]. The maternity/hibernation roost at Menlo Castle and the mating/hibernation roost at Cooper's Cave in Castlegar are key roost sites for the Menlough Lesser horseshoe bat population, which are also supported by a network of smaller day/night roost sites across the local area. The foraging habitat surrounding the maternity roost is vital in supporting the local Lesser horseshoe bat population, as is the extent of foraging habitat and the commuting routes that connect the landscape between those key roost sites at Menlo Castle and Cooper's Cave. Although the proposed road development does not directly affect either the Menlo Castle or Cooper's Cave roosts, it will affect three Lesser horseshoe bat roost sites used by the Menlough population, will result in habitat loss within their foraging area (including in the vicinity of the maternity roost), and will present a barrier to movement between the maternity, mating and hibernation roost sites.

Fifteen buildings which support 20 bat roosts are within the proposed development boundary:

- six Soprano pipistrelle roosts
- one Common pipistrelle roost
- one unidentified Pipistrelle species bat roost
- seven Brown long-eared bats roost
- three Lesser horseshoe bat roosts
- two roosts of unidentified bat species

Fourteen of these buildings will be demolished with one (a Soprano pipistrelle roost) being retained.

Two of the trees along the proposed road development with a high potential to support roosting bats were confirmed as roosting sites, and will be removed:

- one Leisler's bat roost
- one Soprano pipistrelle roost

During construction, the proposed road development will also result in the loss of foraging habitat, habitat severance will affect bat commuting routes, habitat loss will present a barrier to bat flight paths, construction works will cause disturbance to roost sites, and lighting will disturb foraging and commuting bats.

During operation, the proposed road development will present a permanent mortality risk to the local bat populations, will permanently sever bat habitat and commuting routes and present a barrier to bat movements at a landscape scale. Operational lighting will also disturb and displace bats.

Mitigation measures will be implemented during construction to protect bats during building demolitions and tree removal and to preserve flight paths across the construction site. During operation, a series of underpasses and the Castlegar

[5] The Menlough Lesser horseshoe bat population is not connected to the Eborhall Lesser horseshoe bat population, which is the qualifying interest (QI) population for Lough Corrib cSAC. Any predicted impacts on Lesser horseshoe bats associated with the proposed road development will not affect the conservation objectives of the Lough Corrib cSACs QI Lesser horseshoe bat population.

Wildlife Overpass will be installed to allow bats to cross the proposed road development away from traffic, reducing the mortality risk and any permanent barrier effects. The lighting design has minimised the disturbance and displacement effects on bats during operation. The mitigation strategy includes pre-construction monitoring and monitoring of the effectiveness of the mitigation measures during and post-construction.

Despite the implementation of these mitigation measures there will be a significant residual effect on the local Lesser horseshoe bat population at the national geographic scale (given the importance of the local population), and on all other bat species at the local geographic scale.

To further reduce the effects of the residual impacts on the local bat populations, compensation measures are also proposed. These measures are:

- the provision of new roosting sites (new buildings, buildings retrofitted to create roost sites and bat boxes)
- measures to protect these roosts during construction
- and habitat enhancement measures (e.g. planting)

The effectiveness of the mitigation measures will be monitored as part of the monitoring programme.

With the compensation measures implemented the residual impacts of the proposed road development on bats will be reduced from a likely significant residual negative effect on the local bat populations at the national geographic scale to a local geographic scale.

Bats are discussed in detail below with the receiving environment in **Section 8.3.7.2**; evaluation of impacts in **Section 8.5.6.2**; proposed mitigation measures in **Section 8.6.7.2**; residual impacts in **Section 8.7.4.2** and proposed compensatory measures in **Section 8.9.2**.

8.0.6 Badger

Badger are protected under the Wildlife Acts and were recorded across the study area from Na Foraí Maola to the N83 Tuam Road. The highest concentrations of badger activity were recorded in the Menlough area and the area between Lackagh Quarry and the N84 Headford Road. A total of 17 badger setts were identified both within and in the vicinity of the study area.

Although the proposed road development will result in the loss of foraging habitat and disturbance due to light spill during operation, these impacts will not result in any long-term effects on the local population. The proposed road development will result in the loss of three badger setts, which includes the main and a subsidiary sett of one badger group at Lackagh. An artificial badger sett will be provided to reduce the effects of sett loss on this badger group.

Mitigation measures will also be implemented during construction to minimise the effects of disturbance on the local badger population and to avoid badgers being killed during sett removal. During operation, the combination of the network of wildlife passage facilities, culverts, bridges and viaduct structures (e.g. the proposed River Corrib Bridge and the Menlough Viaduct), and mammal fencing will reduce any long-term severance or barrier effects and the mortality risk associated with the proposed road development, such that the local Badger population will not be negatively affected. The effectiveness of the mitigation measures will be monitored post-construction.

Therefore, the proposed road development will not result in likely significant residual effects on the local Badger population.

Badgers are discussed in detail below with the receiving environment in **Section 8.3.7.3**; evaluation of impacts in **Section 8.5.6.3**; proposed mitigation measures in **Section 8.6.7.3** and residual impacts in **Section 8.7.4.3**.

8.0.7 Other Mammal Species

The following terrestrial mammal species protected under the Wildlife Acts were recorded, or are known, from the area surrounding the proposed road development:

- Pine marten
- Wood mouse
- Red squirrel
- Irish stoat
- Irish hare
- Hedgehog
- Pygmy shrew

Fox, Rabbit, Mink and Bank vole were also recorded during the field surveys.

Although the proposed road development will result in the loss of foraging habitat for these mammals, will present a low level of mortality risk and will result in disturbance/displacement effects, these impacts will not result in any long-term effects on local populations.

During operation, the combination of the network of wildlife passage facilities, culverts, bridges and viaduct structures (e.g. the proposed River Corrib Bridge and the Menlough Viaduct) will reduce any long-term severance or barrier effects associated with the proposed road development such that the local populations of these mammal species will not be negatively affected.

Harbour seal, Grey seal, Common dolphin and Harbour porpoise are known from Galway Bay and these species are all protected under the Wildlife Acts – both seal species are also listed on Annex II of the habitats directive and all cetacean species are listed on Annex IV of the Habitats Directive.

Mitigation measures will be implemented to ensure that the proposed road development will not affect water quality in the receiving aquatic or marine environments and therefore, will not affect the marine mammal populations in Galway Bay.

Therefore, the proposed road development will not result in likely significant residual effects on these terrestrial or marine mammal species.

These species are discussed in detail below with the receiving environment in **Section 8.3.7.4**; evaluation of impacts in **Section 8.5.6.4**; proposed mitigation measures in **Section 8.6.7.4** and residual impacts in **Section 8.7.4.4**.

8.0.8 Mollusc species

Neither the White-clawed crayfish, the Freshwater pearl mussel, nor any other legally protected mollusc species, were recorded within the ZoI of the proposed road development.

There is a Freshwater pearl mussel population in the Owenriff River (c.23km to the north, at Oughterard, Co. Galway) which the proposed road development could affect indirectly through impacting on salmonid fish populations in the River Corrib. This was considered and assessed in the NIS, as the Owenriff population are the qualifying interest population for Lough Corrib cSAC. The conclusion of this assessment was that, considering the mitigation measures to protect the aquatic environment, the proposed road development would not affect salmonid fish species in the receiving environment and therefore not affect that Freshwater pearl mussel population.

The Marsh whorl snail is listed as vulnerable in the Irish Red Data List of molluscs (Byrne *et al*., 2009) and was recorded in wetland habitat along the River Corrib, in fringing wetland habitat at the Coolagh Lakes, at Ballindooley Lough and at the marsh in Castlegar. Although the proposed road development will result in some level of habitat loss locally, and may also result in a level of mortality at affected sites during construction, this will not result in any long-term effects on the local population. Mitigation measures will be implemented to ensure that the proposed road development will not affect water quality in the receiving environment during construction or affect the local groundwater regime.

Therefore, the proposed road development will not result in likely significant residual effects on mollusc species.

White-clawed crayfish and Freshwater pearl mussel are discussed in detail below with the receiving environment in **Section 8.3.8.1** and **8.3.8.2**; evaluation of impacts in **Section 8.5.7.1** and **8.5.7.2** and residual impacts in **Section 8.7.5.1** and **8.7.5.2**.

8.0.9 Marsh fritillary butterfly

The Marsh fritillary butterfly is listed on Annex II of the Habitats Directive. A local breeding population is present and is supported by suitable habitat patches across the western part of the study area, some of which are directly affected by the proposed road development.

Although the proposed road development will result in the loss of Marsh fritillary habitat, and will sever some habitat areas within their local range, and will likely cause a low level of mortality during operation, this will not result in any long-tern effects on the local population. However, the mortality risk during site clearance has the potential to have a significant effect on the local Marsh fritillary butterfly population. A mitigation strategy will be implemented to minimise this risk and avoid any population level effects.

Therefore, the proposed road development will not result in likely significant residual effects on the Marsh fritillary butterfly.

Marsh fritillary butterfly are discussed in detail below with the receiving environment in **Section 8.3.8.4**; evaluation of impacts in **Section 8.5.7.4**; proposed mitigation measures in **Section 8.6.8.2** and residual impacts in **Section 8.7.5.4**.

8.0.10 Breeding birds

A wide range of breeding bird species (62 in total) were recorded across the study area. These included species of conservation concern listed on the Amber and Red Birds of Conservation Concern in Ireland (BoCCI) lists, Annex I bird species, and species listed as SCIs for nearby SPA sites. All wild bird species are protected under the Wildlife Acts.

The proposed road development will result in the loss of breeding bird nesting and foraging habitat, it will pose a mortality risk to birds and it will disturb and potentially displace birds from breeding and foraging habitat. However, it will not result in any long-term effects on the majority of local breeding bird populations.

Barn owl are a breeding bird species of high conservation concern in Ireland and are particularly at risk of mortality from collisions with traffic. The nest site at Menlo Castle is in close proximity to the main construction works. Mitigation measures will be implemented to minimise the risk of impacts on Barn owl and to avoid any significant long-term residual impact on the local Barn owl population. These measures include the provision of additional nesting opportunities (nest boxes) and planting in high-risk areas to discourage Barn owl from foraging along the road edge and to encourage Barn owl to fly over the road carriageway above traffic height. The effectiveness of the mitigation measures will be monitored post-construction as part of the monitoring programme.

Although the Peregrine falcon nest site at Lackagh Quarry will be retained, it will be subject to high levels of disturbance during construction and operation. Mitigation measures will be implemented to minimise any disturbance effects (seasonal constraint during construction). However, there remains a risk that the Peregrine falcon will abandon Lackagh Quarry as a nesting site as a result of the proximity of the road carriageway to the existing nest site and due to the lack of suitable alternatives ledges in the quarry post-construction. This is likely to have long-term effects on the Peregrine falcon population at a local and county geographic scale.

Although the proposed road development is not likely to result in any significant residual effects on the majority of breeding bird species, there is likely to be a significant negative residual effect on Peregrine falcon at the county geographic scale.

Breeding birds are discussed in detail below with the receiving environment in **Section 8.3.9.1**; evaluation of impacts in **Section 8.4.8.1**; proposed mitigation measures in **Section 8.5.9.1**; residual impacts in **Section 8.6.6.1** and proposed compensation measures in **Section 8.8.3**.

8.0.11 Wintering birds

A wide range of wintering bird species were recorded across the study area. These included species of conservation concern listed on the Amber and Red BoCCI lists, Annex I bird species, and species listed as SCIs for nearby SPA sites. All wild bird species are protected under the Wildlife Acts.

The proposed road development will result in habitat loss across sites where wintering birds were recorded. It will result in some level of disturbance during operation and the proposed River Corrib Bridge poses a low level of collision risk to birds. However, it is not likely to result in any long-term effects on most local wintering bird populations. Ballindooley Lough, however, is an important local site for wintering birds – fourteen wintering bird species were recorded during the field surveys, including species listed as SCIs for Lough Corrib SPA and Inner Galway Bay SPA. Blasting in the vicinity of Ballindooley Lough during construction has the potential to displace wintering birds from this wetland habitat complex over multiple seasons. A seasonal restriction on blasting in this area will minimise the impact and avoid any long-term effects on wintering birds at Ballindooley Lough. Mitigation measures will also be implemented to ensure that the proposed road development will not affect water quality in the receiving environment during construction, or affect the local groundwater regime that supports wetland used by wintering birds.

Therefore, the proposed road development will not result in likely significant residual effects on wintering birds.

Wintering birds are discussed in detail below with the receiving environment in **Section 8.3.9.2**; evaluation of impacts in **Section 8.4.8.2**; proposed mitigation measures in **Section 8.5.9.2** and residual impacts in **Section 8.6.6.2**.

8.0.12 Amphibians

The Common frog and the Smooth newt are protected under the Wildlife Acts and were recorded in wetland habitats across the local area, including habitat impacted by the proposed road development.

Although the proposed road development will result in a temporary severance/barrier effect during construction, and present a mortality risk during operation, these impacts will not result in any long-term effects on the local population.

Mitigation measures will be implemented during construction to minimise the effects of habitat loss and disturbance to amphibians, to ensure that Common frog or Smooth newt are not killed during site clearance works, and to protect water quality in wetland habitat used by these species. During operation, the combination of the network of wildlife passage facilities, culverts, bridges and viaduct structures (e.g. the proposed River Corrib Bridge and the Menlough Viaduct) will reduce any long-term severance or barrier effects associated with the proposed road development such that the local amphibian populations will not be negatively affected.

Therefore, the proposed road development will not result in likely significant residual effects on amphibian species.

Amphibians are discussed in detail below with the receiving environment in **Section 8.3.10**; evaluation of impacts in **Section 8.4.9**; proposed mitigation measures in **Section 8.5.10** and residual impacts in **Section 8.6.7**.

8.0.13 Reptiles

Common lizard are protected under the Wildlife Acts and were recorded at Troscaigh Thiar, north of Bearna Woods and Knocknafroska/Knocknabrona during the field surveys.

Although the proposed road development will result in a temporary severance/barrier effect during construction, and present a mortality risk during operation, these impacts will not result in any long-term effects on the local population.

Mitigation measures will be implemented during construction to minimise the effects of habitat loss and disturbance on the local Common lizard population and to ensure that lizards are not killed during site clearance works. During operation, the combination of the network of wildlife passage facilities, culverts, bridges and viaduct structures (e.g. the proposed River Corrib Bridge and the Menlough Viaduct) will reduce any long-term severance or barrier effects associated with the proposed road development such that the local lizard populations will not be negatively affected.

Therefore, the proposed road development will not result in likely significant residual effects on the Common lizard.

Reptiles are discussed in detail below with the receiving environment in **Section 8.3.11**; evaluation of impacts in **Section 8.4.10**; proposed mitigation measures in **Section 8.5.11** and residual impacts in **Section 8.6.8**.

8.0.14 Fish

Fish species are protected under the Fisheries Acts, with Atlantic salmon, Brook lamprey and Sea lamprey also listed on Annex II of the Habitats Directive.

The proposed road development will result the loss of aquatic habitat, construction works may disturb fish species, and construction works may pose a temporary barrier to fish movement on minor watercourses. However, it will not result in any long-term effects on local fish populations. The drainage design will protect water quality in the receiving aquatic environment during operation. Mitigation measures will be implemented to ensure that the proposed road development will not affect water quality in the receiving environment during construction, affect the local groundwater regime, and minimise the risk of fish mortality during construction.

Therefore, the proposed road development will not result in likely significant residual effects on fish species.

8.0.15 Significant Residual Impacts

The significant residual impacts remaining after mitigation are those associated with habitat loss (see **Section 8.1.2**), impacts on bats (see **Section 8.1.5**) and impacts on Peregrine falcon (see **Section 8.1.10**). In relation to habitat loss, this includes three priority Annex I habitats (Petrifying springs, Residual alluvial forests and Limestone pavement), four Annex I habitat types (Wet heath, Dry heath, *Molinia* meadow and Calcareous grassland), in addition to five other non-Annex habitat types of a local biodiversity value.

Where possible, compensatory measures will be implemented to reduce or avoid these significant residual impacts. The loss of areas of the Annex I habitats Residual alluvial forests, Dry heath, *Molinia* meadows and Calcareous grassland will be compensated for, as will the loss of broadleaved woodland, hedgerows and treelines, and there will not be any significant residual impacts. The compensatory measures will reduce the residual impact significance on all bat species to a local level.

Despite the implementation of the mitigation and compensation measures proposed, the proposed road development will have the following likely significant residual effects on biodiversity:

- A likely significant residual effect, at the international geographic scale, for the permanent loss of c.0.54ha of the priority Annex I habitat Limestone pavement [*8240]
- A likely significant residual effect, at the national geographic scale, for the permanent loss of c.2.93ha of the Annex I habitat Wet heath [4010]
- A likely significant residual effect, at the county geographic scale, for the permanent loss of a Petrifying spring [*7220] feature at Lackagh Quarry
- A likely significant residual effect, at the county geographic scale, for the potential permanent loss of a Peregrine falcon nest site at Lackagh Quarry
- A likely significant residual effect, at the local geographic scale, on all bat species due to the presence of the proposed road development within their foraging areas
- A likely significant residual effect, at the local geographic scale, for the permanent loss of 15 calcareous springs (FP1) at Lackagh Quarry, c.7.81ha of Dry-humid acid grassland (GS3) and c.0.13ha of Poor fen and flush habitat (PF2).

These significant residual effects will also affect the following local biodiversity areas: Coast Road (R336) to the N59 Moycullen Road, the River Corrib and the Coolagh Lakes, Menlough to Coolough Hill, Ballindooley – Castlegar and the Doughiska area.

Although the significant residual effects associated with the losses of Limestone pavement and Wet heath habitat cannot be directly compensated for, areas of related habitats will be created to provide a biodiversity gain for both peatland and limestone associated habitats locally. The area of Dry heath habitat being provided is c.7.06ha which is greater than the combined losses of all peatland habitats (c.4.78ha). The area of Calcareous grassland habitat being provided is c.7.14ha which is greater than the combined losses of Limestone pavement and Calcareous grassland habitat (c.1.24ha).

8.1 Introduction

This chapter of the EIAR consists of an impact appraisal of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, under the heading of Biodiversity.

In accordance with the requirements of *Directive 2014/52/EU of the European Parliament and of the Council of 16 April 2014 amending Directive 2011/92/EU on the assessment of the effects of certain public and private projects on the environment* (i.e. the EIA Directive), this chapter of the EIAR identifies, describes and assesses the likely direct and indirect significant effects of the proposed road development on biodiversity, with particular attention to species and habitats protected under Directive 92/43/EEC and Directive 2009/147/EC (i.e. the Habitats and Birds Directives). In addition, this chapter of the EIAR also identifies, describes and assesses the likely direct and indirect significant effects of the proposed road development on species protected pursuant to the Wildlife Acts 1976 to 2017.

The EIA Directive does not provide a definition of biodiversity. The Convention on Biological Diversity, however, gives a formal definition of biodiversity in its article 2: "biological diversity means the variability among living organisms from all sources including, inter alia, terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems". Alongside the term “biodiversity” the terms “ecology” and “ecological” are also used throughout this chapter as a broader term to consider the relationships of biodiversity receptors to one another and to their environment.

The chapter is set out as follows:

- **Section 8.2** presents the methodology
- **Section 8.3** describes the existing environment
- **Section 8.4** summarises the main characteristics of the proposed road development which are of relevance for biodiversity
- **Section 8.5** evaluates the impacts of the proposed road development on biodiversity
- **Section 8.6** describes the measures proposed to mitigate these impacts
- **Section 8.7** describes the residual impacts
- **Section 8.8** describes the cumulative impacts

- **Section 8.9** describes the compensatory measures proposed to address the residual impacts
- **Section 8.10** presents a summary of the biodiversity chapter
- **Section 8.11** are the references quoted throughout the chapter

Table 8.1 below presents an outline of where the various groupings of ecological receptors are discussed in this chapter, for ease of reference.

Table 8.1: Ecological Receptors Presented within this Chapter

Ecological Receptor	Information Presented	Section Reference
Designated Areas for Nature Conservation	Receiving Environment	8.3.3
	Evaluation of Impacts	8.5.3
	Mitigation Measures	8.6.1
	Residual Impacts	8.7.1
	Compensation	n/a

	Compensation	n/a

Along with surveys carried out specifically during the EIA phase of this project, this chapter has also utilised the information gathered during the constraints and route selection studies for the proposed road development to inform the biodiversity impact assessment. **Sections 4.3**, **6.5.1** and **7.6.1** of the **Route Selection Report** examined the biodiversity constraints within the scheme study area and compared the potential biodiversity impacts of the respective route corridors. These sections of the Route Selection Report contributed to the design of the proposed road development which this chapter assesses. **Chapter 5, Description of the Proposed Road Development** provides a detailed description of the proposed road development and **Chapter 7, Consturction Activies** outlines how it is proposed to construct the proposed road development.

8.2 Methodology

8.2.1 Introduction

The methodologies used to collate information on the baseline biodiversity environment and assess the potential impacts of the proposed road development are detailed in the following sections.

8.2.2 Legislation and Guidelines

The collation of ecological baseline data and the preparation of this chapter has had regard to the following legislation and guidance documents. This is not an exhaustive list of all legislation and guidelines but the most relevant legislative and guidelines basis for the purposes of preparing this EIAR.

Legislation:

- *Council Directive 92/43/EEC of 21 May 1992 on the conservation of natural habitats and of wild fauna and flora*, hereafter referred to as the Habitats Directive
- *Directive 2009/147/EC of the European Parliament and of the Council of 30 November 2009 on the conservation of wild birds*, hereafter referred to as the Birds Directive
- *European Communities (Birds and Natural Habitats) Regulations, 2011 (S.I. No. 477 of 2011)*, as amended, hereafter referred to as the Birds and Habitats Regulations
- *Directive 2011/92/EU of the European Parliament and of the Council of 13 December 2011 on the assessment of the effects of certain public and private projects on the environment, as amended by Directive 2014/52/EU of the European Parliament and of the Council of 16 April 2014*, hereafter referred to as the EIA Directive
- *Planning and Development Acts 2000 to 2017*, hereafter referred to as the Planning Acts[6]
- *Wildlife Acts 1976 to 2017*, hereafter referred to as the Wildlife Acts
- *Flora (Protection) Order, 2015 (S.I. No. 356 of 2015)*
- *Inland Fisheries Acts 1959 to 2017*, hereafter referred to as the Fisheries Acts.[7]

Guidance Documents:

- *Environmental Impact Assessment of Projects, Guidance on the preparation of the Environmental Impact Assessment Report* (European Commission, 2017)

[6] Updated to 2017 by virtue of Planning and Development (Amendment) Act 2017, s. 2(2).
[7] Updated to 2017 by virtue of Inland Fisheries (Amendment) Act 2017, s. 5(3).

- *Advice notes for Preparing Environmental Impact Statements* (Environmental Protection Agency, Draft September 2015)
- *Guidelines on the information to be contained in Environmental Impact Assessment Reports* (Environmental Protection Agency, Draft August 2017)
- *Guidelines on the Information to be contained in Environmental Impact Statements* (Environmental Protection Agency, 2002)
- *Advice Notes on Current Practice in the Preparation of Environmental Impact Statements* (Environmental Protection Agency, 2003)
- *Guidance on Integrating Climate Change and Biodiversity into Environmental Impact Assessment* (European Union, 2013)
- *Guidelines for Ecological Impact Assessment in the UK and Ireland: Terrestrial, Freshwater and Coastal, 2nd edition* (CIEEM, 2016)
- Environmental Guidelines Series for Planning and Construction of National Roads *(*National Roads Authority, 2005-2009)
- *Guidelines for Assessment of Ecological Impacts of National Road Schemes* (National Roads Authority, 2009)
- *Ecological Surveying Techniques for Protected Flora and Fauna during the Planning of National Road Schemes* (National Roads Authority, 2008a) *Bat Surveys for Professional Ecologists: Good Practice Guidelines (3rd edn)* (Collins, (ed.) 2016)
- *Environmental Impact Assessment of National Road Schemes – A Practical Guide* (National Roads Authority, 2008b)
- *The Bat Workers' Manual, 2nd Edition* (Mitchell-Jones & McLeish, 1999)
- *Bat Mitigation Guidelines for Ireland. Irish Wildlife Manuals, No. 25.* (Kelleher & Marnell, 2006)
- Design Manual for Roads and Bridges (Highways Agency 2001a, 2001b and 2005)
- *Circular NPW 1/10 & PSSP 2/10 Appropriate Assessment under Article 6 of the Habitats Directive: Guidance for Planning Authorities* (National Parks & Wildlife Service, 2010)
- *Circular Letter NPWS 2/07 Guidance on compliance with Regulation 23 of the Habitats Regulations 1997 – strict protection of certain species/applications for derogation licences* (National Parks & Wildlife Service, 2007a)

8.2.3 Data Sources and Consultations

A desktop study was carried out to inform the initial scope of the ecological surveys required to inform the environmental impact assessment. The desktop study involved collection and review of relevant published and unpublished sources of data, collation of existing information on the ecological environment and consultation with relevant statutory bodies.

8.2.3.1 Desk Study

The following sources were consulted during the desktop study to inform the scope of the ecological surveys:

- Online data available on Natura 2000 network of sites (hereafter referred to as European sites)[8] and on Natural Heritage Areas (NHAs) or proposed Natural Heritage Areas (pNHAs) as held by the National Parks and Wildlife Service (NPWS). Available online at <www.npws.ie/protectedsites/> and < http://webgis.npws.ie/npwsviewer/>. Accessed 06/09/2016 and 14/06/2017

[8] Article 3 of the Habitats Directive provides for the establishment of a coherent European ecological network of special areas of conservation, under the title Natura 2000. All Special Protection Areas for birds, as designated by legislation implementing the Birds Directive, are part of this Natura 2000 network. The aim of the network is to aid the long-term survival of Europe's most vulnerable and threatened species and habitats. In Ireland these sites are designated as "European sites" – defined under the Planning Acts and/or Birds and Habitats Regulations as (a) a candidate site of Community importance, (b) a site of Community importance, (c) a candidate special area of conservation, (d) a special area of conservation, (e) a candidate special protection area, or (f) a special protection area. They are commonly referred to in Ireland as Special Areas of Conservation (SACs) and Special Protection Areas (SPAs).

8.2.3.2 Consultations

The following organisations with relevance to ecology were consulted:

- The National Parks & Wildlife Service (NPWS) section of the Department of Culture, Heritage and the Gaeltacht (formerly the Department of Arts, Heritage, Regional, Rural and Gaeltacht Affairs, and previous to that, the Department of Arts, Heritage and the Gaeltacht)
- Inland Fisheries Ireland (IFI)
- Bat Conservation Ireland (BCI)
- BirdWatch Ireland (BWI)
- Botanical Society of Britain & Ireland (BSBI)
- Kate McAney of the Vincent Wildlife Trust, and
- Other members of the public with local knowledge/records (e.g. relating to bat roosts).

A summary of consultations with the NPWS Section of the Department of Culture, Heritage and the Gaeltacht (formely Department of Arts, Heritage, Regional, Rural and Gaeltacht Affairs and previous to that Department of Arts, Heritage and the Gaeltacht)/NPWS and IFI is provided below. Species or plant records are included under the relevant headings in **Section 8.3 Receiving Environment**.

8.2.3.2.1 Department of Culture, Heritage and the Gaeltacht (NPWS)

Six meetings have been held with the NPWS: on 2 July 2014, 26 March 2015, 24 February 2016, 29 March 2017, 18 April 2017 and 03 August 2017. A formal consultation response related to the informal EIS Scoping Report was received from the Department of Arts, Heritage and the Gaeltacht on the 10 August 2016 and two documents related to the EIAR and NIS on the 16 and 18 January 2018 (Ref. G Pre00241/2016 – a copy of this is included in **Appendix A.8.2**). The NPWS made the following comments/observations relevant to the preparation of the EIAR and also provided notes on a draft of the EIA Biodiversity Chapter:

- The EIAR must address likely significant effects on European sites. The EIAR may align with and cross-reference or reflect content of the Natura Impact Statement but may not omit, overlook or exclude consideration of the likely effects on European sites. Issues which were raised by the NPWS specifically of relevance to Appropriate Assessment are listed separately in the Natura Impact Statement and are not repeated here
- The EIAR must assess likely significant effects on Natural Heritage Areas and proposed Natural Heritage Areas which are selected for certain ecological features and these should be used to inform the scope of the scientific assessment and analysis in the EIAR. It must also assess likely significant effects on non-statutory sites such as local biodiversity areas
- Existing guidance on EIA should be followed when preparing the EIAR, while also being cognisant of changes in interpretation and application of the EU Nature Directives and national legislation arising from case law. Terminology used should align with the legislation and case law, and in particular the specific tests of the assessment process
- The EIAR should consider key ecological receptors and should present data, information and analysis specific and relevant to the proposed road development, including characterisation of habitats as Annex I/Annex I priority habitat types (or not as the case may be) with scientific justification and supporting evidence (such as vegetation community data) to support conclusions reached. Botanic surveys should survey for presence of protected or rare species known from or potentially occurring within the locality (e.g. *Pseudorchis albida* and *Allium schoenoprasum*). Assessment of impacts on Annex I habitat types should assess the likely effects on habitat structure and function and should assess whether habitat loss could result in unfavourable or worsening national conservation status
- The EIAR must include a full and detailed description of all elements of the proposed road development
- The EIAR must assess potential cumulative impacts, in particular on existing and permitted proposed developments, along with the details of any mitigation measures that apply. The assessment of cumulative impacts should examine effects arising from existing or historic developments which may have resulted in impacts since the date from which EIA requirements existed
- Full details of mitigation measures should be provided and shown on maps. The likely effects of mitigation measures themselves should also be assessed and mitigated where necessary. Mitigation measures should be demonstrated to be effective in addressing the effects arising and should be demonstrated to be feasible within the specific characteristics and constraints of the proposed development site
- Appropriate specialist supervision should be proposed as necessary to ensure the correct implementation of mitigation measures at all stages of the proposed road development, including advance works contract stages

- The assessments in the EIAR should suffice to support any application for licences or derogations that may be necessary to disturb strictly protected or protected species and their breeding or resting places
- The NPWS are in the process of updating the digital mapping datasets into the ITM projection on modern OSI mapping. For European sites where this has not yet been completed, presenting the boundary of European sites on mapping included in the EIAR/NIS should be based upon an interpretation of its location relative to its intended location on the official 6” mapping (relative to the topographical features it follows on that mapping dataset).

These observations and comments have been taken on board and implemented throughout the EIAR.

8.2.3.2.2 Inland Fisheries Ireland (IFI)

Two meetings were held with IFI to discuss the fisheries value of watercourses crossed by the proposed road development: the first on 14 August 2014 and the second on 15 September 2016.

During these meetings, and in correspondence related to same, IFI made the following observations.

- Overall the area which the proposed road development falls within avoids the more sensitive and important areas for fisheries
- The River Corrib is a nationally important river system for Atlantic salmon. The Bearna Stream supports Sea trout and Atlantic salmon and this watercourse would be one of the main sites for these species in the locality, and other than the River Corrib is the most important stream affected by the proposed road development. IFI recently undertook improvement works to the Bearna Stream, particularly for Sea trout. The Sea trout spawning area in the Bearna Stream is downstream of the proposed road development. The Knocknacarra Stream supports Sea trout and the Newpark Stream (north of Tonabrocky) has trout spawning habitat. The Terryland River has poor habitat for salmonids and has been heavily drained in recent times as part of flood prevention measures. Electrofishing of this watercourse found little or no salmonids or eels present. The Terryland River does have Pike
- IFI had no records of spawning grounds for salmonids at any of the proposed watercourse crossing points along the proposed road development
- The banks of the River Corrib have lamprey spawning sites. IFI have observed Sea lamprey scaling the Salmon Weir and spawning in the upper catchment at Cong – this contradicts some published sources which state that the species was thought to be restricted below the Salmon Weir in Galway City
- Eels are present in good numbers in the River Corrib and may be present in other affected watercourses in smaller numbers. Eel passage has successfully been provided at Salmon Weir to facilitate migration since the 1950s. Any barriers to migration of eel would be of concern

- Ballindooley Lough does not support salmonids or lamprey but is used for coarse fishing (i.e. Perch, Roach, Bream and Pike). This waterbody is sensitive from an angling rather than ecological perspective in terms of fisheries
- Angling and navigation on the River Corrib is of importance. The Coolagh Lakes are not widely fished
- White-clawed Crayfish are present in Lough Corrib (there are small numbers in the Clare River north of the proposed road development) and could also be present in the River Corrib
- Bio-security protocols will be very important for the proposed road development. *Lagarosiphon major* and the Zebra Mussel are significant problems in the Corrib system. IFI guidelines on bio-security will need to be followed for both surveys for the EIAR and at construction stage for the proposed road development
- Japanese Knotweed and Himalayan Balsam are present on both the Terryland River and River Corrib
- IFI's long term aim is to improve the quality of streams and rivers. The proposed road development should not impede the achievement of this aim. The Sea trout population in watercourses along the western section of the proposed road development have collapsed and the long term aim is to restore the species in this area
- Stormwater discharges, in particular direct discharges to watercourses, are of concern. This should be addressed in both the design and construction methodology for the proposed road development
- Fish passage should be provided by burying culverts below bed level, ensuring flow levels are not increased, including bristles or baffles, with maintenance of same where necessary
- Habitat restoration/reinstatement following instream works will be required
- IFI have requested to be present on-site during construction and in particular for any stream diversions. Electrofishing may be required to move any captured fish downstream of construction works
- IFI have requested a detailed method statement from the contractor in advance of instream works
- Instream works will only be permitted between 1 July and end of September in accordance with IFI guidelines (IFI, 2016)
- Access to the River Corrib should be maintained on both the eastern and western banks at the River Corrib crossing location
- Section 50 approval has been granted by OPW for the proposed culverts. These culverts are box culverts with 300mm gravel in the stream bed
- The proposed systems for treatment of surface water from the proposed road development are noted by IFI to generally work well

8.2.4 Study Area and Baseline Data Collection

8.2.4.1 Study Area

The term "scheme study area", when used in this chapter, refers to the wider study area at which ecological constraints were initially identified for the constraints and route selection studies for the project (see **Figures 8.1.1** and **8.1.2**). This is the geographic scale at which many of the EIA level ecological surveys were initially carried out. For many of the ecological receptors, surveys were also carried out within a more restricted study area, focussed on assessing potential impacts within the Zone of Influence (ZoI)[9] of the proposed road development. **Section 8.2.4.2** below, describes the study area(s) for each ecological receptor and, where relevant, these study areas are also shown on the accompanying **Figures 8.1.1** to **8.22.1**.

8.2.4.2 Field Surveys

This section outlines the various ecological survey methodologies used to collate baseline ecological information in the preparation of this chapter. The surveys carried out are summarised below in **Table 8.2** with the full description of the survey methodologies presented in **Appendix A.8.1**.

The scoping exercise undertaken for the constraints and route selection studies for the project identified numerous sensitive ecological receptors within the scheme study area that could potentially have been impacted by the proposed road development. As a result, EIA level surveys for many of these ecological receptors were undertaken at the route selection stage of the project in order to inform the selection of the emerging preferred route corridor, as due to their ecological value they were highly likely to affect the ranking of route options. However, many of these surveys were carried out over a larger survey area (see also **Section 8.2.4.1**) and at a resolution appropriate to gathering information to inform the constraints and route selection studies, hence the requirement to carry out additional surveys for the EIA stage of the project in subsequent seasons/years to supplement the information already gathered and fill any gaps, spatially, in the ecological baseline datasets. Under each section below, where different surveys relating to a particular ecological receptor (e.g. habitats) were undertaken over a number of survey seasons or covering different geographic locations along the route of the proposed road development, each of the surveys undertaken are described in chronological order.

[9] The 'zone of influence' for a development is the area over which ecological features may be subject to significant impacts as a result of the proposed development and associated activities (CIEEM, 2016) – see Section 8.3.1 for more detail on the ZoI as it relates to the proposed road development.

Table 8.2: Ecological Surveys and Survey Dates between 2013 and 2018

Survey	Survey Date(s)	Surveyor(s)
Habitat surveys[10]: • Lough Corrib cSAC – Selected Locations (RS) • Petrifying springs survey (RS) • Lough Corrib candidate Special Area of Conservation (cSAC) Study Area (RS) • Ecological Sites [11] (RS) • Aquatic habitats (RS) • Lackagh Quarry Petrifying spring survey (EIA) • EIA Habitat surveys (EIA)	July to September 2013 March to June 2014 May to September 2014 June to October, 2014 June to September, 2014 June 2015 September to December 2015 July to October 2016 May 2017 to January 2018	Botanical, Environmental & Conservation (BEC) Consultants Ltd., Scott Cawley Ltd. and various independent botanists including Dr Joanne Denyer, Dr John Conaghan, Dr Janice Fuller, Katharine Duff. Eamon O'Sullivan, Roger Goodwillie, Dr Cilian Roden, Michelle O'Neill and Mary O'Connor.
Protected plant species: • Slender naiad *Najas flexilis* (RS) • Varnished hook-moss *Hamatocaulis vernicosus* (RS)	June to September, 2014 September 2014	Dr Cilian Roden Dr Rory Hodd
Otter survey (River Corrib and Coolagh Lakes) (RS)	April and May 2014	Scott Cawley Ltd.
Mammal survey (excluding bats)	April to June and October/November 2015 October 2016 October/November 2017	Scott Cawley Ltd. and Dr Chris Peppiatt
Bat surveys: Winter hibernation surveys (RS and EIA) Building surveys (RS and EIA)	March 2014 & February 2015 & 2016, January 2018 July to October 2014 August /September 2015 July/August 2016	Scott Cawley Ltd., Greena Ecological Consultancy Ltd., Geckoella Ltd. and independent bat specialists including Conor Kelleher, Brian

[10] Some ecological surveys were carried out during the constraints and route selection studies of the project in 2014 and were carried out at a different spatial scale and without reference to any ZoI as it would relate to study area for the route of the proposed road development. These surveys later informed the EIA ecological surveys and for ease of reference are denoted with RS in parenthesis in **Table 8.2**. Those surveys carried out specific to the EIA assessment of the proposed road development and its ZoI are denoted with EIA in parenthesis.

[11] Ecological Sites, in this case, are sites of potential ecological value for the habitats present: i.e. determined to be at least of a Local Importance (higher value) (refer to National Roads Authority, 2009 for more detail). The boundaries of the Ecological Sites were initially defined based on interpretation of orthophotography and collation of available existing habitat information, in conjunction with a ground truthing exercise to verify the orthophotography interpretation. These boundaries were then refined, where appropriate, based on the findings of the various habitat surveys undertaken.

Survey	Survey Date(s)	Surveyor(s)
Tree surveys (EIA)	June/July 2017 August 2018 April to November 2015	Keeley, Isobel Abbott, Barbara McInerney, Caroline Shiel and Barry Ryan
Vehicle transect surveys (RS) Walked transect surveys (RS) Static detector activity surveys from 2014 to 2018 (RS and EIA) Radio-tracking studies (three studies in 2014, one study in 2015) (RS and EIA) Marking studies (RS and EIA)	June/July 2014 June/July 2014 August to November 2014 July to October 2015 July to August 2017 May 2018 July/August 2014 August 2014 September 2014 May 2015 July 2014 to August 2016	
White-clawed crayfish survey (RS)	September, 2014	Scott Cawley Ltd. and Dr Julian Reynolds
Molluscan surveys (includes Freshwater pearl mussel and *Vertigo* snail species surveys) (RS)	August 2014 October 2017 (two additional molluscan sites)	Dr Evelyn Moorkens and Dr Ian Killeen
Marsh fritillary surveys (RS and EIA)	September 2013 September/October 2014 September 2015 September 2016	Woodrow Environmental Consultants Ltd.
Red grouse survey (RS)	June to August, 2014	Dr Chris Peppiatt
Barn owl survey (RS and EIA)	June and July 2014 July 2015 June and July, 2016 May to September 2018	BirdWatch Ireland
Peregrine falcon survey (EIA)	June and July 2016 May to September 2018	BirdWatch Ireland
Breeding bird surveys (EIA)	May and June 2015 June 2016	Dr Chris Peppiatt, Gerry Murphy, John Small
Woodcock survey (EIA)	May/June 2015 & June 2016	Dr Chris Peppiatt
Wintering bird survey (RS)	September 2014 to March, 2015	Scott Cawley Ltd., Dr Chris Peppiatt, Gerry Murphy, John Small and Tom Cuffe.
Amphibian survey (EIA)	April to June 2015 June 2016	Scott Cawley Ltd. and Dr Chris Peppiatt
Reptile survey (EIA)	September/October 2015	Scott Cawley Ltd.
Fisheries surveys (including assessment of biological water quality status) (EIA)	September 2015	Triturus Environmental Services Ltd.

8.2.5 Impact Assessment Methodology

The biodiversity and ecological impacts of the proposed road development have been assessed using the following guidelines:

- *Environmental Impact Assessment of Projects, Guidance on the preparation of the Environmental Impact Assessment Report* (European Commission, 2017)
- *Guidelines on the Information to be contained in Environmental Impact Statements* (Environmental Protection Agency, 2002)
- *Advice Notes on Current Practice in the Preparation of Environmental Impact Statements* (Environmental Protection Agency, 2003)
- *Guidelines on the information to be contained in Environmental Impact Assessment Reports* (Environmental Protection Agency, Draft August 2017)
- *Advice notes for Preparing Environmental Impact Statements* (Environmental Protection Agency, Draft September 2015)
- *Guidelines for Ecological Impact Assessment in the UK and Ireland: Terrestrial, Freshwater and Coastal, 2nd edition* (CIEEM, 2016)
- *Guidelines for assessment of Ecological Impacts of National Road Schemes* (National Roads Authority, 2009)

Valuing the Ecological Receptors

Biodiversity receptors (including identified sites of biodiversity importance) have been valued with regard to the ecological valuation examples set out in the TII guidelines (National Roads Authority, 2009).

All Annex I habitats that lie outside of European sites, are valued as being of national importance, given that these habitats are of high conservation concern. However, priority Annex I habitat types are valued as being of international importance given that they are of the highest conservation concern at a European level (i.e. natural habitat types in danger of disappearance[12]).

Habitat areas within SACs are considered in the context of assessing impacts on the conservation objectives and site integrity of a given European site with regard to the Appropriate Assessment tests set out in Article 6(3) of the Habitats Directive. All European sites are valued as internationally important.

In accordance with TII guidelines (National Roads Authority, 2009), biodiversity features within the Zone of Influence (ZoI) of the proposed road development which are "both of sufficient value to be material in decision making and likely to be affected significantly" are deemed to be 'Key Ecological Receptors' (KERs). These are the biodiversity receptors which may be subject to likely significant effects from the proposed road development, either directly or indirectly. KERs are those biodiversity receptors with an ecological value of local importance (higher value) or greater.

Characterising and Describing the Impacts

[12] From the definition of "priority natural habitat types" in Article 1(d) of the Habitats Directive

The parameters considered in characterising and describing the magnitude or scale of the potential impacts of the proposed road development are outlined in **Table 8.3** below.

Table 8.3: Parameters used to characterise and describe the magnitude or scale of potential impacts

Parameter	Categories
Type of impact	Positive/Neutral/Negative May also include Cumulative Effects, 'Do Nothing Effects', 'Do Minimum Effects', Indeterminable Effects, Irreversible Effects, Residual Effects, Synergistic Effects, Indirect Effects and/or Secondary Effects
Extent	The size of the affected area/habitat and/or the proportion of a population affected by the effect
Duration	The period of time over which the effect will occur[13].
Frequency and Timing	How often the effect will occur; particularly in the context of relevant life-stages or seasons
Reversibility	Permanent/Temporary Will an impact reverse; either spontaneously or as a result of a specific action

The likelihood of an impact occurring, and the predicted effects, are also an important consideration in characterising impacts. The likelihood of an impact occurring is assessed as being certain, likely or unlikely; in some cases it may be possible to definitively conclude that an impact will not occur.

Professional judgement is used in considering the contribution of all relevant criteria in determining the overall magnitude of an impact.

Impact Significance

In determining impact significance, the NRA (2009) and CIEEM (2016) guidelines were followed, which requires examination of the following two key elements:

- Impact on the integrity of the ecological feature
- Impact on its conservation status within a given geographical area

Integrity

The term "integrity" should be regarded as the coherence of ecological structure and function, across the entirety of a site that enables it to sustain all of the biodiversity or ecological resources for which it has been valued (National Roads Authority, 2009).

The term 'integrity' is most often used when determining impact significance in relation to designated areas for nature conservation (e.g. SACs, SPAs or pNHA/NHAs) but can often be the most appropriate method to use for non-

[13] The following terms/definitions for describing the duration of impacts are provided in the Environmental Protection Agency guidelines (Draft August 2017): Momentary Effects - effects lasting from seconds to minutes; Brief Effects - effects lasting less than a day; Temporary Effects - effects lasting less than a year; Short-term Effects - effects lasting one to seven years; Medium-term Effects - effects lasting seven to fifteen years; Long-term Effects - effects lasting fifteen to sixty years; Permanent Effects - effects lasting over sixty years.

designated areas of biodiversity value where the component habitats and/or species exist with a defined ecosystem at a given geographic scale.

An impact on the integrity of an ecological site or ecosystem is considered to be significant if it moves the condition of the ecosystem away from a favourable condition: removing or changing the processes that support the sites' habitats and/or species; affect the nature, extent, structure and functioning of component habitats; and/or, affect the population size and viability of component species.

Conservation Status

The definitions for conservation status given in the EU Habitats Directive 92/43/EEC, in relation to habitats and species, are also used in the CIEEM (2016) and NRA (2009) guidance:

- For natural habitats, conservation status means the sum of the influences acting on the natural habitat and its typical species, that may affect its long-term distribution, structure and functions as well as the long-term survival of its typical species, at the appropriate geographical scale
- For species, conservation status means the sum of influences acting on the species concerned that may affect the long-term distribution and abundance of its populations, at the appropriate geographical scale

An impact on the conservation status of a habitat or species is considered to be significant if it will result in a change in conservation status.

After the definitions provided in the EU Habitats Directive 92/43/EEC, the conservation status of a habitat is favourable when:

- Its natural range and areas it covers within that range are stable or increasing
- The specific structure and functions which are necessary for its long-term maintenance exist and are likely to continue to exist for the foreseeable future
- The conservation status of its typical species is favourable as defined below under species

And, the conservation status of a species is favourable when:

- Population dynamics data on the species concerned indicate that it is maintaining itself on a long-term basis as a viable component of its natural habitats
- The natural range of the species is neither being reduced nor is likely to be reduced for the foreseeable future
- There is, and will probably continue to be, a sufficiently large habitat to maintain its populations on a long-term basis

According to the TII/CIEEM methodology, if it is determined that the integrity and/or conservation status of an ecological feature will be impacted on, then the level of significance of that impact is related to the geographical scale at which the impact will occur (i.e. local, county, national, international). In some cases an impact may not be significant at the geographic scale at which the ecological feature has been valued but may be significant at a lower geographical level. For example, a particular impact may not be considered likely to have a negative effect on the overall conservation status of a species which is considered to be internationally important. However, an impact may occur at a local level on this internationally important species. In this case, the impact on an internationally important species is considered to be significant at only a local, rather than international level.

8.3 Receiving Environment

The following section describes the receiving ecological environment and biodiversity within the Zone of Influence (ZoI) of the proposed road development.

The proposed road development extends around the north of Galway City from the Coast Road (R336), west of Bearna, to the existing N6 at Coolagh, Briarhill. There are four significant structures included in the design of the proposed road development, namely the River Corrib Bridge, Menlough Viaduct, Lackagh Tunnel and Galway Racecourse Tunnel. A full description of the proposed road development is presented in **Chapter 5, Description of the Proposed Road Development**.

The nature of the local receiving environment is heavily influenced by the underlying geology. Lands to the west of the N59 Moycullen Road are underlain by granite and are characterised by a mosaic of peatland habitats set amongst the local road network and associated linear residential development. This area slopes towards Galway Bay to the south and is drained by a network of small streams including Sruthán na Líbeirtí, the Trusky Stream, the Bearna Stream, the Tonabrocky Stream and the Knocknacarra Stream. Lands to the east of the N59 Moycullen Road are underlain by limestone which gives rise to a karst landscape. The NUIG Sporting Campus lie on the western side of the River Corrib. Moving east from the River Corrib the landscape is characterised by a mosaic of semi-natural woodland, scrub and exposed limestone rock as far as Lackagh Quarry. East of here, these habitats exist in more isolated patches amongst the improved agricultural fields and industrial/commercial developments that fringe the eastern edge of Galway City. In the eastern part of the study area the River Corrib (and it's tributary the Terryland River) are the only watercourses present. There are two wetland complexes associated with freshwater lake systems, Coolagh Lakes and Ballindooley Lough, both of which are influenced by the underlying karst groundwater regime.

Section 8.3.1 establishes the ZoI of the proposed road development. **Section 8.3.2** summarises the results of the desk study and consultations undertaken in the preparation of this chapter. **Section 8.3.4** to **Section 8.3.13** describe the ecological baseline as it relates to the ecological receptors recorded, or known from, the study area under the following headings: habitats, rare and protected plant species, non-native invasive plant species, mammals (excluding bats), bats, invertebrate species, bird species, amphibian species, reptiles and fish. **Section 8.3.14** provides a summary of the ecological valuation of each ecological receptor potentially affected by the proposed road development and identifies those which are Key Ecological receptors (KERs) and subject to impact assessment.

8.3.1 Zone of Influence

The Zone of Influence (ZoI), or distance over which a likely significant effect may occur will differ across the Key Ecological Receptors, depending on the potential impact pathway(s). The results of both the desk study and the suite of ecological field surveys undertaken has established the habitats and species present along the proposed road development. The ZoI is then informed and defined by the sensitivities of each of the ecological receptors present, in conjunction with the nature and potential impacts associated with the proposed road development.

The ZoI of the proposed road development in relation to terrestrial habitats is generally limited to the footprint of the proposed road development, and the immediate environs (to take account of shading or other indirect impacts, such as air quality). Hydrogeological/hydrological linkages (e.g. rivers or groundwater flows) between impact sources and wetland/aquatic habitats can often result in impacts occurring at significant distances. The unmitigated hydrogeological ZoI for the proposed road development is shown on **Figure 10.7.1** to **10.7.14** and **10.9.1** to **10.9.14**. In the western part of the study area, it generally follows the proposed development boundary plus a buffer of up to c.30m in places. East of the N59 Moycullen Road, the ZoI is more expansive, given the underlying karst geology and the potential for groundwater impacts within those groundwater bodies traversed by the proposed road development.

With regard to hydrological impacts, the distances over which water-borne pollutants are likely to remain in sufficient concentrations to have a likely significant effect on receiving waters and associated wetland/terrestrial habitats is difficult to quantify and highly site-specific and related to the predicted magnitude of any potential pollution event. Evidently, it will depend on volumes of discharged waters, concentrations and types of pollutants (in this case sediment, hydrocarbons, and heavy metals), volumes of receiving waters, and the sensitivity of the ecology of the receiving waters. In the case of the proposed road development, this includes all freshwater habitat downstream of the proposed watercourse crossings and Galway Bay.

The ZoI of air quality effects is generally local to the proposed road edge and not greater than a distance of 200m.

The ZoI for small mammal species, such as the Pygmy Shrew, would be expected to be limited to no more than 100m from the proposed development boundary due to their small territory sizes and sedentary lifecycle. The ZoI for Otters, Badgers, Stoat, and Hedgehogs may extend over greater distances than small mammal and bird species due to their ability to disperse many kilometres from their natal site. The ZoI of impacts for significant disturbance impacts to Badger and Otter breeding/resting places is 150m from the proposed development boundary.

The ZoI of potential impacts to bat roosts would not be expected to exceed 200m in most cases but as affects are dependent on many factors (such as species, roost type, surrounding habitat, commuting routes etc.), this is assessed on a case by case basis and the ZoI may increase/decrease from this distance accordingly. Given the large foraging ranges for some species[14], the ZoI of potential landscape scale impacts, such as habitat loss and severance, could extend for several kilometres from the proposed road development but the most significant effects are likely to occur within 1km of important roost sites (e.g. maternity roosts).

The ZoI of the proposed road development in relation to likely significant effects on most breeding bird species is generally limited to habitat loss within the footprint of the proposed road development, and disturbance/displacement during construction and disruption in territorial singing due to noise during operation. Disturbance effects may extend for several hundred metres from the proposed road development.

The ZoI in relation to direct impacts to wintering birds could extend up to 300m from the proposed road development for general construction activities, and as far as 800m where prolonged blasting will be carried out, as many species are highly susceptible to disturbance from loud and unpredictable noise during construction. However, as many estuarine bird species use inland habitat areas at distances from the coast, the ZoI for ex-situ impacts could extend a considerable distance from the proposed road development. In the case of the proposed road development, impacts to wintering birds within this 300m band could affect the use of potential ex-situ sites for bird species listed as Special Conservation Interests of the nearby Lough Corrib SPA and Inner Galway Bay SPA.

The ZoI in relation to amphibian species is likely to be limited to direct habitat loss with the proposed development boundary and/or indirect impacts to water quality in wetland habitats hydrologically connected to the proposed road development.

The ZoI in relation to the Common lizard is likely to be limited to direct habitat loss with the proposed development boundary and disturbance/displacement effects in the immediate vicinity during construction.

The ZoI for impacts to aquatic species, such as Atlantic salmon and lamprey species, is limited to those watercourses crossed by the proposed road development or waterbodies to which runoff from the proposed road development could drain to during construction (i.e. Coolagh Lakes). However, impacts could occur at significant distances downstream depending on the magnitude and duration of any pollution event; potentially even affecting species in Galway Bay.

The ecological ZoI of the proposed road development is shown on **Figure 8.12.1** and **Figure 8.13.1**.

8.3.2 Desk Study

The results of the desktop review are provided in **Appendix A.8.18** and are incorporated into the sections below under the relevant headings, as relevant. Additional discussion on local biodiversity areas from the draft *Galway City Biodiversity Action Plan 2014-2024* is also provided below.

---

[14] Leisler's bats have been recorded foraging up to 13km from maternity roost sites (Shiel et al., 1999)

8.3.2.1 Local Biodiversity Areas

The *Galway City Development Plan 2017–2023* and the most recent draft of the *Galway City Biodiversity Action Plan 2014–2024* include reference to a local network of biodiversity areas in the city. These areas are derived from sites identified in the *Galway City Habitats Inventory* (Natura, 2005) and were defined based upon habitat areas of high biodiversity value.

Some of these local biodiversity areas lie within the zone of influence of the proposed road development and, where relevant, the habitats present within these areas are discussed further below in **Section 8.3.4** and the potential impacts assessed in **Section 8.5.4**. The relevant local biodiversity areas are:

- Rusheen Bay – Barna Woods – Illaunafamona
- Cappagh – Ballymoneen
- Ballagh – Barnacranny Hill
- River Corrib and adjoining wetlands
- Menlough to Coolough Hill
- Ballindooley – Castlegar (which is linked to the River Corrib by the Terryland River)
- Galway Racecourse, Ballybrit
- Doughiska
- Mutton Island and nearby shoreline

Local biodiversity areas provide habitat for a range of species with the River Corrib corridor providing an important link between Galway Bay and the mosaic of habitats surrounding the city, which includes the wetland complex associated with Lough Corrib. Important fauna species noted in the most recent draft of the *Galway City Biodiversity Action Plan 2014–2024* include Pine marten *Martes martes*, Wood mouse *Apodemus sylvaticus*, Irish stoat *Mustela erminea hibernica*, Irish hare *Lepus timidus hibernicus*, Hedgehog *Erinaceus europaeus*, Pygmy shrew *Sorex minutus*, Harbour seal *Phoca* vitulina, Fox *Vulpes vulpes*, Bank vole *Myodes glareolus,* Otter *Lutra lutra*, Badger *Meles meles,* Lesser horseshoe bat *Rhinolophus hipposideros*, Leisler's bat *Nyctalus leisleri*, Common pipistrelle bat *Pipistrellus pipistrellus*, Soprano pipistrelle bat *Pipistrellus pygmaeus*, Brown long-eared bat *Plecotus auritus*, Daubenton's bat *Myotis daubentonii*, Natterer's bat *Myotis nattereri* and the Whiskered bat *Myotis mystacinus*. These species are discussed further below in **Section 8.3.7** and the potential impacts assessed in **Section 8.5.6**. The Flora (Protection) Order, 2015 listed species Slender cottongrass *Eriophorum gracile* and the Small white orchid *Pseudorchis albida* are also noted in the plan and are discussed further below in **Section 8.3.5** and the potential impacts assessed in **Section 8.5.5**.

8.3.3 Designated Areas for Nature Conservation

8.3.3.1 European Sites

Candidate Special Areas of Conservation (cSAC) are designated under the EC Habitats Directive (92/43/EEC) as amended, which is transposed into Irish law through a variety of legislation including the Birds and Habitats Regulations and the Planning Acts, for the protection of habitats listed on Annex I and/or species listed on Annex II of the Directive.

Special Protection Areas (SPAs) are designated under the Birds Directive (2009/147/EC) for the protection of protected bird species listed on Annex I of the Directive, regularly occurring populations of migratory species (such as ducks, geese or waders), and areas of international importance for migratory birds.

The proposed road development traverses through, and adjacent to, the Lough Corrib cSAC and there are three other European sites nearby (Lough Corrib SPA is upstream of the proposed road development and Galway Bay Complex cSAC, and Inner Galway Bay SPA are downstream) with a number of other European sites located at a greater distance from the proposed development boundary. There are 19 European sites (cSACs or SPAs) located within 15km[15] of the proposed development boundary (**Figure 8.12.1**) which encompasses all European sites within the ZoI of the proposed road development. **Table 8.4** below lists these sites, their distance from the proposed development boundary, and the sites Qualifying Interests/Special Conservation Interests.

Table 8.4: European Sites (cSACs and SPAs) within 15km of the proposed development boundary

Site Name	Distance[16]	Reasons for Designation – Qualifying Interests (QIs) or Special Conservation Interests (SCIs)
Candidate Special Areas of Conservation		
Lough Corrib cSAC [000297]	crossed by the proposed road develop-ment	[1029] Freshwater pearl mussel *Margaritifera margaritifera* [1092] White-clawed crayfish *Austropotamobius pallipes* [1095] Sea lamprey *Petromyzon marinus* [1096] Brook lamprey *Lampetra planeri* [1106] Atlantic salmon *Salmo salar* (only in fresh water) [1303] Lesser horseshoe bat *Rhinolophus hipposideros* [1355] Otter *Lutra lutra* [1393] Varnished hook-moss *Drepanocladus (Hamatocaulis) vernicosus* [1833] Slender naiad *Najas flexilis* [3110] Oligotrophic waters containing very few minerals of sandy plains (*Littorelletalia uniflorae*)

[15] 15km used as an itial reference scale only and did not inform the definition of the ZoI nor did it influence the identification of designated sites at risk from potential impacts associated with the proposed road development
[16] Distance in km/m from the proposed road development

Site Name	Distance[16]	Reasons for Designation – Qualifying Interests (QIs) or Special Conservation Interests (SCIs)
		[3130] Oligotrophic to mesotrophic standing waters with vegetation of the *Littorelletea uniflorae* and/or of the *Isoëto-Nanojuncetea* [3140] Hard oligo-mesotrophic waters with benthic vegetation of *Chara* spp. [3260] Water courses of plain to montane levels with the *Ranunculion fluitantis* and *Callitricho-Batrachion* vegetation [6210] Semi-natural dry grasslands and scrubland facies on calcareous substrates (*Festuco Brometalia*) (*important orchid sites) [6410] *Molinia* meadows on calcareous, peaty or clayey-silt-laden soils (*Molinion caeruleae*) [7110] * Active raised bogs [7120] Degraded raised bogs still capable of natural regeneration [7150] Depressions on peat substrates of the *Rhynchosporion* [7210] * Calcareous fens with *Cladium mariscus* and species of the *Caricion davallianae* [7220] * Petrifying springs with tufa formation (*Cratoneurion*) [7230] Alkaline fens [8240] * Limestone pavements [91A0] Old sessile oak woods with *Ilex* and *Blechnum* in the British Isles [91D0] * Bog woodland
Galway Bay Complex cSAC [000268][17]	160m	[1140] Mudflats and sandflats not covered by seawater at low tide [1150] Coastal lagoons* [1160] Large shallow inlets and bays [1170] Reefs [1220] Perennial vegetation of stony banks [1310] *Salicornia* and other annuals colonising mud and sand [1330] Atlantic salt meadows (*Glauco-Puccinellietalia maritimae*) [1355] Otter *Lutra lutra* [1365] Harbour seal *Phoca vitulina* [1410] Mediterranean salt meadows (*Juncetalia maritimi*) [3180] Turloughs* [5130] *Juniperus communis* formations on heaths or calcareous grasslands

[17] Inner Galway Bay is also a Ramsar site, under the Ramsar Convention (Ramsar site No. 838) and is a marine protected site under the OSPAR Convention - Galway Bay Complex MPA (O-IE-0002969)

Site Name	Distance[16]	Reasons for Designation – Qualifying Interests (QIs) or Special Conservation Interests (SCIs)
		[6210] Semi-natural dry grasslands and scrubland facies on calcareous substrates (*Festuco Brometalia*) (*important orchid sites) [7210] Calcareous fens with *Cladium mariscus* and species of the Caricion davallianae* [7230] Alkaline fens
Connemara Bog Complex cSAC [002034]	6km	[1065] Marsh fritillary butterfly *Euphydryas* (*Eurodryas, Hypodryas*) *aurinia* [1106] Atlantic salmon *Salmo salar* (only in fresh water) [1150] * Coastal lagoons [1170] Reefs [1355] Otter *Lutra lutra* [1833] Slender naiad *Najas flexilis* [3110] Oligotrophic waters containing very few minerals of sandy plains (*Littorelletalia uniflorae*) [3160] Natural dystrophic lakes and ponds [3260] Water courses of plain to montane levels with the *Ranunculion fluitantis* and *Callitricho-Batrachion* vegetation [4010] Northern Atlantic wet heaths with *Erica tetralix* [4030] European dry heaths [6410] *Molinia* meadows on calcareous, peaty or clayey-silt-laden soils (*Molinion caeruleae*) [7130] Blanket bogs (* if active only) [7140] Transition mires and quaking bogs [7150] Depressions on peat substrates of the *Rhynchosporion* [7230] Alkaline fens [91A0] Old sessile oak woods with *Ilex* and *Blechnum* in the British Isles
Ross Lake and Woods cSAC [001312]	10.2km	[1303] Lesser horseshoe bat *Rhinolophus hipposideros* [3140] Hard oligo-mesotrophic waters with benthic vegetation of *Chara* spp.
Black Head-Poulsallagh Complex cSAC [000020]	10.6km	[1170] Reefs [1220] Perennial vegetation of stony banks [1395] Petalwort *Petalophyllum ralfsii* [3260] Water courses of plain to montane levels with the *Ranunculion fluitantis* and *Callitricho-Batrachion* vegetation [4060] Alpine and Boreal heaths [5130] *Juniperus communis* formations on heaths or calcareous grasslands [6210] Semi-natural dry grasslands and scrubland facies on calcareous substrates (*Festuco Brometalia*) (*important orchid sites)

Site Name	Distance[16]	Reasons for Designation – Qualifying Interests (QIs) or Special Conservation Interests (SCIs)
		[6510] Lowland hay meadows (*Alopecurus pratensis*, *Sanguisorba officinalis*) [7220] Petrifying springs with tufa formation (*Cratoneurion*) [8240] Limestone pavements [8330] Submerged or partially submerged sea caves
Lough Fingall Complex cSAC [000606]	11.1km	[1303] Lesser horseshoe bat *Rhinolophus hipposideros* [3180] * Turloughs [4060] Alpine and Boreal heaths [5130] *Juniperus communis* formations on heaths or calcareous grasslands [6210] Semi-natural dry grasslands and scrubland facies on calcareous substrates (*Festuco Brometalia*) (* important orchid sites) [7210] * Calcareous fens with *Cladium mariscus* and species of the *Caricion davallianae* [8240] * Limestone pavements
Rahasane Turlough SAC [000322]	13.2km	[3180] * Turloughs
Gortnandarragh Limestone Pavement cSAC [001271]	13.4km	[8240] * Limestone pavements
Moneen Mountain cSAC [000054]	13.2km	[1065] Marsh fritillary butterfly *Euphydryas* (*Eurodryas*, *Hypodryas*) *aurinia* [1303] Lesser horseshoe bat *Rhinolophus hipposideros* [3180] * Turloughs [4060] Alpine and Boreal heaths [5130] *Juniperus communis* formations on heaths or calcareous grasslands [6130] Calaminarian grasslands of the *Violetalia calaminariae* [6210] Semi-natural dry grasslands and scrubland facies on calcareous substrates (*Festuco Brometalia*) (*important orchid sites) [7220] * Petrifying springs with tufa formation (*Cratoneurion*) [8240] * Limestone pavements
East Burren Complex cSAC [001926]	13.5km	[1065] Marsh fritillary butterfly *Euphydryas* (*Eurodryas, Hypodryas*) *aurinia* [1303] Lesser horseshoe bat *Rhinolophus hipposideros* [1355] Otter *Lutra lutra* [3140] Hard oligo-mesotrophic waters with benthic vegetation of *Chara* spp. [3180] * Turloughs

Site Name	Distance[16]	Reasons for Designation – Qualifying Interests (QIs) or Special Conservation Interests (SCIs)
		[3260] Water courses of plain to montane levels with the *Ranunculion fluitantis* and *Callitricho-Batrachion* vegetation [4060] Alpine and Boreal heaths [5130] *Juniperus communis* formations on heaths or calcareous grasslands [6210] Semi-natural dry grasslands and scrubland facies on calcareous substrates (*Festuco Brometalia*)(*important orchid sites) [6510] Lowland hay meadows (*Alopecurus pratensis*, *Sanguisorba officinalis*) [7210] * Calcareous fens with *Cladium mariscus* and species of the *Caricion davallianae* [7220] * Petrifying springs with tufa formation (*Cratoneurion*) [7230] Alkaline fens [8240] * Limestone pavements [8310] Caves not open to the public [91E0] * Alluvial forests with *Alnus glutinosa* and *Fraxinus excelsior* (*Alno-Padion*, *Alnion incanae*, *Salicion albae*)

Rahasane Turlough SPA [004089]	13.2km	Whooper Swan (*Cygnus cygnus*) [A038] - wintering Wigeon (*Anas penelope*) [A050] - wintering

Site Name	Distance[16]	Reasons for Designation – Qualifying Interests (QIs) or Special Conservation Interests (SCIs)
		Golden Plover (*Pluvialis apricaria*) [A140] - wintering Black-tailed Godwit (*Limosa limosa*) [A156] - wintering Greenland White-fronted Goose (*Anser albifrons flavirostris*) [A395] - wintering Wetlands & Waterbirds [A999]

A summary of the biodiversity baseline for each of these European sites is provided below, with more detailed baseline information on each of these sites presented in Section 9 of the Natura Impact Statement (NIS).

8.3.3.1.1 Lough Corrib cSAC

The proposed road development and its boundary overlaps with, i.e. traverses through or adjacent to one Euroepean site, namely Lough Corrib cSAC at four locations: at the termination of the proposed drainage outfall from the N59 Link Road North at Kentfield; at the site of the proposed River Corrib Bridge between Dangan and Menlough; to the west of the Coolagh Lakes (Ch. 9+850 to Ch. 10+100); and, to the west and north of Lackagh Quarry where the proposed road development will consist of a tunnel (Lackagh Tunnel) and approach road infrastructure.

The full results of the habitat surveys carried out in Lough Corrib cSAC in 2014 are presented in *N6 Galway City Transport Project – Habitat mapping and assessment of a section of Lough Corrib cSAC and surrounding areas* (Barron et al., 2017), which is included in **Appendix A.8.5**.

In summary, a total of 16 Annex I habitats, covering c.155.2ha, were recorded during the survey of Lough Corrib cSAC between Coolanillaun and Galway City, not all of which were located within Lough Corrib cSAC:

- Dystrophic lakes [3160]
- Wet heaths [4010]
- Dry heaths [4030]
- Alpine and Boreal heaths [4060]
- Calcareous grasslands [6210]
- Orchid-rich calcareous grasslands [*6210]
- *Molinia* meadows [6410]
- Hydrophilous tall-herb communities [6430]
- *Cladium* fens [*7120]
- Blanket bog (inactive) [7130]
- Blanket bog (active) [*7130]
- Transition mires and quaking bogs [7140]
- Alkaline fens [7230]

- Limestone pavement (exposed) [*8240]
- Limestone pavement (wooded) [*8240]
- Alluvial forests [*91E0]

The majority of these habitat types form part of, and are supported by, the wetland complex along the River Corrib corridor and associated with the Coolagh Lakes. The drier heath, grassland and exposed limestone rock habitats are predominantly located on the slopes of an elevated hill to the north of the Coolagh Lakes (the Coolagh Lakes also supports smaller areas of these habitat types beyond the wetland margins).

The River Corrib itself was classified as a Depositing/lowland river (FW2) as part of aquatic habitat surveys carried out in 2014 (**Appendix A.8.20**). The River Corrib channel in the vicinity of the proposed road development, or further downstream, does not correspond with any Annex I habitat type.

Downstream of the proposed River Corrib Bridge, the habitats present within Lough Corrib cSAC along the river banks consists of a mosaic of Wet grassland (GS4) and Reed swamp (FS1). Scrub (WS1), Dry calcareous and neutral grassland (GS1) and woodland (WD1, WN2 and WN6) are also present between the proposed crossing point for the River Corrib Bridge and the Coolagh Lakes. Many of these habitat types correspond with the Annex I habitat types[18] Calcareous grassland [6210], Residual alluvial forests [*91E0], *Cladium* fen [*7210], Hydrophilous tall herb [6430] and Transition mires [7140]. Although only Calcareous grassland and *Cladium* fen are QI habitats for Lough Corrib cSAC, many of the other wetland habitats are likely to provide a supporting role to these habitats within this mosaic.

The proposed drainage outfall from the N59 Link Road North will discharge to a drainage ditch in Lough Corrib cSAC at Kentfield. Habitats in this area included Treeline (WL2), Scrub (WS1) and Dry meadows and grassy verges (GS2), Wet grassland and Reed and large sedge swamp/Tall-herb swamp/Wet grassland (FS1/FS2/GS4). A patch of *Phragmites australis* Reed swamp (FS1) and an area of Rich fen and flush (PF1) are immediately to the east of the proposed development boundary. The fen area corresponds with the PF1_RFLU1a [19] vegetation community (*Carex viridula oedocarpa - Pinguicula vulgaris - Juncus bulbosus* flush; brown moss sub-community) of the Annex I habitat type *Alkaline fens* [7230].

The drainage ditch, to which the drainage outfall discharges, drains to the north-west for c.380m before turning north-east where it connects with the River Corrib after a further c.130m. Along or close to the drainage ditch, within the boundary of Lough Corrib cSAC, are Wet grassland (GS4), Wet heath (HH3), Transition mire (PF3) and Wet willow-alder-ash woodland (WN6) habitats. Some of these

[18] Where abbreviated Annex I habitat names are used throughout this report, nomenclature follows that of *The Status of EU Protected Habitats and Species in Ireland. Overview Volume 1.* (National Parks & Wildlife Service, 2013a)

[19] Alkaline fen vegetation community classification as per the classification system described in Perrin, P.M., Barron, S.J., Roche, J.R. & O'Hanrahan, B. (2014). *Guidelines for a national survey and conservation assessment of upland vegetation and habitats in Ireland. Version 2.0. Irish Wildlife Manuals, No. 79.* National Parks and Wildlife Service, Department of Arts, Heritage and the Gaeltacht, Dublin, Ireland.

correspond with Annex I habitat types: *Molinia* meadow [6410], Wet heath [4010], Transition mire [7140] and Residual alluvial forests [*91E0], respectively.

The Coolagh Lakes correspond with the Annex I Hard water lakes [3140] habitat type and support a wetland complex of Wet grassland (GS4), Wet heath (HH3), Fen (Pf1 and PF2) and Reed swamp (FS1). Many of these habitat types correspond with the Annex I habitat types[20] Residual alluvial forests [*91E0], *Cladium* fen [*7210], Alkaline fen [7230], Hydrophilous tall herb [6430], *Molinia* meadow [6410], Wet heath [4010] and Transition mires [7140]. Although only Calcareous grassland and *Cladium* fen are QI habitats for Lough Corrib cSAC, many of the other wetland habitats are likely to provide a supporting role to these habitats within this mosaic.

The area to the west of the Coolagh Lakes and to the north and east towards Lackagh Quarry consisted of a mosaic of Exposed calcareous rock (ER2), Dry calcareous and neutral grassland (GS1), Oak-Ash-Hazel Woodland (WN2) and Scrub (WS1). Some of these areas corresponded with the Annex I habitats Calcareous grassland [*6210/6210] and Limestone pavement [*8240].

Otter use the River Corrib Corridor (although no holt or couch sites were present in the vicinity of the proposed road development). The River Corrib is an important salmonid watercourse, supporting both Atlantic salmon and Brown trout. There are records of Sea lamprey spawning below the Salmon Weir in Galway City (O'Connor, 2007) and the species has also been recorded by IFI spawning in the upper catchment in Cong, Co. Mayo. Brook lamprey have been recorded widely throughout the River Corrib catchment (O'Connor, 2007). No suitable lamprey ammocoete nursery habitat was recorded in the vicinity of the proposed River Corrib Bridge, or the proposed drainage outfalls to the river.

Whilst there are no records of Atlantic salmon or Sea lamprey at the proposed River Corrib Bridge crossing, the River Corrib provides important habitat for Atlantic salmon, and both lamprey species, particularly in the context of its function as a migration corridor from the sea to the spawning areas for Atlantic salmon and Sea lamprey.

8.3.3.1.2 Galway Bay Complex cSAC

The proposed road development does not traverse the Galway Bay Complex cSAC and given that it lies downstream of the proposed road development, the description here is focussed on the downstream coastal and marine habitats, and the QI species they support, which are the QIs which fall within the zone of influence of the proposed road development. The descriptions are based upon the information presented in the conservation objectives for Galway Bay Complex cSAC, and the relevant supporting documents, and presents summary of the site as a whole.

Galway Bay is classified as the Annex I habitat Large shallow inlets and bays [1160], associated with which are Reefs [1170], Tidal mudflats [1140], Lagoons [*1150], Salicornia mud [1310], Perennial vegetation of stony banks [1220] and Atlantic salt meadows [1330]. These habitats are also supported by a network of

[20] Where abbreviated Annex I habitat names are used throughout this report, nomenclature follows that of *The Status of EU Protected Habitats and Species in Ireland. Overview Volume 1.* (National Parks & Wildlife Service, 2013a)

other habitat types including the freshwater rivers and streams that flow into the bay, the transitional waters of the estuary and terrestrial habitat along the coastline.

Rusheen Bay, to which some of the rivers/streams crossed by the proposed road development will drain (Bearna Stream catchment and the Knocknacarragh Stream), comprises a mosaic of most of these habitat types: Large shallow inlets and bays [1160], associated with which are Reefs [1170], Tidal mudflats [1140], Perennial vegetation of stony banks [1220] and Atlantic salt meadows [1330].

The habitats within Galway Bay also support Qualifying Interests (QI) populations of Otter and Harbour seal.

8.3.3.1.3 Lough Corrib SPA

Lough Corrib SPA is a vast site comprising Lough Corrib, most of its islands, and much of the wetland habitat that surrounds the lake margin. The proposed road development does not traverse the Lough Corrib SPA. However, the closest areas of such wetland habitat to the proposed road development are at Tonacurragh and Coolanillaun where there is a wetland mosaic of bog, heath, reed swamp, marsh and wet grassland habitats.

Although this SPA lies outside, and upstream of, the proposed road development, many bird species listed as Special Conservation Interests (SCIs) of the SPA were recorded at winter bird survey sites across the scheme study area. The habitat types associated with these sites ranged from natural/semi-natural lakes and wetland complexes (Ballindooley Lough, Coolagh Lakes and Lough Inch), the River Corrib, and upland mosaics of bog, heath, wet and acid grasslands, to improved and intensively managed habitats such as agricultural fields and amenity areas within Galway City (e.g. NUIG Sporting Campus).

There were two bird species recorded during the breeding bird surveys which are SCIs of Lough Corrib SPA for their breeding population: Common tern and Black-headed gull. This is generally consistent with the findings of the surveys carried out along the River Corrib corridor in 2005/2006 for the N6 Galway City Outer Bypass Scheme (RPS, 2006), where these species were recorded frequently over the summer months along the river, but in low numbers. The 2005/2006 surveys also recorded another breeding SCI species frequently on the River Corrib during the summer months; Common gull.

Seven bird species which are listed as wintering SCI species for Lough Corrib SPA were recorded at winter bird survey sites within the ZoI of the proposed road development:

- Black-headed gull
- Common gull
- Coot
- Golden plover
- Hen harrier
- Shoveler

- Tufted duck

8.3.3.1.4 Inner Galway Bay SPA

As Inner Galway Bay SPA covers approximately the same area as Galway Bay Complex cSAC, refer to the habitat description above in **Section 8.3.3.1.2**. The habitats within the SPA support the SCI bird species, providing nesting, foraging and roosting sites which include open water, intertidal and terrestrial habitats.

As noted above for Lough Corrib SPA, bird species listed as winter SCI species of the Inner Galway Bay SPA were recorded at many of the winter bird survey sites across the scheme study area, the majority of which are remote from the SPA itself.

There were two bird species recorded during the breeding bird surveys which are listed as SCIs of Inner Galway Bay SPA for their breeding population: Common tern (along the River Corrib) and Cormorant (flying overhead in the vicinity of the River Corrib corridor and in the western part of the scheme study area).

These results are generally consistent with the findings of the surveys carried out along the River Corrib corridor in 2005/2006 for the N6 Galway City Outer Bypass project (RPS, 2006), where these species were recorded frequently over the summer months along the river, but in low numbers.

Twelve bird species which are listed as winter SCI species for Inner Galway Bay SPA were recorded within winter bird survey sites within the ZoI of the proposed road development:

- Bar-tailed godwit
- Black-headed gull
- Common gull
- Cormorant
- Curlew
- Golden plover
- Grey heron
- Lapwing
- Redshank
- Shoveler
- Teal
- Wigeon

8.3.3.2 Natural Heritage Areas & proposed Natural Heritage Areas

National Heritage Areas (NHAs) are designations under Section 16 of the Wildlife Acts to protect habitats, species or geology of national importance.

In addition to NHAs there are proposed NHAs (referred to as pNHAs), which are also sites of significance for wildlife and habitats and were published on a non-statutory basis in 1995, but have not since been statutorily proposed or designated. Proposed NHAs are offered protection in the interim period under the county or city development plans which requires that planning authorities give due regard to their protection in planning policies and decisions[21].

Many of the pNHA sites, and some of the NHAs, in Ireland overlap with the boundaries of European sites.

Only one of these, Lough Corrib pNHA is crossed by the proposed road development. There are three NHAs and 18 pNHAs located within 15km of the proposed development boundary (**Figure 8.13.1**). **Table 8.5** below lists these sites, their distance from the proposed development boundary, and the ecological features for which the sites are designated/proposed.

Table 8.5: Natural Heritage Areas (and proposed Natural Heritage Areas) within 15km of the proposed development boundary

Natural Heritage Areas		
Site Name	**Distance[22]**	**Features of Interest**
Moycullen Bogs NHA [002364]	80m at Na Foraí Maola Thiar Immediately adjacent to the proposed development boundary at Ballagh	Peatland [T010]

8.3.4 Habitats

Overview

The results of the habitat surveys along the route of the proposed road development are described below by habitat type, after Fossitt (2000, see also **Appendix A.8.6**), and where relevant include a description of any corresponding Annex I habitat types that were present (see also **Appendix A.8.3** and **Appendix A.8.4** for results of habitat surveys). The habitats described below relate to habitat polygons within or adjacent to the proposed road development, as shown on **Figures 8.14.1** to **8.14.15** and **Figures 8.15.1** to **8.15.15** along with the full habitat survey results. Full species lists for each habitat type are provided in **Appendix A.8.19**. In general, habitats are described from east to west under the headings below.

The results and summary of the findings of the aquatic habitat surveys have been incorporated into the relevant habitat descriptions below. A full description and species lists are provided in **Appendix A.8.20**.

The habitat types recorded along the route of the proposed road development, and discussed in this section, are as follows:

- Flower beds and borders (BC4)
- Buildings and artificial surfaces (BL3)
- Spoil and bare ground (ED2)
- Recolonising bare ground (ED3)
- Active quarries and mines (ED4)
- Exposed siliceous rock (ER1)
- Exposed calcareous rock (ER2), including the priority Annex I habitat *8240
- Limestone/marl lakes (FL3), including the Annex I habitat 3140
- Mesotrophic lakes (FL4)
- Eutrophic lakes (FL5)
- Turloughs (FL6), which corresponds with the priority Annex I habitat *3180
- Other artificial lakes and ponds (FL8)
- Calcareous springs (FP1), including the priority Annex I habitat *7220
- Reed and large sedge swamps (FS1), including the priority Annex I habitats *7210 and the Annex I habitat 6430
- Tall-herb swamps (FS2), including the Annex I habitats 6430/*7210
- Eroding/upland rivers (FW1)
- Depositing/lowland rivers (FW2)
- Drainage ditches (FW4)
- Improved agricultural grassland (GA1)
- Amenity grassland (improved) (GA2)

- Marsh (GM1)
- Dry calcareous and neutral grassland (GS1), including the priority Annex I habitat *6210/Annex I habitat 6210
- Dry meadows and grassy verges (GS2), including the Annex I habitat 6510
- Dry-humid acid grassland (GS3), including the priority Annex I habitat *6230
- Wet grassland (GS4), including the Annex I habitat 6410
- Dense bracken (HD1)
- Dry siliceous heath (HH1), which corresponds with the Annex I habitat 4030
- Dry calcareous heath (HH2), which corresponds with the Annex I habitat 4030
- Wet heath (HH3), which corresponds with the Annex I habitat 4010
- Rich fen and flush (PF1), including the Annex I habitats 7230/*7210
- Poor fen and flush (PF2)
- (Mixed) broadleaved woodland (WD1)
- Mixed broadleaved/conifer woodland (WD2)
- (Mixed) conifer woodland (WD3)
- Scattered trees and parkland (WD5)
- Hedgerows (WL1)
- Treelines (WL2)
- Oak-ash-hazel woodland (WN2), including the priority Annex I habitat *8240
- Wet willow-alder-ash woodland (WN6), including the priority Annex I habitat *91E0
- Scrub (WS1), including the priority Annex I habitat *8240
- Immature woodland (WS2)
- Ornamental/non-native shrub (WS3)
- Recently-felled woodland (WS5)

Summary of Underlying Geology and Habitat Type

As a consequence of the underlying geology, with the western part of the study area underlain by granite and the eastern by limestone, the nature of the habitats present across the study area were generally acidic west of the N59 Moycullen Road and calcareous to the east.

West of the River Corrib, the habitats generally consisted of a mosaic of agricultural fields, peatland/heath habitats, and scrub, separated into distinct habitat blocks of varying sizes by the local road network and the associated linear residential development. The character of the agricultural fields varied from intensively managed farmland through to abandoned fields overgrown with scrub and bracken. The peatland habitat blocks consisted of predominantly wet heath, dry heath and bog mosaics, with those habitat patches closest to the proposed road development either the edges of larger peatland habitat blocks or smaller, more isolated, remnant patches. Small areas of fen and transition mire were also present. Given the close proximity of Galway City there were also large expanses of urban and residential development adjacent to the proposed road development, particularly around Ballyburke/Rahoon area and where the proposed road development crosses the N59 Moycullen Road at Dangan.

East of the River Corrib, there were two distinct habitat zones; from the River Corrib to the N84 Headford Road comprised of a patchwork of semi-natural woodland, limestone pavement, scrub and calcareous grassland fields. East of the N84 Headford Road was predominantly improved agricultural grasslands surrounded by residential and industrial development in Parkmore, Ballybrit, Briarhill and Doughiska. There were also two wetland complexes of note in this section: the Coolagh Lakes and Ballindooley Lough. There were also some isolated patches of semi-natural habitats, calcareous grassland and limestone pavement, in the Coolagh/Doughiska area.

8.3.4.1 Flower beds and borders (BC4)

This habitat type was widespread along the proposed road development and included ornamental planting associated with residential gardens, commercial developments or industrial complexes/ business parks. The majority of this habitat type is captured on the habitat map by the *Residential* classification (see **Section 8.3.4.34** below).

8.3.4.2 Stone walls and other stonework (BL1)

Stone walls were generally present as either field or property boundaries. In the western part of the study area, many of the stone wall field boundaries were overgrown with scrub and bracken. Plant species recorded in association with the stone walls included: *Asplenium trichomanes*, *Hedera helix*, *Polypodium vulgare*, *Frullania dilatata*, the moss species *Brachythecium rutabulum*, *Dicranum scoparium*, *Homalothecium sericeum*, *Hypnum cupressiforme*, *Isothecium myosuroides*, *Mnium hornum*, *Racomitrium fasciculare* and lichens such as *Cladonia* spp. and other crustose lichens.

8.3.4.3 Buildings and artificial surfaces (BL3)

This classification included buildings (domestic, commercial and industrial), roads, car parks, artificial recreation surfaces (e.g. Astroturf pitches) and other concrete/hard standing areas (e.g. quarrying infrastructure at Lackagh Quarry). Aside from residential properties/developments, the largest expanses of this habitat type within, or adjacent to, the proposed road development were associated with the business parks at Ballybrit, Parkmore and Briarhill, and at the Galway Racecourse. In the case of residential properties, the majority of this habitat type is captured on the habitat map by the *Residential* classification (see **Section 8.3.4.34** below).

8.3.4.4 Spoil and bare ground (ED2)

Across the study area, this habitat type consisted of small areas of bare ground associated with access tracks (either permanent and maintained lanes, or recently cleared ground) or, in the case of the larger expanses at Ballyburke and adjacent to the N59 Link Road North near Bushypark, lands which had been recently cleared for development.

8.3.4.5 Recolonising bare ground (ED3)

Generally small areas of disturbed ground were recorded along the route of the proposed road development but there were a number of larger areas associated with development sites, or larger scale scrub clearance of agricultural fields.

Along the western part of the proposed road development, the cover and composition of recolonising bare ground vegetation varied widely, dependant on the soil type and surrounding drainage. Species included tree/shrub species such as Salix cinerea and Ulex europaeus; the grasses Agrostis capillaris, Agrostis stolonifera, Holcus lanatus and Poa annua; rush and sedge species such as Juncus effusus and Carex disticha; and herb species including Achillea millefolium, Anagallis arvensis, Centaurea nigra, Cirsium arvense, Daucus carota, Hypericum pulchrum, Hypochaeris radicata, Lotus corniculatus, Plantago lanceolata, Plantago major, Potentilla anserina, Senecio jacobaea and Tussilago farfara. Where soils were more acidic/peaty in nature (e.g. at Ch. 4+900 to Ch. 5+000), recolonising ground was characterised by heath species such as Calluna vulgaris, Molinia caerulea, Carex panicea and Ulex gallii in places.

Along the eastern part of the proposed road development, recolonising bare ground included the following species, many of which reflected the calcareous nature of the surrounding habitats in this area: the grasses *Agrostis canina*, *Anthoxanthum odoratum*, *Arrhenatherum elatius*, *Cynosurus cristatus*, *Dactylis glomerata*, *Festuca rubra* and *Poa pratensis*; and herb species such as *Achillea millefolium*, *Centaurium erythraea*, *Euphrasia officinalis* agg., *Hypericum perforatum*, *Lotus corniculatus*, *Leontodon autumnalis*, *Leucanthemum vulgare*, *Linum catharticum*, *Medicago lupulina*, *Odontites verna*, *Potentilla reptans*, *Primula veris*, *Prunella vulgaris*, *Ranunculus repens*, *Senecio jacobaea*, *Succisa pratensis*, *Tussilago farfara* and *Ulex europaeus*.

8.3.4.6 Active quarries and mines (ED4)

Lackagh Quarry was the only quarry site within the proposed development boundary and is an inactive quarry. The quarry was surrounded on the west, north, and eastern sides by high, vertical cliff faces and, despite being sparsely vegetated for the most part, had a diverse assemblage of plant species reflecting the calcareous nature of the substrate and the damp areas created by the seepage lines from the quarry walls: tree/shrub species including *Acer pseudoplatanus*, *Alnus incana* and *Salix cinerea*; and herb species such as *Agrostis stolonifera*, *Anagallis arvensis*, *Asplenium ruta-muraria*, *Blackstonia perfoliata*, *Carex flacca*, *Centaurea nigra*, *Epilobium montanum*, *Epipactis helleborine*, *Equisetum fluviatile*, *Hypericum pulchrum*, *Hypericum tetrapterum*, *Leontodon hispidus*, *Leucanthemum vulgare*, *Linum catharticum*, *Lotus corniculatus*, *Mycelis muralis*, *Petasites fragrans*, *Phyllitis scolopendrium*, *Pimpinella major*, *Plantago lanceolata*, *Potentilla sterilis*, *Senecio jacobaea* and *Solidago virgaurea*. The spring sites in the quarry are discussed separately below under *Calcareous springs*.

8.3.4.7 Exposed siliceous rock (ER1)

Outcropping granite was recorded along the western sections of the proposed road development; most often in association with patches of dry heath on higher ground but also found on raised ground in less intensively managed agricultural fields, and in some residential gardens. Where it was recorded in a mosaic with heath habitats it is mapped and valued as the associated Annex I habitats. Where associated with improved grasslands or exposed rock slabs in residential gardens it is valued as being of a local importance (lower value).

8.3.4.8 Exposed calcareous rock (ER2)

Exposed limestone was recorded widely across the eastern part of the scheme study area. The highest concentrations were present in the area between Menlough Village, Coolough Village, Coill Uachtair and the area surrounding Lackagh Quarry. There was also a relatively large area adjacent to the southern boundary of the Roadstone Quarry at Two-mile-ditch with more isolated, scattered patches in the local area between here and the existing N6 – the most notable of which lay to the south-east of the existing Coolagh Junction.

At all locations, bar the area at Business Park Junction 2, these areas corresponded with the exposed limestone pavement group of the priority Annex I habitat *Limestone pavements* [*8240]. The exposed calcareous rock at Business Park Junction 2 comprised the vertical limestone rock faces in a small abandoned quarry and therefore, did not correspond with the Annex I habitat type.

Limestone pavement consisted of both the 'block' and 'shattered' variants of Limestone pavement (after Wilson & Fernandez, 2013), with the shattered type being most frequent. The exposed variant also included areas of limestone pavement which were being invaded by scrub (almost invariably *Corylus avellana*) which was not yet forming a continuous canopy and was less than 3m in height. The main vascular species included scattered low-growing woody species (e.g. *Hedera helix*, *Rosa spinosissima* or *Rubus fruticosus* agg., or immature *Corylus avellana* or *Ilex aquifolium*) and herbaceous species like *Carex flacca*, *Carlina vulgaris*, *Geranium robertianum*, *Mycelis muralis*, *Senecio jacobaea*, *Sesleria caerulea* and *Teucrium scorodonia*. A suite of calcicole ferns was usually found comprising *Asplenium ruta-muraria*, *Ceterach officinarum* and, in the deeper clefts (grykes), the shade-loving *Phyllitis scolopendrium*. Characteristic bryophytes were *Ctenidium molluscum*, *Neckera crispa* and *Tortella tortuosa*.

The exposed variant of the Annex I Limestone pavement habitat type (LPE) within the ZoI of the proposed road development is summarised below in **Table 8.6** below.

Table 8.6: Areas of the exposed variant of the Annex I habitat Limestone pavement [*8240] within the potential ZoI of the proposed road development

Area	Vegetation Community[23]
South of Bóthar Nua at Ch. 10+040 (outside of any European site)	LPE_1b *Teucrium scorodonia - Sesleria caerulea* pavement
North of Bóthar Nua at Ch. 10+200 – Ch. 10+250 (outside of any European site)	LPE_1b *Teucrium scorodonia - Sesleria caerulea* pavement
Within Lough Corrib cSAC Western and northern boundaries of Lackagh Quarry between Ch. 10+900 and Ch. 11+800	LPE_1b *Teucrium scorodonia - Sesleria caerulea* pavement LPE_1d *Mycelis muralis - Fissidens dubius* pavement 1e *Corylus avellana - Neckera crispa* pavement
Along the eastern boundary of Lackagh Quarry (outside of any European site)	LPE_1b *Teucrium scorodonia - Sesleria caerulea* pavement
South-east of the Coolagh Junction (between N6 and R446) (outside of any European site)	LPE_1e *Corylus avellana - Neckera crispa* pavement

8.3.4.9 Limestone/marl lakes (FL3)

There were two distinct lake complexes present in the vicinity of the proposed road development: Coolagh Lakes and Ballindooley Lough. All of the lakes that make up the Coolagh Lakes complex, and the main waterbody at Ballindooley, corresponded with this habitat classification and the Annex I habitat type *Hard oligo- mesotrophic waters with benthic vegetation of charophytes* [3140]. The full description and aquatic plant species lists for these lakes – and all others surveyed as part of the aquatic habitat survey – are provided in **Appendix A.8.20**.

Coolagh Lakes

The upper lake contained some flowering plants including *Hippuris vulgaris*, *Myriophyllum spicatum*, *Nuphar lutea* and *Elodea canadensis* (which grew at the base of the euphotic zone at about 4m, as did some *Lemna trisulca*). However, *Chara rudis* or *Chara hispida* dominated most of the euphotic zone.

The lower lake also contained large stands of *Chara hispida* and *Chara rudis*, but flowering plants were more abundant with *Lemna trisulca* forming a zone at the base of the euphotic zone (4m) and *Elodea canadensis* intermixed with the *Chara* species. Other species included *Potamogeton lucens*, *Sparganium* sp., *Myriophyllum spicatum* and *Utricularia cf. vulgaris*. Two other species of charophyte, *Chara contraria* and *Chara vulgaris* occurred in small quantities. The lower lake however, was considered to be the borderline eutrophic type FL5 (and not an exceptionally good example of the habitat type), due to the increased

[23] The vegetation communities are assigned based upon the plant species recorded and with reference to the vegetation types described in *National survey of limestone pavement and associated habitats in Ireland. Irish Wildlife Manuals, No. 73* (Wilson, S. and Fernández, F., 2013)

presence of *Elodea canadensis* and *Lemna trisulca* (most likely as a result of eutrophication) and the presence of the non-native invasive Zebra mussel *Dreissena polymorpha*.

Ballindooley Lough

The sub-littoral vegetation was dominated by charophyte algae. *Chara rudis* was exceptionally abundant from 0-3m with some other species occurring in very shallow water including *Chara aspera*, *Chara aculeolata* and *Chara curta*. Flowering plants were rare, as is often the case in marl lakes, with only *Elodea canadensis* and *Utricularia* cf. *vulgaris* observed. The complete dominance of *Chara rudis* however, probably indicates some degree of eutrophication. The rather turbid lake water would support this conclusion. Most of the lake was deeper than the euphotic depth of about 4m and no plants were found.

8.3.4.10 Mesotrophic lakes (FL4)

The smaller circular pond (531194 728778 ITM) at Ballindooley – the northernmost of the three small lakes present – corresponded with this habitat type. It had floating plant species present including *Potamogeton natans*, *Nymphaea alba* and *Sparganium natans*. Sublittoral species included abundant *Chara virgata and Utricularia cf. vulgaris*.

There was also a more transient small lake along the eastern edge of the main lake complex at the Coolagh Lakes (which was dry when surveyed). The aquatic plant species *Typha latifolia* and *Hippuris vulgaris* were present.

8.3.4.11 Eutrophic lakes (FL5)

Two of the small lakes at Ballindooley corresponded with this habitat type. The oval shaped pool nearest the residential houses (ITM grid reference 531244 728619) was shallow with a sublittoral flora of *Elodea canadensis*, *Lemna trisulca* and *Fontinalis antipyretica*. Floating species included *Nymphaea alba*. The abundance *of Lemna* and *Elodea* indicated a eutrophic pond.

The smallest water body, directly south of the main lake (531473 728626 ITM), had *Potamogeton natans*, *Hippuris vulgaris*, *Elodea canadensis*, *Alisma plantago-aquatica* and *Ranunculus trichophyllus* present; suggestive of eutrophic conditions.

8.3.4.12 Turloughs (FL6)

There is one turlough feature within the ZoI of the proposed road development: between Bóthar Nua and Seanbóthar in the Menlough area at Ch. 10+320. Turloughs are depressions, generally in limestone areas, which are intermittently inundated with groundwater and support wetland habitats.

The turlough feature at Menlough corresponded with the priority Annex I habitat type *Turloughs* [*3180] and the *Potentilla anserina-Carex nigra* vegetation community (Waldren, 2015, Ed.). The vegetation was typical turlough marsh vegetation including the following species: *Potentilla anserina*, *Apium inundatum*, *Eleocharis palustris*, *Caltha palustris*, *Rumex crispus*, *Agrostis stolonifera*, *Ranunculus repens*, *Senecio aquaticus*, *Prunella vulgaris*, *Myosotis aquatica*, *Persicaria amphibia*, *Mentha aquatica*, *Glyceria fluitans*, *Filipendula ulmaria*, *Urtica dioica*, *Persicaria maculata*, *Rumex obtusifolius*, *Equisetum palustre* and *Veronica catenata*. Although not associated directly with the ground vegetation, the moss species *Cinclidotus fontinaloides* – a characteristic turlough species – was recorded on stone walls within the turlough feature.

The Turlough habitat within the ZoI of the proposed road development is summarised below in **Table 8.7** below.

Table 8.7: Areas of the Annex I habitat Turloughs [*3180] within the potential ZoI of the proposed road development

Area	Vegetation Community24
Between Bóthar Nua and Seanbóthar in the Menlough/Coolough area at Ch. 10+320 outside a European site	6b Wet Carex nigra vegetation community (Goodwillie, 1992) Potentilla anserina-Carex nigra vegetation community (Waldren, 2015, Ed.)

8.3.4.13 Other artificial lakes and ponds (FL8)

Artificial ponds were present at the proposed Coolagh Junction (road drainage attenuation ponds) and in Lackagh Quarry (associated with the gravel washout area). The plant species associated with the attenuation ponds are described below under the FS1 habitat descriptions; there was no vegetation associated with the gravel washout ponds at Lackagh Quarry.

8.3.4.14 Calcareous springs (FP1)

A total of 27 calcareous springs/seepage lines were recorded in Lackagh Quarry. Of these, 23 had vegetation associated with the seepage line. The most frequently recorded vascular plant species associated with the springs/seepage lines were *Tussilago farfara*, *Leontodon hispidus*, *Carex flacca*, *Epilobium parviflorum*, *Festuca rubra*, *Sonchus oleraceus*, *Holcus lanatus*, *Lotus uliginosus* and *Sesleria caerulea*; the most frequently recorded moss species were *Dicranella varia*, *Didymodon tophaceus*, *Fissidens adianthoides* and *Pellia endiviifolia*.

Six of the springs/seepages (all located on the west face of the quarry) conformed to the priority Annex I habitat *Petrifying springs with tufa formation (Cratoneurion)* [*7220], as the following indicator species for the Annex I habitat type were recorded growing in conjunction with tufa deposits on the cliff faces: *Didymodon tophaceus*, *Pellia endiviifolia*, *Festuca rubra*[25]. The Petrifying springs present were

[24] The vegetation communities are assigned based upon the plant species recorded and with reference to the vegetation types described in *Turloughs over 10 ha: vegetation survey and evaluation* (Goodwillie, R., 1992) and *Turlough Hydrology, Ecology and Conservation* (Waldren, S. 2015, Ed.)

[25] Although these indicator species recorded are not listed as such in the *Interpretation manual of European Union Habitats* EUR28 (CEC, 2013), in an Irish context they are considered by the NPWS to be indicator species for [*7220] (NPWS, 2013b)

generally species poor and considered marginal examples of the habitat type, lacking many of the key indicative species and generally limited in extent; in some cases, occurring only in the immediate vicinity of cushions of *Didymodon tophaceus*. They are also only present due to human activity, with the quarrying of limestone resulting in the creation of suitable habitat for their formation.

The full results of the Petrifying spring survey at Lackagh Quarry are provided in **Appendix A.8.21**.

8.3.4.15 Reed and large sedge swamps (FS1)

Along the western part of the proposed road development, there were scattered small patches of species poor reed swamp in the vicinity of the proposed road development; mostly located along the margins of peatland areas. The vegetation was typically dominated by *Phragmites australis*.

Along the banks of the River Corrib and around parts of the Coolagh Lakes, reed swamp habitat was typically dominated by *Phragmites australis* with species such as *Phalaris arundinacea*, *Typha latifolia*, *Sparganium erectum*, *Equisetum fluviatile*, *Menyanthes trifoliata*, *Epilobium hirsutum*, *Calystegia sepium*, *Lycopus europaeus*, *Lysimachia vulgaris*, *Mentha aquatica*, *Angelica sylvestris*, *Valeriana officinalis*, *Filipendula ulmaria* and *Lythrum salicaria* also present.

Two small areas of reed swamp on the margins of the Coolagh Lakes corresponded with the Annex I habitat type *Hydrophilous tall herb fringe communities of plains and of the montane to alpine levels* [6430], where herb species indicative of this habitat type such as *Calystegia sepium*, *Epilobium hirsutum* and *Equisetum fluviatile* were more abundant amongst the reed stands.

Where *Cladium mariscus* was more dominant, reed swamps corresponded with the priority Annex I habitat type *Calcareous fens with Cladium mariscus and species of the Caricion davallianae* [*7210]. This habitat was abundant around the Coolagh Lakes, but was also recorded to a lesser extent along the backwater to the east of Jordan’s Island and in small patches along the banks of the River Corrib. Other plant species associated with this Annex I habitat type included: *Phragmites australis*, *Calystegia sepium*, *Equisetum fluviatile*, *Lysimachia vulgaris*, *Epilobium hirsutum*, *Mentha aquatica* and *Schoenus nigricans*.

At Ballindooley Lough, *Phragmites australis*, *Schoenoplectus lacustris* and *Cladium mariscus* were the typical species in the reed swamp habitat around the lakes’ margins. As above, the *Cladium mariscus* swamp, which was present at two locations at Ballindooley Lough, corresponded with the priority Annex I *Cladium* fen habitat type.

The existing N6 attenuation ponds at Briarhill supported a relatively species rich wetland for such a man-made feature, including: *Phragmites australis*, *Typha latifolia*, *Sparganium erectum*, *Schoenoplectus lacustris*, *Apium nodiflorum*, *Nasturtium officinale*, *Lemna minor* and *Epilobium hirsutum*.

8.3.4.16 Tall-herb swamps (FS2)

The majority of the tall-herb swamp was recorded along the banks of the River Corrib and around the margins of the Coolagh Lakes – where larger areas were present in the wetland extending north from the lakes, either side of Bóthar Nua.

The most frequently recorded species were *Carex disticha*, *Epilobium hirsutum*, *Equisetum fluviatile*, *Filipendula ulmaria*, *Calliergonella cuspidata*, *Festuca arundinacea*, *Lysimachia vulgaris*, *Phragmites australis*, *Mentha aquatica*, *Valeriana officinalis* and *Galium palustre*. Other typical species present included *Calystegia sepium*, *Iris pseudacorus*, *Menyanthes trifoliata*, *Sparganium erectum*, *Angelica sylvestris*, *Berula erecta* and *Lythrum salicaria*.

The majority of the FS2 areas corresponded with the Annex I habitat type *Hydrophilous tall herb fringe communities of plains and of the montane to alpine levels* [6430].

Due to the abundance of *Cladium mariscus* a single polygon of reed-swamp, c.700m downstream of the proposed River Corrib Bridge on the west bank of the river, corresponded with the *Cladium* fen priority Annex I habitat type [*7210].

In the western part of the study area (Ch. 3+400), there was also a vegetated drain, with *Apium nodiflorum*, *Iris pseudacorus* and *Epilobium hirsutum*, recorded near An Chloch Scoilte Junction which corresponded with the FS2 classification.

8.3.4.17 Eroding/upland rivers (FW1)

The following are the eroding upland rivers crossed by the proposed road development: Sruthán na Líbeirtí (Liberty Stream), Trusky Stream, the Bearna Stream (and tributary), Tonabrocky Stream and the Knocknacarra Stream.

Many of these streams are seasonal in their upper reaches, where they are crossed by the proposed road development. Instream vegetation is generally absent, and in the vicinity of the proposed crossings for the proposed road development, is overgrown with scrub and rank vegetation from the adjacent terrestrial habitats. Where present, coverage is limited and included the following species: *Apium nodiflorum*, *Fontinalis antipyretica*, *Fontinalis squamosa*, *Hyocomium armoricum*, *Mentha aquatica*, *Nasturtium officinale* and *Ranunculus flammula*.

The physical characteristics of the various stream/river channels are described in the fisheries report in **Appendix A.8.17**. Details of the fisheries value of these watercourses is also presented in **Appendix A.8.17** and discussed in **Section 8.3.12** below.

8.3.4.18 Depositing/lowland rivers (FW2)

Two of the watercourses present within the scheme study area were classified as depositing/lowland rivers: the River Corrib and the Terryland River.

River Corrib, from Tonacurragh to Menlo Castle

The vegetation in this section of the river was dominated by charophyte algae in many places, especially *Chara rudis.* In the upper river near the junction of the Friar's Cut, the shore included backwaters dominated by reed swamp and open water with *Chara curta*, *Chara virgata annulata* and cyanobacterial crust on stones, as on the shore of Lough Corrib and other calcareous lakes. In deeper water (1m) *Chara rudis* was dominant with emergent vegetation including *Schoenoplectus lacustris* and *Phragmites australis*. *Chara rudis* extended to 2m depth along with *Zannichella palustris*, *Potamogeton lucens,* a little *Potamogeton crispus* and *Myriophyllum spicatum,* while *Chara globularis* extended to 3m along with some *Nuphar lutea* and abundant Zebra mussels. At this depth a white, shelly marl replaces the dark peat and mud of shallower water. In the main channel the river shelved very steeply and *Potamogeton perfoliatus* occurred.

Midway between the Friar's cut and Menlo Pier the river was divided by a long narrow bank vegetated with swamp (527715 728520 ITM) with species present including *Eleocharis palustris, Hippuris vulgaris, Lythrum salicaria, Ranunculus flammula, Valeriana officinalis, Iris pseudacorus, Schoenoplectus lacustris, Sparganium* sp.*, Menyanthes trifoliata, Calystegia sepium* and *Myosotis laxa*[26].

The shallower western channel, to a depth of 2m, contained reed swamp followed by *Chara virgata annulata*, *Lemna trisulca*, *Elodea canadensis* and *Nuphar lutea* in 1m depth water, and *Potamogeton perfoliatus* beds at 2m. In places, bare areas of mud were colonized *by Nitella opaca*. The main channel shelved very steeply with *Potamogeton perfoliatus*, *Lemna trisulca*, and *Elodea canadensis*, followed by bare ground with Zebra mussels.

On the east bank *Chara rudis* was dominant with some *Potamogeton berchtoldii*, *Lemna trisulca* and *Elodea canadensis*.

Below Menlo Pier the river narrowed and deepened with little vegetation other than *Potamogeton perfoliatus* and *Potamogeton natans* along with some *Chara rudis* in shallow water close to the bank.

The depth of the river varied greatly, with many shallow inshore areas, but the main channel was cut into white marl which exceeded 8m depth in places. Vegetation was largely confined to water less than 4m, but Zebra mussels occurred deeper than this. A variety of flowering plants occurred, especially pond weeds (*Potamogeton* sp.). Nearly all shallow areas of any extent were occupied by *Schoenoplectus* and *Phragmites* reed swamp.

---

[26] Note that these species are provided here for information and do not appear in **Appendix A.8.20** as they were associated with the island habitat

River Corrib main channel, from Menlo Castle to the Salmon Weir

In this section of the river, vegetation was largely confined to shallow areas along the bank and was only found in depths of <2m; mainly as either reed swamp of *Phragmites australis* or *Equisetum fluviatile*, with some stands of *Potamogeton natans* and *Carex rostrata*. *Chara rudis* and some *Chara virgata* were common in the shallow sublittoral. Species composition was similar to, but less diverse than, the section upstream.

Backwater on the east side of Jordan's Island

This section consisted of small pools and channels cut through extensive *Phragmites australis*, *Schoenoplectus lacustris* and *Cladium mariscus* reed swamp. The area contained a diverse flora, especially of charophytes, but like all habitats surveyed showed signs of eutrophication. Species present include *Chara aspera, Chara contraria, Chara curta, Chara globularis, Chara rudis, Chara vulgaris and Chara virgata*. Other aquatic species included *Potamogeton pectinatus, Potamogeton perfoliatus, Potamogeton lucens, Potamogeton natans, Myriophyllum spicatum, Elodea canadensis, Berula erecta, Lemna trisulca, Nuphar lutea, Oenanthe aquatica*. Blanket weed or *Cladophora* sp. was common, suggesting eutrophication.

Terryland River

The Terryland River had a limited aquatic flora present including *Potamogeton natans*, *Callitriche* sp., *Alisma plantago aquatica*, *Chara hispida/rudis*, *Myriophyllum spicatum*, *Sparganium* sp. and *Elodea canadensis*. Large areas of bare mud and extensive development of blanket weed, *Cladophora* sp. indicated significant eutrophication and water quality was poor (see **Section 8.3.12** and **Appendix A.8.17** for the results of the macro-invertebrate water quality monitoring on the Terryland River).

8.3.4.19 Drainage ditches (FW4)

Drainage ditches were associated with agricultural fields, the margins of peatland sites, within and surrounding the Coolagh Lakes, at Ballindooley Lough, and at the Galway Racecourse.

Along the western part of the proposed road development, drainage ditches included species such as *Angelica sylvestris*, *Potamogeton polygonifolius*, *Ranunculus flammula* and *Ranunculus repens*.

Plant species associated with the drainage ditches surrounding the Coolagh Lakes included: *Apium nodiflorum*, *Lemna* sp., *Filipendula ulmaria* and *Lythrum salicaria*. The main channel connecting the Coolagh Lakes with the River Corrib was classified as a drainage ditch, fringed by very dense stands of *Phragmites australis* and *Cladium mariscus*. It was up to 1m deep with *Nuphar lutea*, *Menyanthes trifoliata*, *Elodea canadensis*, *Chara rudis*, and *Lemna trisulca* growing in the channel. *Ranunculus lingua* was conspicuous in the reed swamp on the channel edge.

The drainage ditches at Ballindooley Lough appeared to be regularly dredged and contained a limited flora of *Chara virgata*, *Chara aspera*, *Chara aculeolata*, *Chara rudis, Potamogeton coloratus* and *Lemna trisulca*.

The drainage ditches at the Galway Racecourse supported a diverse range of plant species including, *Equisetum fluviatile*, *Carex rostrata*, *Apium nodiflorum*, *Agrostis stolonifera*, *Potamogeton natans*, *Nasturtium officinale*, *Juncus articulatus*, *Typha latifolia*, *Glyceria fluitans*, *Sparganium erectum*, *Eleocharis palustris*, *Ranunculus flammula*, *Mentha aquatica*, *Galium uliginosum* and *Samolus valerandi*.

8.3.4.20 Improved agricultural grassland (GA1)

Improved agricultural grassland was present throughout, with larger areas recorded at Cappagh, between the Ballymoneen Road and Knocknabrona, around the Rahoon Road Junction, at Bushypark, in the vicinity of Bóthar Nua and Seanbóthar (Menlough/Coolough), and from the N84 Headford Road through to the existing Coolagh Junction. Characteristic species included: grass species such as *Lolium perenne*, *Agrostis stolonifera*, *Dactylis glomerata*, *Holcus lanatus*, *Poa annua*, *Poa trivialis* and *Cynosurus cristatus*; and herb species including *Trifolium repens*, *Trifolium pratense*, *Bellis perennis*, *Urtica dioica*, *Plantago lanceolata*, *Plantago major*, *Cerastium fontanum*, *Cerastium glomeratum*, *Cirsium arvense*, *Potentilla anserina*, *Ranunculus repens*, *Rumex obtusifolius*, and *Taraxacum officinale* agg.

8.3.4.21 Amenity grassland (improved) (GA2)

Other than amenity grasslands associated with residential gardens and landscaped areas in commercial/industrial complexes, the two largest areas of this habitat type were the playing fields at the NUIG Sporting Campus and the racetrack at the Galway Racecourse. Typical grass species included *Agrostis stolonifera*, *Agrostis capillaris*, *Cynosurus cristatus*, *Holcus lanatus* and *Lolium perenne*, along with the following herb species: *Bellis perennis*, *Cirsium arvense*, *Cirsium palustre*, *Cirsium vulgare*, *Plantago lanceolata*, *Plantago major*, *Potentilla anserina*, *Ranunculus repens*, *Rumex crispus*, *Rumex obtusifolius*, *Senecio jacobaea*, *Sonchus asper*, *Taraxacum officinale* agg. and *Trifolium pratense*.

8.3.4.22 Marsh (GM1)

The two small marsh areas at Na Foraí Maola Thoir (Ch. 1+100) were characterised by *Filipendula ulmaria*, *Lythrum salicaria*, *Juncus effusus* with *Ranunculus acris*, *Potentilla anserina*, *Mentha aquatica*, *Typha latifolia*, *Scrophularia auriculata* and *Angelica sylvestris* also present.

There was a small area of marsh habitat at Ballard West (Ch. 3+100). Typical marsh species such as *Lythrum salicaria*, *Mentha aquatica*, *Potentilla palustris*, *Myosotis scorpioides*, and *Hydrocotyle vulgaris* were present along with *Juncus articulatus*, *Carex panicea*, *Ranunculus acris*, *Leontodon autumnalis*, *Solidago virgaurea* and *Hypericum perforatum*.

To the north of Bearna Woods (c.55m east of the proposed development boundary at Ch. 3+900) there was a marsh near the east bank of the Tonabrocky Stream.

Species present included *Holcus lanatus*, *Festuca rubra*, *Molinia caerulea*, *Anthoxanthum odoratum*, *Filipendula ulmaria*, *Angelica sylvestris*, *Lythrum salicaria*, *Carex disticha*, *Carex nigra*, *Equisetum fluviatile*, *Valeriana officinalis*, *Potentilla palustris*, *Potentilla erecta*, *Calliergonella cuspidata* and *Juncus acutiflorus*.

The marsh area near the Rahoon Road Junction (west of Ch. 1+900 along the N59 Link Road South) was characterised by the following species: *Juncus effusus*, *Hydrocotyle vulgaris*, *Juncus acutiflorus*, *Agrostis stolonifera*, *Epilobium hirsutum*, *Typha latifolia*, *Epilobium palustre*, *Lotus pedunculatus*, *Filipendula ulmaria*, *Calliergonella* sp.

The marsh area at Castlegar (Ch. 13+000) is characterised by the following species: *Juncus acutiflorus*, *Agrostis stolonifera*, *Galium palustre*, *Carex nigra*, *Mentha aquatica*, *Comarum palustre*, *Calliergonella cuspidata*, *Epilobium palustre* and *Potentilla anserina*. Locally there is *Carex disticha*, *Carex panicea*, *Carex echinata* and *Carex rostrata* while *Cirsium palustre* is frequent throughout. Other species include *Juncus effusus, Luzula campestris, Menyanthes trifoliata, Hypericum tetrapterum, Filipendula ulmaria, Carex hirta, Molinia caerulea, Salix aurita, Anthoxanthum odoratum, Hydrocotyle vulgaris, Persicaria amphibia, Eleocharis palustris, Glyceria fluitans, Apium nodiflorum, and Ranunculus repens.* At the edges *Centaurea nigra*, *Briza media*, *Knautia arvensis*, *Leucanthemum vulgare* and *Ilex aquifolium* occurred.

8.3.4.23 Dry calcareous and neutral grassland (GS1)

There were scattered patches of neutral grassland present along the route of the proposed road development to the east of the River Corrib, generally associated with agricultural lands that are not intensively managed and subject to low intensity grazing. Typical grass species recorded included *Agrostis stolonifera*, *Agrostis capillaris*, *Holcus lanatus*, *Cynosurus cristatus*, *Anthoxanthum odoratum*, *Lolium perenne* and *Dactylis glomerata*. Herb species included *Achillea millefolium*, *Centaurea nigra*, *Prunella vulgaris*, *Lotus corniculatus*, *Trifolium repens*, *Trifolium pratense*, *Rumex acetosa*, *Urtica dioica*, *Senecio jacobaea*, *Ranunculus repens*, *Prunella vulgaris*, *Plantago lanceolata* and *Taraxacum officinalis* agg.

Given the underlying geology east of the River Corrib, this habitat was much more widespread to the east of the river and this was reflected in the greater species diversity, and in particular calcicole species, recorded.

The majority of calcareous grassland areas did not correspond with the Annex I habitat type *Semi-natural dry grasslands and scrubland facies on calcareous substrates (Festuco-Brometalia) (* important orchid sites)* [*6210/6210], due the lack of sufficient indicator species in the sward. Typical species recorded included *Cynosurus cristatus*, *Holcus lanatus*, *Festuca rubra*, *Dactylis glomerata*, *Agrostis stolonifera*, *Lolium perenne*, *Daucus carota*, *Lotus corniculatus*, *Galium verum*, *Linum catharticum*, *Centaurea nigra*, *Plantago lanceolata*, *Cirsium arvense*, *Senecio jacobaea*, *Prunella vulgaris*, *Trifolium repens*, *Ranunculus acris*, *Trifolium pratense* and *Taraxacum officinale* agg.

In many areas the calcareous grasslands did correspond with the Annex I Calcareous grassland habitat type due to the presence of sufficient high quality positive/positive indicator species (after O'Neill *et al.*, 2013). High quality indicator species recorded in Calcareous grassland within the ZoI of the proposed road development included *Antennaria dioica*, *Anthyllis vulneraria*, *Asperula cynanchica*, *Briza media*, *Campanula rotundifolia*, *Carex caryophyllea*, *Carlina vulgaris*, *Koeleria macrantha* and *Linum catharticum*. Positive indicator species recorded included *Carex flacca*, *Ctenidium molluscum*, *Daucus carota*, *Galium verum*, *Helictotrichon pubescens*, *Leontodon hispidus*, *Lotus corniculatus*, *Pilosella officinarum*, *Ranunculus bulbosus*, *Sesleria caerulea*, *Thymus polytrichus* and *Trisetum flavescens*.

Within Lough Corrib cSAC, calcareous grassland was recorded at three locations within the ZoI of the proposed road development: on the east bank of the proposed River Corrib Bridge crossing (Ch. 9+400 – Ch. 9+475), along the spring/valley leading to the Coolough Lakes (Ch. 9+950), and to the north and west of Lackagh Quarry (Ch. 11+000 – Ch. 11+800) - see **Figure 8.14.7** and **Figure 8.14.8**.

On the east bank of the proposed River Corrib Bridge crossing the grassland was of the *Cynosurus cristatus – Trifolium repens* (3c) vegetation community (westernmost field) and the *Cynosurus cristatus – Trifolium pratense* (3d) vegetation community (easternmost field) and did not correspond with any Annex I habitat types. There was an area of the Annex I habitat type *Semi-natural dry grasslands and scrubland facies on calcareous substrates (Festuco-Brometalia) (* important orchid sites)* [*6210/6210] to the south-east.

Along the spring/valley leading to the Coolough Lakes (the Lough Corrib cSAC boundary here is adjacent to the proposed road development) the grassland was of the *Holcus lanatus – Lolium perenne* grassland (2c) vegetation community and did not correspond with any Annex I habitat types.

Around the margins of Lackagh Quarry and west to Ch. 11+000, the grasslands were of the *Briza media – Thymus polytrichus* grassland (3a) vegetation community. In many cases, particularly to the north and west of the quarry boundary, the *Briza media – Thymus polytrichus* grassland corresponded with both the priority and non-priority classifications of the Annex I Calcareous grassland habitat type. The thin soils supported a highly diverse sward typically containing *Briza media*, *Carex flacca*, *Sesleria caerulea*, *Potentilla erecta*, *Succisa pratensis*, *Centaurea nigra*, *Galium verum* and *Leucanthemum vulgare*. Bryophytes include *Scleropodium purum* and *Ctenidium molluscum*.

The Calcareous grassland habitat within the ZoI of the proposed road development is summarised below in **Table 8.8** below.

Table 8.8: Areas of the Annex I habitat Calcareous grassland [*6210/6210] within the potential ZoI of the proposed road development

Area	Vegetation Community[27]
Within Lough Corrib cSAC c.27m south of the proposed road development along the east bank of the River Corrib	3a *Briza media – Thymus polytrichus* grassland [6210]
Within Lough Corrib cSAC c.20m south of the proposed road development between Ch. 11+050 and Ch. 11+150	3a *Briza media – Thymus polytrichus* grassland [6210]
Within Lough Corrib cSAC above the proposed Lackagh Tunnel (Ch. 11+300) and along the western and northern boundary of Lackagh Quarry between Ch. 11+000 and Ch. 11+800	3a *Briza media – Thymus polytrichus* grassland [*6210]
Adjacent to the proposed development boundary at Ch. 12+000	3a *Briza media – Thymus polytrichus* grassland [6210]
West of the N84 Headford Road Ch. 12+075 – Ch. 12+125	3a *Briza media – Thymus polytrichus* grassland [6210]
Along proposed development boundary at AR 12/02	3a *Briza media – Thymus polytrichus* grassland [6210]
Northern end of Coolagh Junction between Ch. 16+200 – Ch. 16+275	3a *Briza media – Thymus polytrichus* grassland [6210]
Adjacent to the south-western end of the Coolagh Junction	3a *Briza media – Thymus polytrichus* grassland [6210]
Adjacent to southern boundary of the Coolagh Junction	3a *Briza media – Thymus polytrichus* grassland [6210]

8.3.4.24 Dry meadows and grassy verges (GS2)

This habitat type was present across the study area and included abandoned agricultural fields, fields managed for silage/hay, neglected grassed areas associated with residential gardens or waste ground, and roadside verges.

Typical grass species included, *Arrhenatherum elatius*, *Dactylis glomerata*, *Holcus lanatus*, *Festuca rubra*, *Phleum pratense*, *Alopecurus pratensis*, *Agrostis stolonifera*, *Anthoxanthum odoratum* and *Lolium perenne*. Herb species recorded included *Centaurea nigra*, *Heracleum sphondylium*, *Calystegia sepium*, *Urtica dioica*, *Plantago lanceolata*, *Cirsium arvense*, *Ranunculus repens*, *Ranunculus acris*, *Rumex acetosa* subsp. *acetosa*, *Rumex obtusifolius*, *Cerastium fontanum*, *Potentilla anserina*, and *Scorzoneroides autumnalis*.

Across the eastern part of the scheme study area[28], in some instances this habitat type corresponded with the Annex I habitat *Lowland hay meadows (Alopecurus*

[27] The vegetation communities are assigned based upon the plant species recorded and with reference to the vegetation types described in *The Irish semi-natural grasslands survey 2007-2012. Irish Wildlife Manuals, No. 78* (O'Neill et al., 2013)
[28] Almost all occurrences of the 6510 Annex I habitat type were recorded east of the River Corrib.

pratensis, *Sanguisorba officinalis)* [6510]. However, none of these areas are within the ZoI of the proposed road development.

8.3.4.25 Dry-humid acid grassland (GS3)

Dry-humid acid grassland was recorded widely along the western part of the proposed road development in less intensively managed agricultural fields, often on the margins of peatland/heath sites, and frequently in a mosaic with wet grassland. In many cases, the grasslands were noted as being species poor as a result of grazing. Characteristic species included: the grasses, *Agrostis capillaris*, *Cynosurus cristatus*, *Anthoxanthum odoratum*, *Lolium perenne*, *Nardus stricta* and *Festuca rubra*; herb species such as *Rumex acetosa*, *Succisa pratensis*, *Potentilla erecta*, *Galium saxatile*, *Veronica officinalis*, *Achillea millefolium*, *Trifolium pratense* and *Juncus articulatus*; and moss species such as *Hylocomium splendens*, *Hypnum cupressiforme*, *Rhytidiadelphus squarrosus* and *Pleurozium schreberi*. Of note was the record of *Botrychium lunaria*, a species listed as Near Threatened on the Irish Red List for Vascular Plants (Jackson et al., 2016) from Knocknabrona/Knocknafroska in 2015, in an area outside of the proposed development boundary.

At one location in the scheme study area – Carrach, between Bearna Village and Bearna Woods – Dry-humid acid grassland corresponded with the priority Annex I habitat type *Species-rich Nardus grasslands, on siliceous substrates in mountain areas (and submountain areas, in Continental Europe)* [*6230]. However, this area is not within the ZoI of the proposed road development.

8.3.4.26 Wet grassland (GS4)

Wet grassland was recorded across the scheme study area but more frequently west of Ballindooley Lough. It ranged in quality from species poor variants associated with lands managed for agriculture through to more diverse and species rich areas associated with the River Corrib/Coolagh Lakes and at Ballindooley Lough.

In the vicinity of the proposed road development, the more improved wet grassland fields, managed for agriculture, generally comprised rush species such as *Juncus effusus*, *Juncus articulatus* and *Juncus conglomeratus*, grass species including *Agrostis stolonifera*, *Arrhenatherum elatius*, *Holcus lanatus*, and *Lolium perenne*, and with fewer wet grassland herb species present than more semi-natural areas. Herb species recorded in wet grassland included *Angelica sylvestris*, *Carex flacca*, *Carex panicea*, *Cirsium palustre*, *Filipendula ulmaria*, *Galium palustre*, *Hydrocotyle vulgaris*, *Iris pseudacorus*, *Lotus pedunculatus*, *Lythrum salicaria*, *Mentha aquatica*, *Potentilla anserina*, *Potentilla erecta*, *Ranunculus acris*, *Ranunculus repens*, *Ranunculus flammula*, *Stachys palustris* and *Succisa pratensis*. Typical moss species included *Calliergonella cuspidata* and *Rhytidiadelphus squarrosus*.

A wet grassland type, dominated by *Molinia caerulea*, was also recorded in the western part of the scheme study area and was associated with the margins of some of the peatland areas in the vicinity of the proposed road development – at Na Foraí Maola Thiar (at Ar 0/04), at Troscaigh Thiar (Ch. 2+350) and at

Knocknabrona/Knocknafroska (Ch. 7+750). These grasslands corresponded with the 1d *Molinia caerulea – Potentilla erecta* grassland vegetation community (O'Neill et al., 2013). At the Foraí Maola Thiar site, *Potentilla erecta*, *Succisa pratensis*, *Anthoxanthum odoratum*, *Ranunculus acris*, *Ranunculus repens*, *Cirsium vulgare* and *Vicia sepium* were present in the sward but in low amounts. At Troscaigh Thiar, *Juncus acutiflorus* was abundant in the sward with *Sphagnum fallax*, *Succisa pratensis*, *Hylocomium splendens*, *Potentilla erecta*, *Anthoxanthum odoratum*, *Rhytidiadelphus loreus*, *Thuidium* sp., *Rumex acetosa* and *Calluna vulgaris* (rare) also present. At Knocknabrona/Knocknafrosca, Juncus acutiflorus, Sphagnum fallax, Carex panicea, Potentilla erecta, Succisa pratensis, Erica tetralix (rare), Lythrum salicaria and Calluna vulgaris (rare) were also present.

At two locations within the footprint of the proposed road development – at Na Foraí Maola Thiar and Ballindooley Lough – wet grassland corresponded with the Annex I habitat type *Molinia meadows on calcareous, peaty or clayey-silt laden soils (Molinion caeruleae)* [6410]. There was also an area of *Molinia* meadow habitat adjacent to the proposed development boundary at Ch. 3+800.

At Na Foraí Maola, the *Molinia* meadow was characterised by the following indicator species for this Annex I habitat type: *Juncus conglomeratus*, *Carex echinata*, *Carex flacca*, *Filipendula ulmaria*, *Galium palustre*, *Juncus articulatus*, *Lotus pedunculatus*, *Molinia caerulea*, *Potentilla erecta* and *Mentha aquatica*.

Ballindooley Lough is surrounded by a band of wet grassland which corresponds with the *Molinia* meadow Annex I habitat type. The vegetation was characterised by the high-quality positive/positive indicator species *Carex pulicaris*, *Cirsium dissectum*, *Achillea ptarmica*, *Carex echinata*, *Carex panicea*, *Carex nigra*, *Filipendula ulmaria*, *Juncus articulatus*, *Molinia caerulea* and *Potentilla erecta*. *Calliergonella cuspidata* was the main bryophyte species, but *Climacium dendroides and Rhytidiadelphus squarrosus* were also recorded towards the grazed habitat edges. At the edges of the wet meadows, where *Molinia caerulea* was very sparse or absent, other species occurring more frequently included *Potentilla anserina*, *Carex nigra*, *Holcus lanatus*, *Ranunculus repens*, *Galium palustre*, *Festuca arundinacea* and *Eleocharis palustris*. In these areas the grassland did not correspond to the Annex I habitat type. It was noted that the lack of grazing at the southern end has resulted in patches of *Molinia caerulea* becoming very tussocky and the habitat less species diverse. Drainage and drying out of the peat is also likely to be affecting the habitat composition around the lake to a degree.

The *Molinia* meadow habitat within the ZoI of the proposed road development is summarised below in **Table 8.9**.

Table 8.9: Areas of the Annex I habitat *Molinia* meadow [6410] within the potential ZoI of the proposed road development

Area	Vegetation Community[29]
Na Foraí Maola Thiar at Ch. 0+900	1c *Molinia caerulea – Succisa pratensis* grassland
North of Bearna Woods Ch. 3+800	1c *Molinia caerulea – Succisa pratensis* grassland
Ballindooley Lough Ch. 12+250 – Ch. 12+400	1d *Molinia caerulea – Potentilla erecta* grassland

8.3.4.27 Dense bracken (HD1)

This habitat type was most prevalent along the western part of the proposed road development, associated with *Pteridium aquilinum* dominating abandoned agricultural fields (in conjunction with bramble cover in many instances), the margins of less intensively managed agricultural fields, and around the edges of peatland sites in conjunction with dense gorse cover.

8.3.4.28 Dry siliceous heath (HH1)

Patches of dry siliceous heath were present all along the route of the proposed road development to the west of the N59 Moycullen Road, generally relatively small in area, and most often in association with, or forming mosaics with, wet heath, bog and acid grassland. All areas of dry heath vegetation communities recorded within the ZoI of the proposed road development corresponded with the *Ulex gallii - Erica cinerea* dry heath (DH1) vegetation community, characterised by the presence of *Ulex gallii* along with *Erica cinerea* or *Calluna vulgaris*.

Typical dry heath species recorded included the vascular plant species *Ulex gallii*, *Calluna vulgaris*, *Erica cinerea*, *Molinia caerulea*, *Daboecia cantabrica*, *Potentilla erecta*, *Arctostaphylos uva-ursi*, *Pteridium aquilinum*, *Carex binervis*, *Carex panacea*, *Carex echinata*, along with the moss species *Rhytidiadelphus squarrosus*, *Hypnum cupressiforme*, *Hypnum jutlandicum*, and *Pseudoscleropodium purum*, and the lichen *Cladonia* cf *portentosa*. Other species recorded included *Agrostis capillaris*, *Succisa pratensis*, *Teucrium scorodonia*, *Hylocomium splendens*, *Solidago virgaurea*, *Viola* sp., *Dicranum scoparium* and *Campylopus introflexus*.

All instances of dry siliceous heath corresponded with the Annex I habitat type *European dry heaths* [4030]. The siliceous Dry heath habitat within the ZoI of the proposed is summarised below in **Table 8.10**.

[29] The vegetation communities are assigned based upon the plant species recorded and with reference to the vegetation types described in *The Irish semi-natural grasslands survey 2007-2012. Irish Wildlife Manuals, No. 78* (O’Neill et al., 2013)

8.3.4.29 Dry calcareous heath (HH2)

Dry calcareous heath was recorded in the Menlough/Coolough area; sometimes in larger distinct habitat patches but most often in a mosaic with outcropping limestone, scrub and/or calcareous grassland. The two larger areas were to the north of An Seanbóthar and on higher ground near to the eastern shore of the northernmost of the Coolagh Lakes. Typical plant species recorded included the vascular plants *Calluna vulgaris*, *Molinia caerulea*, *Sesleria caerulea*, *Rubus fruticosus* agg., *Carex panicea*, *Carex flacca*, *Carex pulicaris*, *Succisa pratensis*, *Rosa spinosissima*, *Potentilla erecta*, *Hedera helix*, and mosses such as *Thuidium tamariscinum*, *Breutelia chrysocoma* and *Scleropodium purum*.

This habitat corresponded with the *Calluna vulgaris – Antennaria dioica* dry heath (DH5) vegetation community of the Annex I habitat type *European dry heaths* [4030]. The calcareous Dry heath habitat within the ZoI of the proposed road development is summarised below in **Table 8.11**.

---

[30] The vegetation communities are assigned based upon the plant species recorded and with reference to the vegetation types described in *Guidelines for a national survey and conservation assessment of upland vegetation and habitats in Ireland. Version 2.0. Irish Wildlife Manuals, No. 79* (Perrin et al., 2014)

North of Seanbóthar between Ch. 10+450 and Ch. 10+650	DH5 *Calluna vulgaris – Antennaria dioica* dry heath
Coolagh Lakes	DH5 *Calluna vulgaris – Antennaria dioica* dry heath

8.3.4.30 Wet heath (HH3)

Wet heath occurred predominantly across the western part of the scheme study area; with only a few small patches of this habitat type present east of the River Corrib around the margins of the Coolagh Lakes. Typical vascular plant species in those areas in the vicinity of the proposed road development included *Calluna vulgaris*, *Erica tetralix*, *Schoenus nigricans*, *Trichophorum germanicum*, *Ulex gallii*, *Eriophorum angustifolium*, *Eriophorum vaginatum*, *Myrica gale*, *Potentilla erecta*, *Succisa pratensis* and *Juncus articulatus*. Typical moss species recorded included *Cladonia* cf *portentosa*, *Hylocomium splendens*, *Sphagnum capillifolium* subsp. *rubellum*, *Sphagnum cuspidatum*, *Sphagnum denticulatum*, *Sphagnum tenellum*, *Pleurozia purpurea*, *Sphagnum compactum* and *Diplophyllum albicans*.

In all cases this habitat corresponded with the Annex I habitat type *Northern Atlantic wet heaths with Erica tetralix* [4010]. The Wet heath habitat within the ZoI of the proposed road development is summarised below in **Table 8.12**.

Table 8.12: Areas of the Annex I habitat Wet heath [4010] within the potential ZoI of the proposed road development

Area	Vegetation Community[31]
Coolagh Lakes	WH6 *Schoenus nigricans – Molinia caerulea – Myrica gale* wet heath

8.3.4.31 Lowland blanket bog (PB3)

Lowland blanket bog was recorded across the western part of the scheme study area, to the north of the proposed road development. This habitat type was only recorded within the ZoI of the proposed road development at Na Foraí Maola Thiar (Ch. 0+650 – Ch. 0+750) where it formed a mosaic with wet heath, dry heath and scrub at the southern extent of a much larger peatland site within Moycullen Bogs NHA. Approximately 10% of this habitat area corresponded with the Lowland blanket bog classification; although this habitat type did not occur within the proposed development boundary.

Typical vascular plant species present included *Calluna vulgaris*, *Molinia caerulea*, *Schoenus nigricans*, *Rhynchospora alba*, *Erica tetralix*, *Carex panicea*, *Eriophorum angustifolium*, *Eriophorum vaginatum*, *Narthecium ossifragum*, *Trichophorum germanicum*, *Drosera rotundifolia* and *Potentilla erecta*. Typical moss species included *Sphagnum capillifolium* ssp. *rubellum*, *Sphagnum papillosum*, *Sphagnum tenellum*, *Sphagnum cuspidatum*, *Aulacomnium palustre* and *Odontoschisma sphagni*.

Lowland blanket bog habitat corresponded with the Annex I habitat type *Blanket bogs* [*7130]. The Blanket bog habitat within the ZoI of the proposed road development is summarised below in **Table 8.13** below.

Table 8.13: Areas of the Annex I habitat Blanket bog [*7130] within the potential ZoI of the proposed road development

Area	Vegetation Community[32]
Na Foraí Maola Thiar between Ch. 0+650 and Ch. 0+750	BB3 *Eriophorum vaginatum – Sphagnum papillosum* bog

8.3.4.32 Rich fen and flush (PF1)

There was a large Rich fen complex present at Kentfield with one of the fen areas immediately adjacent to the proposed drainage outfall for the N59 Link Road North. This fen polygon corresponded with the RFLU1a vegetation community (*Carex viridula oedocarpa - Pinguicula vulgaris - Juncus bulbosus* flush; brown moss sub-community) of the Annex I habitat type *Alkaline fens* [7230]. *Carex panicea* and *Carex viridula* were the most abundant plant species present with *Molinia caerulea*, *Juncus bulbosus* and *Succisa pratensis* also frequently recorded. Other species recorded included *Hydrocotyle vulgaris*, *Agrostis stolonifera*, *Anagallis tenella*,

[32] The vegetation communities are assigned based upon the plant species recorded and with reference to the vegetation types described in *Guidelines for a national survey and conservation assessment of upland vegetation and habitats in Ireland. Version 2.0. Irish Wildlife Manuals, No. 79* (Perrin et al., 2014)

Calliergonella cuspidata, *Carex flacca*, *Festuca rubra*, *Potentilla erecta*, *Prunella vulgaris*, *Anthoxanthum odoratum*, *Carex echinata* and *Drepanocladus cossonii*.

There were also areas of Rich fen amongst the fringing aquatic vegetation surrounding the Coolagh Lakes (along with a few isolated patches along the banks of the River Corrib, downstream of the proposed River Corrib Bridge) characterised by species such as: *Calliergonella cuspidata*, *Agrostis stolonifera*, *Carex nigra*, *Trifolium repens*, *Carex panicea*, *Potentilla anserina*, *Mentha aquatica*, *Festuca arundinacea*, *Filipendula ulmaria*, *Carex ovalis*, *Anthoxanthum odoratum*, *Cardamine pratensis*, *Epilobium palustre*, *Galium palustre*, *Juncus articulatus*, *Lythrum salicaria*, *Ranunculus flammula*, *Vicia cracca*, *Rhytidiadelphus squarrosus*, *Senecio aquaticus*, *Carex echinata* and *Equisetum fluviatile*. A number of these polygons corresponded with the RFEN1a vegetation community of the Annex I Alkaline fen habitat type due to the presence of the positive indicator species *Campylium stellatum*, *Carex panicea*, *Carex rostrata*, *Carex viridula s. brachyrrhyncha*, *Drepanocladus revolvens* and *Scorpidium scorpioides*[33]. Some Rich fen areas here corresponded with the priority Annex I habitat type *Calcareous fens with* Cladium *mariscus and species of the* Caricion davallianae [*7210], characterised by *Schoenus nigricans*, *Cladium mariscus*, *Campylium stellatum*, *Drepanocladus revolvens*, *Fissidens adianthoides*, *Molinia caerulea*, *Ctenidium molluscum*, *Filipendula ulmaria*, *Phragmites australis*, *Succisa pratensis* and *Carex panicea*.

At Ballindooley Lough, one of the areas of Rich fen corresponds with the RFLU4 vegetation community (*Schoenus nigricans – Scorpidium scorpioides* flush) of the Annex I Alkaline fen habitat type characterised by the following species: *Schoenus nigricans*, *Juncus subnodulosus*, *Molinia caerulea*, *Hydrocotyle vulgaris*, *Carex panacea*, *Carex lepidocarpa*, *Juncus articulatus*, *Ranunculus flammula*, *Cirsium dissectum*, *Parnassia palustris*, *Drosera anglica*, *Calliergonella cuspidata*, *Scorpidium scorpioides*, *Scorpidium cossonii*, *Campylium stellatum* and *Myrica gale*. Some fen areas here also corresponded with the priority Annex I habitat type *Calcareous fens with* Cladium *mariscus and species of the* Caricion davallianae [*7210]

The Alkaline fen and *Cladium* fen habitat within the ZoI of the proposed road development is summarised below in **Table 8.14**.

[33] Guidelines for a national survey and conservation assessment of upland vegetation and habitats in Ireland. Version 2.0. *Irish Wildlife Manuals, No. 79* (Perrin *et al.*, 2014)

Table 8.14: Areas of the Annex I habitat Alkaline fen [7230] and *Cladium* fen [*7210] within the potential ZoI of the proposed road development

Area	Vegetation Community
Kentfield, adjacent to drainage outfall	RFLU1a *Carex viridula oedocarpa - Pinguicula vulgaris - Juncus bulbosus* flush; brown moss sub-community [7230]
Coolagh Lakes	RFEN1a Carex rostrata fen; brown moss sub-community [7230] also *Cladium* fen [*7210]
Ballindooley Lough	RFLU4 *Schoenus nigricans – Scorpidium scorpioides* flush [7230] also *Cladium* fen [*7210]

8.3.4.33 Poor fen and flush (PF2)

There was an area of Poor fen at Na Foraí Maola Thiar (Ch. 0+700 – Ch. 0+800) characterised by the following species: *Juncus effusus*, *Juncus articulatus*, *Sphagnum denticulatum*, *Ranunculus flammula*, *Potamogeton polygonifolius*, *Juncus bulbosus*, *Philonotis fontana*, *Agrostis stolonifera*, *Lythrum salicaria*, *Calliergonella cuspidata* and *Sphagnum palustre*. This corresponded with the *Juncus effusus - Sphagnum cuspidatum/palustre* flush vegetation community (PFLU2). A second area to the north (near the proposed access track) was characterised by *Carex echinata*, *Juncus effusus*, *Juncus conglomeratus*, *Calliergonella cuspidata*, *Eriophorum angustifolium*, *Potentilla palustris*, *Angelica sylvestris*, *Sphagnum papillosum*, *Holcus lanatus*, *Anthoxanthum odoratum* and *Agrostis stolonifera*.

At Knocknafroska (Ch. 7+800 to Ch. 7+975) there were two areas of Poor fen recorded. The smaller area corresponded with the SW1 *Potamogeton polygonifolius* soakway vegetation community Other species present included *Sphagnum* spp., *Polytrichum commune*, *Carex panicea*, *Juncus effusus*, *Juncus bulbosus*, *Ranunculus flammula*, *Anagallis tenella*, *Menyanthes trifoliate* and *Hydrocotyle vulgaris*. The larger area to the north was heavily grazed and dominated by *Juncus effusus* with a layer of *Sphagnum* sp. underneath (including *Sphagnum palustre*). Other species recorded included *Calliergonella cuspidata*, *Holcus lanatus* and *Rumex acetosa*.

8.3.4.34 Residential

This non-Fossitt classification is used to represent residential properties along the proposed road development and generally consist of a mosaic of buildings and artificial surfaces (BL3), amenity grassland (GA2), flower beds and borders (BC4) and ornamental shrubs (WS3), with unmanaged rank grassland areas also occasionally present (GS2).

8.3.4.35 (Mixed) broadleaved woodland (WD1)

There were small stands of broadleaved woodland scattered along the route of the proposed road development from the western end of the proposed road development to the woodlands at Menlough. The largest area was at the NUIG Sporting Campus, where most of the woodland was planted for amenity purposes, and the woodlands at Menlough, which are long established (dating back to the 1800s).

At Na Foraí Maola Thiar (Ch. 0+800 – Ch. 1+000) there was a band of planted trees surrounding a residential garden which included *Acer pseudoplatanus*, *Fagus sylvatica*, *Quercus robur*, *Salix* sp., *Alnus cordata*, *Alnus glutinosa*, *Corylus avellana*, *Crataegus monogyna* and *Prunus* sp.

Along the eastern edge of the Na Foraí Maola Road was a stand of woodland comprising *Acer pseudoplatanus*, *Salix cinerea*, *Fagus sylvatica*, *Quercus robur*, *Alnus cordata*, *Alnus glutinosa*, *Sorbus aria*, *Lonicera periclymenum*, *Hedera helix*, *Dryopteris filix-mas*, *Urtica dioica*, *Blechnum spicant* and *Phyllitis scolopendrium*.

At An Chloch Scoilte Junction (Ch. 3+300 – Ch. 3+400) the woodland species comprised *Fraxinus excelsior*, *Acer pseudoplatanus*, *Rubus fruticosus agg*., *Phyllitis scolopendrium*, *Hedera helix*, *Heracleum sphondylium*, *Crataegus monogyna*, *Cotoneaster* sp., *Urtica dioica*, *Dryopteris filix-mas*, *Polypodium vulgare* and *Symphoricarpos albus*.

At the NUIG Sporting Campus (Ch. 8+725 – Ch. 9+250) there were many stands of maturing amenity broadleaved woodland planting including tree species such as *Acer pseudoplatanus*, *Fraxinus excelsior*, *Fagus sylvatica*, *Tilia cordata*, *Aesculus hippocastanum* and *Ulmus glabra*. The field layer contained species such as *Hedera helix*, *Geum urbanum*, *Vicia sepia*, *Torilis japonica*, *Rubus fruticosus agg*., *Arrhenatherum elatius* and *Brachypodium sylvaticum*.

There were two areas of mixed broadleaved woodland within the boundary of Lough Corrib cSAC, on the eastern bank of the River Corrib (Ch. 9+475 – Ch. 9+650). The main species that made up the woodland flora in the main block were *Fagus sylvatica*, *Fraxinus excelsior*, *Ilex aquifolium* and *Thamnobryum alopecurum*. Also recorded were *Arum maculatum*, *Hedera helix*, *Isothecium alopecuroides*, *Kindbergia praelonga*, *Neckera complanata*, *Radula complanata*, *Lejeunea cavifolia*, *Metzgeria furcata*, *Rhynchostegiella tenella* and *Tortella tortuosa*. The narrow linear strip to the east, at Ch. 9+500, was comprised of *Fagus sylvatica* with an *Ilex aquifolium* understory.

The linear strips of woodland at the City East Business Park Junction comprised *Fraxinus excelsior*, *Acer pseudoplatanus*, *Fagus sylvatica*, *Rubus fruticosus agg*. and *Urtica dioica*.

8.3.4.36 Mixed broadleaved/conifer woodland (WD2)

At the Troscaigh Road L5387 (Ch. 1+550 – Ch. 1+650) there was an area of planted broadleaved/conifer woodland associated with the residential properties. Tree species included *Acer pseudoplatanus*, *Fraxinus excelsior*, *Betula* sp., *Prunus* sp., *Pinus* sp., *Cupressus* sp. and *Rhododendron ponticum*.

A second small area of mixed broadleaved/conifer was present adjacent to the proposed road development at School Road in Castlegar (Ch. 13+150).

8.3.4.37 (Mixed) conifer woodland (WD3)

At the Troscaigh Road L5387 (Ch. 1+550 – Ch. 1+600) there was a small stand of *Pinus* sp. and *Cupressus* sp. mixed conifer woodland; *Rhododendron ponticum*, a non-native invasive plant species listed on the Third Schedule of the European Communities (Birds and Natural Habitats) Regulations, 2011, was also present here.

In a field south of the N59 Moycullen Road (Ch. 8+500) there was a small mixed *Picea* sp. conifer stand.

8.3.4.38 Hedgerows (WL1)

Along the western part of the proposed road development, hedgerow features not associated with residential properties were scarce as most field boundaries were stone walls or formed the edge of larger scrub patches. Many of the hedgerows recorded were over grown stone walls dominated by *Rubus fruticosus* agg. The hedgerows here were generally quite species poor. Typical species included *Prunus spinosa*, *Crataegus monogyna*, *Fraxinus excelsior*, *Rubus fruticosus* agg., *Urtica dioica*, *Hedera helix*, *Calystegia sepium*, *Pteridium aquilinum*, *Lonicera periclymenum*, *Epilobium hirsutum*, *Filipendula ulmaria*, *Germanium robertianum* and *Phyllitis scolopendrium*.

Hedgerows were much more abundant along the eastern part of the proposed road development and included some older more mature hedges. Hedgerows here were often associated with stone walls and where associated with agricultural fields were often dominated by Rubus fruticosus agg. *Crataegus monogyna*, *Prunus spinosa*, *Hedera helix* and *Rubus fruticosus* agg. were the most abundant hedgerow species recorded. Other common species included *Ilex aquifolium*, *Fraxinus excelsior*, *Salix cinerea*, *Corylus avellana*, *Urtica dioica*, *Calystegia sepium*, *Lonicera periclymenum*, *Pteridium aquilinum*, *Lathyrus pratensis* and *Rosa canina*; and *Sorbus aria*, *Viburnum opulus*, *Euonymus europaeus*, *Salix caprea* and *Quercus robur* were recorded occasionally.

8.3.4.39 Treelines (WL2)

Along the western part of the proposed road development, treelines were generally scarce and where present the majority were associated with planting along residential property boundaries. Tree species included *Fraxinus excelsior*, *Acer pseudoplatanus*, *Alnus glutinosa*, *Alnus cordata*, *Populus* sp., *Cupressus* sp., *Pinus* sp. (including *Pinus contorta*), *Picea sitchensis*, *Sorbus aucuparia* and *Fagus sylvatica*.

Treelines were also recorded along the eastern part of the proposed road development but much less frequently, as most field boundaries consisted of stone walls or hedgerows.

8.3.4.40 Oak-ash-hazel woodland (WN2)

The majority of oak-ash-hazel woodland was recorded along the eastern part of the proposed road development, with the most extensive area present between the River Corrib and Lackagh Quarry and large areas also recorded adjacent to the proposed road development (Ch. 13+200 – Ch. 13+900), south of the Roadstone Quarry. Many woodland blocks were small and isolated outside of these areas with only a few patches of oak-ash-hazel woodland recorded along the western part of the proposed road development, including areas of amenity planting at the NUIG Sporting Campus.

Along with *Fraxinus excelsior* and *Corylus avellana*, woody species recorded in these woodlands included *Euonymus europaeus*, *Crataegus monogyna*, *Prunus spinosa*, *Ilex aquifolium*, *Sorbus aria* agg., *Sorbus aucuparia*, *Quercus robur*, *Populus tremula*, *Hedera helix*, *Lonicera periclymenum*, and *Rubus fruticosus* agg. The field layer contained species such as *Fragaria vesca*, *Circaea lutetiana*, *Geranium robertianum*, *Potentilla sterilis*, *Sesleria caerulea*, *Primula vulgaris*, *Geum urbanum*, *Rumex sanguineus*, *Viola* spp., *Phyllitis scolopendrium* and *Arum maculatum*.

The wooded variant of the priority Annex I habitat Limestone pavement [*8240] was recorded in some woodland areas. Wooded Limestone pavement were those areas having a closed canopy of trees at least 3m tall with at least 50% of the surface comprising bedrock at the surface (the bedrock was normally covered by mosses) and retaining some evidence of limestone pavement structure. In the [*8240] wooded limestone pavement habitats encountered, soil was generally present but was thin (< 2cm), though could be deeper in places, for example, in old grykes, due to a build-up of humus. Rocks were sometimes completely covered by bryophytes such as *Eurhynchium striatum*, *Neckera crispa* and *Thamnobryum alopecurum*, but soil was typically lacking underneath the moss growth. These areas often occurred in mosaic with non-Annex I WN2 woodland.

The wooded Limestone pavement habitat (LPW) within the ZoI of the proposed road development is summarised below in **Table 8.15**.

Table 8.15: Areas of the wooded variant of the Annex I habitat wooded Limestone pavement [*8240] within the potential ZoI of the proposed road development

Area	Vegetation Community[34]
Menlough between Ch. 9+840 and Ch. 9+900	LPW_2b *Fraxinus excelsior - Plagiomnium undulatum* woodland
Menlough at Ch. 9+975	LPW_2a *Corylus avellana - Ctenidium molluscum* low woodland
Within Lough Corrib cSAC Adjacent to the proposed road development between Ch. 9+950 and Ch. 10+050	LPW_2a *Corylus avellana - Ctenidium molluscum* low woodland
South of Bóthar Nua at Ch. 10+100	LPW_2a *Corylus avellana - Ctenidium molluscum* low woodland
Bóthar Nua to Seanbóthar between Ch. 10+150 and Ch. 10+500	LPW_2b *Fraxinus excelsior - Plagiomnium undulatum* woodland
Within Lough Corrib cSAC Along the proposed development boundary to the west and north of Lackagh Quarry between Ch. 10+800 and Ch. 11+800	LPW_2a *Corylus avellana - Ctenidium molluscum* low woodland LPW_2b *Fraxinus excelsior - Plagiomnium undulatum* woodland
Within/adjacent to the proposed road development between Ch. 13+200 and Ch. 13+550	LPW_2b *Fraxinus excelsior - Plagiomnium undulatum* woodland
Adjacent to the proposed development boundary between Ch. 13+800 and Ch. 13+875	LPW_2a *Corylus avellana - Ctenidium molluscum* low woodland
Coolagh Junction between Ch. 16+100 and Ch. 16+250	LPW_2a *Corylus avellana - Ctenidium molluscum* low woodland

8.3.4.41 Wet willow-alder-ash woodland (WN6)

Along the western bank of the River Corrib at the NUIG Sporting Campus (Ch. 9+275) there was a narrow linear band of *Salix cinerea* wet woodland (WN6-3c *Alnus glutinosa – Filipendula ulmaria* group, *Salix cinerea – Equisetum fluviatile* vegetation type). *Rubus fruticosus* agg. and *Centaurea nigra* were also prominent species in this section of woodland. This area of woodland did not correspond with the Residual alluvial forest [*91E0] Annex I habitat type. This was distinct from the large area of wet woodland (WN6_3e *Alnus glutinosa – Filipendula ulmaria* group, *Betula pubescens – Mentha aquatica* vegetation type) further downstream which corresponded with the priority Annex I habitat type *Alluvial forests with Alnus glutinosa and Fraxinus excelsior (Alno-Padion, Alnion incanae, Salicion albae)* [*91E0].

A small patch of *Salix cinerea* wet woodland (WN6-3c *Alnus glutinosa – Filipendula ulmaria* group, *Salix cinerea – Equisetum fluviatile* vegetation type) was present within the proposed development boundary at Ch. 9+850 – Ch. 9+900;

[34] The vegetation communities are assigned based upon the plant species recorded and with reference to the vegetation types described in *National survey of limestone pavement and associated habitats in Ireland. Irish Wildlife Manuals, No. 73* (Wilson, S. and Fernández, F., 2013)

and immediately adjacent to the boundary of Lough Corrib cSAC. The woodland here corresponded with the Residual alluvial forest [*91E0] Annex I habitat type. The woodland was dominated by *Salix cinerea* subsp. *oleifolia*, with *Fraxinus excelsior*, *Agrostis stolonifera*, *Rubus fruticosus* agg., *Filipendula ulmaria* and *Eurhynchium striatum* recorded frequently. Other species present included: *Juncus effusus*, *Hedera helix*, *Lythrum salicaria*, *Galium palustre*, *Geranium robertianum*, *Crataegus monogyna*, *Prunus spinosa*, *Galium aparine*, *Rumex sanguineus*, *Equisetum fluviatile*, *Epilobium hirsutum*, *Corylus avellana*, *Ranunculus repens* and the moss species *Calliergonella cuspidatum*, *Eurhynchium striatum*, *Kindbergia praelonga* and *Thamnobryum alopecurum*.

The Residual alluvial forest habitat within the ZoI of the proposed road development is summarised below in **Table 8.16**.

Table 8.16: Areas of the Annex I habitat Residual alluvial forests [*91E0] within the potential ZoI of the proposed road development

Area	Vegetation Community[35]
Downstream of the proposed road development on west bank of River Corrib Ch. 9+250 – overlaps slightly with the south-eastern edge of the proposed development boundary	WN6-3c *Alnus glutinosa – Filipendula ulmaria* group, *Salix cinerea – Equisetum fluviatile* vegetation type
Adjacent to the proposed road development between Ch. 9+800 and Ch. 9+900	WN6-3c *Alnus glutinosa – Filipendula ulmaria* group, *Salix cinerea – Equisetum fluviatile* vegetation type

8.3.4.42 Scrub (WS1)

Patches of scrub were widespread along the proposed road development ranging in size from small isolated patches to larger expanses, where previously grazed land had been abandoned or where scrub is encroaching on semi-natural habitats. In the western part of the study area, the larger areas of scrub were generally associated with the margins of bog/heath areas where scrub is encroaching from adjoining low intensity or abandoned agricultural fields. Typical species (and in some cases the predominant species in some areas) were *Ulex europaeus*, *Prunus spinosa*, *Crataegus monogyna*, *Salix cinerea* and *Rubus fruticosus* agg. In the eastern part of the study area, the scrub was generally dominated by *Corylus avellana*, *Prunus spinosa* and/or *Crataegus monogyna*.

In some instances, polygons mapped as scrub corresponded with Annex I habitat types. In most cases the scrub is the dominant habitat in a mosaic with other Fossitt habitat types and it is those other habitats, not the scrub itself, that correspond with Annex I habitat types. As an example, scrub was often recorded in a mosaic with dry heath habitats which corresponded with the Annex I Dry heath habitat type but as scrub was dominant in the recorded polygon it was mapped as such. Where this

[35] The vegetation communities are assigned based upon the plant species recorded and with reference to the vegetation types described in *Results of monitoring survey of old sessile oak woods and alluvial forests. Irish Wildlife Manuals, No. 71* (O'Neill, F.H. & Barron, S.J., 2013)

was the case, these Annex I habitat areas are described under the appropriate sections – e.g. Dry heath [4130] is described under the *Dry siliceous heath (HH1)* heading above.

However, areas of limestone pavement that were being invaded by scrub (almost invariably *Corylus avellana*), where the scrub was not forming a continuous canopy and was less then 3m in height, corresponded with the exposed limestone pavement group (LPE) of the priority Annex I habitat type *Limestone pavements* [*8240]. The main vascular species include scattered low-growing woody species (e.g. *Rubus fruticosus*, *Rosa spinosissima*, *Hedera helix* or immature *Corylus avellana* or *Ilex aquifolium*) and herbaceous species like *Sesleria caerulea*, *Teucrium scorodonia*, *Mycelis muralis*, *Geranium robertianum*, *Senecio jacobaea*, *Carlina vulgaris* and *Carex flacca*. A suite of calcicole ferns is usually found comprising *Asplenium ruta-muraria*, *Ceterach officinarum* and, in the deeper clefts (grykes), the shade-loving *Phyllitis scolopendrium*. Characteristic bryophytes are *Ctenidium molluscum*, *Tortella tortuosa* and *Neckera crispa.*

The scrub covered Limestone pavement habitat within the ZoI of the proposed road development is summarised below in **Table 8.17**.

Table 8.17: Areas of the scrub covered variant of the Annex I habitat Limestone pavement [*8240] within the potential ZoI of the proposed road development

Area	Vegetation Community[36]
Within Lough Corrib cSAC Adjacent to the proposed road development between Ch. 10+000 and Ch. 10+050	LPE_1e *Corylus avellana - Neckera crispa* pavement
Within Lough Corrib cSAC Along the proposed development boundary to the west and north of Lackagh Quarry between Ch. 10+900 and Ch. 11+800	LPE_1e *Corylus avellana - Neckera crispa* pavement

8.3.4.43 Immature woodland (WS2)

There was one area of young planted *Alnus glutinosa* woodland near the Boleybeg Bóithrín (Ch. 4+650) that corresponded to this habitat type.

8.3.4.44 Ornamental/non-native shrub (WS3)

Areas of ornamental/non-native shrub were generally associated with amenity planting at residential properties, residential developments and areas infested with non-native invasive plant species such as *Fallopia japonica* (areas of invasive plant species are discussed in more detail below under the Non-Native Invasive Plant Species section).

[36] The vegetation communities are assigned based upon the plant species recorded and with reference to the vegetation types described in *National survey of limestone pavement and associated habitats in Ireland. Irish Wildlife Manuals, No. 73* (Wilson, S. and Fernández, F., 2013)

8.3.4.45 Recently-felled woodland (WS5)

There was one area of recently felled *Corylus avellana* woodland in close proximity to the proposed road development at Ballindooley (Ch. 12+450 – Ch. 12+500).

8.3.5 Rare and protected plant species

Slender cottongrass *Eriophorum gracile* was the only protected plant species recorded during the course of the habitat surveys. It was recorded at two locations: Tonabrocky Bog and in Coolanillaun. Its presence at Tonabrocky Bog is consistent with the findings of the desktop review; the location at Coolanillaun is a new record for the species. Neither location is within the ZoI of the proposed road development.

The Small white orchid *Pseudorchis albida* was not recorded at the Doughiska site during the habitat surveys in June of 2014.

Both of the above species are protected under the Flora (Protection) Order, 2015.

The presence of the Flora (Protection) Order, 2015 (FPO) listed bryophyte species Varnished hook-moss was confirmed at Gortachalla, 9.4km to the north of the scheme study area. This plant species is listed on Annex II of the Habitats Directive and listed as qualifying interest species of Lough Corrib cSAC.

Records of all rare or protected plant species known from the scheme study area, or recorded during the field surveys, are shown on **Figure 8.2.1**.

8.3.6 Non-native invasive plant species

There were three non-native invasive plant species listed on the Third Schedule of the European Communities (Birds and Natural Habitats) Regulations, 2011 present within, or in close proximity to, the proposed road development. The locations of these non-native invasive plant species are summarised below in **Table 8.18** and shown on **Figures 8.15.1** to **8.15.15**.

Table 8.18: Summary of Non-native Invasive Plant Species Listed in the Third Schedule of the Birds and Habitats Regulations 2011 Recorded along or adjacent to the Proposed Road Development

Common Name	Scientific Name	Location
Japanese knotweed	*Fallopia japonica*	Along farm track, south of proposed Bearna West Roundabout, adjacent to the proposed road development Along eastern side of the Troscaigh Road (L5387) at Ch. 1+575 In rough grassland field with scrub, south-east of Ch. 5+250 near Ballyburke, outside of the proposed development boundary Adjacent to residential property located c.70m east of

Common Name	Scientific Name	Location
		the proposed drainage outfall at Rahoon In area of recolonising bare ground, north of Bóthar Diarmuida Junction, within the proposed development boundary between Ch. 0+325 and Ch. 0+425 along the N59 Link Road South In area of recolonising bare ground, between Ch. 8+350 and Ch. 8+400, within the proposed development boundary In woodland/scrub, between Ch. 8+800 and Ch. 8+950 at the NUIG Sporting Campus, adjacent to the proposed development boundary Along the Coolough Road In residential garden, and on adjacent rough grassland areas, within the proposed development boundary between Ch. 12+200 and Ch. 12+375 at the N84 Headford Road Junction
Himalayan knotweed	*Persicaria wallichii*	c.80m (east) and c.135m (west) from the proposed road development between Knocknafroska and the N59 Moycullen Road
Rhododendron	*Rhododendron ponticum*	In woodland within the proposed development boundary along eastern side of the Troscaigh Road (L5387) Adjacent to residential property located c.90m east of the proposed drainage outfall at Rahoon

8.3.7 Mammals

8.3.7.1 Otter

Otter, and their breeding and resting places, are protected under the Wildlife Acts. Otter are also listed on Annex II and Annex IV of the EU Habitats Directive.

Evidence of Otter *Lutra lutra* activity was abundant and widespread along the River Corrib corridor and the south-eastern shore of Lough Corrib. Otter were also recorded in the catchment of the Bearna Stream and the Tonabrocky Stream. The desktop review found that Otter have been recorded along the River Corrib corridor between the coast and Lough Corrib, along the coastline from Bearna to Oranmore, and at Ballindooley Lough[37].

One potential Otter holts and eight Otter couch sites were recorded within the study area. The potential holt site, and the majority of the couch sites, were recorded at Coolanillaun, along the southern shore of Lough Corrib and along the east bank of the River Corrib. Couch sites were also recorded at the Coolagh Lakes and on Jordan’s Island. The status, description and distance from the proposed road development of each of these features are provided below in **Table 8.19**. The results of the Otter surveys are shown on **Figures 8.3.1** to **8.3.14**.

Table 8.19: Results of the Otter surveys – Otter holts and couches

Ref. No.	Feature	Status and description
H1	Couch site	Active couch site along river bank >1km from the proposed road development
H2	Couch site	Active couch site along river bank >1km from the proposed road development
H3	Couch site	Active couch site along river bank c.450m from the proposed road development
H4	Potential natal holt	Dense scrub patch with abundant Otter signs surrounding and in the vicinity, well-worn and used trails leading into scrub – evidence suggestive of juvenile Otter being present. >1km from the proposed road development
H5	Couch site	Active couch site along river bank >1km from the proposed road development
H6	Couch site	Active couch site along river bank >1km from the proposed road development
H7	Couch site	Active couch site along river bank >1km from the proposed road development

[37] At Ballindooley Lough, the mammal survey study area focussed on the southern section of this wetland complex (refer to **Figure 8.3.8** and **Figure 8.3.9**) and Otter were not recorded in this area during the survey.

Ref. No.	Feature	Status and description
H8	Couch site	Active couch site along river bank >1km from the proposed road development
H9	Couch site	Active couch site along river bank c.600m from the proposed road development

8.3.7.2 Bats

Bats, and their breeding and resting places, are protected under the Wildlife Acts. All bat species are also listed on Annex IV of the EU Habitats Directive; with the Lesser horseshoe bat also listed on Annex II.

Significant bat surveys were carried out in the preparation of this EIAR, and the results of these are set below. The results of these surveys are also presented in **Figures 8.4.1** to **8.4.2** and **Figures 8.17.1** to **8.22.1**.

Separate reports on the results of the radio-tracking studies undertaken in 2014 and 2015 are provided in **Appendix A.8.7**, **Appendix A.8.9** and **Appendix A.8.10**. A separate report on the full results of the static detector monitoring undertaken in 2014 are detailed in **Appendix A.8.8**.

The structure of this section is such that each bat species is described in turn. The results of the various surveys are presented to allow an understanding of each species in terms of its distribution across the scheme study area.

8.3.7.2.1 Lesser horseshoe bat Rhinolophus hipposideros

The results of the bat surveys as they relate to the Lesser horseshoe bat are shown on **Figure 8.18.1**.

Historical records

Prior to the commencement of the surveys to inform the Constraints and Route Selection Studies for the proposed road development, there were a small number of records of Lesser horseshoe bats from the scheme study area. They comprised records of the bat roosts at Menlo Castle, suspected night roosts at a barn in Menlough Village and two sheds in Coolough collected as part of the previous studies for the 2006 Galway City Outer Bypass (RPS, 2006). Menlo Castle has been regarded to be a key maternity colony for the area since it was found in August 2000 and has since been monitored annually by the NPWS. Ad-hoc observations during other bat surveys (e.g. BATLAS 2010) also noted Lesser horseshoe bat activity on the western side of the River Corrib at Dangan.

Surveys carried out for previous environmental assessments recorded Lesser horseshoe bats at NUIG (McCarthy, Keville and O’Sullivan, 2014a) and Killarainy near Moycullen (RPS, 2013a).

The general lack of historical roost records and ad-hoc observations for this species did not necessarily suggest their low density or absence from specific areas. It is more likely to have been due to both the lack of targeted surveys for this species and the tendency for it to be overlooked due to its very quiet and narrowly-focused echolocation calls, which allows it to be detected only at very close range.

Identification of locations used for winter hibernation

Unlike other Irish bat species, the Lesser horseshoe bat hibernates in the open, hanging from the ceiling of caves, cellars and other structures kept cool in winter. Therefore, it is much easier to find than other bat species at this time of year.

Following the collation of the historical data at the end of 2014, the examination of historical maps and records of caves and underground structures provided a list of locations that could be potential sites used for hibernation. **Figure 8.18.1** shows these locations. These included:

- Menlo Castle
- Merlin Castle
- Ballybrit Castle
- Roscam Round Tower
- Cooper's Cave
- Newry's Cave
- Dangan Ice House
- Souterrain in the townland of Lydican

The interior of Ballybrit Castle and Merlin Castle were inaccessible for the winter surveys that were undertaken in 2014 and therefore use of these castles by this species could not be ruled out. Evidence of Lesser horseshoe bats was only found in the rear of Cooper's Cave near Castlegar, where a small number of fresh droppings characteristic of this species were recorded, suggesting recent use.

Daytime visual inspections of accessible locations were also undertaken in February and March 2015. Six Lesser horseshoe bats were recorded within Cooper's Cave on the February 2015 visit. All bats were in a state of hibernation. It was noted that two of the bats were ringed. The ring numbers (which could be read without disturbing the bats) corresponded to the following bats ringed as part of the bat surveys in summer 2014: one was a male bat ringed and radio-tracked at Menlo Castle on the 30 August 2014; the other, a male bat ringed and radio-tracked at Cooper's Cave on the 1 September 2014. This confirmed that some of the individuals using the Menlo Castle summer roost also used the cave as a hibernation site, and that bats using Cooper's Cave in summer months also used the cave as a hibernation site.

Cooper's Cave was also checked again on 24 February 2016 and four Lesser Horseshoe bats were recorded in a state of hibernation. None of these bats were ringed. Surveys in January 2018 recorded six hibernating Lesser horseshoe bats present on the 8 January and three on the 11 January (including one ringed bat).

No bats were seen or otherwise recorded within Newry's Cave in Merlin Woods in 2015 and 2016. It became evident during visits in 2015 that this site floods via underground springs up to ceiling level and therefore would be unsuitable for hibernating bats.

Since Lesser horseshoe bats are known to travel outside their summer ranges to reach hibernation sites, it was necessary to examine similar potential hibernation sites outside of the scheme study area. Checks for bats (and particularly ringed bats) using other known underground sites were carried out in February 2015. Five Lesser horseshoe bats (not ringed) were found hibernating in Cloonnabinnia Cave, outside Moycullen. A large pile of Lesser horseshoe bat droppings were also found in Moycullen Cave suggesting that it is used as a roosting site but this may be used at other times of year. In 2018, winter surveys at Moycullen Cave and at Cloonnabinnia Cave recorded three Lesser horseshoe bats which were found hibernating at each location.

Attempts were made to gain access to land where the cave curiously named "Rhinolophus Retreat" is located; however, entry to lands was not possible. A souterrain near Athenry was also visited but found to be probably unsuitable for use by Lesser horseshoe bats as the entrance was blocked.

The results of the surveys of potential hibernation sites for this species of bat indicated that Cooper's Cave and Menlo Castle provide winter hibernation conditions, for several individuals, in the vicinity of the proposed road development. However, both sites are vulnerable to human disturbance or changes within the roosts due to rockfall. There is also the possibility that other concealed voids in limestone features could also host hibernating bats.

Identification of locations used in summer

Evidence of Lesser horseshoe bats was recorded at 15 structures, including Menlo Castle (PBR06) during the summer roost surveys in 2014 and 2015. Most roosts were located in the vicinity of Menlough and Castlegar. Outside these two areas, a day roost (PBR178) containing 9 bats, including 5 juvenile bats, was located in the garage of a house in the Aughnacurra residential estate, on the western side of the River Corrib, adjacent to the NUIG Sporting Campus. In August 2018, two counts were undertaken at this roost: twelve Lesser horseshoe bats were recorded on the first night, and ten on the second. Two of the lesser horseshoe bats present at the Aughnacurra roost on the 28 August 2018 were ringed, confirming the link between the roost sites at Menlo Castle, Cooper's cave and this satellite roost[38].

A night roost was also found in another garage in this estate (PBR210) (refer to **Figure 8.18.1** for these locations).

Other Lesser horseshoe bat roosts found on the western side of the city and surrounding environs included two night roosts in vicinity of Bearna Woods

[38] To the best of the author's knowledge, at the time of writing, the only Lesser horseshoe bat ringing programme undertaken locally in recent years was that undertaken in 2014 and 2015 as part of the N6 GCRR surveys, where bats captured at Menlo Castle and Cooper's Cave were ringed (see Appendix A.8.1, Section 1.4.9). Therefore, the ringed Lesser horseshoe bats observed at Aughnacurra are individuals ringed during the 2014/2015 studies at Menlo Castle and Cooper's Cave

(PBR124, PBR115), north of Bearna (PBR217) and a roost in the townland of Aubwee just off the N59 Moycullen Road to the north west of the city (PBR44). All "night roosts" were confirmed as such, when Lesser horseshoe bat droppings were recorded but the structure was deemed to be unsuitable as a day roost and no bats were seen in-situ.

On the eastern side of the city and surrounding environs, one Lesser horseshoe bat night roost (PBR21) was located adjacent to the Corinthian's Rugby Club off the N83 Tuam Road to the north east of the city, while a day roost with a single bat was found in a disused bungalow adjacent to Ballindooley Lough (PBR25).

Lesser horseshoe bats at Menlo Castle (PBR06) were monitored from 2006-2017 by the NPWS and more recently by surveyors from Scott Cawley Ltd. (see **Table 8.20** below for count results). Lesser horseshoe bats can be very difficult to count on emergence as they tend to fly in and out of the roost entrance. Monitoring of the roost in 2016, 2017 and 2018 used infra-red cameras and reflects the most accurate count for this roost.

Table 8.20: Numbers of Lesser Horseshoe bats recorded emerging from Menlo Castle

Date	Count	Source	Comments
16/06/2006	2	NPWS	-
24/06/2009	26	NPWS	-
07/07/2009	38	NPWS	-

02/07/2012	27	NPWS	-
13/06/2013	21	NPWS	-
04/06/2014	18	NPWS	-
18/06/2014	35	NPWS	-
29/06/2015	32	NPWS	-
29/06/2015	32	Scott Cawley Ltd	-
09/07/2015	29	NPWS	-
09/07/2015	29	Scott Cawley Ltd	Inclement weather
20/08/2015	28	NPWS	-
20/08/2015	28	Scott Cawley Ltd	Two bats did not emerge
29/08/2016	35	Scott Cawley Ltd	Counted from infra-red video camera footage. 2-3 bats may have remained in the roost.
11/08/2017	43	Scott Cawley Ltd	Counted from infra-red video camera footage. 1 bat exited from small chimney.
22/08/2018	20	Scott Cawley Ltd.	Counted from infra-red video camera footage.
27/08/2018	15	Scott Cawley Ltd.	Counted from infra-red video camera footage.

The roost numbers showed considerable variability in the counts but averaged 27 bats over the last ten years. This may be explained by bats using different (unknown) exit points on some nights, difficulties in counting in low light conditions, and weather conditions in preceding nights which may have forced some bats to use alternative roosts. Infra-red footage suggested that bats fly out at very low levels at high speeds and could have been easily overlooked by conventional emergence monitoring techniques.

Additional data on the roosts used by this species was collected during the radio-tracking in 2014 and 2015. Thirteen Lesser horseshoe bats were captured and fitted with radio-transmitters in the first radio-tracking session in August 2014. Ten of these (seven females and three males) were caught at the Menlo Castle roost (PBR06) and three (all males) were caught at Cooper’s Cave (PBR112). Five bats were captured and fitted with radio-transmitters in the September session; one (female) was caught in Menlough Woods and four (three males and one female) were captured at Cooper’s Cave (PBR112). The radio-tracking in August 2014 resulted in the identification of six day roosts and 11 night roosts for this species. Three of the six daytime roosts and seven of the 11 night roosts had already been identified as Lesser horseshoe roosts from the building inspections undertaken in 2014. Nine additional daytime roosts and eight additional night roosts were subsequently identified in the September 2014 session of radio-tracking. Only three roosts (Menlo Castle PBR06, Cooper’s cave PBR112 and a shed in Angliham Quarry PBR126) were used by bats during both tracking sessions. All roosts used by radio-tracked bats were located in the vicinity of Menlough Village, Coolough, Castlegar and Angliham Quarry.

To conclude, the surveys found Lesser horseshoe bats using several roosts in the daytime in summer including those consistently used such as Menlo Castle and Cooper’s Cave. Inspections of other structures and radio-tracking recorded other day roosts and a network of night roosts (**Figure 8.18.1**).

Eborhall House and Ballymaglancy Cave, located to the north of Lough Corrib, are both important roost sites for breeding and hibernating Lesser horseshoe bats respectively. Eborhall House is the “qualifying” roost for the Lough Corrib cSAC whilst the nearby Ballymaglancy Cave is a cSAC in its own right (No. 000474) and is thought to provide hibernation roosts for the bats from Eborhall House.

As part of the assessment of the potential movement of this bat species across the landscape, it was deemed important to determine if any of the ringed bats[39] that were roosting near the proposed road development were also using these “qualifying” roosts, even though they are located a considerable distance to the north (more than 30km).

Surveys were undertaken at Eborhall House and Ballymaglancy Cave to determine the presence of Lesser horseshoe bats that were ringed at roosts within the study area. These were undertaken under licence DER/BAT 2015-03, DER/BAT 2016-09, DER/BAT 2016-28 and DER/BAT 2017-06) on 21 October 2015, 23 August 2016 and 14 July 2017. Surveys in 2015 were undertaken by Paul Scott (Scott Cawley Ltd) with Mr John Higgins (NPWS Local Conservation Ranger) and in

[39] See the species accounts in this section for details on bats that were ringed.

2016 by Dr Daniel Buckley and in 2017 by Paul Scott. Daytime visual surveys were undertaken to count and identify any marked bats. Only the October 2015 surveys included Ballymaglancy Cave. No ringed bats from the study area were recorded during these visits.

Evidence of bat activity

This section summarises the results of the various surveys that recorded Lesser horseshoe bat activity across the scheme study area (**Figure 8.18.1**). Survey methods included vehicle transects, walked transects and use of static detectors at fixed locations in 2014 and 2015 covering both summer, autumn and winter seasons. The results of the radio-tracking are also summarised separately in this section.

Lesser horseshoe bats were not recorded during the vehicle transect surveys but would not normally be expected to be easily detected using that survey methodology, due to their quiet and directional echolocation calls. However, the walked transect surveys recorded this species at Menlo Castle and Cooper's Cave. Static bat detectors deployed during the walked transects recorded them by a culvert on the existing N6 (where the Terryland River flows under the road), by the Coolagh Lakes and by Ballindooley Lough.

The static bat detectors deployed in 2014 (**Figure 8.4.1**, **Figure 8.4.2** and **Figure 8.22.1**), recorded Lesser horseshoe bats at 14 locations. Sites S5, S6 and S21 recorded the highest amount of activity for this species, which was not surprising as these locations are all in close proximity to Menlo Castle (see summary of radio-tracking studies below). Beyond the Menlough area, Lesser horseshoe bats were also recorded at a woodland edge in the Ballindooley area (S2), close to a known roost identified during the building surveys, in the hazel scrub-limestone pavement complex east of Menlough (S4 and S22), within the grounds of Glenlo Abbey Hotel (S8), in Castlegar Valley (S10), on three sites on the north western edge of Galway City (S11, S13 and S15), the outskirts of Bearna Village (S19), and two sites on the north eastern edge of Galway City just to the north of Galway Technology Park (S1, S24).

The static detectors deployed in 2015 along the route of the proposed road development (at that time) recorded Lesser horseshoe bats at 15 locations. Activity was recorded within the known foraging area of the Menlough roost as suggested by the radio-tracking results (see below), including along the woodland edges, south of Menlo Castle, within the limestone pavement area between Menlough and the N84 Headford Road, Lackagh Quarry and on field boundaries north of Castlegar Village, into the area south of Castlegar Village where Cooper's Cave is located.

Lesser horseshoe bat activity was also recorded within the grounds of NUIG, east of Galway Racecourse and on the Bearna Stream, north of Bearna Woods.

For the crossing point surveys, possible recordings of Lesser horseshoe bats that were made on both microphones, that could suggest bats flying across the proposed road development, were recorded at two sites for Lesser horseshoe bat: CP7 and CP9. CP7 had one potential crossing record, while CP10 had 35 potential crossing records.

Monitoring of bat activity at Cooper's Cave, Newry's Cave and the City Centre Railway Tunnel took place in the autumn of 2014 and late winter in 2015. A small number of Lesser horseshoe bat calls were recorded on the 26 and 28 September 2014 in Newry's Cave. A large number of Lesser horseshoe bat calls were recorded throughout September 2014 and October 2014 in Cooper's Cave, which would suggest that Cooper's Cave is used in the mating season by this species. Lesser horseshoe bat activity was recorded at Cooper's Cave and Menlo Castle but not at any of the other locations during the late winter activity seasons in 2015. Therefore, based on these activity surveys it was concluded that Lesser horseshoe bats use Menlo Castle and Cooper's Cave throughout the year – Menlo Castle for breeding and hibernation and Cooper's Cave for mating and hibernation.

The radio-tracking surveys allowed the patterns of foraging and flight paths to be identified for this species. In August 2014, the maximum foraging distance from Menlo Castle ranged from 0.59km up to 5.15km, with the average maximum distance of foraging area from the roost being 2.93km. On average, males foraged slightly further afield, with the average maximum distance from the roost 3.68km, while females averaged a maximum distance of 2.29km.

In September 2014, the maximum foraging distance from the roost ranged from 1.11km up to 4.4km with the average maximum distance of foraging from the roost being 3.39km. On average, males foraged a maximum distance from the roost of 2.88km, while females averaged a maximum distance of 4.16km.

The overall foraging area in August 2014 comprised 21.75km^2 (MCP[40]) or 13.7km^2 (MLP[41]), whilst it was 56.10km^2 (MCP) or 26.46km^2 (MLP) in September 2014. Foraging areas recorded in both August and September 2014, overlapped in woodland and field boundaries in the Menlo Castle and Menlough Village areas; suggesting that these areas were core foraging areas. See Figures 57 and 58 in **Appendix A.8.7**. The area of overlapping areas from August and September 2014 was 11.96km^2 (MCP) or 8.1km^2 (MLP). Field systems and quarries north-east and east of Menlo Castle and field systems north of Cooper's Cave also served as foraging areas. The majority of Lesser horseshoe bat foraging areas in August and September 2014 overlapped in the area of the River Corrib, field boundaries and woodland around Menlo Castle and Menlough Village, limestone pavement, woodland, scrub and lake around Coolough and Menlough Village, field boundaries and scrub around Castlegar and Ballindooley Lough, and an abandoned quarry in Angliham.

None of the foraging areas recorded in 2014 extended south of the existing N6, towards Galway City.

In May 2015, four bats were captured and tagged. Two of the bats had been captured, tagged and ringed in 2014. Rings were placed on the new bats.

Three day roosts were identified during the radio-tracking session in 2015. Three out of the four bats consistently used the maternity roost in Menlo Castle (PBR06). One bat utilised a previously-unknown roost in a boulder field located in an abandoned quarry just south of Coolagh Lakes (PBR218) over several days before

[40] MCP = Minimum convex polygon
[41] MLP = Multilateral polygon

returning back to Menlo Castle (PBR06). Another bat used a void within a natural limestone structure located within Menlough Woods to roost (PBR219). All of these daytime roosts were also used for short periods of resting at night.

The overall foraging area of Lesser horseshoe bats tracked in 2015 covered 16km^2 (MCP) or 10.22km^2 (MLP). The core foraging area of all bats extended over 1.25km^2. The majority of foraging areas overlapped in the area of Menlo Castle, Menlough Woods and Menlough Village in a similar pattern recorded in 2014. This was considered to be the core foraging area from where bats travelled both, north towards Lough Corrib and south following the River Corrib, in some cases all the way to the coast of Galway.

The overall foraging area in 2015 was smaller than recorded in the late summer/early autumn tracking periods in 2014. It is likely that the low night-time temperatures in 2015 resulted in shorter foraging periods and shorter travel distances.

Based on the results of the radio-tracking studies carried out in 2014 and 2015, it was concluded that Lesser horseshoe bats utilised existing woodlands, field boundaries and watercourses for foraging and navigating during this period. Areas of scrub over limestone pavement were often used as foraging areas for prolonged periods of time. Quarries in the Galway area appeared to be of importance to Lesser horseshoe bats with records of bats spending time both feeding and night roosting there. Areas used both during the late maternity period in summer as well as for foraging in preparation for hibernation in late summer are regarded to be crucial in supporting the local Lesser horseshoe bat population.

The radio-tracking studies confirmed a strong link between the maternity roost present at Menlo Castle (PBR06) and Cooper's Cave (PBR112). Although there was a direct connection between both sites via the River Corrib and Terryland River, the radio-tracked bats tended not to utilise this potential commuting route and instead travelled overland via Lackagh Quarry to the Terryland River Valley, via a small area of green space around Castlegar Village. Bats were regularly recorded commuting between the roosts and have been confirmed to be a part of the same Lesser horseshoe bat population.

Radio-tracking data also suggested that Cooper's Cave (PBR112) is an important roosting site for male Lesser horseshoe bats in summer and an important autumn mating site in the area, as well as a hibernation site, for this species.

In order to record and assess bat activity within the lands proposed for habitat enhancement, four SM2BAT+ ultrasound detectors were placed along hedgerows from 28 July - 11 August 2017. Detectors were also placed in hedgerows on the bóithrín at Menlo which is crossed by the proposed road development. Lesser horseshoe bats were recorded at both locations with 132 recordings made in the proposed habitat enhancement lands and 81 recording made along the bóithrín. An SM2BAT+ detector was also deployed from 2 – 15 May 2018 at one of the same locations within the lands proposed for habitat enhancement and two detectors were also deployed in the field to the south toward the River Corrib in order to measure usage of different areas over the same time period. On this second occasion, Lesser horseshoe bats were recorded at all three locations with 102 recordings made by the two detectors in the fields to the south and only 12 recordings in the proposed habitat enhancement lands.

These results demonstrated that the proposed habitat enhancement area was accessible for Lesser horseshoe bats and is a suitable area for increasing the amount of foraging habitat within it.

Analysis of the relative importance of Menlo Castle

Counts of Lesser horseshoe bats made at Menlo Castle were compared to other roost counts in County Galway and beyond to determine the level of importance of Menlo Castle. Based on counts from 2006 - 2016, the maternity roost at Menlo Castle makes up approximately 0.6% (min 0.1% - max 0.6%) of the summer population of Lesser horseshoe bats for the national population of this species and 6% (min 2% - max 6%) of the County Galway summer population. Therefore, while the roost at Menlough does not meet the threshold of representing 1% of the national population to make it of National Importance (National Roads Authority, 2009), it does exceed this threshold at the county level and therefore is regarded to be of County Importance.

Based on the distribution of maternity roosts in the range of this species in Ireland, the Menlo Castle maternity roost and the local population it supports meets the criteria of being of National Importance, whereby "a smaller population may qualify as nationally important where the population forms a critical part of a wider population or the species is at a critical phase of its life cycle." (National Roads Authority, 2009).

There are only six known maternity roosts in and around Lough Corrib, with the majority of roosts concentrated on the northern shores near Cong. Only two roosts are located on the southern end: Ross Lake Gatehouse and Menlo Castle. These southern roosts may be an important stepping-stone for long-term movements and gene flow between bat populations in North Galway and Mayo and populations in South Galway and Clare. Recent counts from Ross Lake Gate House have shown that this roost has undergone significant deterioration resulting in decline in numbers from 150 bats in 1994 to five bats in 2011 (Rebecca Teesdale pers. comm., 2014 and p44 in Roche et al, (2015)). A decline in the Ross Lake roost could potentially increase the relative importance of the roost at Menlo Castle as a stepping stone roost as it would be the only significant maternity colony at the southern end of Lough Corrib. There is no evidence to suggest that Menlo Castle Lesser horseshoe bat population is connected to the Eborhall Lesser horseshoe bat population, which is the qualifying interest (QI) population for Lough Corrib cSAC. Any predicted impacts on Lesser horseshoe bats associated with the proposed road development will not affect the conservation objectives of the Lough Corrib cSACs QI Lesser horseshoe bat population, nor the QI Lesser horseshoe bat populations of any other European sites.

The numbers of bats using Cooper's Cave (PBR112) is hard to quantify due to the lack of access to roosting areas underground and the seasonal and gender specific variability in its use. It clearly is used by males and females some of which roost there in summer and also use it for mating. The cave system also supported a small population of hibernating Lesser horseshoe bats (usually averaging 4 bats) although the cave system could not be accessed in its entirety, so more bats could have been present further underground. The surveys have indicated that Menlo Castle and Cooper's Cave provide hibernation conditions for the local population although since both locations cannot be fully accessed to count individuals, the population size cannot be fully determined. Given the lack of other maternity roosts in the locality which could otherwise be a source of additional bats to occupy hibernacula, it is very unlikely that the winter roost population differs from the summer roost population in the Menlo Castle-Cooper's Cave complex.

8.3.7.2.2 Leisler's bat Nyctalus leisleri

The results of the bat surveys as they relate to Leisler's bat are shown on **Figure 8.19.1**.

Historical records

Leisler's bats have been recorded across the scheme study area as bat detector records and have also been recorded using bat boxes in Rusheen Bay, which are the only previous roost records for this species. Detector records include NUIG (A.P. McCarthy Planning Consultants (2007a), McCarthy, Keville & O'Sullivan (2014a) McCarthy, Keville & O'Sullivan (2014b)), Moycullen and Ballycuirke Lough (Galway County Council/Roscommon National Roads Design Office (2011). Since this bat can travel long distances from its roost each night, detector records do not necessarily suggest that bats are roosting nearby.

Identification of Roosts

No winter roost sites were recorded in any of the surveys for the proposed road development. Radio-tracking of three bats captured in 2014 and 2015 provided locations of four day roosts (PTR45, PB134, PBR139, PBR146).

In 2014, a single male Leisler's bat was captured and tagged in Menlough Woods. Radio-tracking indicated that the maximum distance that this individual was recorded travelling was 4.85km over a foraging area of 8.96km^2 that encompassed the southern area of Lough Corrib, the River Corrib and the Menlough area. Two roosts used by this individual were also located; a large modern house along the N84 Headford Road near Ballinfoyle and an Ash tree at the edge of Menlough Woods (PTR45).

Another two male Leisler's bats were captured, ringed and tagged in Bearna Woods in the second session in 2014. However, data was only collected for one of these bats as the second could not be located. The bat that could be tracked was found to roost during the day at two modern dwelling houses on the Cappagh Road (PBR139, PBR146). This bat had a recorded foraging area of 13.62km^2 (MCP) that encompassed the southern area of Lough Corrib, along the River Corrib corridor and the Menlough area.

Evidence of bat activity

Leisler's bats were recorded widely across the scheme study area during the walked and vehicle transect surveys. However, few calls were recorded within the city limits. The species was recorded at every static detector location.

The static detectors deployed in 2015 recorded Leisler's bats at 32 locations (out of a total of 42) along the route of the proposed road development. The highest levels of activity were recorded over the River Corrib (RS7) and Lackagh Quarry (RS13).

During the crossing point surveys, indications of potential crossings were recorded at 6 sites for Leisler's bat; CP5, CP6, CP8, CP10, CP14, CP15. It is reasonable to assume that the approach taken for detecting bat crossings of the proposed road development by this species is not as effective as it might be for other species. The Leisler's bat loud echolocation calls would be received by both microphones simultaneously and crossings would not be possible to prove. However, since this is a fast and high-flying bat it is regarded to be less impeded by severance of features at ground level (an "open airspace species" according to Elmeros et al, 2016).

8.3.7.2.3 Common pipistrelle bat Pipistrellus pipistrellus

The results of the bat surveys as they relate to the Common pipistrelle bat are shown on **Figure 8.21.1**.

Historical records

Common pipistrelle bats have been recorded across the scheme study area including the grounds of NUIG (A.P. McCarthy Planning Consultants (2007a), McCarthy, Keville & O'Sullivan (2014a) McCarthy, Keville & O'Sullivan (2014b)). None of these would appear to be records of roost sites and are generally records from bat detector surveys.

Identification of locations used in summer

Building inspections carried out in 2014 and 2015 identified four roosts used by Common pipistrelle bats. One was located in an outbuilding in the Ballindooley area (PBR07), a small roost of 3-4 bats was found in a large shed adjacent to the N83 Tuam Road in Cappanabornia (PBR228) and single bats were observed at the stable block in Galway Racecourse in Ballybrit (PBR205) and an abandoned bungalow to the north of Bearna Village (PBR220).

Six Common pipistrelle bats were captured during the radio-tracking session in 2014; two at NUIG, two at the NUIG Sporting Campus, and two at Menlough Woods. The male and female bats captured in NUIG were tagged, ringed and tracked to their day roosts. The female was found to roost in two modern buildings in a housing estate at Ballymoneen (PBR141, PBR147) on the north western edge of the city, while the male was found to roost in two modern agricultural barns in Cloonacauneen (PBR148, PBR149), to the north of the Roadstone Quarry.

No winter roosts for this species have been recorded.

Evidence of bat activity

Common pipistrelle bats were recorded widely across the scheme study area during the walked and vehicle transect surveys. However, very few calls were recorded within the city limits, apart from areas adjacent to the River Corrib. The species was recorded at every static detector location in 2014.

The static detectors deployed along the proposed road development recorded Common pipistrelle bats at 34 locations. The highest level of activity was recorded in Lackagh Quarry (RS13), a hedgerow in a field adjacent the N83 Tuam Road (RS26), a hedgerow adjacent to the existing N6 roundabout (RS29) and along a hedgerow bordering the Barr Aile Road, north of Bearna Village (RS40).

During the crossing point surveys, possible crossing records were recorded at 16 sites for Common pipistrelle bats. Seven sites recorded more than 10 possible crossings for this species; CP6, CP9, CP10, CP11, CP14, CP15, CP16. Relatively high number of possible crossings were recorded at CP9 (88 possible crossings) and CP10 (630 possible crossing records).

8.3.7.2.4 Soprano pipistrelle bat *Pipistrellus pygmaeus*

The results of the bat surveys as they relate to the Soprano pipistrelle bat are shown on **Figure 8.21.1**.

Historical records

This species has been previously recorded across the scheme study area and included records at Dangan, (A.P. McCarthy Planning Consultants, 2007a), Merlin Park (Browne and Fuller, 2009), Bearna Woods (Browne et al, 2009), Ballyquirke (Galway County Council/Roscommon National Roads Design Office, 2011) and NUIG (McCarthy, Keville and O'Sullivan, 2009a, 2014a, 2014b). A historical record was also provided by the NPWS of a roost from Menlough Village in 2014 (R. Teasdale, pers. comm, 2015) a single bat was known to roost in Menlo Castle in 2000 (RPS, 2006)

Identification of locations used in summer

Building inspections carried out in 2014, 2015 and 2016 identified 13 roosts of this species. These were located in Aubwee, Ballybrit, Ballindooley, Letteragh, Gortacleva, Roscam, Bearna Woods, Bearr Aile, Truskey West, Aughnacurra and Coolagh. Seven of these roost sites were at locations with unoccupied farm buildings and houses (PBR196, PBR205, PBR237, PBR241, PBR42, PBR44, PBR49), and roosts were found in occupied buildings in Bearna Woods (PBR222), Aughnacurra residential estate (PBR177, PBR255) and Coolagh (PBR179).

A single Soprano pipistrelle bat was observed emerging from an oak tree (PTR40) in a field located to the south of Menlo Castle in the summer of 2015.

Evidence for bat activity

Soprano pipistrelle bats were recorded widely across the scheme study area during the walked and vehicle transect surveys. However, very few calls were recorded within the more developed areas within Galway City apart from areas adjacent to the River Corrib. This species was recorded at all 24 static detector locations deployed in 2014.

The static detectors deployed in 2015 recorded soprano pipistrelle bats at 37 (out of a total of 42) locations along the route of the proposed road development. The highest levels of activity were recorded near the River Corrib (RS1 and RS2), in proximity to a confirmed roost in Aughnacurra Housing Estate (RS8) and a hedgerow adjacent to the existing Coolagh Roundabout (RS29).

During the crossing point surveys, bat activity suggesting possible crossings was recorded at all 21 survey locations for soprano pipistrelle bats. Thirteen sites along the route of the proposed road development recorded more than 10 possible crossing records for this species.

8.3.7.2.5 Nathusius' pipistrelle bat *Pipistrellus nathusii*

The results of the bat surveys as they relate to Nathusius' pipistrelle bat are shown on **Figure 8.20.1**.

Historical records

This is the only bat species that has not been previously recorded in the scheme study area. Only one record exists at a county level for an ad-hoc observation made in Oughterard in 2007, according to the Bat Conservation Ireland database.

No roosts were found for this species.

Evidence for bat activity

Nathusius' pipistrelle bats were recorded during the walked and vehicle transect surveys in 2014 but on a much rarer basis than the other two *Pipistrellus* species. They were recorded in an area of farmland east of Galway Technology Park, Bearna Woods, Coolagh Lakes and Letteragh.

The species was recorded at 20 (out of a total of 24) static detector locations in 2014, although they again were much less frequent than the other *Pipistrellus* species but suggested that the species was more widespread than was shown by the walked and vehicle transects. Sites with highest numbers of calls included S20, S16, S21 and S06, which were located around the River Corrib.

The static detectors deployed in 2015 along the route of the proposed road development recorded Nathusius' pipistrelle bats at one (out of a total of 42) location, in Lackagh Quarry (RS13), where two calls were recorded.

During the crossing point surveys, evidence for Nathusius' pipistrelle bats crossing the route of the proposed road development were recorded at CP14 and CP20 (2 out of a total of 21). Only single "passes" were recorded.

8.3.7.2.6 Unidentified Pipistrelle Species *Pipistrellus* sp.

The results of the bat surveys as they relate to Pipistrelle bats, not identified to species level, are shown on **Figure 8.21.1**.

Common pipistrelle bats have their peak echolocation call strength at 45kHz and Soprano pipistrelle bats at 55kHz. Pipistrelle bat species that echolocate between 48 and 52kHz cannot be accurately identified by their calls and are described as "unidentified" Pipistrelle bat species.

Identification of locations used in summer

No winter roosts for this species were recorded.

Two unidentified Pipistrelle bat roosts were recorded during building inspections in 2014 and 2015. A roost of unknown number was found in a farm house to the west of Bearna Village (PBR224) during an internal survey whilst an old unidentified Pipistrelle bat dropping was found in a bungalow within the grounds of Galway Racecourse in Ballybrit (PBR242).

An unidentified Pipistrelle bat was observed with an endoscope in a crevice in an ash tree (PTR54) in hazel scrub on limestone pavement located to the north of Coolagh Lakes in 2015.

Evidence for bat activity

Bat calls that could not be assigned to either Common or Soprano pipistrelle bats were recorded widely across the study area during the walked and vehicle transects undertaken in 2014. The static detectors deployed in 2015 recorded unidentified Pipistrelle bats at 32 locations along the route of the proposed road development. The highest activity was recorded near the River Corrib (RS1), Lackagh Quarry (RS13) and along a hedgerow near Castlegar Village (RS19).

The static detectors deployed in 2015 recorded unidentified Pipistrelle bats at 32 (out of a total of 42) locations along the route of the proposed road development. During the crossing point surveys, bat activity suggesting possible crossings were recorded at 14 (out of a total of 21) sites for unidentified Pipistrelle bat species. Two sites recorded more than 10 possible crossing records for this species group: CP9 and CP10.

8.3.7.2.7 Brown long-eared bat *Plecotus auritus*

The results of the bat surveys as they relate to the Brown long-eared bat are shown on **Figure 8.20.1**.

Historical records

Baseline data, presented in documentation supporting planning applications in the scheme study area, have recorded a Brown long-eared bat roost of more than 20 bats in Menlo Castle (RPS, 2006) although this was not recorded during the current series of surveys. This commonly-occurring and widespread species is known to occur in Merlin Woods (Browne and Fuller, 2009), NUIG Campus (McCarthy, Keville and O’Sullivan. (2014a)), Clydagh Bridge and Ballyquirke (north of the scheme study area) (Galway County Council/Roscommon National Roads Design Office. (2011). Bat Conservation Ireland records for this species show a small number of records in the scheme study area.

Identification of locations used in summer

27 roosts of this species were recorded during the building inspections in 2014-2017. Seven of the roosts could support maternity colonies; a period house on the Letteragh Road (PBR49), Merlin Castle (PBR51), an abandoned bungalow on the R338 to Oranmore (PBR89), a barn on the R399 east of Ballybrit (PBR100), the

attic of two houses in Aughnacurra Housing Estate (PBR178, PBR256) and a modern house in the Heath Housing Estate (PBR173).

Twelve additional roosts were also classified as night roosts, while the remaining eight were not classified. The night roosts were found in the following locations; an abandoned house adjacent to the Corinthians RFC (PBR21), an abandoned house in Rockmount (PBR15), an abandoned three outbuildings near Ballindooley Lough (PBR17, PBR25, PBR111), an outbuilding and archway in Menlough (PBR82, PBR156), an unfinished modern house in Gortacleva (PBR138), a shed in Barr Aile (PBR217), and a shed in Garraun (PBR194), cottage in Ballintemple (PBR105).

During the radio-tracking in August 2014, four brown long-eared bats were captured; two bats at Bearna Woods, one bat at Menlough Woods, and one bat at Cooper’s Cave. The female brown long-eared captured at Cooper’s Cave was fitted with a radio transmitter and tracked to its daytime roost; a bungalow in Castlegar (PBR145). An emergence count carried out on this building observed six bats leaving the roost. As this bat was an adult female it is likely that this building was being used as a maternity roost. This bat was also tracked during the September radio-tracking session and was found to repeatedly roost in the same bungalow. On one night the bat was recorded night roosting in a stone arch between Menlough Village and Menlo Castle (PBR156) during heavy rain. The maximum commuting distance recorded for this individual in a single night was approximately 4.07km. The foraging area of 2.18km^2 (MCP) mainly encompassed the valley where Cooper’s Cave was located but also around Ballindooley Lough.

Evidence for bat activity

Brown long-eared bats were only recorded at two locations during the walked and vehicle transects but these results are typical for this bat species which echolocates very quietly and is therefore difficult to pick up on a heterodyne bat detector on a moving transect. However, they were recorded at 18 (out of a total of 24) static detector locations in 2014, indicating that the species is quite widespread in the scheme study area, consistent with the findings of the summer roost surveys.

The static detectors deployed in 2015 recorded brown long-eared bats at only two (out of a total of 42) sites along the route of the proposed road development, adjacent to the River Corrib (RS1 and RS7).

8.3.7.2.8 *Myotis* bat species

The results of the bat surveys, as they relate to bats identified to the *Myotis* genus level, are shown on **Figure 8.20.1**.

The *Myotis* genus includes three bat species resident in Ireland: Daubenton’s bat *Myotis daubentonii*, Natterer’s bat *M. nattereri* and the Whiskered bat *M. mystacinus.* There can be difficulty in differentiating between the bats using their echolocations calls as there can be similarity between them. Therefore, they have been grouped together for the purposes for reporting these results.

Historical records

Previous bat studies have reported in excess of 20 Daubenton's bats recorded roosting in southern façade of Menlo Castle in 2000. There was no roost recorded in 2005 and 2006, but bats were recorded foraging. Less than 30 Natterer's bats were recorded roosting in outbuildings of Menlo Castle in 2000 but no roost was recorded in 2005 and 2006 ((RPS, 2006). Myotis bats were recorded on the NUIG Campus (McCarthy, Keville & O'Sullivan (2014). There was also an historical record of a roost of Natterer's bats at St James's Church, Bushypark. Natterer's bats were also recorded as part of the surveys carried out for the proposed R336 to N59 Road Scheme (RPS, 2013a). Daubenton's bats have been recorded on the River Corrib from the NUIG campus (McCarthy, Keville and O'Sullivan. (2014a, 2014b)) and also in most watercourses within the city and around its environs. This species is regularly sighted around the Galway Cathedral during bat walks by Galway Bat Group (C. Carlin, pers comm 2015).

Whiskered bats are rarely recorded across the area and only *ad-hoc* records from Bat Conservation Ireland exist.

Identification of locations used in summer

Four Natterer's bat roosts were recorded during the inspections of buildings in 2015 (PBR17, PBR20, PBR64, PBR82). These roosts were confirmed based on the presence of droppings, which were analysed using DNA sequencing to confirm the species identity.

An emergence survey of Menlo Castle (PBR06), carried out on the 8 July 2014, found Daubenton's bats to be still roosting in the castle. Numbers of bats were estimated to be less than 20 bats.

During the radio-tracking in August 2014, nine Daubenton's bats (one female and eight males) were captured in Menlough Woods and a single male Daubenton's bat was captured at Cooper's Cave. One of the male Daubenton's bats captured in Menlough Woods was tagged and tracked. It was found to roost in a stonewall structure on the eastern bank of the River Corrib (PBR133). An emergence count undertaken shortly after recorded 25 Daubenton's bats to be roosting in the wall, suggesting that this was likely to be a maternity roost for this species.

During the second radio-tracking session in August, ten Daubenton's bats were captured (one from Merlin Wood, three from NUIG, and six from Menlough Woods) and four were tagged (one female from Merlin Wood, two females and one male from NUIG). Roosting information was recorded for three of the Daubenton's bats tracked during the second August session. They were found to roost in three buildings (PBR142, PBR143, PBR144) and two bridges (PBR150, PBR152) in Galway City Centre. Foraging data was recorded in the September tracking session for two Daubenton's bats that were captured during the second August session. One bat travelled a maximum distance of 1.06km and had a foraging area of 0.26km^2 (MCP) encompassing Merlin Woods and the Coolagh lakes. The other had a maximum distance of 2.48km and had a foraging area of 0.55km^2 (MCP) encompassing the River Corrib from Menlo Castle into Galway City Centre.

Two male whiskered bats were captured and tagged during the second radio-tracking session in August 2014 (one from NUIG and one from Merlin Woods). However, the bat caught in Merlin Woods could not be relocated after tagging. The other Whiskered bat was found to roost in two modern dwelling houses (PBR140, PBR151) in a residential estate by the Sports Centre, near Bearna Woods. Foraging data for this individual was gathered during the September radio-tracking session. The maximum distance this bat travelled was 3.71km and had a foraging area of 2.02km^2, encompassing areas of scrub and rough grassland in the Bearna area.

A Natterer's bat was captured in Menlough Woods in August 2014 but was not prioritised for tracking at that time and hence not fitted with a radio-tag. Another male Natterer's bat was captured, ringed and tagged in Menlough Woods during the September radio-tracking session; however, no data was recorded from this bat, possibly due to the bat leaving the area, or transmitter failure.

Evidence of bat activity

During the walked and vehicle transect surveys and the static detector surveys in 2014 and 2015, the majority of *Myotis* calls were not identified by species due to the overlap in call characteristics between species when analysed. However, on a number of occasions, *Myotis* species were confirmed by visual observations coinciding with echolocation calls. Natterer's bats were recorded at Bearna Woods and Daubenton's bats were seen foraging on the River Corrib and the Terryland River. The majority of *Myotis* bat calls were recorded along the River Corrib and Terryland River during the walked and vehicle transects but were infrequently recorded across the rest of the scheme study area.

Myotis calls were recorded across all 24 static detector locations in 2014, although at a lower frequency than pipistrelle species. Location S07 recorded the highest amount of *Myotis* activity. This site was close to the River Corrib and the known Daubenton's maternity roost.

The static detectors deployed in 2015 along the route of the proposed road development recorded *Myotis* bats at 25 (out of a total of 42) locations. Activity levels for this species at static locations along the route of the proposed road development was low for this species group but the highest activity was recorded along the River Corrib (RS1), Lackagh Quarry (RS13), an area of woodland adjacent to the N84 Headford Road near Ballindooley and along a stream surrounded by fields and scrub in Ballard East.

During the crossing point surveys, possible crossing records were recorded at 7 (out of a total of 21) sites for *Myotis* bat species, with 1-3 possible crossings recorded at each of these sites.

8.3.7.2.9 Survey Limitations

A total of 230 structures and 62 trees were assessed as part of the collection of baseline data on the bat populations within the area of the proposed road development. This unprecedented level of surveying allowed a detailed picture of the species assemblage present in the study area and informed the constraints and route selection studies, the design of the proposed road development and the preparation of this EIAR.

All structures within the proposed development boundary which may be affected, either directly or indirectly, were surveyed to record potential usage by bats. In most cases it was possible to carry out internal and external checks for signs of bats in daytime as well as dusk and/or dawn surveys. Inevitably in a few cases, access to inside the structure was not possible. In such cases, surveys at night were undertaken to record any bats emerging from or returning to the structure.

Some surveys (e.g. radio-tracking surveys in 2015) may have been affected by cool night time temperatures and may have forced bats to reduce foraging time. Overall, the repeated surveys carried out since 2014 have allowed bats to be surveyed over multiple seasons which reduce the bias caused by suboptimal weather conditions.

8.3.7.3 Badger

Badger, and their breeding and resting places, are protected under the Wildlife Acts.

Evidence of Badger *Meles meles* activity was found across the study area from Na Foraí Maola to the N83 Tuam Road. The highest concentrations of badger activity were recorded in the Menlough area and the area between Lackagh Quarry and the N84 Headford Road. The survey results show a much greater distribution of Badgers across the study area than suggested by the findings of the desktop review. There was a single 2km grid squares (M32I) where the National Biodiversity Data Centre (NBDC) database had a record for Badger but the species was not recorded in that overlapping portion of the mammal survey study area and M32I. However, the survey did record Badger 50m to the north.

A total of 17 badger setts were identified both within and in the vicinity of the study area. The majority of setts were recorded as part of the 2015 multidisciplinary survey but some records for setts further from the proposed road development were recorded in 2014, during the course of other survey work. Sixteen were active at the time of the survey with the remaining sett (S1) showing no signs of recent use. The status, description and distance from the proposed development boundary of each of the setts is provided below in **Table 8.21**. The results of the mammal survey are shown in **Figures 8.3.1** to **8.3.14**.

Table 8.21: Results of the Badger survey – Badger setts

Ref. No.	Type of sett[42]	Status and description
S1	Disused sett	Inactive sett located beneath blackthorn tree. Single entrance. c.160m south-east of the proposed road development at Ch. 3+930
S2	Potential main sett	Active sett located in area of scrub along field boundary;

[42] Main sett = breeding sett, focus of most badger activity; Annexe sett = large sett, usually within 50m of the main sett; Subsidiary sett = smaller sett, not peripheral, within territory of badger social group; Outlier sett = small sett, usually on periphery of group territory; Minor sett = incidental sett, not on periphery of group territory.

Ref. No.	Type of sett[42]	Status and description
		numerous tunnels/pathways into the undergrowth c.90 m north-west of the N59 Link Road South at Ch. 1+800
S3	Main sett	Active sett located in woodland near field boundary wall. Single entrance sett with abundant fresh spoil, bedding and latrines. Adjacent to (<5m from) the proposed road development at Ch. 9+500
S4	Annex sett	Active sett located amongst holly bushes under limestone boulder. Single entrance with fresh spoil, bedding and latrine. c.85m south-east of the proposed road development at Ch. 9+500
S5	Subsidiary sett	Active sett located along field boundary. Single entrance with bedding and latrine. c.430m south-east of the proposed road development at Ch. 9+500
S6	Main sett/Annex sett	Active sett located in area of scrub. At least two entrances fresh spoil, bedding. >500m from the proposed road development
S7	Main sett/Annex sett	Active sett located under limestone. Two entrances fresh spoil, bedding. >500m from the proposed road development
S8	Main	Active sett located between limestone boulders. 10 plus entrances. Latrines and abundant activity signs. c.55m south of proposed road development (Bóthar Nua tie-in) at Ch. 10+200
S9	Potential main sett	Active sett located in hazel woodland at base of boulder pile. Single entrance. Large spoil heap, fresh spoil and bedding present. Within proposed development boundary at Ch. 11+810

Ref. No.	Type of sett[42]	Status and description
S10	Subsidiary sett	Active sett with two entrances, located under scrub along field boundary. Fresh spoil and bedding. c.45m north-east of the proposed road development at Ch. 11+810
S11	Subsidiary sett	Active sett located in dense scrub at field boundary. Single entrance. Within proposed development boundary at Ch. 12+025
S12	Main	Active sett located in scrub along field boundary. Six entrances. >500m from the proposed road development
S13	Subsidiary sett	Active sett located within improved grassland field. Single entrance. Recent digging. c.130m south of proposed development boundary at Ch. 13+425
S14	Subsidiary sett	Active sett located along field boundary. Two entrances. Recently digging. Within proposed development boundary at Ch. 13+775
S15	Subsidiary sett	Active, single entrance. Recent digging. c.100m north-west of AR 13/03
S16	Subsidiary sett	Active, single entrance. Recent digging and fresh spoil/bedding present. c.150m to the west of the proposed N59 drainage
S17	Subsidiary sett	Active, two entrances. Latrines, recent digging and fresh spoil/bedding. c.52m north of the proposed N59 drainage

Survey Limitations

Due to the presence of dense vegetation/scrub cover there were some locations within the study area, and within the proposed development boundary, which could not be fully accessed during the survey. These are shown on **Figures 8.3.1** to **8.3.14**. No evidence of Badger activity was recorded around the perimeter, or in the vicinity of, any of the inaccessible areas directly affected by the proposed road development.

The inaccessible areas have been considered in determining the impact significance and are reflected in the mitigation strategy. Sufficient data was gathered to reliably inform the impact assessment despite not being able to fully access these areas.

8.3.7.4 Other Mammal Species

Pine marten *Martes martes* were recorded along the Monument Road in Menlough and would be expected to be present in woodlands in the area. Pine marten have also been recorded in Bearna Woods and at Mincloon (NBDC on-line database records).

Evidence of Wood mouse *Apodemus sylvaticus* and Red squirrel *Sciurus vulgaris* was recorded east of the River Corrib, in woodlands east of Menlough Village, around Lackagh Quarry west of the proposed N84 Headford Road Junction, and south of the Roadstone Quarry at Two-mile-ditch. Red squirrel is known from the Menlough area, Merlin Park Woods, Ballygarraun/Two-mile-ditch, and woodlands in the Ardaun area (NBDC on-line database records).

An Irish stoat *Mustela erminea hibernica* was recorded on Bóthar Nua (roadkill). Irish hare *Lepus timidus hibernicus* was recorded in various habitat types (i.e. scrub, wet/improved grassland) in the western part of the study area; including lands within the proposed development boundary. Both species have been recorded in the study area previously (NBDC on-line database records and McAney, 2010).

Other terrestrial mammal species protected under the Wildlife Acts and likely to be present and widespread given the habitat types and existing land uses, and existing records from the NBDC's online database, include the Hedgehog *Erinaceus europaeus* and the Pygmy shrew *Sorex minutus*. Based upon the findings of the desktop review, Galway Bay supports a diverse range of marine mammal species, including: Harbour seal *Phoca vitulina*, Grey seal *Halichoerus grypus*, Common dolphin *Delphinus delphis* and Harbour porpoise *Phocoena phocoena*. All cetacean species are also protected under the Habitats Directive (Annex IV).

Evidence of Fox *Vulpes vulpes* and Rabbit *Orytolagus cuniculus* were also recorded across the study area. Evidence of Mink *Mustela vison* was recorded along the western bank of the River Corrib (*i.e.* north and south of Ch. 9+250) and a drainage ditch located near Ballindooly Lough (*i.e.* between Ch. 12+250 and Ch. 12+300). Bank vole *Myodes glareolus* and Wood mouse were recorded along a stream within the NUIG Sporting Campus. Although these species are not afforded legal protection under the Wildlife Acts, they form part of the local biodiversity resource and are noted here in that context.

8.3.8 Invertebrates

The following section presents the results of the baseline invertebrate surveys carried out to inform the impact assessment. Dedicated surveys were carried out for these species because they are legally protected (i.e. all are listed on Annex II of the Habitats Directive with the White-clawed crayfish and the Freshwater pearl mussel also protected under the Wildlife Acts) and, in the case of the Marsh fritillary butterfly and *Vertigo antivertigo*, that they are rare in Ireland[43] and at particular risk of habitat loss impacts associated with the proposed road development.

8.3.8.1 White-clawed crayfish

There were no White-clawed crayfish recorded at any of the survey sites within the scheme study area. No other evidence of the presence of the species within the scheme study area was observed (i.e. Otter spraints will commonly contain crayfish remains if they form part of their diet).

The survey was carried out in September 2014 during a period of low water levels, considered to aid in indicating those streams suitable of supporting White-clawed crayfish, and relatively high water temperatures, which would be expected to encourage crayfish activity.

All watercourses in the western part of the scheme study area were considered unsuitable to support the species, the water chemistry being too acidic and the lack of suitable habitat and/or quality; many of these streams were small or intermittent.

The Terryland River and the River Corrib appeared to be suitable for White-clawed crayfish but none were recorded. The Merlin Park Stream was considered unsuitable.

8.3.8.2 Freshwater pearl mussel

There were no populations, or individual records, of the Freshwater pearl mussel recorded within the scheme study area. The full results of the Freshwater pearl mussel surveys are provided in **Appendix A.8.11**.

The watercourses present were found to be poor habitat for the species, and although the Bearna Stream had good potential, no mussels were found. While the Lough Inch River itself had poor habitat and was affected by various pressures, this watercourse was upstream of, and in direct connectivity with, the Knock River - the confluence of the Lough Inch River and the Knock River is upstream of a known Freshwater pearl mussel population. The Knock/Lough Inch catchment is shown on **Figure 8.5.1**.

Although no freshwater pearl mussel were present with the ZoI of the proposed road development, impacts to salmonid fish species could indirectly affect the Freshwater pearl mussel population in Lough Corrib cSAC; the QI population is in the Owenriff River, c.23km to the north.

8.3.8.3 Other Annex II molluscan species

A total of 39 molluscan species were recorded during the molluscan survey, none of which were nationally or internationally rare or protected, with a range of between one and twelve species per surveyed site. The species assemblage recorded in some areas (e.g. Wetland habitats associated with the Coolagh Lakes and some

[43] The Marsh fritillary butterfly is listed as Vulnerable in *Ireland Red List No. 4 – Butterflies* (Regan et al., 2010) and *Vertigo antivertigo* as Vulnerable, in *Ireland Red List No. 2 – Non-Marine Molluscs* (Byrne et al., 2009)

Calcareous grassland habitat nearby) was considered to be of local interest. The full results of the molluscan surveys are presented in **Appendix A.8.12**. Species are listed according to the nomenclature of Anderson (2005).

There were no legally protected *Vertigo* species recorded during the survey. Three other Vertigo species (*Vertigo pygmaea*, *Vertigo antivertigo* and *Vertigo substriata*) were recorded, suggesting that the habitat conditions were not quite even in wetness and/or calcareous enough for the three Annex II *Vertigo* species. The remainder of the species recorded were typical of wet grassland, reed bed, riparian fringe, and fen habitats. Together the sites displayed a good range of species assemblage with good variety across the sites, reflecting the level of variation in wetness and vegetative succession of different areas. It should be noted that the Marsh whorl snail *Vertigo antivertigo* is listed as vulnerable in the Irish Red Data List of molluscs (Byrne *et al*., 2009). This species was recorded in wetland habitat on the east bank of the River Corrib between Menlo Castle and Menlo Graveyard and north of the outflow channel from the Coolagh Lakes, in the fringing wetland habitat along the western side of the Coolagh Lakes, at Ballindooley Lough and at the marsh in Castlegar.

The highest quality molluscan habitat was found towards the southern end of the Coolagh Lakes, concentrated in the high quality fen and transitional habitat areas (see **Figure 8.5.1** and the full survey report in **Appendix A.8.12**). Here the most concentrated searches for *Vertigo geyeri* were undertaken but no individuals of this species were found in the field or in samples removed for laboratory analysis.

The Marsh whorl snail population is valued as being of Local Importance (higher value).

8.3.8.4 Marsh fritillary

2013 Survey

The survey was conducted from 23 – 27 September 2013, covering 57 survey sites and approximately 491.8ha. Suitable Marsh fritillary habitat was recorded at 29 of those sites, unsuitable habitat at 17 sites, and the remaining 11 were not surveyed due to access restrictions. The area of suitable habitat accounted for 61.2ha, or 12.4% of the sites surveyed.

Two larval webs were recorded at a single site during the survey. However, two locations found to support relatively large concentrations of larval webs in 2014 were not surveyed in 2013. The full results of the 2013 Marsh fritillary survey are provided in **Appendix A.8.14**; the location of the larval webs are shown on **Figures 8.6.1** and **8.6.8**.

2014 Survey

A total of 196 polygons were surveyed in 2014, comprising a total area of 936ha. A total of 105 areas of suitable Marsh fritillary habitat were mapped, comprising a total area of 80.6ha. The quality of habitat ranged from marginal sparse through to good condition. Many areas were fairly rank and were likely to be limited in their longevity, with management often apparently abandoned or affected by access due to development in the vicinity.

A total of 111 webs were located within around 40 areas of suitable habitat. Eleven of the webs were located in four different areas identified as suitable habitat in the 2013 surveys but with no webs recorded in that year. The rest of the webs were recorded in areas that had not previously been surveyed. Webs located included both active webs and hibernation webs.

The full results are discussed in the 2014 Marsh fritillary survey report in **Appendix A.8.13**, and shown on **Figures 8.6.1** and **8.6.8**.

2015 Survey

In 2015, the survey switched from the larger scale of the scheme study area to a more focussed survey of suitable habitat patches within, and in the vicinity of, the proposed development boundary (see **Figures 8.6.1** and **8.6.8**). A total of 42.7ha were surveyed, comprising around 3ha within the proposed development boundary.

The majority of areas surveyed comprised suitable habitat, although levels of suitability varied (largely related to management issues specific to 2015). The exception to this was one area, comprising 1.15ha of suitable habitat in 2014 and holding Marsh fritillary webs, which was found to be largely lost due to infilling. It was noted that some areas that were of limited suitability in 2014 (largely due to heavy grazing), comprised suitable habitat in 2015. Conversely, some areas that were in good condition in 2014 were found to be overgrazed in 2015. In addition, one area that was considered to be suitable habitat in 2014 (though marginal) was considered to fall outside that classification due to ongoing agricultural improvement in 2015.

A total of 12 webs were located across five polygons within the survey areas (see **Figures 8.6.1** and **8.6.8**). This compares with 39 webs recorded with those same areas in 2014. No webs were recorded within the proposed development boundary. Webs located included both active webs and hibernation webs.

In 2014, webs were more widely spread throughout suitable habitat, while webs in 2015 were more limited in distribution. This may be attributable, in part at least, to the difference in weather in the two years. A relatively warm and settled summer in 2014 would allow for a good emergence season and distribution of adult females to new areas. Weather in 2015 provided sub-optimal conditions for the species both during the flight period and the early part of the larval stage. This has the potential to both limit distribution of the species at the adult stage and survival of the species at the early larval stage.

2016 Survey

A total of 42.4ha were surveyed on the 14, 15 and 26 September 2016, of which c.6.1ha was within the proposed development boundary.

A total of 56 webs were located within the survey areas in 2016 (see **Figures 8.6.1** and **8.6.8**), which compares with 12 webs recorded with the area in 2015 and 39 webs in 2014. In 2016, a total of 13 webs were recorded within the proposed development boundary, with a further 33 webs recorded within 50m of the proposed development boundary and 6 within 100m.

The section between Ch. 0+700 and Ch. 1+600 comprised a wide-ranging area of good quality habitat. Many areas in the eastern part were in better condition for the species than in the previous 2 years; possibly due to reduced grazing pressure. Despite this, webs were only recorded in the western part of the survey area.

The habitat area between Ch. 2+200 and Ch. 2+550 held an active and core population with the number of larval webs increasing from two in 2014, to seven in 2015 and to 35 in 2016. Although high quality habitat, the area between Ch. 2+900 to Ch. 3+050 only supported a single web in 2015 and again in 2016. The high-quality habitat area between Ch. 3+550 and Ch. 3+800 held 14 larval webs in 2016; compared with three in 2014 and a single web in 2015. The quality of the habitat in the area between Ch. 4+700 and Ch. 5+100 has deteriorated year on year over the survey period due to infilling and overgrazing and no larval webs were recorded here in 2016. No larval webs have been recorded in the suitable habitat areas at Ballagh (Ch. 7+700 to Ch. 8+000).

Overall, the Marsh fritillary butterfly population is valued as being of County Importance.

8.3.9 Birds

8.3.9.1 Breeding birds

All wild birds, and their nests and eggs, are protected under the Wildlife Acts. Some bird species are also listed on Annex I of the EU Birds Directive (see **Table 8.22** for those Annex I bird species recorded during the breeding bird surveys).

The results of the various breeding bird surveys carried out to inform this assessment are summarised below.

Breeding Bird Survey

The general breeding bird surveys recorded a total of 62 species across the study area, including; 3 species listed as SCIs for nearby SPAs, 2 Birds Directive Annex I species, 6 Red list[44], 23 Amber list and 33 Green list bird species.

Table 8.22 below provides a summary of the findings of the breeding bird surveys[45] with respect to those species which are of conservation concern and are considered to be Key Ecological Receptors (KERs):

- Special Conservation Interests (SCIs), for a breeding population, of nearby SPAs
- Species listed under Annex I of the Birds Directive (2009/147/EC)
- Red and Amber BoCCI species listed for their breeding populations
- The results of the breeding bird surveys are shown on **Figures 8.7.1** to **8.7.14** with the full list of bird species recorded provided in **Appendix A.8.22**. The full

[44] Birds of Conservation Concern in Ireland (BoCCI) after Colhoun & Cummins, 2013

[45] Surveys were also carried out to establish the local Barn owl breeding population (a BoCCI Red List species), which confirmed a nest site at Menlo Castle, and this species is also included in **Table 8.22**.

results of the desktop review are presented in **Appendix A.8.18**. Of note in that regard are the results of the bird surveys carried out in 2005/2006 as part of the N6 Galway City Outer Bypass project (RPS, 2006) which demonstrates the importance of the River Corrib corridor for bird species

Table 8.22: Breeding Birds of Conservation Concern Recorded during the Breeding Bird Survey[46]

Common name / *Latin name*/BoCCI Code	**Distribution in the study area**	**Conservation Importance**		
		BoCCI (breeding)	**Annex I**	**SCI[1]**
Barn owl *Tyto alba* (BO)	One nest site known at Menlo Castle	Red	-	-
Black-headed gull *Larus ridibundus* (BH)	Widespread throughout	Red	-	Lough Corrib SPA
Curlew *Numenius arquata* (CU)	Observed once at Ballindooley Lough	Red	-	-
Grey wagtail *Motacilla cinerea* (GL)	Observed once west of the Galway Racecourse	Red	-	-
Herring gull *Larus argentatus* (HG)	Widespread throughout, more frequent west of the River Corrib	Red	-	-
Meadow pipit *Anthus pratensis* (MP)	Widespread west of the River Corrib, and between Ballybrit and the existing N6	Red	-	-
Whinchat *Saxicola rubetra* (WC)	Ballagh area (single record)	Red	-	-
Cormorant *Phalacrocorax carbo* (CA)	Widespread west of the River Corrib	Amber	-	Inner Galway Bay SPA & Connemara Bog SPA
Common tern *Sterna hirundo* (CN)	Observed once at the proposed River Corrib Bridge	Amber	√	Inner Galway Bay SPA & Lough Corrib SPA
Coot *Fulica atra* (CO)	Observed between the River Corrib and Bóthar Nua, and once near Ballybrit	Amber	-	-
Great black-backed gull *Larus marinus* (GB)	Observed west of Bearna, at the River Corrib, and once at Ballindooley Lough	Amber	-	-

[46] Note that some of the species listed are also KERs for their wintering populations—see **Table 8.23**

Common name / *Latin name*/BoCCI Code	**Distribution in the study area**	**Conservation Importance**		
		BoCCI (breeding)	**Annex I**	**SCI[1]**
Goldcrest *Regulus regulus* (GC)	Widespread west of the River Corrib	Amber	-	-
Greenfinch *Carduelis chloris* (GR)	Widespread west of the River Corrib and east of the River Corrib, only recorded at Ballybrit	Amber	-	-
House martin *Delichon urbicum* (HM)	Observed near the Letteragh Road and between Ballindooley Lough and Ballybrit	Amber	-	-
House sparrow *Passer domesticus* (HS)	Observed near the Letteragh Road and at Ballybrit	Amber	-	-
Kestrel *Falco tinnunculus* (K.)	Observed near Bearna Woods, Letteragh Road, Lackagh Quarry and the existing N6	Amber	-	-

Little grebe *Tachybaptus ruficollis* (LG)	Observed at the proposed River Corrib Bridge and Ballindooley Lough	Amber	-	-
Linnet *Carduelis cannabina* (LI)	Widespread throughout	Amber	-	-
Mistle thrush *Turdus viscivorus* (M.)	Observed at Ballard West, Knocknafroska, Menlough and Lackagh Quarry	Amber	-	-
Peregrine *Falco peregrinus* (PE)	Observed near Lackagh Quarry and the N83 Tuam Road	Green	√	-
Robin *Erithacus rubecula* (R.)	Widespread throughout	Amber	-	-
Skylark *Alauda arvensis* (S.)	Observed at Troscaigh Thiar, Cappagh and Ballybrit	Amber	-	-
Stonechat *Saxicola torquata* (SC)	Observed west of Bearna, near Cappagh, Knocknafroska and between Ballybrit and the existing N6	Amber	-	-

Common name / *Latin name*/BoCCI Code	Distribution in the study area	Conservation Importance		
		BoCCI (breeding)	Annex I	SCI[1]
Stock dove *Columba oenas* (SD)	Observed once near Clybaun Road	Amber	-	-
Starling *Sturnus vulgaris* (SG)	Widespread throughout	Amber	-	-
Sparrowhawk *Accipiter nisus* (SH)	Observed once at Galway Racecourse	Amber	-	-
Swift *Apus apus* (SI)	Observed twice near the NUIG Sports Campus	Amber	-	-
Swallow *Hirundo rustica* (SL)	Widespread west of the River Corrib, and observed near Ballybrit	Amber	-	-
Sand martin *Riparia riparia* (SM)	Observed around Lackagh Quarry and Ballindooley Lough	Amber	-	-
Wheatear *Oenanthe oenanthe* (W.)	Rahoon area (single record)	Amber	-	-

[1] Listed as SCIs for their breeding populations

Of note, was that Ringed plover were recorded twice during the breeding bird surveys, once in late May 2015 and once in late June 2015, exhibiting breeding behaviour near the western edge of Galway Racecourse.

Barn Owl Survey

A total of 76 sites were surveyed in 2014 for the presence of Barn owl within the study area for the proposed road development. A total of 47 (63%) sites were considered to be entirely unsuitable for Barn owl (Category 0). Of the remaining 29 (27%) sites which could potentially be used by Barn owl, 11 (14%) offered potential for roosting but not for nesting (Category 1). Five (6%) were assessed as having likely roosting and/or nesting opportunities (Category 2) and the remaining 13 (15%) offered excellent roosting and nesting opportunities (Category 3). The locations of the surveyed sites, and their suitability for Barn owl, are shown on **Figures 3.3** and **3.4** of the Barn owl survey report in **Appendix A.8.15**.

The presence of Barn owl was confirmed at five of these sites which are within the scheme study area. These included two castles (nest sites at Menlo Castle and Ardfry House), a ruined mansion (roost site at Rinville House), a derelict two-story farmhouse and a quarry (both roost sites). The distribution of these sites is shown on **Figure 8.8.1**. Two sites, Ardfry Castle and Menlo Castle, were confirmed as nest sites. A ruined mansion (Rinville House) was classed as regular roosts which are likely to be associated with both nesting pairs, and an independent occasional roosting site in a derelict farm house was also recorded. Monitoring revealed that both nesting sites failed to breed in 2014.

All sites which were classed as suitable for Barn owl during the 2014 survey (Category 2 and Category 3; 20 sites in total), were re-visited between June and August in both 2015 and 2016. Two sites (a farmhouse and cottage) which were previously classified as suitable (both Category 3) in 2014 had been demolished and were no longer available to Barn owl. All remaining 18 sites were deemed still suitable for Barn owl. Evidence of Barn owl occupation was recorded at two sites in 2015, namely Menlo Castle and Rinville House, both of which had been active in 2014. There were no signs to indicate recent use of Ardfry Castle, a farmhouse at Carnmore, or at Angliham Quarry where evidence of Barn owl had been recorded in 2014. In addition, a farmhouse with adjacent outbuildings at Ballard, where a Barn owl had been reported by a member of the public in the winter of 2015, showed no evidence of recent use in July 2015. Evidence of Barn Owl occupation was confirmed at a single site in 2016 (Rinville House).

Figure 4.7 and Table 4.2 in **Appendix A.8.15**, shows the distribution and suitability of all sites surveyed in 2015. As with 2014, no breeding sites were confirmed in either 2015 or 2016.

Barn Owl activity was not recorded at Menlo Castle in 2018 and the site was deemed to be unoccupied during that nesting season. There was no evidence of Barn Owl observed during day time inspections in and around the castle and no activity recorded by nocturnal watches.

<u>Other raptors recorded during the 2014 and 2015 Barn owl surveys</u>

Other raptor species which were encountered during survey work in 2014 and 2015 were also recorded. A total of 21 raptor and owl sites (not including Barn owl) were confirmed in 2014 and 2015, which included nine Kestrel sites (four nests and five roosts), six Peregrine sites (four nests and two roosts), three Sparrowhawk sites (two nest sites and one displaying pair) and three Long-eared owl nests, see Figure 4.10 in **Appendix A.8.15**.

Peregrine falcon Survey

Peregrine falcon occupancy was recorded in three quarries in the survey area in May and June 2016, all of which held breeding pairs (see **Appendix A.8.16**). One breeding pair was successful (Roadstone Quarry at Twomileditch), with pairs in two quarries (Angliham and Lackagh Quarries) failing to raise young. All three quarry sites which held breeding pairs in 2016 were known sites where Peregrine have previously nested and are regarded as traditional nesting sites. The specific nesting location was recorded for the single successful pair (Roadstone Quarry at Twomileditch) in 2016, for the other two quarries that supported nest sites (Angliham and Lackagh) it was not possible to record a nest location in 2016, however the location of the eyries in previous years is documented. In 2017, Lackagh Quarry was monitored to determine breeding status and the nest site location, which confirmed a breeding pair and which identified the location of the traditional nest ledge. In 2018, a breeding pair of Peregrine falcon was again confirmed in Lacklagh Quarry and was successful in fledging young. The nest site was also confirmed in 2018 although it was at a different location to that recorded in previous years.

Red grouse

No sightings, or evidence, of Red grouse was recorded during the survey; or during the general breeding bird survey. During the course of other survey work in September 2014 (and over the course of the winter bird survey work from October 2014 to March 2015), evidence of Red grouse (droppings) was recorded adjacent to the scheme study area at Na Foraí Maola/Lough Inch (Arup, 2016).

8.3.9.2 Wintering birds

The winter bird surveys recorded a wide range of bird species at sites across the study area.

Table 8.23 below provides a summary of the findings of the winter bird surveys with respect to those species which are of highest conservation concern, and were recorded within winter bird survey sites:

- Special Conservation Interests (SCIs), for a wintering population, of nearby SPAs
- Species listed under Annex I of the Birds Directive (2008/144/EC)
- Red and Amber BoCCI species listed for their wintering populations

The full results of the winter bird surveys (for all surveyed sites within the wider scheme study area) are provided in **Appendix A.8.23**. Other record for wintering bird species from Galway City and environs are presented in the full results of the desktop review in **Appendix A.8.18**. Of note in that regard are the results of the bird surveys carried out in 2005/2006 as part of the N6 Galway City Outer Bypass project (RPS, 2006) which demonstrates the importance of the River Corrib corridor for bird species.

Table 8.23: Wintering Birds of Conservation Concern Recorded during the Winter Bird Survey

Common name / *Latin name*	**Conservation Importance**		
	BoCCI (wintering)	**Annex I**	**SCI**
Bar-tailed godwit *Limosa lapponica*	Amber	✓	Inner Galway Bay SPA
Black-headed gull *Larus ridibundus*	-	-	Lough Corrib SPA Inner Galway Bay SPA
Bittern *Botaurus stellaris*	-	✓	-
Common gull *Larus canus*	-	-	Lough Corrib SPA Inner Galway Bay SPA
Cormorant *Phalacrocorax carbo*	Amber	-	Inner Galway Bay SPA

Common name / *Latin name*	**Conservation Importance**		
	BoCCI (wintering)	**Annex I**	**SCI**
Coot *Fulica atra*	Amber	-	Lough Corrib SPA
Curlew *Numenius arquata*	Red	-	Inner Galway Bay SPA
Golden plover *Pluvialis apricaria*	Red	✓	Lough Corrib SPA Inner Galway Bay SPA
Great crested grebe *Podiceps cristatus*	Amber	-	-
Great northern diver *Gavia immer*	Amber	-	Inner Galway Bay SPA
Grey heron *Ardea cinerea*	-	-	Inner Galway Bay SPA
Hen harrier *Circus cyaneus*	Amber	✓	Lough Corrib SPA
Lapwing *Vanellus vanellus*	Red	-	Inner Galway Bay SPA
Light-bellied brent goose *Branta bernicla hrota*	Amber	-	Inner Galway Bay SPA
Little grebe *Tachybaptus ruficollis*	Amber	-	-
Merlin *Falco columbarius*	-	✓	-
Mute swan *Cygnus olor*	Amber	-	-
Oystercatcher *Haematopus ostralegus*	Amber	-	-
Peregrine falcon *Falco peregrinus*	-	✓	-
Redshank *Tringa totanus*	Red	-	Inner Galway Bay SPA
Shoveler *Anas clypeata*	Red	-	Lough Corrib SPA Inner Galway Bay SPA
Snipe *Gallinago gallinago*	Amber	-	-
Teal *Anas crecca*	Amber	-	Inner Galway Bay SPA
Tufted duck *Aythya fuligula*	Red	-	Lough Corrib SPA
Turnstone *Arenaria interpres*	Green	-	Inner Galway Bay SPA
Wigeon *Anas penelope*	Red	-	Inner Galway Bay SPA

Seven bird species which are listed as SCIs for Lough Corrib SPA were recorded during the survey: Black-headed gull, Common gull, Coot, Golden plover, Hen harrier, Shoveler and Tufted duck. Given the potential link for these birds to the SPA populations, they are valued as being of International Importance.

Fifteen bird species which are listed as SCIs for Inner Galway Bay SPA were recorded during the survey: Bar-tailed godwit, Light-bellied brent goose, Black-headed gull, Cormorant, Common gull, Curlew, Golden plover, Grey heron, Lapwing, Great-northern diver, Redshank, Shoveler, Teal, Turnstone and Wigeon. Given the potential link for these birds to the SPA populations, they are valued as being of International Importance.

Six species listed on Annex I of the Birds Directive (2008/144/EC) were also recorded during these surveys (some of which are also SCIs of the SPAs discussed and valued above): Bar-tailed godwit, Bittern, Golden plover, Hen harrier, Merlin and Peregrine falcon. The non-SCI Annex I bird species are valued as follows: Bittern, as a scarce visiting species not listed as being of conservation concern nationally, is valued as being of County Importance; Merlin, as a species of medium conservation concern which is likely to have a limited population at a county level, is valued as being of County Importance; Peregrine falcon, as a species of low conservation concern but which is likely to have a limited population at a county level, is valued as being of County Importance.

Of the bird species recorded during the winter bird surveys, seven are on the BoCCI Red List for their wintering populations: Curlew, Golden plover, Lapwing, Redshank, Shoveler, Tufted duck and Wigeon. All are SCI species for the nearby SPAs and are valued accordingly.

Of the bird species recorded during the winter bird surveys, 12 are on the BoCCI Amber List for their wintering populations: Bar-tailed godwit, Cormorant, Coot, Great crested grebe, Great northern diver, Hen harrier, Light-bellied brent goose, Little grebe, Mute swan, Oystercatcher, Snipe and Teal. Those species listed as SCIs for the nearby SPAs are valued as above. Great crested grebe and Little grebe are likely to have a limited population at a county level and are valued as being of County Importance. Mute swan, Oystercatcher and Snipe are relatively common wintering species at a county level but are likely to have a more limited population at a local level and are valued as being of Local Importance (higher value).

Species Accounts

Brief species accounts from the winter bird surveys are provided for these species below; the winter bird survey site reference numbers are given below in parenthesis. For the locations of the winter bird survey sites, refer to **Figure 8.9.1**.

<u>Bar-tailed godwit</u>

Nine Bar-tailed godwit were recorded at one winter bird survey site, Ballindooley Lough (WB02), on a single occasion in February 2015.

<u>Black-headed gull</u>

Black-headed gull were the most frequently recorded species and were distributed widely across the area, but mainly east of the River Corrib (recorded from 10 out of 17 winter bird sites within the ZoI of the proposed road development), and in numbers ranging from single individuals to a flock of 119 birds. Those sites within the ZoI which recorded larger flocks of over 40 individuals were the River Corrib corridor (WB12) and the NUIG Sporting Campus (WB45).

Bittern

A single Bittern was recorded at the Coolagh Lakes (WB04) in February 2015.

Common gull

Common gull were recorded widely across the study area (recorded from eight out of 17 winter bird sites within the ZoI of the proposed road development) and in numbers ranging in size from single individuals to a flock of 78 birds. The species was most frequently recorded on the River Corrib (WB12) and at the NUIG Sporting Campus (WB45) – on six and three occasions respectively. Common gull were recorded more infrequently at the other surveyed sites, and in low numbers; they were only recorded on one of the seven survey visits at five of the eight sites within the ZoI. The largest flocks were recorded along the River Corrib corridor (WB12) where flocks of 48 and 78 were recorded in the area immediately upstream of the Salmon Weir in September and November 2014, respectively.

Cormorant

Cormorant were recorded at five winter bird survey sites within the ZoI of the proposed road development: Ballindooley Lough (WB02), Coolagh Lakes (WB04), An Chloch Scoilte (WB07), west of Lough Inch (WB08) and the River Corrib (WB12). However, in all instances the numbers recorded were low; generally, one or two individuals with the exception of a record for four in February 2015 along the River Corrib (WB12).

Coot

Coot were recorded at three of the winter bird survey sites within the ZoI of the proposed road development: Ballindooley Lough (WB02), the Coolagh Lakes (WB04), and along the River Corrib corridor (WB12). Although Coot were regularly recorded at all of these sites, the numbers were relatively low with a maximum of 11 recorded at Ballindooley Lough in February/March 2015.

Curlew

Curlew were distributed widely across the scheme study area, and were recorded at eight of the 17 winter bird survey sites within the ZoI of the proposed road development. At the majority of survey sites and dates on which they were recorded, fewer than 10 birds were present. The largest flocks were recorded along the River Corrib corridor (WB12) south of Glenlo Abbey Hotel where a flock of 16 was recorded in October 2014 and at Galway Racecourse (WB23)—in the playing pitch to the west of the racecourse (grid reference (ITM) 533091 727407) — where a flock of 37 were recorded January 2015. The species was only regularly recorded at Ballindooley Lough (WB02), where it was present on six of the seven survey visits, with eight or fewer birds present on each occasion.

Golden plover

Golden plover were recorded at one winter bird survey site within the ZoI of the proposed road development, WB08 to the west of Lough Inch, during four out of the seven survey visits. The species were recorded in relatively small numbers (maximum of nine birds) on all but one occasion, when a flock of 73 were recorded in November 2014.

Great crested grebe

Great crested grebe (two birds) were recorded once on the River Corrib corridor (WB12) near Glenlo Abbey Hotel in October 2014.

Great northern diver

A single Great northern diver was recorded in Galway Bay at Ballyloughaun (WB30).

Grey heron

Grey heron were recorded at six of the 17 winter bird survey sites within the ZoI of the proposed road development: Ballindooley Lough (WB02), Cappagh (WB03), Coolagh Lakes (WB04), An Chloch Scoilte (WB07), west of Lough Inch WB08, and the River Corrib corridor WB12. The species was recorded in relatively small numbers, a maximum of three birds were recorded at WB08 in March 2015, with most records being of single birds.

Hen harrier

A single Hen harrier was recorded in the area east of Lough Inch (WB06) in January 2015.

Lapwing

Lapwing were recorded at two winter bird survey sites within the ZoI of the proposed road development: Ballindooley Lough (WB02) where a flock of 16 and a single individual were recorded on January and March 2015 respectively; and, west of Lough Inch (WB08), where 17 were recorded in October 2014.

Light-bellied brent goose

Light bellied brent geese were recorded at Galway Golf Course (WB19), Nimmo’s Pier/Claddagh area (WB38) and along the coastline of Galway Bay between Roscam Point and Oranmore (WB71). The largest numbers were recorded at WB38 in January and March 2015 (127 and 83 respectively).

Little grebe

Little grebe were recorded at four winter bird survey sites: Ballindooley Lough (WB02), Coolagh Lakes (WB04), west of Lough Inch (WB08) and the River Corrib corridor (WB12). The numbers recorded were generally low (< five birds). The species were recorded on all seven survey visits at Coolagh Lakes (WB04) and the River Corrib corridor (WB12). The species was recorded on five out of seven of the survey visits (November 2014 through to March 2015) at Ballindooley Lough

(WB02) and only on one occasion in December 2014 at the survey site to the west of Lough Inch (WB08).

Merlin

A single Merlin was recorded in the area west of Lough Inch (WB08) in December 2014.

Mute swan

Mute swans were recorded at five winter bird survey sites: Ballindooley Lough (WB02), Coolagh Lakes (WB04), west of Lough Inch (WB08), the River Corrib corridor (WB12) and the Terryland River Valley (WB14). The numbers recorded were generally low (< eight birds). The species were recorded on all seven survey visits on the River Corrib corridor (WB12), with 14 birds recorded near Glenlo Abbey Hotel in February 2015. The species was recorded on six out of seven of the survey visits to the survey site west of Lough Inch (WB08) (September 2014 and November 2014 through to March 2015) and at the Coolagh Lakes (WB04) (October 2014 through to March 2015). The species was recorded on five out of seven survey visits to Ballindooley Lough (WB02) (October 2014 through to January 2015 and March 2015), and on one occasion on the Terryland River (WB14) in February 2015.

Oystercatcher

Oystercatcher were distributed widely across the scheme study area and recorded from five out of 17 winter bird sites within the ZoI of the proposed road development. Numbers ranged from single individuals to a flock of 34 birds. The sites that recorded larger flocks of over 20 individuals were the NUIG Sporting Campus (WB45) where 34 birds were recorded in December 2014.

Peregrine

Peregrine were recorded at one winter bird survey site within the ZoI of the proposed road development, at the Roadstone Quarry (WN17). At the Roadstone Quarry a single bird was recorded on three occasions in December 2014, February 2015 and March 2015. Peregrine were also recorded at Angliham Quarry, c.1km north of the proposed road development.

Redshank

Redshank were recorded at two winter bird survey sites within the ZoI of the proposed road development; west of Lough Inch (WB08) and the River Corrib corridor (WB12). Only two birds were recorded at WB08 in March 2015 and only single birds were recorded at WB12, near Waterside, in November and December 2014.

Shoveler

Shoveler were recorded on, or flying into, only one of the winter bird survey sites in 2014/15: Ballindooley Lough (WB02). They were recorded on five out of the seven survey visits, in numbers ranging from 10 to 144 birds.

Snipe

Snipe were distributed widely across the study area (recorded from eight out of 17 winter bird sites within the ZoI of the proposed road development) and in numbers ranging from single individuals to a flock of 37 birds. The numbers recorded across the sites were generally low (<10). Ballindooley Lough (WB02) had the largest flock of 37 in March 2015, with a flock of 28 in December 2014 and in September and November 2014 one and two birds respectively. A flock of 15 birds was recorded in November 2014 at the Terryland River Valley (WB14), and a flock of 14 recorded at the survey site to the west of Lough Inch (WB08) in January 2015.

Teal

Teal were recorded at five winter bird survey sites within the ZoI of the proposed road development: Ballindooley Lough (WB02), Coolagh Lakes (WB04), west of Lough Inch (WB08), Ballagh (WB10) and the Terryland River Valley (WB14). The numbers recorded at WB04, WB08 and WB10 were generally low (<6 birds) and Teal were not present regularly throughout the winter period (recorded on two, four and one occasion, respectively). Teal were recorded on, or flying into, Ballindooley Lough (WB02) and the Terryland River (WB14) during all survey visits. At Ballindooley Lough numbers ranged from three in September 2014, to 146 in January 2015, and at the Terryland River numbers ranged from nine in October 2014 to 29 in January 2015.

Tufted duck

Tufted duck were recorded at only one site, Ballindooley Lough (WB02), where the species was recorded on four occasions over the winter (November 2014, January 2015, February 2015 and March 2015). The maximum number recorded was a count of 26 in January 2015.

Turnstone

Five Turnstone were recorded in Galway Bay at Ballyloughaun (WB30) in October 2014.

Wigeon

Wigeon were recorded at one winter bird sites Ballindooley Lough (WB02) on one occasion in February 2015, when 28 birds were present.

8.3.10 Amphibians

Two amphibian species were known to be present within the study area; the Common frog *Rana temporaria* and the Smooth newt *Triturus vulgaris*[47]. Both are legally protected under the Wildlife Acts (including their breeding and resting places). Common frog have been recorded throughout the study area, most often in the upland habitats west of the River Corrib and along the River Corrib corridor. Smooth newt have been recorded in the vicinity of Bearna Woods, Salthill,

[47] Records from the National Biodiversity Centre's online database. For full details of the desk review, refer to **Appendix A.8.18**.

Terryland Park and at Renmore. Local landowners have also reported the presence of Smooth newt on lands near Coolagh Lakes.

During the surveys carried out in 2014, Common frog (adults, juveniles and tadpoles) were recorded at 21 of the 52 surface water/drainage features surveyed across the study area. Smooth newts were recorded at nine of the 52 surface water/drainage features surveyed across the scheme study area; most which were located west of the River Corrib. A summary of the Smooth newt survey results are provided below in **Table 8.24**.

Two ad-hoc observations of Smooth newt and four ad-hoc observations of Common frog were recorded within the study area during the multidisciplinary surveys.

The results of the amphibian survey are shown on **Figures 8.10.1** to **8.10.8**.

Table 8.24: Summary of Smooth newt records from the amphibian surveys

Location	Feature	Note
East of the proposed road development within area of scrub and rough grassland, c.35 m east of Ch. 0+500	Well	3 females and 3 males
South-east of the proposed road development within area of scrub, c.10 m south-east of Ch. 5+175	Pond	1 female
West of the proposed road development/Ballymoneen Road at Ch. 0+100	Drainage ditch	4 unidentified
North of the proposed road development within area of scrub, between Ch. 5+700 to Ch. 5+800	Drainage ditch	1 unidentified and 2 females
South of the proposed road development within area of scrub, c.50m south of Ch. 5+800	Drainage ditch	4 gravid females and 1 male
Within the proposed road development, south-east of proposed Letteragh Road Junction at Ch. 1+600	Pond	2 gravid females
Area of scrub within the proposed road development, east of proposed N59 Letteragh Junction at Ch. 7+850	Pond	1 juvenile male
Gravel wash-out ponds in Lackagh Quarry	Pond	1 unidentified
Cattle trough at Lackagh Quarry c.40m north of the proposed road development at Ch. 11+775	Cattle trough	1 female
Within Development boundary in marsh scrub area between Ch. 13+000 and Ch. 13+050	Pond	2 males, 1 female and 1 unidentified gravid female.
Galway Racecourse, >280m from the proposed road development	Drainage Ditches	10 males, 5 females, 5 unidentified (>20 newts). Gravid females present.

The Common frog and Smooth newt populations are valued as being of Local Importance (higher value).

8.3.11 Reptiles

There were records for the Common Lizard *Zootoca (Lacerta) vivipara* from Menlough, Merlin Park Woods, and various locations around Galway City: the River Corrib corridor, Salthill and Cappagh[48]. The Common lizard is legally protected under the Wildlife Acts (including their breeding and resting places).

The Common lizard survey was conducted between the 24 September and 4 October 2015. Common lizard were recorded at five of the 10 survey sites (A, B, C, E, and F); all of which were west of the River Corrib (**Figures 8.10.1** to **8.10.8**). All of these sites were within the footprint of the proposed road development, or adjacent to the proposed development boundary in habitat mosaics of heath, scrub and wet or acid grassland. The lizard survey results are summarised below in **Table 8.25**.

Table 8.25: Summary of Common lizard survey results

Survey Site	Result
A	27 / 28 September 2015 – 1 adult 28 / 29 September 2015 – 1 adult
B	24 / 25 September 2015 – 1 juvenile 27 / 28 September 2015 – 1 juvenile
C	27 / 28 September 2015 – 1 juvenile
E	25 / 26 September 2015 – 1 adult 26 / 27 September 2015 – 1 adult 28 / 29 September 2015 – 1 adult
F	24 / 25 September 2015 – 1 juvenile 27 / 28 September 2015 – 1 juvenile

One ad-hoc observation of the species was recorded at Knocknafroska during the multidisciplinary survey in May 2015, near the N59 Link Road North.

The results of the reptile survey are shown on **Figures 8.10.1** to **8.10.8**.

The Common lizard population is valued as being of Local Importance (higher value).

8.3.12 Fish

The results of the various fisheries surveys carried out between the 22 and 30 September 2015, along with the findings of the desktop study, are summarised below. The locations of sampling points/areas are shown on **Figure 8.11.1**, with the full results (including the macro-invertebrate species lists) provided in **Appendix A.8.17**. Fish species are protected under the Fisheries Acts and by fishing by-laws.

[48] Records from the National Biodiversity Centre's online database. For full details of the desk review, refer to **Appendix 8.18**.

Atlantic salmon, Sea lamprey and the Brook lamprey are listed on Annex II of the EU Habitats Directive.

Sruthán na Líbeirtí

Sruthán na Líbeirtí was described during the fisheries habitat survey as a seasonal stream having moderate quality, semi-natural salmonid and European eel *Anguilla anguilla* habitat in the lower reaches; the electrofishing survey recorded small numbers of European eel in the lower reaches. Water quality in Sruthán na Líbeirtí was assessed as being moderately polluted (Q3[49]).

In terms of its fisheries value, Sruthán na Líbeirtí is valued as being of Local Importance (lower value).

Trusky Stream

The upper part of the Trusky Stream, where it is crossed by the proposed road development, was described during the fisheries habitat survey as a seasonal stream with some moderate semi-natural salmonid habitat; although the electrofishing survey did not record any fish species present. The lower reaches however, were described as having Brown trout *Salmo trutta* spawning habitat and good quality nursery habitat for European eel elver and juvenile Flounder *Platichthys flesus*. Fish species recorded during the electrofishing were Brown trout, European eel, Flounder and Three-spined stickleback *Gasterosteus aculeatus*. Water quality in the Trusky Stream was assessed as being moderately polluted (Q3).

In terms of its fisheries value, the upper reaches of the Trusky Stream is valued as being of Local Importance (lower value); the lower reaches, as Local Importance (higher value).

Bearna Stream

The Bearna Stream was considered excellent quality salmonid spawning and nursery habitat, and European eel habitat. The electrofishing survey recorded both Brown trout and European eel. Water quality in the Bearna Stream was assessed as being unpolluted (Q4).

The tributary of the Bearna Stream was described as a seasonal stream with some moderate semi-natural salmonid and eel habitat; although the electrofishing survey did not record any fish species present. Water quality in the Bearna Stream tributary was assessed as being moderately polluted (Q3).

In terms of its fisheries value, the Bearna Stream was valued as being of Local Importance (higher value). The seasonal unnamed tributary is valued as being of Local Importance (lower value).

Tonabrocky Stream

The upper reaches, in the vicinity of the proposed road development, had poor quality fisheries habitat being predominantly a dry drainage channel with localised pockets of water.

---

[49] After Toner *et al.*, 2005: Q5, Q4-5 and Q4 = Unpolluted, Class A; Q3-4 = Slightly polluted, Class B; Q3 or Q2/3 = Moderately polluted Class C; and, Q2, Q1/2 or Q1 = Seriously polluted Class D.

The lower reaches of the Tonabrocky Stream are considered excellent quality salmonid and eel habitat, including salmonid spawning habitat. The electrofishing survey recorded Brown trout. Electrofishing surveys carried out by Inland Fisheries Ireland (IFI) in 2008 recorded Atlantic salmon parr (*Salmo salar*), Brown trout, Sea trout smolts and European eel. IFI have also recorded Sea trout spawning in the lower reaches of the stream. Water quality in the Tonabrocky Stream was assessed as being unpolluted (Q4).

In terms of its fisheries value, the upper reaches of the Tonabrocky Stream is valued as being of Local Importance (lower value); the lower reaches, as Local Importance (higher value).

Knocknacarra Stream

The upper reaches of the Knocknacarra Stream were largely seasonal ditches with little or no fisheries value; large sections of the lower reaches are culverted. That tidal section of the stream, between the culvert and the estuary, are important as a transitional nursery habitat for estuarine fish and European eel, Grey mullet *Chelon labrosus*, Sand goby *Pomatoschistus minutes* and Flounder were recorded there during the electrofishing survey. Water quality in the Knocknacarra Stream was assessed as being moderately polluted (Q3).

In terms of its fisheries value, the upper reaches of the Knocknacarra Stream were valued as being of Local Importance (lower value); the lower reaches, at the estuary, as Local Importance (higher value).

River Corrib

The River Corrib is an important salmonid watercourse, supporting both Atlantic salmon and Brown trout, and is a designated salmonid watercourse under the European Communities (Quality of Salmonid Waters) Regulations, 1988. The River Corrib system is also designated under the Habitats Directive as a candidate Special Area of Conservation for Atlantic salmon, Sea lamprey *Petromyzon marinus* and Brook lamprey *Lampetra planeri*—Lough Corrib cSAC. The River Corrib is also an important catchment for the European eel *Anguilla anguilla*. Water quality in the lower reaches of the River Corrib is classified as unpolluted (Q4) by the EPA (sampled at the Salmon Weir - http://gis.epa.ie/Envision).

In terms of its fisheries value, the River Corrib was valued as being of International Importance.

Terryland River

The channel of the Terryland River is highly modified in parts, and showing signs of organic pollution, which limits its fisheries value. European eel were the only fish species recorded during the electrofishing surveys. Water quality in the Terryland River was assessed as being moderately polluted (Q2-3).

In terms of its fisheries value, the Terryland River was valued as being of Local Importance (lower value).

Coolagh Lakes

The Coolagh lakes were of some importance for coarse fish species. Fyke netting recorded Perch *Perca fluviatilis*, Roach *Rutilus rutilus* and European eel. The spring feed stream supplying the lakes was electrofished but no fish species were recorded. The Coolagh Lakes does not have a Water Framework Directive water quality status assigned to it.

In terms of their fisheries value, the Coolagh Lakes were valued as being of Local Importance (lower value).

Ballindooley Lough

Ballindooley Lough was considered to be an excellent coarse fishery with the fyke netting survey recording Pike *Esox lucius*, Perch, Rudd *Scardinius erythropthalmus* and Tench *Tinca tinca*. Ballindooley Lough does not have a Water Framework Directive water quality status assigned to it.

In terms of its fisheries value, Ballindooley Lough was valued as being of Local Importance (higher value).

Corrib Estuary and Galway Bay

The Corrib Estuary and Galway Bay are important transitional and marine fisheries habitat, supporting a range of fish species (The Central and Regional Fisheries Boards, 2009). The Corrib Estuary and Galway Bay are also designated under the Habitats Directive as a candidate Special Area of Conservation for Atlantic salmon — Galway Bay Complex cSAC. The transitional waters of the Corrib Estuary and the coastal waters of Galway Bay are classified by the EPA as unpolluted (http://gis.epa.ie/Envision).

In terms of its fisheries value, Galway Bay was valued as being of International Importance.

8.3.13 Local Biodiversity Areas

The local biodiversity areas include within the *Galway City Development Plan 2017–2023* and the most recent draft of the *Galway City Biodiversity Action Plan 2014-2024*, are derived from habitat mapping carried out in 2004. The results of the biodiversity surveys carried out since 2013, in the preparation of this assessment, have highlighted many other areas that would be considered to be locally important biodiversity areas. In many cases, these would encompass greater areas than that considered in the draft *Galway City Biodiversity Action Plan 2014-2024* given that the current survey areas extend beyond the city boundary. The locations of the biodiversity surveys and receptors across the local area are shown on **Figures 8.1 – 8.22** and described under the various sections above.

For the purposes of this assessment, the following biodiversity areas are considered; which include the local biodiversity areas from the draft *Galway City Biodiversity Action Plan 2014-2024*:

- The Coast Road (R336) to the N59 Moycullen Road (which includes the Cappagh – Ballymoneen and the Ballagh – Barnacranny Hill local biodiversity areas from the draft *Galway City Biodiversity Action Plan 2014-2024*)

  This local biodiversity area encompasses a mosaic of peatland habitats extending from near the coastline west of Bearna across to the N69 Moycullen Road – the peatland areas form part of a larger expanse of peatland habitat that extend off to the north-west, into the Connemara Bogs cSAC. In terms of habitats, it includes the Annex I habitats Wet heath, Dry heath, *Molinia* meadows and Blanket bog, amongst large areas of scrub, bracken, acid and wet grasslands, along with fens and upland/eroding streams. These habitats in turn support a diverse range of fauna species including: bats, Otter, Badger, the Marsh fritillary butterfly, breeding birds, wintering birds (including species listed as SCIs of the local SPA sites), amphibians, reptiles and fish species. Parts of this site lie within Moycullen Bogs NHA

- Rusheen Bay – Bearna Woods – Illaunafamona

  This local biodiversity area is described in the draft *Galway City Biodiversity Action Plan 2014*-2024 as follows "It incorporates several types of shoreline including glacial cliffs, gravel banks, rocky shore, sandy shore, muddy sand and saltmarsh. It also has several types of woodland in Barna Woods together with various semi-natural grassland types between Silver Strand and Gentian Hill. The coast is very indented with a number of sheltered feeding and roosting areas for significant numbers of wintering birds. The dynamic complex of shingle bars and saltmarsh at Illaunafamona is included in this area." This area lies within Galway Bay Complex cSAC and Inner Galway Bay SPA

- The River Corrib and the Coolagh lakes (which includes the River Corrib and adjoining wetlands local biodiversity areas from the draft *Galway City Biodiversity Action Plan 2014-2024*)

  This local biodiversity area supports a range of aquatic and wetland habitats ranging from rivers and lakes to reed swamp, wet woodland, marsh, wet grassland, fens and heath. These include a diverse range of Annex I habitats including Hard water lakes, Wet heath, *Molinia* meadow, *Cladium* fen, Hydrophilous tall herb habitat, Alkaline fen, Transition mire and Residual alluvial forests. Drier areas within this habitat complex support the Limestone pavement and Calcareous grassland Annex I habitat types. These habitats in turn support a diverse range of fauna species including: bats, Otter, Badger, breeding birds, wintering birds (including species listed as SCIs of the local SPA sites), molluscs, amphibians and fish species. This area includes part of Lough Corrib cSAC and part of Lough Corrib pNHA

- Menlough to Coolough Hill (including Lackagh Quarry)

  This local biodiversity area comprises a mosaic of semi-natural woodland, broadleaved woodland, exposed limestone rock, scrub and semi-natural grasslands, and a quarry site. This includes a range of Annex I habitat types, including: Limestone pavement, Calcareous grassland, Turloughs and Petrifying springs. These habitats in turn support a diverse range of fauna species including: bats (including a Lesser horseshoe bat maternity and hibernation roost), Otter, Badger and breeding birds (including a Barn owl nest site). This area includes part of Lough Corrib cSAC and part of Lough Corrib pNHA

- Ballindooley – Castlegar (which is linked to the River Corrib by the Terryland River valley)

  This local biodiversity area comprises a mosaic of wetland habitats associated with Ballindooley Lough (including reed swamp, wet grassland, fen and wet woodland) and areas of semi-natural woodland and exposed limestone rock. This includes a diverse range of Annex I habitat types including Hard water lakes, Alkaline fen, *Cladium* fen, Residual alluvial forests and Limestone pavement. These habitats in turn support a diverse range of fauna species including: bats, Badger, breeding birds, wintering birds (including species listed as SCIs of the local SPA sites), amphibians and fish species

- Galway Racecourse, Ballybrit

  Although primarily consisting of amenity grassland around the margins, the centre of the racecourse supports semi-natural grasslands, and the Marsh fritillary butterfly was recorded here in 2014

- Doughiska

  This biodiversity area comprises a mosaic of semi-natural grassland and exposed limestone rock, with some semi-natural woodland cover and scrub patches, amongst improved agricultural fields. In places the grassland habitats correspond with the Annex I Calcareous grassland habitat type, and the exposed or wooded limestone rock with Annex I Limestone pavement.

- Galway Bay (which includes the Mutton Island and Nearby Shoreline local biodiversity areas from the draft *Galway City Biodiversity Action Plan 2014-2024*).

  Galway Bay Complex cSAC and Inner Galway bay SPA lie within this biodiversity area. This biodiversity area includes a diverse range of shoreline, transitional, estuarine and marine habitats which in turn support a rich species assemblage. The Annex I habitats present include Large shallow inlets and bays, associated with which are Reefs, Tidal mudflats, Lagoons, Salicornia mud, Perennial vegetation of stony banks and Atlantic salt meadows. These habitats support the SCI bird species of Inner Galway bay SPA, providing nesting, foraging and roosting sites which include open water, intertidal and terrestrial habitats. The habitats within Galway Bay also support a diverse range of invertebrate and plant communities (marine and intertidal) and fish species, along with Otter, Harbour seal and cetaceans

8.3.14 Summary Ecological Valuation and Identification of Key Ecological Receptors

Table 8.26 below summarises the ecological evaluation of all receptors taking into consideration legal protection, conservation status and local abundance. Key Ecological Receptors (KERs) are identified in blue in the table. Species, habitats and features not qualifying as KERs are not subjected to impact assessment in line with current best practice of assessing the impacts on what are determined to be important ecological or biodiversity features: CIEEM and TII guidelines (CIEEM, 2016 and National Roads Authority, 2009).

All designated areas for nature conservation that lie within the ZoI of the proposed road development are considered to be KERs given that they are sites selected specifically for biodiversity conservation. Those designated areas for nature conservation that lie beyond the ZoI of the proposed road development are not considered to be at risk of impact and are therefore, not considered to be KERs.

In almost all cases, habitat and species valued as being of local importance (higher value), or higher, are considered to be KERs as they are important contributors to the local biodiversity resource and are of conservation concern, at least locally. However, some of the higher biodiversity value habitats and species included in **Table 8.26** below are not considered as KERs because, although they are present within the wider scheme study area, they lie beyond the ZoI of the proposed road development (as noted in the table below) and are therefore not at risk of being affected during construction or operational phases of the proposed road development.

Habitats valued as being of a local importance (lower value) are not considered to be KERs in this assessment. This is not to say that they are of no biodiversity value, but that impacts on these habitat types in their local context are not likely to result in a significant effect on biodiversity. It should be noted that this relates to the impact on the habitat itself as distinct from considering the role these habitat types play in supporting KER species – impacts of the proposed road development in that sense are captured and assessed under the relevant species' headings in **Section 8.5**.

These lower biodiversity value habitats include built or artificially created habitats, transient habitats as a result of disturbance, or those that have been highly anthropogenically modified (e.g. BC3, BL3, ED2, ED3, ED4, FL8, GA1, GA2, WS3, WS5). These habitat types tend to be associated with residential, commercial or industrial development, roads and highly managed amenity areas. It also includes grassland habitats that are relatively species poor and bracken, which is considered to be a problem species in terms of biodiversity for many habitat types.

In some cases, local importance (lower value) habitat can be associated with, or develop into, higher value habitats and where this is the case it is captured in valuing and considering whether a particular habitat type is a KER for this assessment. One example of this is the habitat Exposed calcareous rock (ER2). As a quarry wall feature it is considered a local importance (lower value) habitat type. In many cases it can be associated with the Annex I habitat Limestone pavement and is valued accordingly. Limestone quarry walls can also support calcareous springs (or the priority Annex I habitat Petrifying springs) and where this is the case the spring features are considered and valued separately in **Table 8.26** below.

Non-native invasive plant species are not considered as KERs, as they can result in negative effects on biodiversity and it is in that context they are included within the impact assessment.

The local biodiversity areas are, by definition, important locally. However, they support a range of habitats and species that are valued individually below; with the valuations ranging from local importance (e.g. spoil and bare ground) through to internationally important (e.g. priority Annex I habitats). Therefore, they are considered to be KERs but are not given an ecological valuation separate from the biodiversity receptors presented below and assessed in this chapter.

Table 8.26: Ecological Evaluation and Identification of KERs[50]

Ecological Receptor	Ecological Valuation	KER
Designated Areas for Nature Conservation		
Lough Corrib cSAC	International	Yes
Galway Bay Complex cSAC	International	Yes
Lough Corrib SPA	International	Yes
Inner Galway Bay SPA	International	Yes
Moycullen Bogs NHA	National	Yes
Lough Corrib pNHA	International#	Yes
Galway Bay Complex pNHA	International†	Yes
Other designated areas for nature conservation	International - National	No, as beyond the ZoI of the proposed road development (see NIS for more detailed discussion in relation to European sites – cSACs and SPAs)
Habitats (outside of designated areas for nature conservation)		
Flower beds and borders (BC4)	Local Importance (Lower Value)	No
Buildings and artificial surfaces (BL3)	Local Importance (Lower Value)	No
Spoil and bare ground (ED2)	Local Importance (Lower Value)	No
Recolonising bare ground (ED3)	Local Importance (Lower Value)	No
Active quarries and mines (ED4)	Local Importance (Lower Value)	No
Exposed siliceous rock (ER1)	Local Importance (Lower Value)	No
Exposed calcareous rock (ER2)		
Limestone pavement [*8240]	International Importance	Yes
Quarry walls	Local Importance (Lower Value)	No

[50] KERs are highlighted blue

Ecological Receptor	Ecological Valuation	KER
Limestone/marl lakes (FL3)		
Hard water lakes [3140]	National Importance	Yes
Mesotrophic lakes (FL4)		
Part of Ballindooley complex	County Importance[51]	Yes
Eutrophic lakes (FL5)		
Part of Ballindooley complex	County Importance[52]	Yes
Turloughs (FL6)		
Turloughs [*3180]	International Importance	Yes
Other artificial lakes and ponds (FL8)	Local Importance (Lower Value)	No
Calcareous springs (FP1) Priority		
Petrifying springs [*7220]	International Importance	Yes
Non-Annex I habitat type	Local Importance (Higher Value)	Yes
Reed and large sedge swamps (FS1)		
Cladium fen [*7210]	International Importance	Yes
Hydrophilous tall herb [6430]	National Importance	Yes
Non-Annex I habitat type	Local Importance (Higher Value)	Yes
Tall-herb swamps (FS2)		
Cladium fen [*7210]/Hydrophilous tall herb [6430]	International/National Importance	Yes
Non-Annex I habitat type	Local Importance (Higher Value)	Yes
Eroding/upland rivers (FW1)	Local Importance (Higher Value)	Yes
Depositing/lowland rivers (FW2)		
River Corrib	International Importance	Yes
Terryland River	Local Importance (Higher Value)	Yes
Drainage ditches (FW4)	Local Importance (Higher Value)	Yes
Improved agricultural grassland (GA1)	Local Importance (Lower Value)	No
Amenity grassland (improved) (GA2)	Local Importance (Lower Value)	No
Marsh (GM1)	Local Importance (Higher Value)	Yes
Dry calcareous and neutral grassland (GS1)		
Calcareous grassland [*6210/6210]	International/National Importance	Yes
Non-Annex I habitat type	Local Importance (Higher Value)	Yes
Non-Annex I habitat type	Local Importance (Lower Value)	No
Dry meadows and grassy verges (GS2)		
Lowland hay meadows [6510]	National Importance	No, as not within ZoI of the proposed road development
Non-Annex I habitat type	Local Importance (Higher Value)	Yes
Non-Annex I habitat type	Local Importance (Lower Value)	No

[51] On the basis that it forms part of the wetland complex at Ballindooley Lough
[52] On the basis that it forms part of the wetland complex at Ballindooley Lough

Ecological Receptor	Ecological Valuation	KER
Dry-humid acid grassland (GS3)		
Species rich *Nardus* upland grassland [*6230]	National Importance	No, as not within ZoI of the proposed road development
Non-Annex I habitat type	Local Importance (Higher Value)	Yes
Non-Annex I habitat type	Local Importance (Lower Value)	No
Wet grassland (GS4)		
Molinia meadow [6410]	National Importance	Yes
Non-Annex I habitat type	Local Importance (Higher Value)	Yes
Non-Annex I habitat type	Local Importance (Lower Value)	No
Dense bracken (HD1)	Local Importance (Lower Value)	No
Dry siliceous heath (HH1)		
Dry heath [4030]	National Importance	Yes
Dry calcareous heath (HH2)		
Dry heath [4030]	National Importance	No, as not within ZoI of the proposed road development
Wet heath (HH3)		
Wet heath [4010]	National Importance	Yes
Rich fen and flush (PF1)		
Alkaline fens [7230]/*Cladium* fen [*7210]	International Importance	Yes
Non-Annex I habitat type	County Importance	Yes
Non-Annex I habitat type	Local Importance (Higher Value)	Yes
Poor fen and flush (PF2)		
Non-Annex I habitat type	County Importance	No, as not within ZoI of the proposed road development
Non-Annex I habitat type	Local Importance (Higher Value)	Yes
Residential	Local Importance (Lower Value)	No
(Mixed) broadleaved woodland (WD1)	Local Importance (Higher Value)	Yes
Mixed broadleaved/conifer woodland (WD2)	Local Importance (Higher Value)	Yes
(Mixed) conifer woodland (WD3)	Local Importance (Higher Value)	Yes
Scattered trees and parkland (WD5)	Local Importance (Lower Value)	No, as not within ZoI of the proposed road development
Hedgerows (WL1)	Local Importance (Higher Value)	Yes
Treelines (WL2)	Local Importance (Higher Value)	Yes
Oak-ash-hazel woodland (WN2)		
Limestone pavement [*8240]	International Importance	Yes
Non-Annex I habitat type	Local Importance (Higher Value)	Yes
Wet willow-alder-ash woodland (WN6)	International Importance	Yes

Ecological Receptor	Ecological Valuation	KER
Residual alluvial forest [*91E0]		
Non-Annex I habitat type	Local Importance (Higher Value)	Yes
Scrub (WS1)		Yes

8.4 Characteristics of the Proposed Road Development

A detailed description of the proposed road development and construction activities are provided in **Chapter 5, Description of Proposed Road Development** and **Chapter 7, Construction Activities**.

The main characteristics of the proposed road development of relevance to the ecological assessment are outlined under construction and operation phases in the following.

8.4.1 Construction Phase

The main characteristics of the construction stage of the proposed road development that have potential for ecological impact are:

- Site preparation and clearance, including ground investigations, archaeological test trenching and fencing
- Removal of properties, boundaries, amenities
- Earthwork activity, including removal of topsoil, general earthworks and operation of construction traffic
- Construction of significant earthworks, including cuttings and rock cuttings (< 3m deep) and embankments (< 3m high)
- Construction of the new road, link roads and associated local road re-alignments, including provision of noise barriers, lighting, gantries signage, *etc*.
- Construction of new structures, including under and overbridges, culverts, a c.650m long bridge crossing of the River Corrib and its valley, a c.310m length of viaduct, and 2 separate sections of tunnel – one of c.270m length at Lackagh Quarry, and a second of c.240m length at Galway Racecourse.

8.4.2 Operational Phase

The main characteristics of the operation stage of the proposed road development that have potential for ecological impact are:

- The presence and operation (traffic) of the road
- The presence of additional roadside lighting

8.5 Evaluation of Impacts

8.5.1 Introduction

The following section presents the assessment of impacts on biodiversity within the Zone of Influence (ZoI) of the proposed road development. As outlined in **Section 8.2.5**, this is focussed on the Key Ecological Receptors (KERs) identified in **Section 8.3.14**. This includes consideration of the Do-Nothing impact – i.e. the existing trends with the potential to affect biodiversity in the absence of the proposed road development.

8.5.2 Do Nothing Impact

Existing trends

Across the study area, as evidenced from a review of historical orthophotos and the *Galway City Habitats Inventory* dataset (Natura, 2005), there have been changes to the biodiversity baseline in recent decades: the most significant change likely to have been habitat loss to development and habitat degradation impacts, primarily as a result of either agricultural intensification/reclamation or scrub encroachment through agricultural abandonment. The existing road network has limited drainage control or pollution control measures and, with increasing traffic numbers, may have had some effects on biodiversity in the receiving environment.

There have been habitat losses to development in the area between the Cappagh and Ballymoneen Roads, and along the network of local roads which extend north from the R336 coast road, e.g. Na Foraí Maola Road, Troscaigh Road, Bearna to Moycullen Road LL1321 and the Aille Road L5384. In some cases areas of peatland habitats have likely been affected. Where agricultural management has been reduced, or has been abandoned altogether, fields are becoming overgrown by gorse, bramble scrub and/or dense bracken cover. In places this is encroaching upon peatland habitat. This is most evident in the western part of the study area in those isolated peatland habitat blocks set between the network of local roads and the associated ribbon-type residential development. Sections of watercourses have been culverted as a consequence of development; the most extensive of which are associated with the Knocknacarra Stream. Coolough, Ardaun and Doughiska have seen losses of Limestone pavement [*8240] and most likely also areas of semi-natural grassland habitat [e.g. 6210] since 1994 as a result of road development, residential and industrial development, and agricultural land use change/improvement. Quarrying activities in the local area have resulted in the loss of limestone pavement and potentially also areas of calcareous grassland habitats since the year 2000. Scrub encroachment has also reduced the extent of exposed limestone pavement habitat area at Menlough, in the area between Bóthar Nua and Seanbóthar.

There is little historical baseline data to establish trends for fauna species locally although the habitat changes that have occurred may have had some effects, both positive and negative, on fauna biodiversity and distributions locally.

Likely Future Trends

As the full extent of the proposed road development passes through lands zoned under either the Galway City Council Development Plan 2017-2023, the Galway County Council Development Plan 2015-2021, the Bearna Local Area Plan 2007-2017, or the Ardaun Local Area Plan 2018-2024, the current land use zonings provide the best indication of what the future short to medium-term biodiversity trends might be, as they will influence and direct development in the surrounding area. It is also likely that traffic numbers will continue to increase on a road network with limited drainage control or pollution control measures, which may have effects on biodiversity receptors in the receiving environment.

The area around Sruthán na Líbeirtí is zoned for environmental management, as is the Trusky Stream corridor and the coastline – this zoning aims to protect areas of high biodiversity and promote sustainable development. An area east of Sruthán na Líbeirtí, and to the west of Bearna Woods, is zoned green wedge with the area in between zoned as rural fringe, these zonings limit the types of future development on those lands.

The area between Bearna Woods and the River Corrib is a mix of residential, amenity, agri-amenity and agriculture zonings. The lands between the proposed road development and the Cappagh Road are predominantly zoned residential, with some amenity and industrially zoned areas. Similarly, lands around NUIG and the N59 Moycullen Road are a mix of residential and amenity zonings. Sitting between both these areas is a large expanse of lands zoned for agriculture – which includes part of the Moycullen Bogs NHA at Tonabrocky. A second area at na hAille comprises both agricultural and agri-amenity land use zoning.

Between Menlough and the N83 Tuam Road, lands to the north of the proposed road development are largely zoned agricultural (in line with their current use) with a band of agri-amenity zoned lands extending from Menlough Village to Galway City along the east bank of the River Corrib. There is a small pocket of light-industrial and residential zoned lands along the N84 Headford Road, residential along the N83 Tuam Road and areas of light residential zoning at Menlough and adjacent to the southern end of Lackagh Quarry.

Aside from Galway Racecourse (which is zoned as an amenity area), lands between the N83 Tuam Road and the R339 are zoned for industrial, residential or commercial uses.

The majority of lands adjoining the proposed road development at Doughiska (east of the existing N6 and between the R446 and the R449) fall within what is the Ardaun Local Area Plan boundary. The *Ardaun Local Area Plan 2018-2026* includes large areas zoned for development. West of the existing N6 in this area is largely zoned for residential development.

Current biodiversity trends are likely to continue in areas zoned for environmental management, green wedge, rural fringe or agriculture with some limited development and land use change likely. Amenity or agri-amenity zoned areas are likely to come under some level of increased pressure from developing and constructing additional recreational infrastructure and through increased human presence and disturbance. Areas zoned for residential, commercial or industrial purposes are likely to have the greatest effects on local biodiversity through habitat loss and/or modifications (potentially affecting Annex I and other semi-natural habitats) and any associated effects on fauna species.

However, any effects on biodiversity are likely to be moderated by the environmental protective policies in both the *Galway City Council Development Plan 2017-2023*, *Galway County Development Plan 2015-2021*, the *Bearna Local Area Plan 2007-2017*, and the *Ardaun Local Area Plan 2018-2024*.

The interaction between the existing trends, future trends, and other plans or projects with the proposed road development are considered and assessed further in the cumulative impacts section (Section 8.9).

8.5.3 Designated Areas for Nature Conservation

This section describes and assesses the potential for the proposed road development to result in likely significant effects on designated areas for nature conservation at cSACs/SACs, SPAs, NHAs or pNHAs. In the context of European sites this is focussed on the habitats and species for which the sites are selected (QIs for cSACs and SCIs for SPAs) and the conservation objectives supporting their conservation status in each site. This assessment is directly related to the assessment methodology for European sites required under the Habitats Directive, which is presented in the Natura Impact Statement (NIS) for the proposed road development.

In the case of NHAs and pNHAs the assessment considers whether the integrity[54] of any such site would be affected by the proposed road development with reference to the ecological features for which the site is designated, or is proposed.

8.5.3.1 European Sites

In the context of assessing whether the proposed road development is likely to result in an impact on the integrity of any European sites, the tests and assessment presented in the NIS fulfil this role. The NIS considers whether the proposed road development will affect the conservation objectives supporting the favourable conservation condition of the European site's QIs/SCIs and as a result presents an assessment of whether the integrity of any European sites would be affected – i.e. if the proposed road development would adversely affect on the integrity of a European site, this would constitute a likely significant effect in the context of the EIA Directive.

The nature and scale of the proposed road development, the identified potential impacts and their relationship to European sites were considered in order to determine which European sites were within the ZoI of the proposed road development, in view of best scientific knowledge and in view of conservation objectives, and therefore potentially at risk of the proposed road development affecting their conservation objectives. The potential impacts associated with the proposed road development are discussed below in relation to those European sites within its ZoI (see also Section 6 of the NIS).

[54] Refer to **Section 8.2.5** for definition and impact assessment methodology

The Zone of Influence (ZoI) is a distance within which the proposed works could potentially affect the conservation condition of QI habitats or QI/SCI species of a European site.

The mechanism to define the ZoI is summarised as follows:

- Consider the nature, size and location of the proposed road development
- Consider the sensitivities of the ecological receptors
- Identify impact sources and pathways
- Determine the ZoI based on the extent of the impact

Considering the ZoI, in the absence of mitigation measures, the proposed road development was assessed as having the potential to adversely affect the integrity of the following four European sites (refer to Section 8 of the NIS):

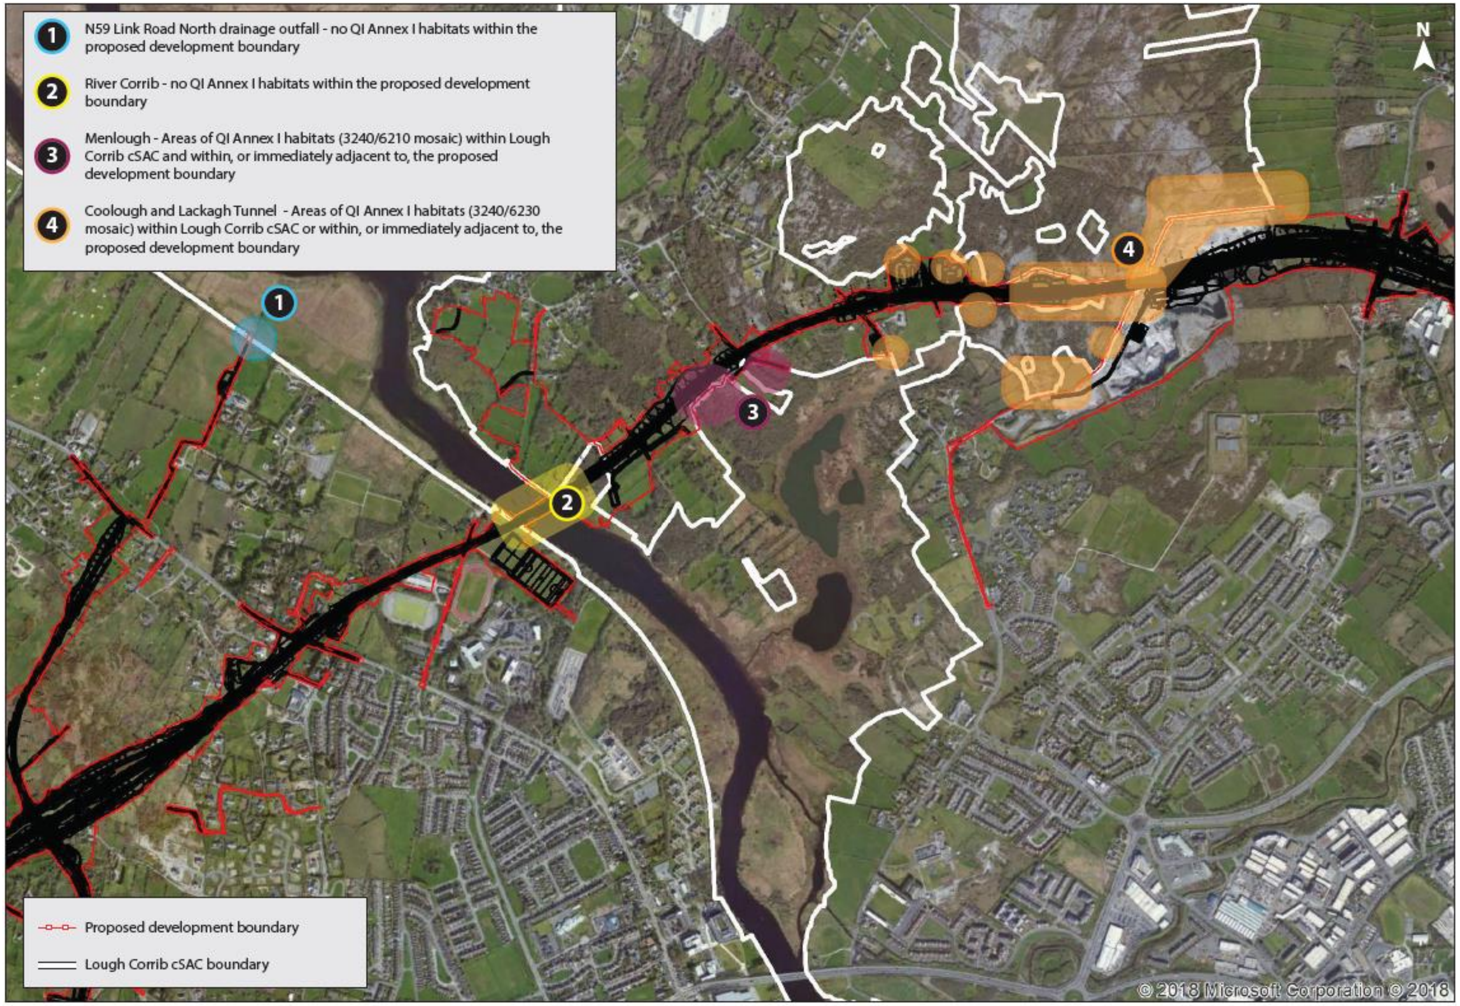
- Lough Corrib cSAC
- Lough Corrib SPA
- Galway Bay Complex cSAC
- Inner Galway Bay SPA

The locations of these European sites relative to the proposed road development, and the predicted ZoI, are shown on **Figure 8.12.1**.

Lough Corrib cSAC

The proposed road development and its boundary overlaps with, i.e. traverses through or adjacent to one Euroepean site, namely Lough Corrib cSAC at four locations: at the termination of the proposed drainage outfall from the N59 Link Road North at Kentfield; at the site of the proposed River Corrib Bridge between Dangan and Menlough; to the west of the Coolagh Lakes (Ch. 9+850 to Ch. 10+100); and, to the west and north of Lackagh Quarry where the proposed road development will consist of a tunnel (Lackagh Tunnel) and approach road infrastructure. Refer to **Plate 8.1** below. The proposed road development also traverses a number of groundwater bodies that support groundwater dependant wetland habitats within European sites and traverses a number of watercourses that lie within or drain to a Euorpean site.

Plate 8.1: Proposed Road Development overlap with European sites



The potential impacts to the Lough Corrib cSAC are discussed below under the following headings:

- Habitat loss
- Habitat degradation as a result of tunnelling/excavation associated with construction of the Lackagh Tunnel
- Habitat degradation as a result of hydrogeological impacts
- Habitat degradation as a result of hydrology impacts
- Habitat degradation as a result of air quality impacts
- Habitat degradation as a result of introducing/spreading non-native invasive plant species
- Mortality risk from construction works and road traffic

Habitat loss

There are no areas of QI Annex I habitats within Lough Corrib cSAC that lie beneath the footprint of the proposed road development or will be directly impacted. Neither will the proposed road development result in the direct loss of any habitats that support the QI habitats that are present in Lough Corrib cSAC. However, within Lough Corrib cSAC there are areas of the QI habitats Limestone pavement [*8240] and Calcareous grassland [6210] that lie within the proposed development boundary yet outside of the footprint of the proposed road developmnet which could be directly impacted, if not protected from construction works. With respect to these QI habitats and their conservation objectives, habitat loss could affect the habitat area of Calcareous grassland and Limestone pavement within Lough Corrib cSAC, and could also affect the distribution of these habitat types within the European site.

Habitat degradation as a result of tunnelling/excavations associated with construction of the Lackagh Tunnel

Construction of the Lackagh Tunnel could affect the structural integrity of the rock mass above, and result in damage to, or loss of, the QI Annex I habitats Limestone pavement and Calcareous grassland within Lough Corrib cSAC at the surfacce. With respect to these QI habitats and their conservation objectives, habitat loss could affect the habitat area of Calcareous grassland and Limestone pavement within Lough Corrib cSAC, and could also affect the distribution of these habitat types within the European site.

Habitat degradation as a result of hydrogeological impacts

The construction of the Lackagh Tunnel and the piers for Menlough Viaduct have the potential to affect the existing groundwater regime locally within the Lough Corrib Fen 1 (Menlough) GWB, the Lough Corrib Fen 1 (Lackagh) GWB and the Clare-Corrib GWB. This in turn could affect the groundwater supply to the Western and Eastern Coolagh Springs that contributes groundwater to the Coolagh Lakes and the associated QI wetland habitats in Lough Corrib cSAC[55]. With respect to the QI habitats and species and their conservation objectives, this impact could affect:

- The natural hydrological regime (e.g. water levels and flooding) and water chemistry
- The area, local distribution and condition of groundwater dependant wetland habitat
- The vegetation composition, diversity, structure and distribution, the abundance and distribution of typical and locally distinctive species associated with QI habitats

The drainage design of the proposed road development avoids any long-term impacts to the existing groundwater regime that could affect any of the groundwater dependant habitats in Lough Corrib cSAC. However, mitigation measures are required in the event that any groundwater conduits are encountered during construction and to ensure that karst features do not affect the functioning of the infiltration basins during operation.

Habitat degradation as a result of hydrological impacts

The proposed road development could affect surface water quality in the receiving environment which supports aquatic/wetland habitats within Lough Corrib cSAC. These habitats in turn support the QI aquatic species present: Otter, Atlantic salmon, Sea lamprey and Brook lamprey. With respect to the QI habitats and species and their conservation objectives, this impact could affect:

- Habitat area, distribution and condition/quality, along with vegetation composition, diversity, structure and distribution, and the abundance and distribution of typical and locally distinctive species
- Fish populations (including Atlantic salmon) through affecting fish numbers, population structure and habitat quality, which can also affect recruitment in the Freshwater pearl mussel populations upstream
- Otter abundance and distribution, prey abundance and the availability of holt and couch sites

Habitat degradation as a result of air quality impacts

Dust deposition arising from construction activities could locally affect the extent, diversity, and vegetation composition or structure of habitats within Lough Corrib cSAC that are present in the vicinity of the proposed road development.

[55] The Western Coolagh Spring is the main contributor to the Coolagh Lakes with a substantial groundwater supply through the underlying limestone bedrock. The Eastern Coolagh Spring only contributes a very small amount of surface water flow as any groundwater seepage to this spring is from the subsoil clays.

Habitat degradation as a result of introducing/spreading non-native invasive plant species

Introducing/spreading non-native invasive plant species could locally affect the extent, diversity, and vegetation composition or structure of habitats within Lough Corrib cSAC.

Mortality risk from construction works and road traffic

Constructing a bridge over the River Corrib poses a mortality risk to aquatic species beneath in the river; albeit a low level risk of having any long-term population level effects, given the temporary nature of the proposed works.

Operation of the proposed road development present a permanent risk of Otter mortality along the River Corrib corridor, and in the vicinity of the Coolagh Lakes, due to road traffic collisions and could have long-term effects on the Otter population of Lough Corrib cSAC.

Refer also to Table 9.16 and Table 9.17 in the NIS for how these impacts relate to the QI habitats and species and the specific conservation objectives of each QI potentially affected by the proposed road development.

Lough Corrib SPA

As the proposed road development does not traverse the SPA, none of the SCI species, or their supporting habitats within the SPA, are directly impacted by the proposed road development.

However, there are the following impacts by which the proposed road development could (in the absence of mitigation measures) affect the SCI bird species of Lough Corrib SPA and their supporting wetland habitats:

- Habitat degradation as a result of hydrogeological impacts
- Habitat degradation as a result of hydrological impacts
- Disturbance/displacement

Habitat degradation as a result of hydrogeological impacts

The proposed road development could affect the groundwater quality at potential ex-situ sites used by wintering bird species listed as SCIs for Lough Corrib SPA. This impact could affect the type, quality and extent of suitable habitat available to SCI bird species at ex-situ sites which lie within the hydrogeological ZoI. This impact could affect the type, quality and extent of suitable habitat available to SCI bird species locally and therefore, the number and range of areas available to the SPAs SCI bird populations and could have effects on their long-term population trends.

The design of the proposed road development avoids any long-term impacts to the existing groundwater regime that would affect any of the potential ex-situ sites used by SCI listed wintering birds. However, mitigation measures are required in the event that any groundwater conduits are encountered during construction and to ensure that karst features do not affect the functioning of the infiltration basins during operation.

Habitat degradation as a result of hydrological impacts

The proposed road development could affect the quality of surface water in the receiving environment which supports freshwater and wetland habitats at potential ex-situ sites used by SCI birds species of Lough Corrib SPA (Ballindooley Lough in particular). This impact could affect the type, quality and extent of suitable habitat available to SCI bird species locally and therefore, the number and range of areas available to the SPAs SCI bird populations and could have effects on their long-term population trends.

Disturbance/displacement

Long-term blasting in the vicinity of Ballindooley Lough could displace SCI listed bird species from this site for one or more winter seasons. Displacing SCI bird species from Ballindooley Lough, an important local site for some of the wintering bird species listed as SCIs for Lough Corrib SPA, could potentially negatively affect the long-term population trends of wintering SPA population.

The following, are the bird species listed as SCIs for Lough Corrib SPA which were recorded within the ZoI of the proposed road development and are therefore, at risk of significant effects: Shoveler, Tufted duck, Hen harrier, Coot, Golden plover, Black-headed gull, Common gull and Common tern. Wetlands are also listed as an SCI and could also be affected by the proposed road development. None of the other SCIs are at risk of impacts from the proposed road development as they are not present within the ZoI of the proposed road development.

Refer also to Table 9.30 and Table 9.31 in the NIS for how these impacts relate to the SCI species and the specific conservation objectives of each SCI potentially affected by the proposed road development.

Galway Bay Complex cSAC

As the proposed road development does not traverse Galway Bay Complex cSAC, none of the QI habitats or species will be directly impacted by the proposed road development and there is no risk of direct habitat loss or habitat fragmentation or direct mortality risk to QI species within the European site. Galway Bay Complex cSAC is also beyond the ZoI of any air quality or hydrogeological effects from the proposed road development. There is also no risk of disturbance associated with either construction or operation of the proposed road development affecting Otter or Harbour seal populations within Galway Bay Complex cSAC.

However, there are the following impacts by which the proposed road development could (in the absence of mitigation measures) affect the QI habitats and species of Galway Bay Complex cSAC:

- Habitat degradation as a result of hydrological impacts
- Habitat degradation as a result of introducing/spreading non-native invasive plant species
- Barrier effect
- Mortality risk

Habitat degradation as a result of hydrological impacts

The proposed road development could affect surface water quality in the receiving environment which supports freshwater, wetland and marine habitats, within Galway Bay Complex cSAC. These habitats in turn support Otter and the Harbour seal. With respect to the QI habitats and species and their conservation objectives, this impact could affect:

- The structure, extent and distribution of intertidal and marine communities associated with QI habitats
- The number and extent of typical plant and animal species associated with QI habitats
- Habitat area and distribution along with the vegetation structure and composition
- Otter prey abundance and the availability of holt and couch sites
- The condition of Harbour seal breeding and haul out sites

Habitat degradation as a result of introducing/spreading non-native invasive plant species

Introducing/spreading non-native invasive plant species could affect the extent, distribution, extent and diversity of Calcareous grassland habitats around Rusheen Bay and also affect the structure and composition of the vegetation.

Barrier effect

Introducing new culverts on watercourses within the Bearna Stream catchment may present a barrier to Otter movement throughout that catchment, potentially affecting the Otter population of Galway bay Complex cSAC.

Mortality risk

Introducing new road crossings on watercourses within the Bearna Stream catchment increases the risk of road traffic collisions with Otter, potentially affecting long-term population trends of the Otter population of Galway bay Complex cSAC.

Refer also to Table 9.23 and Table 9.24 in the NIS for how these impacts relate to the QI habitats and species and the specific conservation objectives of each QI potentially affected by the proposed road development.

Inner Galway Bay SPA

As the proposed road development does not cross the SPA, none of the SCI species, or their supporting habitats within the SPA, are directly impacted by the proposed road development. At its nearest point, the proposed road development is more than 1km from the SPA boundary and therefore, there is no risk of disturbance/displacement of SCI birds from habitats within the SPA.

However, there are the following impacts by which the proposed road development could (in the absence of mitigation measures) potentially affect the SCI bird species of Inner Galway Bay SPA and their supporting wetland habitats:

- Habitat degradation as a result of hydrogeological impacts
- Habitat degradation as a result of hydrological impacts
- Disturbance/displacement

Habitat degradation as a result of hydrogeological impacts

The proposed road development could affect the groundwater quality at potential ex-situ sites used by wintering bird species listed as SCIs for Inner Galway Bay SPA. This impact could affect the type, quality and extent of suitable habitat available to SCI bird species at ex-situ sites which lie within the hydrogeological ZoI. This impact could affect the type, quality and extent of suitable habitat available to SCI bird species locally and therefore, the number and range of areas available to the SPAs SCI bird populations and could have effects on their long-term population trends.

The design of the proposed road development avoids any long-term impacts to the existing groundwater regime that would affect any of the potential ex-situ sites used by SCI listed wintering birds. However, mitigation measures are required in the event that any groundwater conduits are encountered during construction and to ensure that karst features do not affect the functioning of the infiltration basins during operation.

Habitat degradation as a result of hydrological impacts

The proposed road development could affect the quality of surface water in the receiving environment which supports freshwater, wetland and marine habitats, within Inner Galway Bay SPA and at potential ex-situ sites used by SCI birds species (Ballindooley Lough in particular). This impact could affect the type, quality and extent of suitable habitat available to SCI bird species locally and therefore, the number and range of areas available to the SPAs SCI bird populations and could have effects on their long-term population trends.

Disturbance/displacement

Long-term blasting in the vicinity of Ballindooley Lough could displace SCI listed bird species from this site for one or more winter seasons. Displacing SCI bird species from Ballindooley Lough, an important local site for some of the wintering bird species listed as SCIs for Inner Galway Bay SPA, could potentially negatively affect the long-term population trends of wintering SPA population.

As Galway Bay lies downstream of the proposed road development, and lies within its ZoI, all bird species listed as SCIs for Inner Galway Bay SPA are at risk from impacts associated with the proposed road development: Great northern diver, Cormorant, Grey heron, Light-bellied brent goose, Wigeon, Teal, Shoveler, Red-breasted merganser, Ringed plover, Golden plover, Lapwing, Dunlin, Bar-tailed godwit, Curlew, Redshank, Turnstone, Black-headed gull, Common gull and Common tern. Wetlands are also listed as an SCI and could also be affected by the proposed road development.

Refer also to Table 9.37 and Table 9.38 in the NIS for how these impacts relate to the SCI species and the specific conservation objectives of each SCI potentially affected by the proposed road development.

8.5.3.2 Natural Heritage Areas and proposed Natural Heritage Areas

Considering the ZoI of the proposed road development, in the absence of mitigation measures the proposed road development has the potential to have a likely significant effect upon the following three NHAs/pNHAs:

- Lough Corrib pNHA
- Moycullen Bogs NHA
- Galway Bay Complex pNHA

The locations of these designated areas for nature conservation relative to the proposed road development, and the predicted ZoI, are shown on **Figure 8.13.1**.

8.5.3.2.1 Moycullen Bogs NHA

The proposed road development lies immediately adjacent to Moycullen Bogs NHA at Tonabrocky. This portion of the NHA consists of a mosaic of Lowland blanket bog (PB3) which included the Annex I habitats Blanket bog [*7130] and *Rhynchosporion* depressions [7150], Wet heath (HH3) which corresponded with the Annex I habitat Wet heath [4010], Transition mire (PF3) which corresponded with the Annex I habitat Transition mires [7140], Dry heath (HH1) which corresponded with the Annex I habitat Dry heath [4030] and Scrub (WS1).

Habitat Degradation – Air Quality

Emissions from car exhausts, and the deposition of particulate matter and heavy metals produced by engine, brake and tyre wear, can contribute to increased deposition of pollutants such as oxides of nitrogen (NO_X, NO_s), volatile organic compounds (VOCs), particulate matter (PM), heavy metals (HM) and ammonia (NH_4) in the vicinity of a road carriageway. This can affect the ecosystems and vegetation present, influencing plant growth rates and species composition, diversity, and abundance.

The current understanding of air quality impacts from roads and their interaction/effects on ecology are set out in the TII guidance document *Guidelines for the Treatment of Air Quality During the Planning and Construction of National Road Schemes* (National Roads Authority, 2011) and two UK reports: *The Ecological Effects of Diffuse Air Pollution from Road Transport* (Bignal et al., 2004) and *The Ecological Effects of Air Pollution from Road Transport: An Updated Review* (Natural England, 2016).

Although carbon monoxide (CO), carbon dioxide (CO_2) and sulphur dioxide (SO_2) are generated by vehicles they are not currently thought to be of importance in terms of contributing to air quality impacts to vegetation and are not discussed further (Bignal et al., 2004; Natural England, 2016).

Construction Impacts

Dust emissions associated with construction works could, in extreme circumstances, affect adjoining habitats, potentially burying sensitive habitats or plant species. Best practice construction methodologies (e.g. watering of the construction site/access roads and road cleaning) and mitigation measures (dust screens during construction – see **Section 8.6.3**) have been designed to minimise construction generated dust and to contain it within the proposed development boundary.

Operational Impacts

NOx, NOs and NH3

Air quality modelling of NO_x concentrations and deposition rates were calculated along the proposed road development at distances up to 200m from the proposed road development (refer to **Section 16.5.4** of **Chapter 16, Air Quality and Climate** for details). The Air Quality Standards Regulations (AQS) 2011 (S.I. No. 180 of 2011) have a limit value of 30µg/m^3 for the protection of vegetation.

In the majority of areas, the worst-case predicted annual average NO_x concentrations at various distances from the proposed road edge comply with the limit value of 30µg/m^3 for the Do-Something scenario, in 2024 and in 2039, including background concentrations. This includes the areas adjacent to the boundary of Moycullen Bogs NHA, where the road edge lies 40m from the NHA boundary. Predicted concentrations are in compliance with the Air Quality Standard for the protection of vegetation (limit value of 30µg/m^3). Therefore, even at 10m from the proposed road edge, harmful effects on vegetation from NO_x are not likely.

The contribution of the proposed road development to the NO_2 dry deposition rate along a 200m transect from the proposed road edge is well below the critical load for the lower boundary limit of inland and surface water habitats of 5-10 Kg(N)/ha/yr (National Road Authority, 2011) and therefore, harmful effects on vegetation within Moycullen Bogs NHA from NO_2 are not likely.

Ammonia (NH_3) is emitted in small amounts by vehicles but atmospheric concentrations are well below critical levels for this pollutant (Bignal et al., 2004 and Natural England, 2016) and therefore, effects on vegetation within Moycullen Bogs NHA from ammonia are not likely.

Volatile Organic Compounds (VOCs)

In terms of volatile organic compounds (VOCs), modelled benzene concentrations are well below the air quality standard of 5µg/m^3 for the protection of human health and the environment as a whole (refer to **Section 16.5.4** of **Chapter 16, Air Quality and Climate** for details). Comparisons of emission factors of VOCs (mg/vehicle/km) have been examined in order to estimate an appropriate ratio of ethylene to benzene. The highest ratio of ethylene to benzene determined was 3:1, for vehicles which were primarily diesel emissions. Increases in ethylene from the proposed road development have been predicted using this ratio and the predicted levels were low at 10m from the proposed road edge (refer to **Section 16.5.4** of **Chapter 16, Air Quality and Climate** for details). No background data is available for ethylene. There is little evidence of ecological damage by vehicle related VOCs and given the low concentrations predicted, no impacts on vegetation within Moycullen Bogs NHA are likely.

Partiulate Matter and Heavy Metals

Heavy metals from car emissions are associated with emissions of Particulate Matter, PM_{10} (particulate matter less than 10µm) and $PM_{2.5}$ (particulate matter less than 2.5µm). An assessment of emissions of PM_{10} and $PM_{2.5}$ was prepared in accordance with TII guidelines using the DMRB modelling spreadsheet. Predicted concentrations are compared to the air quality standard of 40µg/m3 and 25µg/m3 respectively for the protection of human health and the environment as a whole. The maximum predicted concentrations along the route of the proposed road development for the Do-Something scenario, including background concentrations, were well below these standards (refer to **Chapter 16, Air Quality and Climate** for details).

Particulate matter (PM) and heavy metals (HM) decay at an exponential rate with distance from a road and the highest concentrations are generally present within 20-30m. Given the 20-30m zone within which the majority of PM/HM would be deposited, that Moycullen Bogs NHA lies c.40m from the proposed road edge, the low concentrations predicted, and dispersion due to wind, impacts on vegetation within the NHA from PM or HM are not likely.

Conclusion

During operation, air quality impacts from the proposed road development on vegetation within Moycullen Bogs NHA are not likely to occur and will not result in a likely significant negative effect, at any geographic scale.

Habitat Degradation – Non-native Invasive Plant Species

Planting, dispersing, or allowing/causing the dispersal, spread or growth of certain non-native plant species is controlled under Article 49 of the European Communities (Birds and Natural Habitats) Regulations, 2011; and refers to plant or animal species listed on the Third Schedule of those regulations (see also **Section 8.3.6**).

As the proposed road development lies immediately adjacent to the boundary of Moycullen Bogs NHA, the accidental spread of such non-native invasive plant species as a result of construction works has the potential to have long-term impacts upon habitat areas within the NHA; potentially affecting plant species composition, diversity and abundance.

Introducing any of these non-native invasive plant species to Moycullen Bogs NHA has the potential to result in a likely significant negative effect, at a national geographic through affecting habitat area and quality within the NHA. Mitigation measures have been designed to avoid this impact (see **Section 8.6.6**).

Habitat Degradation – Hydrogeology

Moycullen Bogs NHA is beyond the hydrogeological ZoI of the proposed road development (**Figures 10.7.1** to **10.7.14**, **10.8.1** to **10.8.14**, **10.9.1** to **10.9.14** and **10.10.1** to **10.10.14**) both in terms of the potential for impacts on groundwater quantity and/or groundwater quality that support the habitats therein. Therefore, the proposed road development cannot impact on any habitats or species within Moycullen Bogs NHA as a consequence of any impacts on the existing hydrogeological regime and is not likely to have a significant effect on the NHA in that regard.

Habitat Degradation – Surface Water Quality

During construction, contaminated surface water runoff and/or an accidental spillage or pollution event has the potential to have a significant negative effect on habitats and species in the adjoining Moycullen Bogs NHA. The effects of frequent and/or prolonged pollution events in a peatland complex have the potential to be extensive and far-reaching and could potentially have significant long-term effects.

However, it is considered unlikely that a pollution event of such a magnitude would occur during construction, or be any more than temporary in nature. Nevertheless, a precautionary approach is being taken in assuming a level of risk of water quality impacts. Consequently, detailed mitigation measures have been designed to further minimise the risk of the proposed road development having any perceptible effect on habitat quality in Moycullen Bogs NHA during construction (see **Section 8.6.4**).

Habitat degradation as a consequence of construction effects on surface water quality has the potential to affect the peatland habitat complex, and the species it supports in Moycullen Bogs NHA and therefore, has the potential to result in a significant negative effect.

Overall, in the absence of mitigation the proposed road development has the potential to affect the integrity of, and therefore have a significant negative effect on, Moycullen Bogs NHA as a result of air quality, non-native invasive plant species and surface water quality impacts during construction, potentially at the national geographic scale at which this receptor is valued.

8.5.3.2.2 Lough Corrib pNHA and Galway Bay Complex pNHA

In the case of Galway Bay Complex pNHA, which is remote from the proposed development boundary, the potential impact pathways connecting the proposed road development to Galway Bay are as presented and assessed in the NIS for Galway Bay Complex cSAC and Inner Galway Bay SPA (and summarised in **Section 8.5.3.1** above). As the proposed road development has the potential to adversely affect the integrity of Galway Bay Complex cSAC and Inner Galway Bay SPA, and hence the receiving marine environment in Galway Bay, it also has the potential to have a significant negative effect on Galway Bay Complex pNHA.

In relation to Lough Corrib pNHA, the potential impact pathways connecting the proposed road development to the pNHA site are also as per those presented above in **Section 8.5.3.1** and in the NIS for Lough Corrib cSAC and Lough Corrib SPA. However, the zone within which the proposed road development directly interacts with Lough Corrib pNHA is much smaller than that associated with Lough Corrib cSAC, and only includes the main river channel and banks. As the proposed road development has the potential, in the absence of mitigation measures, to adversely affect the integrity of Lough Corrib cSAC and Lough Corrib SPA, it also has the potential to affect the integrity of, and therefore have a significant negative effect on, Lough Corrib pNHA.

The proposed road development also has the potential to affect biodiversity in a broader sense than just the QIs/SCIs of those European sites. Where biodiversity receptors in Lough Corrib pNHA or Galway Bay Complex pNHA do not form part of the QIs/SCIs in the NIS assessment, they are considered under the other individual impact assessment headings for each KER below.

8.5.4 Habitats

This section assesses the potential impact of the proposed road development on habitats. Its focus is on habitat impacts outside designated areas for nature conservation which are discussed separately in **Section 8.5.3**, and detailed in the NIS.

In terms of quantifying the magnitude of effects for both Annex I and non-Annex I habitats, the estimated percentage of the local habitat resource being affected is based upon the total area of a given habitat type that was recorded within the scheme study area, regardless of whether it was within a designated area for nature conservation or not. This provides some local context as to the magnitude of the habitat loss and whether the impact is significant or not, and at what geographic scale.

8.5.4.1 Construction Phase Impacts

Habitat Loss & Fragmentation

The construction of the proposed road development will result in habitat loss across its length, totalling approximately 280ha. Some of the habitat types directly affected are considered to be of International/National importance, given their priority Annex I/Annex I status under the Habitats Directive. In the western part of the study area the Annex I habitats affected are Dry heaths [4030], Wet heath [4010], *Molinia* meadows [6410] and Blanket bog (active) [*7130]. East of the River Corrib the Annex I habitat types affected are Limestone pavement [*8240], Calcareous grassland [6210], Residual alluvial forests [*91E0], Turloughs [*3180], Petrifying springs [*7220] and *Molinia* meadows [6410]. These cover an area of approximately 8.8ha.

Other habitat types considered to be of a Local Importance (higher value) will also be lost as a result of the proposed road development. These include hedgerows (WL1), treelines (WL2), sections of stream/river channel (FW1), grasslands (GS1, GS2, GS3 and GS4), woodlands (WD1 and WN2) and scrub (WS1). These cover an area of approximately 75.5ha[56].

The remaining areas of habitat within the proposed development boundary (c.196ha) are made up of habitats of a Local Importance (lower value). This is

[56] Although some of the local importance habitats types (both higher and lower value) will be directly affected within Lough Corrib cSAC (e.g. WD1, WN2 and BL3) none of these habitat types are QIs, or support QI habitats or species, and losses of these habitat types within Lough Corrib cSAC will not affect the site's conservation objectives

primarily made up c.76ha of Improved agricultural grassland (GA1), c.32ha of Buildings and artificial surfaces (BL3), c.18ha of Spoil and bare ground (ED2), c.17ha of Dry calcareous and neutral grassland (GS1), c.14ha of Dense bracken (HD1), c.10ha of residential properties and c.9ha of Amenity grassland (improved) (GA2). Flower beds and borders (BC4), Recolonising bare ground (ED3), Other artificial lakes and ponds (FL8), Dry meadows and grassy verges (GS2), Dry-humid acid grassland (GS3), Wet grassland (GS4) and Ornamental/non-native shrub (WS3) make up the remainder.

The various KER habitat types affected, and the areas involved, are summarised below in **Table 8.27**. These calculations include all KER habitat areas within the proposed development boundary, as the possibility of areas within the proposed development boundary but outside of the footprint of the proposed road development itself being affected by construction activities cannot be ruled out.

Habitat loss may also lead to habitat fragmentation in many instances; creating new divisions of existing habitat blocks or contributing to an existing trend of fragmenting semi-natural habitat blocks — as has been happening to some areas of upland habitat in the western part of the study area, as a result of other development.

In the assessment below, where reference areas are used to calculate the percentage habitat loss of areas of Local Importance (higher value) these include areas that correspond with Annex I habitat types (where applicable).

The mitigation measures that have been designed to avoid or reduce the effects of direct impacts to habitats are in **Section 8.6.2**.

Table 8.27: KER habitat types within the proposed development boundary

Habitat type	Extent[57]
International Importance	
Turlough [*3180]	One (c.0.04ha of c.0.1ha is within fenceline)
Petrifying springs [*7220]	One feature
Residual alluvial forests [*91E0]	c.0.1ha
Limestone pavement [*8240]	c.2.3ha[58]
National Importance	
Wet heath [4010]	c.1.22ha
Wet heath/Dry heaths mosaic [4010/4030]	c.0.7ha
Dry heaths [4030]	c.1.96ha
Wet heath/Dry heath/*Molinia* meadow [4010/4030/6410]	c.0.43ha
Calcareous grassland [6210]	c.1.14ha
Molinia meadow [6410]	c.1.02ha

[57] This includes either a measure of habitat area (ha), linear length of habitat lost (m/km), or a total number of point features affected (e.g. spring/seepage sites), as appropriate.
[58] Some of the Limestone pavement habitat within the proposed development boundary lies within Lough Corrib cSAC – some of which also included areas of Calcareous grassland [6210] in a mosaic.

Habitat type	**Extent[57]**
Limestone pavement/Calcareous grassland mosaic [*8240/6210]	c.0.12ha
Local Importance (higher value)	
Calcareous springs (FP1)	Fifteen features
Reed and large sedge swamps (FS1)	c.0.14ha
Tall-herb swamp (FS2)	c.0.03ha
Eroding/upland rivers (FW1)	c.120m of Sruthán na Líbeirtí c.220m of the Trusky Stream c.140m of the Bearna Stream (and tributary) c.475m of the Tonabrocky Stream see **Section 8.5.4.3** for more details
Drainage ditches (FW4)	c.0.12ha
Marsh (GM1)	c.0.2ha
Dry calcareous and neutral grassland (GS1)	c.13.7ha
Dry calcareous and neutral grassland/Scrub mosaic (GS1/WS1)	c.1.55ha
Dry meadows and grassy verges (GS2)	c.8.2ha
Dry-humid acid grassland (GS3)	c.7.81ha
Wet grassland (GS4)	c.11.14ha
Poor fen and flush (PF2)	c.0.13ha
(Mixed) broadleaved woodland (WD1)	c.4.25ha
Mixed broadleaved/conifer woodland (WD2)	c.0.03ha
(Mixed) conifer woodland (WD3)	c.0.01ha
Oak-ash-hazel woodland (WN2)	c.4.18ha
Scrub (WS1)	c.21.12ha
Scrub/ Dry meadows and grassy verges (WS1/GS2)	c.1.47ha
Scrub/Oak-ash-hazel woodland/ Exposed calcareous rock (WS1/WN2/ER2)	c.1.3ha
Hedgerows (WL1)	c.7.8km
Treelines (WL2)	c.4km

Habitat Degradation – Surface Water Quality

During construction, contaminated surface water runoff and/or an accidental spillage or pollution event into any surface water feature has the potential to have a significant negative impact on water quality and consequently affect aquatic and wetland habitats in the receiving environment. The effects of frequent and/or prolonged pollution events in a river system have the potential to be extensive and far-reaching and could potentially have significant long-term effects. In a worst-case scenario, estuarine and coastal habitats downstream could also be affected.

However, it is considered unlikely that a pollution event of such a magnitude would occur during construction, or be any more than temporary in nature. Nevertheless, a precautionary approach is being taken in assuming a level of risk of water quality impacts. Consequently, detailed mitigation measures are required to further minimise the risk of the proposed road development having any perceptible effect on water quality during construction.

Habitat degradation as a consequence of construction effects on surface water quality has the potential to affect the conservation status of aquatic, wetland or estuarine/marine habitats and therefore, has the potential to result in a significant negative impact.

The mitigation measures that have been designed to avoid or reduce the potential impacts of the proposed road development on surface water quality are presented in **Section 8.6.4**.

Habitat Degradation – Hydrological Regime

Construction works at the watercourse crossings along the proposed road alignment can have a temporary impact on the flow and flooding regime locally. None of these are predicted to have any long-term effects that would give rise to a likely significant negative effect on any aquatic habitats or species through effects on the hydrological regime (for more detail refer to **Section 11.5** of **Chapter 11, Hydrology**).

Habitat Degradation – Groundwater

Any effects on the existing hydrogeological baseline supporting lakes, turloughs, and wetland or peatland habitats has the potential to negatively impact upon habitat extent and distribution, and vegetation structure and composition. The potential effects of impacting upon the existing hydrogeological regime are not necessarily limited to habitats within the proposed development boundary but can be far-reaching, with significant negative long-term effects[59].

There will be no impacts to groundwater recharge rates during construction that will have any effect on biodiversity receptors. All groundwater intercepted by construction works will be managed and discharged within the same GWB and will remain within the surface water catchment that they would naturally have been received by. The groundwater recharge rate will not change in the Galway Granite Batholith aquifer (the area west of the N59 Moycullen Road) with only a temporary minor increase in the recharge rate (between 0.1m and 0.4m) in the Visean Undifferentiated Limestone aquifer (the area east of the N59 Moycullen Road). Although there will be some loss of aquifer volume in the Galway Granite Batholith aquifer and the Visean Undifferentiated Limestone aquifer, it will have an imperceptible impact on the groundwater resource (for more detail refer to **Section 10.5** of **Chapter 10, Hydrogeology**).

During construction, deep excavations or tunnelling are likely to interact with groundwater. As a consequence, construction works have the potential to affect groundwater levels from construction dewatering or drawdown associated with

[59] The potential hydrogeological ZoI of the proposed road development is shown on **Figures 10.7.1** to **10.7.14**, **10.8.1** to **10.8.14**, **10.9.1** to **10.9.14** and **10.10.1** to **10.10.14**.

excavations. There is also the potential that construction works could impact on groundwater flow paths or conduits, potentially affecting groundwater dependant or supported habitats and/or species. There is also a higher risk of impacts to groundwater quality through contaminated surface water runoff and/or an accidental spillage or pollution. As above in relation to surface water features, impacts on the groundwater could potentially have a significant negative effect on biodiversity.

Based on the findings of the hydrogeological impact assessment in **Chapter 10, Hydrogeology**, the proposed road development does not pose a risk to the groundwater supply to Ballindooley Lough. Nor does it pose a risk of affecting the turlough features at Menlough (c.320m north-west of Ch. 10+100), at Ballinfoyle c.190m south of Ch. 12+100, and at Ballindooley c.400m north of the N84 Headford Road Junction.

The proposed road development does however, have the potential to affect the groundwater supply to the Coolagh Lakes (which form part of the Lough Corrib cSAC) and the turlough located between Bóthar Nua and Seanbóthar (Ch. 10+320). Although the magnitude of the impact cannot be fully quantified, on a precautionary basis it is assessed as having the potential to affect water levels at these features and thereby, affect the supported aquatic and wetland habitats. The assessment of impacts relating to European sites are discussed separately in **Section 8.5.3.1**, and detailed in the NIS.

The proposed Menlough Viaduct will be constructed over the Turlough located between Bóthar Nua and Seanbóthar (Ch. 10+320). Although none of the supporting piers will be located within the Turlough, there is the potential for construction works to affect the supporting hydrogeological regime.

Habitat degradation as a consequence of construction effects on the existing groundwater resource and regime has the potential to affect the conservation status of groundwater dependant aquatic or wetland habitats and species and therefore, has the potential to result in a significant negative impact.

A more detailed description of how the proposed road development could affect the existing hydrogeological regime during construction is presented in **Chapter 10, Hydrogeology**.

The mitigation measures that have been designed to avoid or reduce the potential impacts of the proposed road development on groundwater are presented in **Section 8.6.5**.

Habitat Degradation – Air Quality

As discussed above in **Section 8.5.3.2**, the proposed road development has the potential to generate dust during construction works which could affect vegetation in habitat areas adjacent to the proposed development boundary. Mitigation measures have been designed to contain dust emissions during construction (see **Section 8.6.3**).

Habitat Degradation – Non-native Invasive Plant Species

Planting, dispersing, or allowing/causing the dispersal, spread or growth of certain non-native plant species is controlled under Article 49 of the European Communities (Birds and Natural Habitats) Regulations, 2011; and refers to plant or animal species listed on the Third Schedule of those regulations (see also **Section 8.3.6**).

The accidental spread of such non-native invasive plant species as a result of construction works has the potential to impact upon terrestrial habitats[60]; potentially affecting plant species composition, diversity and abundance over the long-term. This is not only confined to habitats within and immediately adjacent to the proposed development boundary but includes habitat areas along the network of proposed haul routes associated with the proposed road development (**Figure 7.101** to **7.118**).

The effects of introducing such non-native invasive plant species to highly sensitive and ecologically important habitat areas (e.g. designated area for nature conservation or areas of Annex I habitat) have the potential to result in a likely significant negative effect, at geographic scales ranging from local to international. Mitigation measures have been designed to avoid this potential impact (see **Section 8.6.6**).

Habitat Degradation – Tunnelling/Excavation

Tunnelling works or deep excavations have the potential to affect the structural integrity of the ground above a tunnel excavation, or that of the ground immediately adjacent to a deep cutting/excavation. This in turn can affect the habitats present.

This potential impact is only likely to arise in to the habitats present within Lough Corrib cSAC and either above the proposed Lackagh Tunnel or immediately adjacent to the cutting associated with the western approach to same. At this location, the overlying/adjoining habitats within Lough Corrib cSAC comprise a mosaic of wooded Limestone pavement [*8240], scrub covered Limestone pavement [*8240], exposed Limestone pavement [*8240], and Calcareous grassland [6210]. All of these habitat types are QI habitats of Lough Corrib cSAC. This assessment is discussed separately in **Section 8.5.3.1**, and detailed also in the NIS.

8.5.4.2 Operational Phase Impacts

Habitat Degradation – Surface Water Quality

During operation, there will be drainage outfalls to all river/stream catchments crossed by the proposed road development. Therefore, there is a risk that discharges from the road drainage network could affect water quality, potentially over the long-term, and consequently impact upon aquatic/wetland habitats. In a worst-case-scenario, this could result in long-term effects upon habitat extent and distribution, vegetation structure and composition.

[60] Non-native invasive aquatic plant species (or fauna species) were not recorded in the aquatic habitats which will be impacted by construction works.

The proposed drainage design consists of a petrol interceptor followed by attenuation and constructed wetland (where drainage will be discharged to the existing surface water/drainage network)—as described in detail in **Section 5.5.4.8** of **Chapter 5**, **Description of Proposed Road Development**. The drainage design, along with the design of any culverts associated with the proposed road development and any stream/river realignments, also ensures that during operation there will not be any perceptible impacts on the functioning of the existing hydrological regime (e.g. flood risk, flow rates or river morphology).

Habitat degradation as a consequence of operational effects on surface water is not predicted to affect the conservation status of any aquatic, wetland or estuarine/marine habitats and will therefore, not result in a likely significant effect, at any geographic scale.

Habitat Degradation – Groundwater

There will be no impacts to groundwater recharge rates during construction that will have any effect on biodiversity receptors as all groundwater intercepted by the road drainage will be discharged to the same GWB. The infiltration basins will lead to local increases in the groundwater table but overall there will be no net change to the groundwater resource.

There will be no active dewatering, of the bedrock aquifer, required during the operation phase but passive dewatering, of the bedrock aquifer, will occur at a number of cutting locations and the drainage associated with the proposed road development will cause the groundwater levels to adjust locally. This impact on the hydrogeological regime has the potential to affect the conservation status of groundwater dependant aquatic or wetland habitats and species and therefore, has the potential to result in a significant negative impact.

Impacts to groundwater quality could be caused by discharging contaminated road runoff to ground or where leachate/runoff from limestone fill could affect the pH of acidic groundwater along the western section of the proposed road development.

The proposed drainage design consists of a petrol interceptor followed by attenuation and infiltration ponds (where discharging to ground) — as described in detail in **Section 5.5.4.8** of **Chapter 5, Description of Proposed Road Development**. The functioning and effectiveness of the proposed road drainage network are discussed in more detail in **Chapter 11, Hydrology**. The drainage design, including the design of the infiltration basins, minimises the risk of a pollution event during operation affecting groundwater quality. Risk of spillage is low (<0.5%) and any impacts that do accidentally occur will be temporary. However, it is important that they are inspected to ensure that karst features do not affect the functioning of the infiltration basins during operation. If this is identified during routine inspections of the infiltration basins then mitigation is required to ensure any issues are addressed so that they continue to function as designed over the design life of the proposed road development

Local impacts to the local water chemistry, in terms of pH change, may apply where limestone derived alkaline material is placed over granite bedrock. Surface water run-off, interflow or groundwater movements through such material has the potential to impact local areas of peatland habitats by changing the pH of the recharge water particularly where this alkaline material is saturated (below the groundwater table). This potential impact will only apply to adjacent peatland habitats within hydrogeological Zone of influence of the proposed road development. The use of limestone based road material for the pavement and capping layers does not pose such a risk as these layers will be protected from direct surface water and groundwater infiltration and are located in the unsaturated zone above the groundwater table. This protection is provided by the road bitumen surface and the use of native topsoil capping along the grass verge and embankment sections of the proposed road development. Restriction on the use of limestone derived formation material will apply locally to road sections in the vicinity of peatland habitats within the granite bedrock area (west of the existing N59 Moycullen Road).

A more detailed description of how the proposed road development could affect the existing hydrogeological regime during construction is presented in **Chapter 10, Hydrogeology**.

The mitigation measures that have been designed to avoid or reduce the potential impacts of the proposed road development on groundwater are presented in **Section 8.6.5**.

Habitat Degradation – Shading

There are two elevated structures associated with the proposed road development which will have some level of shading effect on the habitats beneath during operation: the proposed River Corrib Bridge (Ch. 8+850 to Ch. 9+500) and the proposed Menlough Viaduct (Ch. 10+100 to Ch. 10+420). The retaining wall along the southern edge of the proposed road carriageway between Ch. 9+840 and Ch. 10+025 also has the potential to cause a shading effect on adjacent habitats. Shading effects include both a reduction in sunlight and a reduction in direct precipitation reaching plants beneath the bridge structure, affecting species communities, diversity and distribution. This potential impact will only arise in situations where habitats are being retained beneath the structure, as opposed to where habitats will be permanently lost as a result of construction works.

Habitat Degradation – Non-native Invasive Plant Species

Given the presence of non-native invasive plant species listed on the Third Schedule of the European Communities (Birds and Natural Habitats) Regulations, 2011 in the immediate vicinity of the proposed road development, there is the potential that these species will recolonize vegetated areas within the proposed development boundary post-construction. As such, there is a risk that routine maintenance works may inadvertently spread contaminated vegetation cuttings.

The effects of introducing such non-native invasive plant species to highly sensitive and ecologically important habitat areas (e.g. designated areas for nature conservation or areas of Annex I habitat) have the potential to result in a significant negative effect, at geographic scales ranging from local to international. Mitigation measures have been designed to avoid this potential impact (see **Section 8.6.6**).

Habitat Degradation – Air Quality

NO_x, NO_s and NH_3

Air quality modelling of NO_x concentrations and deposition rates were calculated along the route of the proposed road development at distances up to 200m from the proposed road development (refer to **Chapter 16, Air Quality and Climate** for details). The Air Quality Standards Regulations (AQS) 2011 (S.I. No. 180 of 2011) have a limit value of 30µg/m^3 for the protection of vegetation.

In the majority of areas, the worst-case predicted annual average NO_x concentrations at various distances from the proposed road edge comply with the limit value of 30 µg/m^3 for the Do-Something scenario, in 2024 and in 2039, including background concentrations. All predicted concentrations are in compliance with the Air Quality Standard for the protection of vegetation (limit value of 30µg/m^3). Therefore, even at 10m from the proposed road edge in these locations, harmful effects on vegetation from NO_x are not likely.

The exception is the zone between the N84 Headford Road and the N83 Tuam Road where, due to the higher predicted traffic numbers, the limit value of 30µg/m^3 is exceeded marginally within 10m of the proposed road edge (predicted NO_x concentrations of 30.53µg/m^3). This reduces to below the limit value by 20m. In this area, there are no sensitive ecological receptors (e.g. Annex I habitats) within 20m of the proposed road edge and harmful effects on vegetation in ecologically sensitive areas nearby are not likely.

The contribution of the proposed road development to the NO_2 dry deposition rate along the 200m transect from the proposed road edge is well below the critical load for the lower boundary limit of inland and surface water habitats of 5-10 Kg(N)/ha/yr (National Road Authority, 2011) and therefore, harmful effects on vegetation from NO_2 are not likely.

Ammonia (NH_3) is emitted in small amounts by vehicles but atmospheric concentrations are well below critical levels for this pollutant (Bignal et al., 2004 and Natural England, 2016) and therefore, effects on vegetation are not likely.

Volative Organic Compounds

In terms of volatile organic compounds (VOCs), modelled benzene concentrations are well below the air quality standard of 5µg/m^3 for the protection of human health and the environment as a whole (refer to **Section 16.5.4** of **Chapter 16, Air Quality and Climate** for details). Comparisons of emission factors of VOCs (mg/vehicle/km) have been examined in order to estimate an appropriate ratio of ethylene to benzene. The highest ratio of ethylene to benzene determined was 3:1, for vehicles which were primarily diesel emissions. Increases in ethylene from the proposed road development have been predicted using this ratio and the predicted levels were low at 10m from the proposed road edge (refer to **Section 16.5.4** of **Chapter 16, Air Quality and Climate** for details). No background data is available for ethylene. There is little evidence of ecological damage by vehicle related VOCs and given the low concentrations predicted, no significant impacts on vegetation along the proposed road development are likely.

Particulate Matter and Heavy Metals

Heavy metals from car emissions are associated with emissions of Particulate Matter, PM_{10} (particulate matter less than 10µm) and $PM_{2.5}$ (particulate matter less than 2.5µm). An assessment of emissions of PM_{10} and $PM_{2.5}$ was prepared in accordance with TII guidelines using the DMRB modelling spreadsheet. Predicted concentrations are compared to the air quality standard of 40µg/m^3 and 25µg/m^3 respectively for the protection of human health and the environment as a whole. The maximum predicted concentrations along the proposed road development for the Do-Something scenario, including background concentrations, were well below these standards (refer to **Section 16.5.4** of **Chapter 16, Air Quality and Climate** for details).

Particulate matter (PM) and heavy metals (HM) decay at an exponential rate with distance from a road and the highest concentrations are generally present within 20-30m. Given the 20-30m zone within which the majority of PM/HM would be deposited, the low concentrations predicted, and dispersion due to wind, significant impacts on vegetation from PM or HM along the proposed road development are not likely.

8.5.4.3 Impact Assessment on Habitats

Turloughs [*3180]

Turloughs (FL6) which corresponds with this Annex I habitat type

The structure proposed for the Menlough Viaduct passes over the Turlough at Ch. 10+320 and avoids any direct impacts. This retention of the Turlough habitat in this area is captured in the mitigation strategy (**Section 8.6**) and shown on **Figure 8.23.7**. Construction and the long-term presence of the piers, whilst not located within the Turlough, they are situated immediately adjacent to it, pose a risk to the supporting hydrogeological regime and may affect both the functioning of the Turlough and the vegetation community present. Construction works also pose a pollution risk to groundwater and surface water quality.

The presence of groundwater conduits connecting the infiltration ponds at Ch. 10+650 to Ch. 10+800 to the Turlough, and also in relation to the infiltration ponds at Ballindooley Lough (Ch. 12+200) is unknown. If groundwater conduits do connect road drainage to the turlough there is the potential for impacts which could affect the vegetation composition and diversity.

Accidentally introducing non-native invasive plant species into turlough habitat could also increase the extent and magnitude of road effects, degrading the habitat quality; as could dust deposition during construction. Air quality effects on turlough habitat during operation are not likely to affect plant species composition, diversity or abundance.

There is therefore a risk that the proposed road development could result in the loss of turlough habitat, or have long-term effects on plant species composition. Such an impact would constitute a negative effect on conservation status[61] and result in a likely significant negative effect, at the international geographic scale.

Petrifying springs [*7220]

Calcareous springs (FP1) which corresponds with this Annex I habitat type

Six Calcareous springs corresponding with the Annex I habitat Petrifying springs [*7220] were recorded in Lackagh Quarry (see **Figure 8.15.8**).

One of these Petrifying springs (at the location of the proposed access road c.30m south of the mainline at Ch. 11+380) will be directly affected by the proposed road development and will be permanently lost.

The next Petrifying spring feature to the north, which lies c.25m to the north of the mainline at Ch. 11+400, lies within the area where rock stabilisation measures are required as part of the construction of the eastern entrance to the Lackagh Tunnel (see **Chapter 9, Soils and Geology**). Although no impacts are predicted as a result of any effects on the existing hydrogeological regime during construction or operation (refer to **Chapter 10, Hydrogeology**), the installation of rock stabilisation measures here could potentially directly impact on this Petrifying spring and result in the permanent loss of this feature.

None of the other four Petrifying spring features will be directly impacted by the proposed road development or affected in any way through impacts to the existing hydrogeological regime, during either construction or operation.

Loss of Petrifying spring features, as priority Annex I habitats, has the potential to result in a significant negative effect at the national or international geographic scales but only where habitat impacts would affect the habitat's conservation status at those levels. In order for habitat area loss to affect a habitat's favourable conservation status at a national level, it must affect the national favourable reference area (FRA), as this is the reference value against which the area parameter is measured in the context of assessing conservation status.

---

[61] The methodology for determining effects on the conservation status on Annex I habitats at a national level is assessed under the headings of range, area, structure & function, and future prospects (NPWS 2013a, 2013b, 2013c). Under the area criterion, any loss of habitat area with respect to the Favourable Reference Range (FRA) results in the habitat moving from Favourable conservation status (if that is the baseline condition) to either Inadequate or Bad. If the baseline condition is either Inadequate or Bad, then additional habitat loss is adding to an existing decline and potentially inhibiting efforts to maintain or restore Annex I habitats at favourable conservation status at a national level. The FRA for any of the Annex I habitat types affected by the proposed road development are either estimates based on partial data, or values much greater than the current area based upon a statistically robust estimate—generally to account for historic losses or impacts Since the Habitats Directive came into force in 1994. The FRA are also not spatially defined. In applying the precautionary principle, due to the absence of a clearly defined FRA, the loss of any area of Annex I habitat is considered to be affecting conservation status at the geographic scale at which the particular Annex I habitat has been valued.
The same assessment methodology also applies when assessing conservation condition at a site level.

The FRA for this habitat type is defined as 0.139km^2 in NPWS (2013b) and it notes therein that "There is no evidence of decline in extent since the Directive came into force and therefore the current area is set as the Favourable Reference Area". The current FRA is based upon the data presented in NPWS (2013b) and as the 10km grid square within which the Petrifying springs affected by the proposed road development are located (M32) is not within the current Favourable Reference Range (FRR) of this habitat type, they cannot form part of the national FRA. Therefore, their loss cannot affect the conservation status of this habitat type at either the national or international geographic scales.

There is little data available as to the current number of Petrifying spring sites at the county level. However, considering the restricted range of this habitat type in County Galway (based upon the data presented in NPWS, 2013b) it is likely that the number of sites is restricted and the loss of even a single Petrifying spring is likely to be a significant negative effect, at the county geographic scale.

Residual alluvial forests [*91E0]

Wet willow-alder-ash woodland (WN6) which corresponds with this Annex I habitat type

The proposed road development will result in the permanent loss of approximately 0.1ha of Residual alluvial forest habitat. This equates to approximately 0.73% of this Annex I habitat type mapped within the scheme study area. Although, given the expanse of unsurveyed wet woodland habitat present along the River Corrib and on the shores of Lough Corrib to the north of the scheme study area, this percentage figure is likely to be an overestimate of the loss of Residual alluvial forest habitat locally.

Habitat degradation as a result of effects on the existing hydrogeological regime during construction and operation have the potential to affect areas of Residual alluvial forest that form an element of the wetland habitats supported by the Coolagh Lakes.

Accidentally introducing non-native invasive plant species could also increase the extent and magnitude of potential impacts due to the proposed road development; as could an accidental pollution event affecting the River Corrib, the Coolagh Lakes or Ballindooley Lough. There are no areas of this habitat type within the ZoI of air quality impacts with the potential to affect plant species composition, diversity or abundance.

Despite the relatively small area of habitat loss, the loss of any area of this priority Annex I habitat constitutes a negative effect on conservation status. Therefore, the loss of Residual alluvial forest habitat associated with the proposed road development will result in a likely significant negative effect, at the international geographic scale.

Wet heath [4010] & Dry heaths [4030]

Dry siliceous heath (HH1) and Wet heath (HH3) which corresponds with this Annex I habitat type

Wet heath and Dry heaths are assessed together, as both habitat types generally form intricate mosaics with one another in areas affected by the proposed road development. From Bearna to Ballagh (Ch. 0+000 to Ch. 8+300) a total of c.5.15ha of heathland habitats will be permanently lost as a direct result of construction works or through indirect hydrogeological effects: approximately 1.96ha of Dry heaths, 2.06ha of Wet heath[62], 0.7ha of Dry heaths/Wet heaths mosaic, c.0.43ha of Wet heath/*Molinia* meadow/Dry heath mosaic between Ch. 2+920 and Ch. 3+040 (in the ratio of 82/15/3%, respectively) and c.0.01ha of Dry heath/Scrub mosaic along the access road at Na Foraí Maola Thiar.

In the context of the total area of these Annex I habitat types recorded within the scheme study area, the areas lost represent approximately 1.8%. However even the areas of heath habitat recorded within the scheme study area are only likely to represent a proportion of the actual local heathland habitat resource[63]. Therefore, the actual percentage of habitat loss is likely to be much smaller.

The proposed road development will also increase the fragmentation of heathland habitats; although the affected habitat blocks are already isolated from the larger more cohesive areas to the north at Na Foraí Maola, Lough Inch, Cappagh, Tonabrocky and Ballagh which will be unaffected.

Habitat degradation as a result of effects on the existing hydrogeological regime during construction and operation is also likely to affect the areas of Wet heath along the proposed road development. The construction hydrogeological ZoI will be temporary and is not predicted to have long-term effects on its own. However, the operational hydrogeological ZoI (in the context of groundwater drawdown effects) extends beyond the proposed development boundary to include additional areas of heathland habitat. This is not likely to have any long-term effects on areas of Dry heath, but Wet heath habitats is likely to dry out to some degree, with decreasing effect from the road edge. As it is not possible to quantify the effects of the predicted groundwater drawdown of Wet heath habitat condition, a precautionary approach is being taken in assuming any Wet heath habitat within the operational hydrogeological ZoI will be permanently lost. For the purposes of the impact assessment, it is also assumed that in a mosaic of Dry heath and Wet heath that all habitat affected in this way is Wet heath (a worst-case approach as Dry heath is not likely to be affected by the effects of operational groundwater drawdown). The area of potential Wet heath habitat within this zone is c.0.84ha. The likelihood is that the species composition will change to resemble more of a Dry heath habitat type. Peatland habitats within the hydrogeological ZoI could be affected by

[62] This c.2.06ha of Wet heath habitat includes an area of c.1.23ha that lies within the proposed development boundary and will be directly impacted, and an additional c.0.84ha that lies outside of the proposed development boundary but within the hydrogeological ZoI.
[63] Based upon a review of available orthophotography for the km grid square M22 (which covers the western part of the scheme study area), approximately 40km^2 of upland habitats are likely to be present but are not described or mapped. These are likely to be a mosaic of heath and bog habitats.

groundwater pH change and mitigation measures will be implemented to avoid this impact.

Accidentally introducing non-native invasive plant species into heath areas could also increase the extent and magnitude of road effects on these habitat types, degrading the habitat quality; as could an accidental pollution event or dust deposition during construction. Air quality effects on heathland habitats during operation are not likely to affect plant species composition, diversity or abundance.

Despite the relatively small area of habitat loss, and that the areas that will be lost are a multitude of small, isolated habitat patches, considering the likely effects and ongoing pressures on these habitat types locally, the loss of any area of these Annex I habitats constitutes a negative effect on conservation status. Therefore, the loss of Wet heath and Dry heath habitat associated with the proposed road development will result in a likely significant negative effect, at the national geographic scale.

Calcareous grassland [6210]

Dry calcareous and neutral grassland (GS1) which corresponds with this Annex I habitat type

The proposed road development will result in the permanent loss of approximately 1.14ha of Calcareous grassland habitat: c.0.09ha at Lackagh Quarry (Ch. 11+750), three small patches between Ch. 12+000 and Ch. 12+220 (totalling c.0.13ha), and c.0.92ha at Doughiska (between Ch. 16+220 and Ch. 16+320). In the context of the total area of Calcareous grassland habitat recorded within the scheme study area, the areas lost represent approximately 2.23%. The Calcareous grassland habitat affected is the non-priority variant [6210] and as such, is valued as being of national importance.

There is also some Calcareous grassland habitat present in a mosaic with Limestone pavement within the boundary of Lough Corrib cSAC and, as assessed in the NIS, it is not directly impacted by the proposed road development (this is captured in the mitigation strategy and shown on **Figure 8.23.8** as habitat areas to be retained).

All of the affected areas are small, isolated grassland patches and therefore, the proposed road development will not have any significant fragmentation impacts on Calcareous grassland habitat locally.

Accidentally introducing non-native invasive plant species into Calcareous grassland habitat could also increase the extent and magnitude of road effects, degrading the habitat quality; as could an accidental pollution event or dust deposition during construction. During operation, air quality effects on Calcareous grassland habitat in the vicinity of the proposed road development are not likely to affect plant species composition, diversity or abundance.

Despite the relatively small area of habitat loss, and that the areas that will be lost are a multitude of small, isolated habitat patches, considering the likely effects and ongoing pressures on Calcareous grassland habitat locally, the loss of any area of this Annex I habitat constitutes a negative effect on conservation status. Therefore, the loss of the non-priority Calcareous grassland habitat associated with the proposed road development will result in a likely significant negative effect, at the national geographic scale.

Molinia meadow [6410]

Wet grassland (GS4) which corresponds with this Annex I habitat type

The proposed road development will result in the permanent loss of approximately 0.94ha of *Molinia* meadow habitat: an area of c.0.08ha at Na Foraí Maola (Ch. 0+900) and c.0.93ha at the southern end on the Ballindooley Lough wetland complex (Ch. 12+250 to Ch. 12+400).

In the context of the total area of *Molinia* meadow habitat recorded within the scheme study area, the areas lost represent approximately 4%. Although as noted above for the heath habitats, given the local expanse of unsurveyed upland habitat present to the north of the scheme study area this percentage figure is likely to be an overestimate of the loss of *Molinia* meadow habitat locally.

The *Molinia* meadow at Na Foraí Maola is an isolated patch with no existing connectivity to other semi-natural habitat sites across the proposed road development, largely due to the existing local road network and residential development. Therefore, habitat fragmentation effects are not likely to arise. The *Molinia* meadow affected at Ballindooley is at the very southern end of the wetland complex which itself is an isolated wetland ecosystem. Therefore, habitat fragmentation is not likely to effect the habitat or the wetland complex overall.

Accidentally introducing non-native invasive plant species into *Molinia* meadow habitat could also increase the extent and magnitude of road effects, degrading the habitat quality; as could an accidental pollution event or dust deposition during construction. During operation, air quality effects on *Molinia* meadow habitat in the vicinity of the proposed road development are not likely to affect plant species composition, diversity or abundance.

Despite the relatively small areas of habitat loss, considering the likely effects and ongoing pressures on *Molinia* meadow habitat locally the loss of any area of this Annex I habitat constitutes a negative effect on conservation status. Therefore, the loss of *Molinia* meadow habitat associated with the proposed road development will result in a likely significant negative effect at the national geographic scale.

Limestone pavement [*8240]

Exposed calcareous rock (ER2), Oak-ash-hazel woodland (WN2) and Scrub (WS1) which corresponds with this Annex I habitat type

There is c.2.3ha of Limestone pavement habitat present within the proposed development boundary. This figure includes c.0.12ha of Limestone pavement/Calcareous grassland mosaic above the Lackagh Tunnel. Of this c2.3ha, c.1.85ha lies outside of the boundary of Lough Corrib cSAC. The remainder lies within the boundary of Lough Corrib cSAC and, as assessed in the NIS, is not directly or indirectly impacted by the proposed road development (this is captured in the mitigation strategy and shown on **Figures 8.23.7** to **8.23.8** as habitat areas to be retained).

Therefore, the proposed road development has the potential to affect approximately 1.85ha of Limestone pavement habitat which lies within the proposed development boundary, and outside of Lough Corrib cSAC. In the context of the total area of

Limestone pavement habitat recorded within the scheme study area (c.180ha), the areas lost represent approximately 1%. Other areas of Limestone pavement habitat, outside of the area covered by the habitat surveys, have been mapped locally to the north of Menlough Village near Coolanillaun and Angliham Quarry (Natura, 2005) which cover an area of c.22ha. Adding this marginally reduces the percentage loss to c.0.9%.

The design of the proposed road development includes for a culvert structure to span over c.0.04ha of exposed Limestone pavement (LPE) at Ch. 10+030. This will ensure that this area of Limestone pavement is not permanently removed, the natural clint and grike structure of the pavement area is retained, and does not affect its area, or range at any geographic scale. However, some level of vegetation removal is likely to be required to facilitate construction of the culvert, and the resulting shading effects of the structure (c.4.5m high and c.30m wide, over approximately 68% of this habitat patch) will likely affect the extent and species composition of the vegetation cover beneath the structure, reducing the quality of the Limestone pavement habitat remaining. However, in the context of the overall area of Limestone pavement habitat present locally (c.202ha, of which the area partially beneath the culvert represents <0.02%), affecting the quality of such a small area is preferable than loss of the area entirely and reduces the magnitude of the impact the proposed road development will have on this habitat type.

The Menlough Viaduct passes over c.0.7ha of Limestone pavement habitat between Ch. 10+100 and Ch. 10+425; the construction of which is likely to affect the habitats beneath through vegetation removal during site clearance, habitat loss, and shading from the viaduct structure during operation. The affected habitat areas include c.0.05ha of wooded Limestone pavement (LPW) west of Bóthar Nua (Ch. 10+100) and, between Bóthar Nua and Seanbóthar (Ch. 10+130 to Ch. 10+475), c.0.07ha of LPE and c.0.67ha of LPW. The construction methodology described in the constructability report in **Appendix A.7.2**, will ensure that construction impacts will only be temporary for the majority of this area due to the limestone pavement protection system that will be used. Use of this protection system will result in any vegetation beneath it being supressed for the duration of construction. Although some level of vegetation is likely to recolonise when the temporary protection system is removed, this will be inhibited by the shading effects of the viaduct structure and the existing species composition is not likely to fully re-establish itself. The area of Limestone pavement that will be permanently lost to the supporting piers is c.0.05ha. Although the viaduct will reduce the quality of Limestone pavement habitat remaining, as above, the area affected is relatively small in the context of the local habitat resource (c.0.03%) and retaining, rather than the permanent loss of, Limestone pavement habitat reduces the magnitude of the impact the proposed road development will have on this habitat type.

The other Limestone pavement areas within the proposed development boundary, but outside of Lough Corrib cSAC, is a total area of c.1.1ha. Construction works are likely to result in either the loss of, or significant damage to, these Limestone pavement habitat areas.

There is also c.0.44ha of Limestone pavement and Calcareous grassland within Lough Corrib cSAC which lie above the proposed Lackagh Tunnel. Although this habitat area will not be directly affected by the proposed road development, tunnelling beneath it poses a risk to the structural integrity of the rock mass that supports surface above and therefore, could affect these Annex I habitats. This is assessed further in the NIS.

In terms of habitat fragmentation, the only area of Limestone pavement outside of Lough Corrib cSAC that will be bisected by the proposed road development is that beneath the Menlough Viaduct. As this structure will be elevated on piers across its length (between Ch. 10+100 to Ch. 10+425), and substantial areas of this habitat type remain on either side, the proposed road development will not have any significant fragmentation impacts on Limestone pavement habitat locally.

Accidentally introducing non-native invasive plant species into Limestone pavement habitat areas could also increase the extent and magnitude of road effects on these habitat types, degrading the habitat quality; as could an accidental pollution event or dust deposition during construction. Air quality effects on exposed or wooded Limestone pavement habitats during operation are not likely to affect plant species composition, diversity or abundance.

Despite the relatively small area of habitat affected by the proposed road development in the context of the local resource, considering the likely effects and ongoing pressures on Limestone pavement habitat, the loss of any area of this Annex I habitat constitutes a negative effect on conservation status. Therefore, the loss of Limestone pavement habitat associated with the proposed road development will result in a likely significant negative effect at the international geographic scale.

Hard water lakes [3140]

Limestone/marl lakes (FL3) which corresponds with this Annex I habitat type

The complex of Hard water lakes at the Coolagh Lakes are within Lough Corrib cSAC and are assessed in the NIS. There are no direct impacts on this habitat type in Lough Corrib cSAC. The proposed road development has the potential to affect both the groundwater and surface water regimes supporting the Hard water lake habitat in Lough Corrib cSAC.

Although there are no direct impacts on Ballindooley Lough, run-off from the proposed road development during construction has the potential to affect surface water quality. Ballindooley Lough is upgradient from the proposed road development, in terms of groundwater flow, and there is therefore no potential for groundwater impacts to the lake itself.

As an Annex I habitat type, negatively affecting the water quality status of Ballindooley Lough has the potential to degrade the Hard water lake habitat and result in a likely significant residual effect, at the national geographic scale.

Alkaline fen [7230]

Rich fen and flush (PF1) which corresponds with this Annex I habitat type

The Alkaline fen along the River Corrib and associated with the Coolagh Lakes are within Lough Corrib cSAC and, as assessed in the NIS, there are no direct impacts on this habitat type in Lough Corrib cSAC. The proposed road development has the potential to affect both the existing groundwater regime and surface water quality (during construction in the absence of mitigation measures) supporting wetland habitats in Lough Corrib cSAC.

Although there are no direct impacts on Ballindooley Lough, run-off from the proposed road development during construction has the potential to affect surface water quality and the Alkaline fen habitat associated with the wetland complex there. Ballindooley Lough is upgradient from the proposed road development, in terms of groundwater flow, and there is therefore no potential for groundwater impacts to those areas of the wetland complex that support Alkaline fen habitat.

As an Annex I habitat type, negatively affecting surface water quality at the Ballindooley Lough wetland complex has the potential to degrade the Alkaline fen habitat and potentially result in a likely significant residual effect at the national geographic scale.

Hydrophilous tall herb [6430]

Reed and large sedge swamps (FS1), Tall-herb swamps (FS2) and Marsh (GM1) which corresponds with this Annex I habitat type

The Hydrophilous tall herb habitat along the River Corrib and associated with the Coolagh Lakes are within Lough Corrib cSAC and are assessed in the NIS. There are no direct impacts on this habitat type in Lough Corrib cSAC. The proposed road development has the potential to affect both groundwater and surface water quality supporting wetland habitats, including Hydrophilous tall herb habitat, in Lough Corrib cSAC.

Cladium fen [*7210]

Reed and large sedge swamps (FS1), Tall-herb swamps (FS2) and Rich fen and flush (PF1) which corresponds with this Annex I habitat type

The *Cladium* fen along the River Corrib and associated with the Coolagh Lakes are within Lough Corrib cSAC and are assessed in the NIS. There are no direct impacts on this habitat type in Lough Corrib cSAC. The proposed road development has the potential to affect both groundwater and surface water quality supporting wetland habitats in Lough Corrib cSAC.

Although there are no direct impacts on this habitat type at Ballindooley Lough, run-off from the proposed road development during construction has the potential to affect surface water quality and the *Cladium* fen habitat associated with the wetland complex there. Ballindooley Lough is upgradient from the proposed road development, in terms of groundwater flow, and there is therefore no potential for groundwater impacts to those areas of the wetland complex that support Alkaline fen habitat.

As a priority Annex I habitat type, negatively affecting surface water quality at the Ballindooley Lough wetland complex has the potential to degrade the *Cladium* fen habitat and potentially result in a likely significant residual effect, at the international geographic scale.

Mesotrophic lakes (FL4) and Eutrophic lakes (FL5)

These lakes form part of the larger wetland complex associated with Ballindooley Lough. Although direct impacts on the eutrophic lake that lies within the proposed road development are not likely to occur, run-off from the proposed development during construction has the potential to affect the quality of these lake habitats at Ballindooley. Similarly, the existing groundwater regime could be affected by works within that portion of the eutrophic lake that lies within the proposed road development and the hydrogeological ZoI.

Negatively affecting the habitat quality of these lakes has the potential to result in a significant residual effect at the county geographic scale.

Calcareous springs (FP1)

There were 21 Calcareous springs, not corresponding to the priority Annex I habitat Petrifying springs, recorded in Lackagh Quarry. Of these, 15 will be lost as a result of construction works: four in the vicinity of the eastern entrance to the Lackagh Tunnel, 9 along the northern wall of the quarry where material will be benched up against the cliff face as a stabilisation measure, and two south of the proposed mainline between Ch. 11+700 and Ch. 11+750. The loss of a large proportion of the springs within the quarry complex, particularly considering their scarcity locally, will result in a likely significant negative effect at the local geographic scale.

Reed and large sedge swamps (FS1)

The loss of a relatively small area (c.0.14ha) of what is a locally common habitat, supporting typical species of that habitat type (*Phragmites australis* reed swamp), is not likely to affect the long-term presence or viability of this habitat type locally. However, the proposed road development does have the potential to affect water quality at Ballindooley Lough which could affect a much larger area of this habitat type (c.3.6ha or 7.8% of the local habitat resource).

Therefore, the proposed road development has the potential to affect this habitat's conservation status and result in a likely significant negative effect at the local geographic scale.

Tall-herb swamps (FS2)

An area (c.0.03ha) of Tall-herb swamp at Ch. 3+400 will be permanently lost to the proposed road development. The loss of such a small proportion of what is a locally common habitat (c.0.8% of the c.4.09ha recorded locally within the habitat survey areas), supporting typical species of that habitat type (*Apium nodiflorum*, *Iris pseudacorus* and *Epilobium hirsutum*), is not likely to affect the long-term presence or viability of this habitat type locally. The percentage loss calculated is also likely to be an overestimate of the actual magnitude of habitat loss given the extensive wetland complex present beyond, and upstream of, the scheme study area at Coolanillaun and Tonacurragh.

Therefore, the proposed road development is not likely to affect this habitat's conservation status locally or result in a likely significant negative effect at the local geographic scale.

Eroding/upland rivers (FW1)

A full description of the hydrological baseline of each of the watercourses discussed below is provided in **Chapter 11, Hydrology**.

<u>Sruthán na Líbeirtí</u>

There is approximately 530m of Sruthán na Líbeirtí within, or along, the proposed development boundary. Of this, approximately 120m will be permanently lost to construction works, with the remaining length of stream channel located along the proposed development boundary and therefore, may be affected to some degree by construction works. The impact associated with the loss of instream habitat will be offset slightly by the creation of two new sections of stream channel, c.45m and c.40m in length. The impact associated with the loss of instream habitat will be further reduced by the creation of a new section of stream channel within the culvert structure, c.125m in length. As a seasonal stream in the upper reaches (where it is directly impacted by the proposed road development), with no fish species recorded during the fisheries surveys, the loss of natural stream channel habitat is not considered to be a likely significant negative effect at any geographic scale.

Impacts to water quality in Sruthán na Líbeirtí during construction however, have the potential to have a significant negative effect, at the local geographic scale.

<u>Trusky Stream</u>

The proposed road development will result in the loss of approximately 220m of the Trusky Stream channel during construction. The impact associated with the loss of instream habitat will be offset slightly by the creation of a new section of stream channel, c.65m in length. The impact associated with the loss of instream habitat will be further reduced by the creation of a new section of stream channel within the culvert structure, c.50m in length.

As a seasonal stream in the upper reaches (where it is directly impacted by the proposed road development), with no fish species recorded during the fisheries surveys, the loss of natural stream channel habitat is not considered to be a likely significant negative effect at any geographic scale.

Impacts to water quality in the Trusky Stream during construction however, have the potential to have a significant negative effect, at the local geographic scale.

<u>Bearna Stream</u>

There is approximately 345m of the Bearna Stream (and c.240m of its unnamed tributary) within, or along, the proposed development boundary. Of this, approximately 140m of the natural river channel will be permanently lost to construction works, with the remaining length of river channel located along the proposed development boundary and therefore, may be affected to some degree by construction works. The impact associated with the loss of instream habitat will be reduced by the creation of new sections of stream channel within the culvert structures, c.140m in length. As a seasonal stream in the upper reaches (where it is directly impacted by the proposed road development), with no fish species recorded during the fisheries surveys, the loss of natural stream channel habitat is not considered to be a likely significant negative effect at any geographic scale.

Impacts to water quality in the Bearna Stream during construction however, have the potential to have a significant negative effect, at the local geographic scale.

Tonabrocky Stream

Approximately 475m of the Tonabrocky Stream channel will be permanently lost to construction works. The impact associated with the loss of instream habitat will be offset slightly by the creation of a new section of stream channel, c.250m in length. The impact associated with the loss of instream habitat will be further reduced by the creation of a new section of stream channel within the culvert structure, c.80m in length.

As a seasonal stream in the upper reaches (where it is directly impacted by the proposed road development), with a low fisheries value, the loss of natural stream channel habitat is not considered to be a likely significant negative effect at any geographic scale.

Impacts to water quality in the Tonabrocky Stream during construction however, have the potential to have a significant negative effect, at the local geographic scale.

Knocknacarra Stream

The Knocknacarra Stream is of a low ecological value in its upper reaches, where it is directly affected by the proposed road development. It is seasonal with little water present in the upper reaches, heavily culverted along a significant proportion of its length (almost 50% - see **Section 11.3.5.4** of **Chapter 11, Hydrology**), and no fish were recorded here during the fisheries survey. Its fisheries value is limited to the tidal section at the estuary, after it emerges from an extensive culverted section.

Therefore, the loss of natural river channel habitat is not considered to be a likely significant negative effect, at any geographic scale.

Impacts to water quality in the Knocknacarra Stream during construction however, have the potential to have a significant negative effect, at the local geographic scale.

Depositing/lowland rivers (FW2)

A full description of the hydrological baseline of each of the watercourses discussed below is provided in **Section 11.3.5** of **Chapter 11, Hydrology**.

River Corrib

The potential for the proposed road development to impact upon the River Corrib is assessed in **Section 8.5.3.1** above and in the NIS.

Terryland River

The proposed road development will not have any direct impact on the Terryland River. As described in **Section 11.3.5.5** of **Chapter 11, Hydrology**, the proposed road development will not affect the flow regime of the Terryland River nor will it have any perceptible impact on water quality. The proposed N83 Flood Relief Measures will result in a slight increase in flood levels within the Terryland River channel, due to the discharge of flood waters into that catchment. However, the flood impact on the Terryland basin will only be slight given the extensive flood storage and flood area within this basin.

Considering the above, and that the Terryland River is heavily modified, with poor water quality and of a low fisheries value, the proposed road development will not result in a likely significant negative effect, at any geographic scale.

Drainage ditches (FW4)

The only notable network of drainage ditches in the eastern part of the study area are those associated with the wetland habitat complex at Ballindooley Lough. None of these features will be lost as a result of construction works although construction works in the vicinity pose a risk of affecting water quality and consequently the supported aquatic vegetation. In the western part of the study area, drainage ditches are a more common habitat; associated with the boundaries of wet grassland fields and the margins of the numerous heath and peatland habitat blocks. The design of the proposed road development includes for drainage pipes and structures that will maintain the functioning of drainage and surface water networks, where these are crossed by the proposed road development. Although the actual losses of drainage ditches cannot be fully quantified (for the most part due to their seasonal nature), given the likelihood of there being extensive drainage networks associated with the locally extensive heath, peatland and wetland habitat complexes, any losses associated with the proposed road development are not likely to affect the long-term presence or viability of this habitat type locally.

Therefore, the proposed road development is not likely to affect this habitat's conservation status locally or result in a significant negative effect at the local geographic scale.

Marsh (GM1)

The proposed road development will result in the loss of a small number of marsh areas at Na Foraí Maola Thiar, An Chloch Scoilte and Castlegar: totalling c.0.2ha. This equates to approximately 2.9% of this habitat type mapped within the scheme study area, a percentage which is likely to be an overestimate of the actual magnitude of habitat loss given the extensive wetland complex present beyond, and upstream of, the scheme study area at Coolanillaun and Tonacurragh. None of the surrounding marsh areas fall with the ZoI of potential hydrological or hydrogeological effects.

The affected habitat patches are small, isolated and do not form an integral part of any larger semi-natural mosaics. They also did not support any atypical or notable plant communities or species. The larger marsh areas recorded during the habitat surveys are associated with the wetland complex at Coolanillaun and these are beyond the ZoI of the proposed road development. Therefore, impacts on those areas that will be lost is not likely to affect the long-term presence or viability of this habitat type locally.

Therefore, the proposed road development is not likely to affect this habitat's conservation status locally or result in a significant negative effect at the local geographic scale.

Dry calcareous and neutral grassland (GS1)

The proposed road development will result in the permanent loss of c.13.7ha of Dry calcareous/neutral grassland, and c.1.55ha of a mosaic of Dry calcareous/neutral grassland and Scrub, valued as being of Local Importance (higher value). This equates to, at most, approximately 8.4% of the total area of Dry calcareous/neutral grassland habitat recorded within the scheme study area. However, based on a review or orthophotography of the surrounding local area (not covered within the extents of the habitat map) there is likely to be a much greater area of this habitat type present locally and the quoted 8.4% is likely to be an overestimate of the percentage habitat loss.

Therefore, the proposed road development is not likely to affect this habitat's conservation status locally or result in a significant negative effect at the local geographic scale.

Dry meadows and grassy verges (GS2)

The proposed road development will result in the permanent loss of c.8.2ha of dry meadows and grassy verges habitat valued as being of Local Importance (higher value). This equates to approximately 5.2% of the total area of acid grassland habitat recorded within the scheme study area. However, based on a review or orthophotography of the surrounding local area (not covered within the extents of the habitat map) there is likely to be a much greater area of this habitat type present locally and the quoted 5.2% is likely to be an overestimate of the percentage habitat loss.

Therefore, the proposed road development is not likely to affect this habitat's conservation status locally or result in a significant negative effect at the local geographic scale.

Dry-humid acid grassland (GS3)

The proposed road development will result in the permanent loss of c.7.81ha of Dry-humid acid grassland habitat valued as being of Local Importance (higher value).

The area of Dry-humid acid grassland habitat permanently affected is approximately 10.4% of the area of this habitat recorded locally. Additional areas of habitat would be expected to be present locally, associated with the margins of peatland habitat and low-intensity managed agricultural fields present to the north and west of the proposed road development in the western part of the study area. However, these areas are likely to be relatively small based upon its extent and distribution across the habitat mapped area and are not likely to significantly affect the relative percentage loss of this habitat type locally.

Accidentally introducing non-native invasive plant species into Dry-humid acid grassland habitat could also increase the extent and magnitude of road effects, degrading the habitat quality; as could an accidental pollution event or dust deposition during construction. During operation, air quality effects on Dry-humid acid grassland habitat in the vicinity of the proposed road development are not likely to affect plant species composition, diversity or abundance.

Therefore, the proposed road development is likely to affect this habitat's conservation status locally and result in a significant negative effect at the local geographic scale.

Wet grassland (GS4)

The proposed road development will result in the permanent loss of c.11.14ha of wet grassland habitat valued as being of Local Importance (higher value). This equates to approximately 4.7% of the total area of wet grassland habitat recorded within the scheme study area. However, based on a review or orthophotography of the surrounding local area (not covered within the extents of the habitat map) there is likely to be a much greater area of this habitat type present locally and the quoted 4.7% is likely to be an overestimate of the percentage habitat loss.

Therefore, the proposed road development is not likely to affect this habitat's conservation status locally or result in a significant negative effect at the local geographic scale.

Rich fen and flush (PF1)

The Rich fen and flush habitat along the River Corrib and associated with the Coolagh Lakes are within Lough Corrib cSAC and are assessed in the NIS, where relevant in relation to the QIs of the cSAC. There are no direct impacts on this habitat type in Lough Corrib cSAC. The proposed road development has the potential to affect both groundwater and surface water quality supporting wetland habitats in Lough Corrib cSAC.

Although there are no direct impacts on this habitat type at Ballindooley Lough, run-off from the proposed road development during construction has the potential to affect surface water quality and the rich fen and flush habitat associated with the wetland complex there. Ballindooley Lough is upgradient from the proposed road development, in terms of groundwater flow, and there is therefore no potential for groundwater impacts to those areas of the wetland complex that support rich fen and flush habitat.

As a priority Annex I habitat type, negatively affecting surface water quality at the Ballindooley Lough wetland complex has the potential to degrade the *Cladium* fen habitat and potentially result in a significant residual effect, at the international geographic scale.

Poor fen and flush (PF2)

The proposed road development will result in the direct, permanent loss of c.0.13ha of Poor fen and flush habitat. There will also be an additional indirect hydrogeology impact on the fen habit at Knocknafroska (Ch. 7+800 to Ch. 7+975) as a result of groundwater drawdown will result in an additional area of c.0.27ha being permanently affected.

The area of Poor fen and flush habitat permanently affected is approximately 18% of the area of this habitat recorded locally and has all been valued as being of a local importance (higher value). Additional areas of habitat would be expected to be present locally, associated with the expanses of peatland habitat present to the north and west of the proposed road development in the western part of the study area.

However, these areas are likely to be small based upon its extent and distribution across the habitat mapped area and are not likely to significantly affect the relative percentage loss of this habitat type locally.

Dust deposition during construction could also increase the extent and magnitude of road effects, degrading the habitat quality. During operation, air quality effects on Poor fen and flush habitat in the vicinity of the proposed road development are not likely to affect plant species composition, diversity or abundance.

Therefore, the proposed road development is likely to affect this habitat's conservation status locally and result in a significant negative effect, at the local geographic scale.

(Mixed) broadleaved woodland (WD1)

The proposed road development will result in the permanent loss of c.4.25ha of (Mixed) broadleaved woodland; equating to approximately 18.8% of the local resource of this habitat type. The most significant blocks of woodland affected are near the west bank of the River Corrib (Ch. 9+460 to Ch. 9+625) where one block of c.0.8ha and a second block of c.1.55ha of woodland will be lost (this second woodland block also lies within Lough Corrib cSAC). In terms of the potential Lough Corrib cSAC impact, this is discussed separately in **Section 8.5.3.1**, under the heading of Designated Areas for Nature Conservation, and in the NIS.

Accidentally introducing non-native invasive plant species into woodland habitat could also increase the extent and magnitude of road effects, degrading the habitat quality; as could an accidental pollution event or dust deposition during construction. During operation, air quality effects on woodland habitat in the vicinity of the proposed road development are not likely to affect plant species composition, diversity or abundance.

Even considering that much of the affected woodland blocks have been planted, many for amenity purposes, the loss (and fragmentation) of such a relatively large proportion of broadleaved woodland is likely to affect this habitat's conservation status locally and result in a significant negative effect at the local geographic scale.

Mixed broadleaved/conifer woodland (WD2)

The proposed road development will result in the permanent loss of c.0.03ha of Mixed broadleaved/conifer woodland at Ch. 1+580, next to the Troscaigh Road (L5387). This is part of a small woodland block (c.0.18ha) associated with the adjoining residential property. The habitat loss will not fragment the woodland nor is it likely to affect the long-term presence or viability of this habitat type locally, there are five other mixed broadleaved/conifer woodland blocks mapped within the scheme study area, totalling an area of c.2.75ha.

Therefore, the proposed road development is not likely to affect this habitat's conservation status locally or result in a significant negative effect at the local geographic scale.

(Mixed) conifer woodland (WD3)

The proposed road development will result in the permanent loss of <0.01ha of Mixed conifer woodland at Ch. 1+580, next to the Troscaigh Road (L5387). This is part of a small woodland block (c.0.05ha) associated with the adjoining residential property. The habitat loss will not fragment the woodland nor is it likely to affect the long-term presence or viability of this habitat type locally.

Therefore, the proposed road development is not likely to affect this habitat's conservation status locally or result in a significant negative effect at the local geographic scale.

Oak-ash-hazel woodland (WN2)

The proposed road development will result in the permanent loss of c.4.18ha of Oak-ash-hazel woodland; the majority of which is located near Menlough Village. This equates to approximately 1.8% of the total area of Oak-ash-hazel woodland mapped within the scheme study area.

Accidentally introducing non-native invasive plant species into woodland habitat could increase the extent and magnitude of road effects, degrading the habitat quality; as could an accidental pollution event or dust deposition during construction. During operation, air quality effects on woodland habitat in the vicinity of the proposed road development are not likely to affect plant species composition, diversity or abundance.

Although the area directly impacted is relatively small, the potential for indirect impacts could result in long-term impacts occurring and affecting a much greater area. Therefore, the proposed road development has the potential to affect this habitat's conservation status locally and result in a likely significant negative effect at the local geographic scale.

Scrub (WS1)

The proposed road development will result in the permanent loss of c.21.12ha of Scrub across the study area; the majority of which will occur between Bearna and Ballagh. This equates to approximately 5.3% of the total area of scrub habitat mapped within the scheme study area.

However, based on a review or orthophotography of the surrounding local area (not covered within the extents of the habitat map) there is likely to be a much greater area of this habitat type present locally and the quoted 5.3% is likely to be an overestimate of the percentage habitat loss. Dust deposition during construction could also increase the extent and magnitude of road effects, degrading the habitat quality. However, given the extent of this habitat type locally, this will not pose a risk to this habitats conservation status at a local level. During operation, air quality effects on scrub habitat in the vicinity of the proposed road development is not likely to affect plant species composition, diversity or abundance.

Therefore, the proposed road development is not likely to affect this habitat's conservation status or result in a significant negative effect at the local geographic scale.

Hedgerows (WL1)

The proposed road development will result in the permanent loss of c.7.8km of Hedgerow; the majority of which will occur in the eastern part of the study area.

Although there is not sufficient data to quantify the magnitude of hedgerow loss in a local context, it is likely that the extent and distribution of the habitat locally will be affected over the long-term. Particularly considering that Hedgerows are scarce or absent from much of the study area owing to the prevalence of stone walls as field boundaries and, in the western part of the scheme study area, extensive scrub encroachment.

Accidentally introducing non-native invasive plant species could increase the extent and magnitude of road effects, degrading the habitat quality; as could an accidental pollution event or dust deposition during construction. During operation, air quality effects on hedgerow habitat in the vicinity of the proposed road development are not likely to affect plant species composition, diversity or abundance.

Therefore, the proposed road development is likely to affect this habitat's conservation status locally and result in a significant negative effect, at the local geographic scale.

Treelines (WL2)

The proposed road development will result in the permanent loss of c.4km of Treelines along its length.

Although there is not sufficient data to quantify the magnitude of Treeline loss in a local context, it is likely that the extent and distribution of the habitat locally will be affected over the long-term; particularly considering the scarcity or absence of mature treelines within the study area.

Accidentally introducing non-native invasive plant species could increase the extent and magnitude of road effects, degrading the habitat quality; as could an accidental pollution event or dust deposition during construction. During operation, air quality effects on treeline habitat in the vicinity of the proposed road development are not likely to affect plant species composition, diversity or abundance.

Therefore, the proposed road development is likely to affect this habitat's conservation status locally and result in a significant negative effect, at the local geographic scale.

8.5.5 Rare and protected plant species

There are no rare or legally protected plant species present within the proposed development boundary. There are also no rare or legally protected plant species present in locations remote from the proposed road development that could be indirectly affected by impacts on the receiving hydrogeological or hydrological environments, through dust deposition, shading effects or through introducing/spreading non-native invasive plant species. Therefore, no impacts are predicted.

8.5.6 Mammals

8.5.6.1 Otter

8.5.6.1.1 Construction Phase Impacts

Although it cannot be predicted if Otter will establish new holt or couch sites within the ZoI of the proposed road development before construction works commence, it is a possibility and this scenario has been taken into account in the mitigation strategy (refer to **Section 8.6.7.1.1**).

Loss of breeding/resting sites

Based on the findings of the field surveys carried out, as there were no Otter breeding or resting places, holt or couch sites, present within the boundary of the proposed road development, there will not be any loss of holt or couch sites as a result of construction works.

Habitat Loss

In the context of rivers directly impacted by the proposed road development, Otter were recorded along the River Corrib and within the catchment of the Tonabrocky Stream.

In the context of river systems, the Threat Response Plan Otter *Lutra lutra* 2009-2011 document (Department of the Environment, Heritage and the Gaeltacht, 2011) defines terrestrial Otter habitat as a 10m zone of riparian habitat along the river banks. On all watercourses crossed by the proposed road development, bar the River Corrib, construction works will result in the permanent loss of some level of riparian vegetation; primarily within the construction footprint of the crossing structure (or temporary crossing structures) but also, in many cases, to construct the drainage outfalls to the surface water network. Instream habitat will also be lost, or be highly modified, as a result of construction works to install culverts. The level of permanent habitat loss will be greatest on watercourses where stream realignments are proposed as part of the design: Sruthán na Líbeirtí, the Trusky Stream and the Tonabrocky Stream.

On the River Corrib, the construction of the proposed bridge structure will not result in the loss of any instream habitat nor will it result in the permanent loss of Otter habitat on the west or east bank of the river within 5m of the river bank. Nevertheless, some vegetation cutting/removal would likely be required to facilitate the construction works and on an ongoing basis as part of the maintenance works associated with the proposed road development during operation. Some effects to any remaining vegetation underneath the bridge structure would also be expected as a result of shading effects. The construction of the drainage outfalls to the River Corrib will, however, result in the loss of approximately 3m of riparian habitat on each bank.

Habitat losses of such a comparatively small scale, in the context of the instream and riparian habitat resource in all surface water catchments crossed by the proposed road development which support Otter, would not constitute a significant decline in the extent of available Otter habitat and will not affect the local Otter population's ability to maintain itself, even in the short-term. Even in a case where it would be partially converted to hard surfaces, such as where a precast concrete culvert is installed, Otter routinely use highly modified habitat within culverts and beneath bridges.

Habitat loss associated with the construction of the proposed road development will not have a likely significant effect on the conservation status of Otter and will not have a likely significant negative effect, at any geographic scale.

Habitat degradation - water quality

During construction, contaminated surface water runoff and/or an accidental spillage or pollution event into any surface water feature has the potential to have a significant negative impact on water quality and consequently an impact on Otter; either directly (e.g. acute or sub-lethal toxicity from pollutants) or indirectly (e.g. affecting their food supply or supporting habitats). The effects of frequent and/or prolonged pollution events in a river system have the potential to be extensive and far-reaching and could potentially have significant long-term effects.

However, it is considered unlikely that a pollution event of such a magnitude would occur during construction, or be any more than temporary in nature. Nevertheless, a precautionary approach is being taken in assuming a level of risk of water quality impacts and detailed mitigation measures are required to further minimise the risk of the proposed road development having any perceptible effect on water quality during construction.

Habitat degradation as a result of effects on surface water quality during construction has the potential to affect the species' conservation status and result in a likely significant negative effect, at a local geographic scale. Mitigation measures have been designed to protect water quality during construction (see **Section 8.6.4**).

Habitat Severance/Barrier Effect

The physical disturbance to the stream/river channels and the associated riparian margins will result in the severance of river habitat, at least temporarily, during construction. This may also result in some level barrier effect during construction works, on all watercourses.

However, given that Otter are generally nocturnal in habitat and works will typically be carried out during normal daylight working hours, affected Otters would be expected to habituate to the altered landscape and any resulting barrier effect would be temporary in nature (see below on disturbance/displacement and the habituation of Otters to disturbance).

The severance/barrier effect of construction works on Otter is not likely to affect the local population, over even the short-term, and is not likely to affect the species conservation status and result in a significant negative effect, at any geographic scale.

Disturbance/displacement

There were no Otter breeding or resting places present within the ZoI of the proposed road development. Therefore, there will not be any disturbance or displacement effect on such sites associated with construction works.

Otter were recorded widely along the River Corrib corridor, and in the Tonabrocky Stream catchment, and therefore increased human presence and/or noise and vibration associated with construction works, has the potential to (at least temporarily) displace commuting or foraging Otter.

Otter are known to tolerate human disturbance, including road traffic, under certain circumstances (Bailey & Rochford, 2006, The Environment Agency, 2010, Irish Wildlife Trust, 2012). This is also evidenced by the presence of Otter signs along the River Corrib through the NUIG Campus (see **Figures 8.3.1** to **8.3.14**[64]), the presence of an active Otter couch site within 50m of the Quincentenary Bridge, and the presence of Otter (including holt sites) in the urban centre of Galway City.

As construction works will typically be undertaken during normal daylight working hours and Otter are generally nocturnal in habit, and that Otter can (in many circumstances) tolerate high levels of human presence and disturbance, displacement of Otter from their habitat is extremely unlikely to affect the local Otter population. Therefore, disturbance during construction is not likely to have a significant effect on the species' conservation status and will not result in a likely significant negative effect, at any geographic scale.

8.5.6.1.2 Operational Phase Impacts

Habitat Severance/Barrier Effect

The installation of new culverts or bridge structures has the potential to result in a permanent barrier to Otter movement along watercourses crossed by the proposed road development. Particularly during periods of spate flow or flooding, where increased water volumes and flow rates may render the structure impassable by Otter.

In the case of the proposed River Corrib Bridge, this impact will not arise as it is a clear span structure and will not affect the existing hydrological regime or functioning of the floodplain (see **Chapter 11, Hydrology**). Therefore, the Otter population associated with the River Corrib (and thus Lough Corrib cSAC) will not be affected in this regard. However, on all other watercourses (whether used by Otter at present, such as the Tonabrocky Stream, or not) the risk of the crossing structure resulting in a barrier effect is possible.

[64] There is a distinct difference in recorded levels of Otter signs/activity between the west and east banks of the River Corrib in the vicinity of the proposed River Corrib Bridge; with Otter clearly favouring the east bank of the River Corrib than that on the side of NUIG Sporting Campus. Although whether this is as a result of the west bank being more accessible to the public (and hence subject to higher levels of disturbance, particularly due to the presence of dogs), as a result of the open, and sparsely vegetated, nature of the riparian margin on the west bank, or some combination of the two, is unknown.

The habitat severance/barrier effect to Otter associated with the proposed road development has the potential to affect local Otter populations over the long-term, potentially affecting the species' conservation status, and result in a likely significant negative effect, at a local geographic scale. Mitigation measures to maintain mammal passage along watercourses used by Otter have been designed (see **Section 8.6.7.1.2**).

Disturbance/displacement

As discussed above in relation to construction impacts, Otter can be relatively tolerant of human and traffic disturbance. Any increased level of disturbance associated with the operation of the proposed road development is therefore, extremely unlikely to result in any perceptible disturbance/displacement of Otter from their habitat.

Nocturnal mammals, such as the Otter, would be likely to be disturbed by the introduction of artificial light into established breeding and foraging areas (Rich & Longcore, 2005).

Lighting will be provided for the proposed NUIG Sports Pitches. Whist there is planning permission to floodlight the existing pitches adjacent to the river, they are currently unlit. There is no holt located within or near the area of light spill from the proposed lighting for the proposed NUIG Pitches. The light spill will not impede Otter from using the River Corrib for feeding or commuting.

There will be no light spill to any other watercourses where Otter were recorded and there will not be any impacts in that regard.

Disturbance or displacement associated with the operation of the proposed road development is not likely to affect the conservation status of Otter and therefore, will not result in a likely significant negative effect, at any geographic scale.

Habitat degradation - water quality

There will be outfall points to surface water features from the road drainage network during operation. The proposed drainage design for the mainline of the proposed road development incorporates pollution control measures (this includes petrol interceptors, wetland and other measures, such as SuDS) followed by either infiltration ponds (where discharging to ground) or attenuation ponds (where drainage will be discharged to the existing surface water/storm sewer), as described in detail in **Chapter 5, Description of Proposed Road Development**.

Those sections of the road drainage that are to be discharged to ground, pose no risk to surface water quality. It is extremely unlikely that the normal operating water quality of the drainage outfalls discharging to the existing surface water/drainage network, even in the unlikely event of a pollution incident, would have any perceptible impact on water quality in receiving watercourses. The functioning and effectiveness of both elements of the road drainage network are discussed in more detail in **Chapter 11, Hydrology**.

Habitat degradation as a result of effects on surface water quality during operation is not likely to have any effect on the Otter population or its conservation status, and therefore will not result in a likely significant negative effect, at a local geographic scale.

Mortality Risk

The introduction of the proposed road development into a rural landscape, which includes new watercourse crossings, will permanently increase the risk of road traffic collisions with Otter; particularly where Otter have been recorded (see **Figures 8.3.1** to **8.3.14**). The exceptions to this are along the River Corrib, where the proposed road development is elevated above the river and floodplain such that it would not be accessible by Otter, and the Menlough Viaduct which is elevated above the turlough at Ch. 10+320.

Although it is not possible to quantify the magnitude of the effect, the increased collision risk has the potential to result in long-term effects on Otter populations locally, potentially affecting their local conservation status.

Collision risk to Otter associated with the proposed road development has the potential to result in a likely significant negative effect, at the local geographic scale. Mitigation measures have been designed to avoid this potential impact (see **Section 8.6.7.1.2**).

8.5.6.2 Bats

This section of the impact assessment deals with impacts on bats species. Firstly, it describes the different types of impacts that could potentially affect all bat species and then secondly deals with the potential impacts on each species individually.

8.5.6.2.1 Construction Phase Impacts

Roost Loss

Fifteen buildings supporting 20 bat roosts are within the proposed development boundary (6 Soprano pipistrelle roosts (PBR177, 179, 196, 205, 255, 267), 1 Common pipistrelle roost (PBR205), 1 unidentified Pipistrelle bat roost (PBR182), 7 Brown long-eared bats roosts (PBR 183, 178, 179, 196, 204, 256, 267), 3 Lesser horseshoe bat roosts (PBR178, 204, 210) and two unidentified species bat roosts (253, 270). Six of these are structures used by more than one bat species. **Figures 8.18.1** to **8.21.1** show the locations of these roosts.

Fourteen of these structures are proposed for demolition (see **Table 8.28** below), with one of the structures (PBR241) to be retained, protected from adverse impacts and bat roost features fitted to the structure. One structure (PBR183) will be demolished but an outbuilding will be retained for the purposes of compensation for loss of other roosts.

Table 8.28: Bat roosts to be removed as part of the proposed road development

Approx. Chainage	Roost reference	Roost type
Ch. 5+550	PBR267	Building. Roost for small numbers of Soprano pipistrelle and Brown long-eared bats (likely to be a transition/occasional roost)
Ch. 8+600	PBR256	Building. Brown long-eared maternity roost.
Ch. 8+650	PBR255	Building. Roost for small numbers of Soprano pipistrelle bats (likely to be a transition/occasional roost)
Ch. 8+650	PBR178	Building. Lesser horseshoe bat roost. Juvenile bats present late in the maternity season but not proven to be a maternity roost. Loss of maternity roost for Brown long-eared bats
Ch. 8+700	PBR177	Building. Roost for small numbers of Soprano pipistrelle bats (likely to be a transition/occasional roost)
Ch. 8+750	PBR210	Building. Lesser horseshoe bat night roost
Ch. 10+050	PBR179	Building. Roost for small numbers of Soprano pipistrelle and Brown long-eared bats (likely to be a transition/occasional roost)
Ch. 11+400	PBR253	Building. Roost for small numbers of unidentified bats (likely to be a transition/occasional roost)
Ch. 12+150	PBR204	Building. Lesser horseshoe bat and Brown long-eared bat day/night roost for small numbers of bats
Ch. 12+150	PBR182	Building. Roost for small numbers of unidentified Pipistrelle bats (likely to be a transition/occasional roost)
Ch. 12+150	PBR196	Building. Roost for small numbers of Soprano pipistrelle and Brown long-eared bats (likely to be a transition/occasional roost)
Ch. 12+960	PBR183	Building. Roost for small numbers of Brown long-eared bats (likely to be a transition/occasional roost)
Ch. 15+100	PBR205	Building. Roost for small numbers of Common and Soprano pipistrelle bats (likely to be a transition/occasional roost)
Ch. 15+250	PBR270	Building. Roost, possibly abandoned. Unidentified species

Two trees will be felled (PTR48, PTR43) that have been confirmed as supporting bats (Leisler's bat and Soprano pipistrelle bat respectively) and an additional 13 trees have high (category 1) potential to support bats and will also be felled. **Figures 8.16.1** to **8.16.15** show the locations of these trees.

The potential impacts of the permanent loss of these 14 roost structures, apart from the Lesser horseshoe bat roosts, and the two trees are deemed to be significant at a local level as they are valued as important at the local geographic level, almost all had a low number of bats using them and were recorded using other roost sites across the study area which will not be impacted by the proposed road development.

The impacts of the loss of the Lesser horseshoe bat roosts are potentially significant at a national level in the absence of mitigation measures. Evidence confirms that the roost at Aughnacurra (PBR178) is a satellite roost linked to Menlo Castle. Given that the physical structure of the Menlo Castle roost may be deteriorating, the Aughnacurra roost could be a relatively new addition to their network of roosts. The Aughnacurra satellite roost (PBR178) is within a sub-optimal building in terms of the preferred building type for this species and its occupation by bats may be a reflection of the lack of availability of better roost opportunities in the area.

Therefore, the loss of the satellite Lesser horseshoe bat roost at Aughnacurra (PBR178) and the loss of other Lesser horseshoe bat night roosts (PBR204, PBR210) within their foraging area could result in a likely significant effect on the Lesser horseshoe bat at a national geographic scale, in the absence of any measures to address this impact.

In the context of the potential impact on the Lough Corrib cSAC, of which Lesser horseshoe bats are a QI, although this species is present within the study area, the roost that forms the QI population for this European site (Eborhall House) is more than 30km away from the proposed road development, on the northern shore of Lough Corrib. This distance would be regarded to be beyond the normal core foraging range of the Eborhall House population and beyond the normal commuting range of this species except on exceptional occasions or over long periods of time – for example, bats dispersing and moving between areas in the wider landscape over a period of many years/generations. Furthermore, radio-tracking surveys of the Menlough population of bats (which were identified within the study area) undertaken for this project in 2014 and 2015 (*N6 Galway City Transport Project Route Selection Report*, Arup, 2016) did not suggest any evidence of movement between that population and the Eborhall House roost. Given the lack of any linkage between the study area and the roosts that are the reason for designation of this European site, likely significant effects on the Lough Corrib cSAC's Lesser horseshoe bat population have been ruled out.

Twelve other bat roosts were deemed to be in close proximity to the proposed road development (within 100m) of the proposed development boundary. Potential direct impacts are predicted on these roosts as a result of disturbance during the construction phase, although it is acknowledged that in some areas this impact may be of a lower magnitude than others as the boundary is set back from the actual construction footprint.

These roosts include night roosts for Lesser horseshoe bats, day roosts for Soprano and Common pipistrelle bats, Leisler's bats and a possible maternity roost for Brown long-eared bats. This is predicted to result in a likely significant effect at a local geographic scale for all of these species, in the absence of mitigation. **Table 8.29** describes these roosts.

Only PBR173 and PBR154 are suspected to be vulnerable to a significant level of construction impacts. PBR173 is a suspected maternity roost for Brown long-eared bats and PBR154 is a known night and occasional day roost for small numbers of Lesser horseshoe bats alongside the N84 Headford Road. All other roosts are set back from the proposed development boundary or are in locations where the construction works for the proposed road development are less likely to be as intrusive.

The species that is potentially incurring the greatest potential loss of roosting is the Soprano pipistrelle bat population, which also happens to be the most commonly occurring bat in the country and recorded at almost all recording locations in the study area.

The impact on population of Lesser horseshoe bats lost as a result of demolition comes from the loss of one property at Aughnacurra (PBR178), a satellite roost to Menlo Castle (PBR06) (which itself will not be affected by the demolition works).

Table 8.29: Bat roosts adjacent to the proposed road development or known to be used by bats that cross the proposed road development

Approx. Chainage	Roost reference	Roost type

Ch. 13+000	PBR145	Building. Possible maternity roost for Brown long-eared bats, small roost
Ch. 13+000	PBR153	Building. Lesser horseshoe bat day/night roost
Ch. 13+600	PBR192	Building. Roost for small numbers of Brown long-eared bats (likely to be a transition/occasional roost)
Ch. 13+900	PBR228	Building. Roost for small numbers of Common pipistrelle bats (likely to be a transition/occasional roost)

Approx. Chainage	Roost reference	Roost type
Ch. 14+450	PBR242	Building. Roost for small numbers of unidentified Pipistrelle bats (likely to be a transition/occasional roost)
Ch. 13+000	PBR54	Building. Day/night roost for small numbers of Lesser Horseshoe bats. This roost is linked to the Menlo Castle roost and Cooper's Cave
Ch. 13+100	PBR112	Cooper's Cave. Day/night roost for small numbers of Lesser Horseshoe bats. Mating, summer and hibernacula. This roost is linked to Menlo Castle and bats cross the proposed road development in several places when moving between the two roosts

The potential impacts on these roosts varies considerably as it depends on the degree of linkages between the roost and the proposed road alignment, the degree of severance of connecting features, potential effects of light spill etc. These impacts are therefore addressed in the relevant sections below. Mitigation to protect bats during the removal of roosts are detailed in **Section 8.6.7.2.1**.

Habitat Loss

Bats rely on suitable semi-natural habitats which support the insect prey upon which they feed. The proposed road development will result in the loss of such habitats used for feeding by all bat species recorded in the study area. The studies of several different species as part of the collection of baseline data has demonstrated that more open habitats including pastures, open heathland and suburban gardens are also used by bats. Therefore, there are actually very few areas within the corridor of the proposed road development that are considered unsuitable for bats. These would be restricted to locations where the proposed road development crosses main roads and connects to the existing dual carriageway near Oranmore. All other locations are potentially used by bats.

The direct loss of foraging habitats will have an adverse effect on the individual bats that have been using these areas as it represents a loss of feeding resources. Where these feeding resources are close to roosts it may lead to decline in use of the roosts as bats tend to feed close to roost especially prior to giving birth when they need to save energy. Scientific data has been collected so that the extent of the foraging habitat used by the Lesser Horseshoe bats roosting at Menlo Castle has been determined. However, for other confirmed roosts the extent of the foraging habitats can only be estimated. Scientific data on the mean size of foraging areas for each species was sourced from research literature and was used to identify likely core foraging areas for the other species of bats.

The UK Bat Conservation Trust (BCT) has published research results on the identification of Core Sustenance Zones (CSZs) for different bat species. A CSZ refers to the area surrounding a communal bat roost within which habitat availability and quality will have a significant influence on the “resilience and conservation status” of the colony using the roost. The 2016 guidance states that:

"*With reference to planning and development the core sustenance zone is:*

- *The area surrounding the roost within which development work can be assumed to impact the commuting and foraging habitat of bats using the roost, in the absence of information on local foraging behaviour. This will highlight the need for species-specific survey techniques where necessary.*
- *The area within which mitigation measures should ensure no net reduction in the quality and availability of foraging habitat for the colony, in addition to mitigation measures shown to be necessary following ecological survey work."*

The core sustenance zone for the Irish bat species are listed below in **Table 8.30** with an indication of the level of confidence attached to the zone size.

Table 8.30: Bat roosts adjacent to the proposed road development and CSZ

Species	CSZ radius (km)	Confidence in zone size
Lesser horseshoe bat	2-3	Good: The CSZ in the context of the roost at Menlo Castle and at Coopers Cave is regarded to be 3km (mean maximum foraging distance 2.93km in August 2014, 3.39km in August 2014, 2.86km in May 2015). This has been calculated using the same approaches as outlined in the BCT guidance. In the context of other day roosts the CSZ of 2km has been applied.
Brown long-eared bat	3	Poor. No data on mean-maximum distance between roost and foraging areas available from the literature. In addition, the calculated weighted average (based on the number of bats used to calculate the CSZ) (3.45km) lies just below the threshold where it was rounded down to give a CSZ size of 3km. The CSV of the Brown Long-eared bat that was studied during radio-tracking in 2014 is regarded to be approximately less than 4km radius (maximum foraging distance was 4.07km but data collection only took place over 2 days). Since only one bat was tracked, the BCT recommended CSZ distance of 3km has been used.
Daubenton's bat	4	Poor. No data on mean-maximum distance between roost and foraging areas available from the literature. In addition, the calculated weighted average (based on the number of bats used to calculate the CSZ) (3.5001km) lies just above the

Species	CSZ radius (km)	Confidence in zone size
		threshold where it was rounded up to give a CSZ size of 4km. The maximum foraging distances of the Daubenton's bats that were studied has shown a limited feeding area within the Corrib corridor up to 2.5km from the roost. Due to the low numbers of bats that were analysed the BCT recommended CSZ distance of 4km has been used.
Natterer's bat	4	Good. Calculation based on a reasonable sample size from multiple colonies and studies.
Whiskered bat	1	Poor. Data available from multiple colonies but only for a single study for M. mystacinus.
Common pipistrelle bat	2	Moderate. Data available from multiple colonies but only from a single study.
Soprano pipistrelle bat	2	Good. Calculation based on a reasonable sample size from multiple colonies and studies.
Nathusius' pipistrelle bat	3	Poor. Calculation based on small sample size.
Leisler's bat	4	Poor. Calculation based on small sample size.

Unidentified bats have been given a CSZ radius of 3km which represents the average of the above CSZ radii.

For all confirmed roosts that were identified during the field surveys, the proportion of the CSZ that will be lost as a result of the proposed road development was calculated (refer to **Appendix E** for details). Whilst the CSZ is a generic radial distance from the roost, in some cases not all of this habitat would be regarded to be suitable foraging habitat for bats as it included built land with little suitable habitat to provide foraging resources. Bats will therefore not use all of the CSZ; they will selectively feed in the most resource-rich areas. However, such potentially unsuitable areas within the footprint of the proposed road development were not deducted from the CSZs for each roost, thereby giving a worst-case scenario for the assessment of impacts. CSZs around night roosts have not been included in this analysis as theoretically these roosts occur within the CSZ of the associated day roost.

The level of significance of the loss of these habitats is described in terms of impacts on individual roosts and then on the patterns of bat foraging as suggested by the bat activity data.

It is important to note that the percentage loss of area within the CSZ does not account for any additional barrier effects provided by the road which could prevent bats reaching foraging areas on the other side of the proposed road development. Research by Berthinussen and Altringham (2012a, 2012b, 2015) has identified landscape-scale reductions in bat activity and diversity as a result of the construction of road developments in the UK. Whilst barrier effects and severance of flight paths has been clearly demonstrated, the causes of displacement of bats from the margins of the corridor of the proposed road development are less clear. (Also see Bontadina et al. (2002), Reiter et al., (2013), CALTRANS (July 2016): *Technical Guidance for the Assessment and Mitigation of the Effects of Traffic Noise and Road Construction Noise on Bats*, Luo et al., (2015)).

The scale of significance of habitat loss during construction was therefore influenced by:

- the nature of the roost (transition/occasional roost occasionally used by small numbers of bats compared to maternity roosts for larger numbers of bats)
- Records of bats within the CSZ indicating concentrations of feeding within the CSZ which could suggest some areas being more important than others
- Proportion of suitable habitat within the CSZ
- Potential for the proposed road development to form a barrier to reaching the remaining portions of the CSZ (i.e. whilst the loss of CSZ may be very small, bats may not be able to reach it and consequently a larger proportion of the CSZ may actually be unavailable)

Table 8.31 describes the scale of the loss of habitats within the theoretical CSZ for each bat roost within the proposed development boundary. **Table 8.32** describes the scale of habitat loss associated with bat roosts which will not be removed as a consequence of the proposed road development.

Table 8.31: Extent of direct habitat loss within the theoretical core sustenance zone relating to the roosts within the proposed development boundary (* takes into account that c.10ha of foraging habitat is being retained intact within the boundary of the proposed road development at Menlough)

Approx. Chainage	Roost reference	Species	Area of habitat loss within the CSZ	% of CSZ	Likely significance of Impact of habitat loss
Ch. 3+320	PBR241 (Building to be retained)	Soprano pipistrelle bats	37ha	2.95%	The CSZ includes Bearna Woods on the opposite side of the road though access may be severed by the proposed road development. This species has been recorded to the north west where there is good foraging habitat available. Habitat unlikely to be a limiting factor in the locality. Due to the small size of the roost, the availability of suitable foraging habitat and the lack of evidence for severance of key roost attributes this impact is likely to result in a significant negative effect at a local geographic scale only.
Ch. 5+550	PBR267	Soprano pipistrelle bats Brown Long-eared bats	46ha 79ha	3.66% 2.79%	The CSZ includes a large proportion (estimated at >30%) of built land which is unlikely to actually be part of the CSZ. Brown long-eared bats have been recorded at 3 other locations to the north and west where there is good foraging habitat available. Habitat unlikely to be a limiting factor in the locality. Due to the small size of the roost, the availability of suitable foraging habitat and the lack of evidence for severance of key roost attributes this impact is likely to result in a significant negative effect at a local geographic scale only.
Ch. 8+600	PBR256	Brown Long-eared bats (maternity)	100ha*	3.54%	The CSZ includes a mixture of suburban, dense urban and rural landscapes. A large proportion of the CSZ area is of low suitability and this is to the south (opposite side) of the proposed road development. Few records of this species are found south of the road so it is predicted that bats in this

Approx. Chainage	Roost reference	Species	Area of habitat loss within the CSZ	% of CSZ	Likely significance of Impact of habitat loss
					roost are likely to rely on the local wooded suburbs in Aughnacurra, Glenlo Abbey and Menlough Village and are likely to use the unlit River Corrib corridor to move across the local landscape. The N59 Moycullen Road is currently likely to present a degree of barrier effect to regular movements as it is illuminated by pole mounted lights. Bats will also be able to continue using the unlit Corrib river corridor during the construction phase. Overall, the impact of habitat loss during construction is likely to result in a significant negative effect at a local geographic scale since these bats will be able to utilise the majority of suitable habitat in the CSV that is currently available to them.
Ch. 8+620	PBR178	Lesser horseshoe bat Brown long-eared bats	64ha* 101ha*	5.1% 3.57%	Lesser horseshoe bats: The radio-tracking studies did not record any of the tagged bats using this roost so it cannot be stated with confidence these bats use the same foraging areas as the bats from Menlo Castle/Cooper's Cave. However, it would be reasonable to assume that they prefer similar habitats including woodland, scrub, suburban gardens and wetlands. The loss of the habitats for any remaining bats is likely to result in a significant negative effect at a local geographic scale, as the proportion of suitable habitat within the CSZ is predominantly to the north away from the proposed road development. Despite several studies in the NUIG Campus to the south of the road, the records of Lesser horseshoe bats there appears to be relatively few and perhaps limited by the open landscape and effects of public lighting nearby.

Approx. Chainage	Roost reference	Species	Area of habitat loss within the CSZ	% of CSZ	Likely significance of Impact of habitat loss
Ch. 8+650	PBR255	Soprano pipistrelle bats	64ha*	5.1%	The CSZ includes a mixture of suburban, dense urban and rural landscapes. A large proportion of the CSZ area is of low suitability and this is to the south (opposite side) of the proposed road development. Few records of this species are found south of the road so it is predicted that bats in this roost are likely to rely on the local wooded suburbs in Aughnacurra, Glenlo Abbey and Menlough Village and are likely to use the unlit River Corrib corridor to move across the local landscape. The N59 Moycullen Road is currently unlikely to present a degree of barrier effect to regular movements as this species is recorded on both sides. Bats will also be able to continue using the unlit River Corrib corridor during the construction phase. Overall, the impact of habitat loss during construction is likely to result in a significant negative effect at a local geographic scale since these bats will be able to utilise the majority of suitable habitat in the CSV that is currently available to them and are not reliant on having to cross the construction area to reach foraging areas.
Ch. 8+700	PBR177	Soprano pipistrelle bats	65ha*	5.18%	The CSZ includes a mixture of suburban, dense urban and rural landscapes all of which may be utilised by this species. A large proportion of the CSZ area is of lower suitability and this is to the south (opposite side) of the proposed road development. This species has been recorded widespread across its theoretical CSZ. The N59 Moycullen Road is currently unlikely to present a degree of barrier effect to regular movements as this species is recorded. Bats will also

Approx. Chainage	Roost reference	Species	Area of habitat loss within the CSZ	% of CSZ	Likely significance of Impact of habitat loss
					be able to continue using the unlit Corrib river corridor during the construction phase. Overall, the impact of habitat loss during construction is likely to result in a significant negative effect at a local geographic scale, since these bats will be able to utilise the majority of suitable habitat in the CSV that is currently available to them and are not reliant on having to cross the construction area to reach foraging areas.
Ch. 10+050	PBR179	Soprano pipistrelle bats Brown long-eared bats	75ha 116ha	5.97% 4.1%	The CSV for both species includes the River Corrib which appears to be an important feature for bats and will not be affected in terms of habitat loss or its function as a corridor to permit passage to other foraging areas. The loss of the foraging habitats near the roost is a small proportion of that located in the surrounding area and it is unlikely the loss will result in a significant negative effect any greater than at the local geographic scale. Foraging opportunities will still be available on both sides of the proposed road development immediately adjacent to the fenceline for both species so if there is a barrier effect caused during construction then this is unlikely to translate into a decline in foraging close to the road.
Ch. 11+400	PBR253	Unidentified bats	122ha (3km radius CSZ)	4.32%	The CSZ is centred over Lackagh Quarry which itself offers little suitable feeding habitat but clearly, as suggested by the radio-tracking and use of unattended detectors, was used by seven species of bats. Areas of open water and the shelter offered by the quarry walls may offer good conditions for feeding. The area of the proposed road development will use all of the quarry area during construction but the topography

Approx. Chainage	Roost reference	Species	Area of habitat loss within the CSZ	% of CSZ	Likely significance of Impact of habitat loss
					of the quarry lend itself to providing linear “guides” across the construction area. Given that the roost itself is unlikely to harbour large numbers of bats, it is likely that the roost does not rely on the immediate surrounding habitat. Therefore, the loss of the habitat is not likely to result in a significant negative effect any greater than at the local geographic scale.
Ch. 12+150	PBR204	Lesser horseshoe bats Brown long-eared bats	76ha (2km radius CSZ) 126ha	6.05% 4.46%	The immediate surroundings of the roost are the detached dwellings and other properties fronting the N84 Headford Road. The surrounding habitats are deemed to be of moderate suitability for both species but better to the north than toward the city to the south. The loss of the habitat is unlikely to manifest itself in a loss of foraging resources as habitats to the north will still be accessible. However, this section was identified as a location where Lesser horseshoe bats cross the width of the alignment and thereby the loss of the connecting habitats could restrict movements for some of the bats from the Menlo Castle/Cooper’s Cave roosts. This barrier effect caused by habitat loss could cause a potential impact predicted to be significant at a National geographic scale in the absence of mitigation due to the importance of this crossing point for Lesser horseshoe bats at this location. The impact on Brown long-eared bats is likely to result in a significant negative effect at a local geographic scale due to the more widespread occurrence of this species in the CSZ as suggested by the other survey results.

Approx. Chainage	**Roost reference**	**Species**	**Area of habitat loss within the CSZ**	**% of CSZ**	**Likely significance of Impact of habitat loss**
Ch. 12+150	PBR182	Unidentified pipistrelle bats	126ha	4.46%	This roost was not deemed to be a currently active roost and only two droppings were found so the effects of habitat loss of this roost is likely to, at most, result in a significant negative effect at a local geographic scale.
Ch. 12+150	PBR196	Soprano pipistrelle Brown long-eared bats	78ha 126ha	6.21% 4.46%	This roost hosts a single bat or small numbers of both species. Its theoretical CSZ includes stretches from the River Corrib in the west to the Galway Racecourse to the east and includes habitats of high suitability mostly in the northern half and around the Coolagh Lakes. In reality, the likely CSZ does not include the most built-up areas of developed lands to the south and probably includes Ballindooley Lough and its network of hedgerows. The loss of the roost and the habitats within the theoretical CSZ is unlikely to affect the local population of both species which will still have plenty of foraging habitat available. They are also less likely to be significantly affected by the barrier effects posed by the habitat loss due to the small numbers of bats involved.
Ch. 12+960	PBR183	Brown long-eared bats	118ha	4.17%	The habitats closest to this suspected transition/occasional or night roost for this species were relatively open and not regarded to be optimal feeding habitat for this species. The likely CSZ would be expected to exclude lands to the southwest toward Ballinfoyle which are more built up and be skewed toward the rural landscape to the north and west. Since there will be plenty of foraging habitats available to the local bat population for this species, the only impact that could potentially be significant could be caused by the barrier effect of removal of connecting landscape features. Bats of this species that were radio-tracked in 2014 (bat no.

Approx. Chainage	Roost reference	Species	Area of habitat loss within the CSZ	% of CSZ	Likely significance of Impact of habitat loss
					5) generally stayed to the south of the proposed road development footprint.
Ch. 15+100	PBR205	Common and Soprano pipistrelle bats	92ha	7.32%	Bats in this roost at the racecourse are likely to have their CSZ encompassing lands to the east and the west as suggested by the suitable habitats found there and bat detector records for both species in these areas. The CSZ is unlikely to stretch to the southwest due to lack of suitable habitats there so even if there is a barrier effect caused by habitat loss there is not likely to be a significant negative effect.
Ch. 8+750	PBR210	Lesser horseshoe bat	NA	NA	Night roost for Lesser horseshoe bats. Since this is within the range of a day roost (likely to be PBR178 or PBR06) the impact on the CSZ is covered by the commentary above.
Ch. 15+250	PBR270	Unidentified bat species	106	3.76	This roost may be abandoned as evidence was limited to small number of old droppings. Bats in this roost to the east of the racecourse are likely to have their CSZ encompassing lands to the east and the west as suggested by the suitable habitats found there. The CSZ is unlikely to stretch to the southwest due to lack of suitable habitats there so even if there is a barrier effect caused by habitat loss there is not likely to be a significant negative effect.

Table 8.32: Extent of direct habitat loss around confirmed bat roosts (day roosts close to the proposed development boundary, but not to be removed) (* takes into account that c.10ha of foraging habitat is being retained intact within the boundary of the proposed road development at Menlough)

Chainage	Roost reference	Species	Area of suitable habitat loss	% of likely core foraging area.	Likely significance of Impact of habitat loss
Ch. 1+600	PBR225	Soprano pipistrelle bats Brown long-eared bats	35ha 44ha	2.79% 1.56%	This roost is a possible maternity roost for Soprano pipistrelle bats and is located close to the footprint of the proposed road development. Whilst screened by a cluster of trees, the buildings will be close to earthworks and site clearance and be adversely affected by these. Surrounding habitats are mostly heath and peatland and whilst open in nature they do support feeding resources as suggested by detector records for this species along the minor roads. The impact of habitat loss is likely to result in a significant negative effect at a local geographic scale during construction due to the barrier effect likely to be posed by the proposed road at this location.
Ch. 4+500	PBR139	Leisler's bat.	100ha	1.99%	This property on the Cappagh Road was used by a tagged Leisler's bat. This species is known to move roost locations frequently and is also less affected by severance of landscape connectivity. It is predicted that there will be little material disturbance to the landscape close to the roost and that the habitat loss is unlikely to affect this small roost.
Ch. 7+400	PBR49	Soprano pipistrelle Brown long-eared bats	64ha 82ha*	5.1% 2.9%	This roost on the Letteragh Road is likely to be supported by the woodland immediately surrounding the buildings and also small clusters of woodland and hedgerows to the southwest at Mincloon. The removal of habitats will include some optimum habitat for both species and will also pose a considerable barrier effect to movements to the north east from the roost due to the proposed N59 Letteragh Junction. Overall the

Chainage	Roost reference	Species	Area of suitable habitat loss	% of likely core foraging area.	Likely significance of Impact of habitat loss
					potential impact is likely to result in a significant negative effect at a local geographic scale.
Ch. 8+150	PBR173	Brown long-eared bats	92ha*	3.25%	This potential maternity roost for this species is located close to the footprint of the proposed road development and it is likely that the removal of habitats will result in loss of foraging and connections to other foraging resources. However, habitats preferred by this species would be the taller dense hedgerows and gardens in The Heath to the south which will remain connected to the current roost location. However, the indirect effects of habitat loss may result in disturbance to the roost on the basis of proximity alone. Such an impact is likely to result in a significant negative effect, at a local geographic scale.
Ch. 0+50 N59 Link Road	PBR73	Natterer's bat	122ha*	2.43%	This roost at St James's Church was recorded by Members of Galway Bat Group. This is only one of three roosts for this species and bat detector records for Myotis species generally are thinly distributed across the study area. The location of the roost is close to a proposed link road in cut which could affect flight paths if bats are present. Significant impacts on this species are unlikely given the absence of any evidence that the roost is occupied. The N59 Moycullen Road is also illuminated at this location and may prevent bats flying eastwards. Suitable habitat for this species are also found to the south and landscape connectivity in this location will not be compromised by the proposed road development.
Ch. 9+375	PBR06	Lesser horseshoe bat	88ha* (based on merged	3.35%	Menlo Castle roost is located at the edge of the proposed development boundary for the proposed road development but is 140m from the likely working area. This distance is unlikely

Chainage	Roost reference	Species	Area of suitable habitat loss	% of likely core foraging area.	Likely significance of Impact of habitat loss
		Daubenton's bats.	radio tracked bats MCPs from 2014 and 2015) 11ha* (based on core foraging area recorded May 2015) 129ha*	8.8% 2.57%	to directly affect the roost during the construction as most Lesser horseshoe bats were noted to fly straight into the adjoining hedgerows and hugged the edge of the castle. The loss of habitats is likely to affect the foraging resources to the highest degree during the pre-partum period (May-June) when female bats tend to hunt close to the roost. Radio-tracking of bats in 2015 in this period notes that the CSZ is bisected by the road corridor with c.45ha left to the southeast and c 70ha to the northwest. There is suitable habitat within 2km of the roost that bats are known to use at other times of year and it is not unreasonable that bats may adapt their CSZ geometry to address changes in the landscape providing there are linkages to do so. Nevertheless, the potential loss of pre-parturition feeding habitat (11ha, of which 8ha is thought to be optimum feeding habitat) and the potential indirect loss of feeding habitats due to a barrier effect (45ha) is likely to result in a significant negative effect at a national geographic scale, as it could threaten the long-term viability of the roost. The potential impact on the Daubenton's roost during construction is not deemed to be significant as bats will be able to reach feeding ground in the river corridor unimpeded and there will be no loss of this habitat type from their CSZ. Other habitats types will be removed but are less likely to be utilised as suggested by radio-tracking data collected for this species.
Ch. 13+000	PBR145	Brown long-eared bats	120ha	4.24%	This roost was used by a post-lactating female which could be a small maternity roost for this species. It was captured at Cooper's Cave and is therefore known to fly in the area south of Castlegar. In the absence of any radio-tracking data to

Chainage	Roost reference	Species	Area of suitable habitat loss	% of likely core foraging area.	Likely significance of Impact of habitat loss
					confirm the location of the CSZ, it is predicted that the loss of habitat to the north of the roost may cause depreciation in the foraging resources available to the colony and lowering of fecundity. It is unlikely that the roost would be abandoned as there is still plenty of foraging habitat available to the south. Therefore, such an impact is likely to result in a significant negative effect at a local geographic scale.
Ch. 13+000	PBR153	Lesser horseshoe bat	100ha	3.54%	This shed/stable was used as a day/night roost by a single tagged bat (No. 12) in 2014. This bat foraged almost exclusively south of this roost between Castlegar and Cooper's Cave and particularly in the network of small fields south of Castlegar. Since there was little evidence of bats using this roost on a continuous basis and little evidence for flights across the proposed road development, the effects on this roost alone is not deemed to be significant. However, if the habitat loss prevents the passage of individuals between the Menlo Castle maternity roost and Cooper's Cave then it may isolate this roost from the core population in Menlough. The impact is likely to result in a significant negative effect at a local geographic scale.
Ch. 13+600	PBR192	Brown long-eared bats	133ha	4.7%	This roost is thought to support a small number of bats of this species as suggested by the droppings but no live bats were noted in 2015 or 2016. The property is close to the edge of the proposed construction area and any linear features connecting bats to the scrub and woodland to the north will be severed. Connectivity to the south toward Castlegar will be maintained and it is predicted that this habitat is sufficient to support this small roost. Nevertheless, the loss of the connectivity to the

Chainage	Roost reference	Species	Area of suitable habitat loss	% of likely core foraging area.	Likely significance of Impact of habitat loss
					north and the potential disturbance caused by habitat loss may cause abandonment of the roost which is likely to result in a significant negative effect at a local geographic scale.
Ch. 13+900	PBR228	Common pipistrelle bats	76ha	6.05%	This small roost of bats (3-4 no.) is predicted to have its CSZ primarily to the north and east, especially the scrub and the quarry close by. There are well distributed detector records for this species throughout the theoretical CSZ. Loss of habitat close to the roost may displace bats from feeding near the construction area but the availability and connectivity to habitat to the north and east will be maintained. The impact is likely to result in a significant negative effect at a local geographic scale if the roost is used less frequently or abandoned altogether, although the latter is not predicted since the building is well screened from the construction area by trees and scrub.
Ch. 14+450	PBR242	Unidentified pipistrelle bats	82ha	6.53%	The small numbers of bats thought to use this roost near the Galway Racecourse are likely to have their CSZ encompassing lands to the east and the west as suggested by the suitable habitats found there. The CSZ is unlikely to stretch to the southwest due to lack of suitable habitats. However, there may be a barrier effect caused by habitat loss preventing bats reaching lands to the north and east of the road during the construction phase although this will be temporary and likely to be reversed once the Galway Racecourse (ST14/02) tunnel is covered. The impact is likely to result in a significant negative effect at a local geographic scale for this roost.

Chainage	Roost reference	Species	Area of suitable habitat loss	% of likely core foraging area.	Likely significance of Impact of habitat loss
Ch. 13+100	PBR112	Lesser Horseshoe bats	124ha	4.39%	Cooper’s Cave. Passage between here and Menlo Castle is likely to be significantly affected by the barrier effects posed by the loss of connecting features during construction of the proposed road development. This potential impact is likely to result in a significant negative effect at a national geographic scale due the level of importance that the cave plays in the life cycle of the bat population in this area.

The proportion of habitat loss relating to each roost being lost is less than 7% of the CSZ in all cases except for PBR225 (stable block at Galway Racecourse) and less than 5% of the CSZ in the majority of cases. In the case of PBR225 the majority of the "real" CSZ is likely to extend to the quarry to the north west and agricultural land as foraging opportunities are more limited in the urban landscapes to the south. Much of the "real" CSZ is not affected by the proposed road development.

For Pipistrelle bat species which are adapted to feeding in a wide variety of landscape types[65], the impact of habitat loss during construction is not predicted to be significant since these bats will be able to utilise the majority of suitable habitat in their CSZ that is currently available to them and are not reliant on having to cross the construction area to reach foraging areas. This applies particularly to roosts to the north of the proposed road development as the majority of optimal feeding areas are outside of the urban city core which lies to the south.

For Lesser horseshoe bats which show a greater preference for following linear landscape features between roosts and foraging areas[66], the potential impact of habitat loss is compounded by the barrier effect which may prevent bats using suitable habitats on the other side of the proposed road development or moving between day and night roosts or between different roosts used at other times of year. Impacts are regarded to be potentially significant at a county level if the foraging range is affected (e.g. by not being able to reach night roosts) or national-scale where the fecundity or mortality rates are affected due to lack of feeding resources as a result of loss of feeding habitat and barrier effects. Significant efforts have been made to provide effective methods to getting bats across the construction areas and underneath or over the proposed road development so that they can avail of habitats on both sides of the proposed road development.

The magnitude of habitat loss for Lesser horseshoe bats has been measured in terms of the physical loss of the most important habitat as a result of the proposed road development. The area deemed to be of highest importance for Lesser horseshoe bats is regarded to be the core foraging area used by Menlo Castle (PBR06) radio-tracked bats in summer 2015. Prior to the birthing period in mid-June, female bats will utilise the best foraging habitats closest to the roost and research in at least one study (Bontadina et al, 2002[67]) has highlighted the importance of habitat within 600m of the roost. Whilst 11ha of habitat will be lost (which equates to nearly 9% of the core foraging area estimated after radio-tracking in 2015) only 7ha is regarded to be optimum feeding habitats for this species. This area of woodland, scrub, hedgerows and grassland will be lost in the area from the River Corrib to the Bothár Nua which spans the core foraging area for the Menlo Castle roost (PBR06).

---

[65] In the CEDR guidelines they are in Group C: Bats with medium manoeuvrability. They often hunt and commute along vegetation or structures at variable heights, but rarely close to or within the vegetation. May also hunt in open areas. Commuting over open stretches generally takes place at low to medium heights (typically 2 – 10m) with no clear tendency to lower flight.

[66] In the CEDR guidelines they are in Group A: Extremely manoeuvrable bats, which often fly within foliage, or close to vegetation, surfaces and structures at variable flight heights. When commuting, they often follow linear and longitudinal landscape elements. Low-flying (typically < 2m) when commuting over open gaps.

[67] Bontadina, F., Schofield H. and Naef-Daenzer B. (2002) *Radio-tracking reveals that Lesser horseshoe bats (Rhinolophus hipposideros) forage in woodland*. J. Zool., Lond. 258, 281-290.

The loss of this 7ha equates to 5.6% of the core foraging area (125ha) recorded in 2015 which is regarded to be the area of highest importance for the roost[68], although not all of the core foraging area is used equally by bats. The loss of habitat within the core foraging area for the Menlo Castle Lesser horseshoe roost (PBR06) is deemed to be a potentially significant factor threatening the viability of the roost there. If bats cannot feed close to the roost, especially close to the birthing period, then fecundity may be reduced. When compounded by other potential effects of the proposed road development (collision, barrier effects) this relatively small loss of habitat might have a significant effect on the population.

Other bat roosts in proximity along the proposed road development are unlikely to be associated with such optimum bat habitats. The loss of woodland in the Menlough area is unavoidable as the belt of woody vegetation on the northeast bank of the river stretches from the Quincentenary Bridge in the city all the way to Menlough Village and therefore the proposed road development will inevitably cross it at some location.

In order to prevent the loss of foraging habitats resulting in an adverse impact on bat species at either a local, county or national geographic scale, design measures have been incorporated into the design of the proposed road development.

The tables above (**Table 8.31** and **Table 8.32**), documents the impact predictions relating to each individual roost site that will either be removed as part of the construction phase or are close enough to the working footprint so as to warrant concern. There are other roosts further away from the proposed road development that have their CSZs that overlap with the proposed road development and could be adversely affected by the loss of foraging habitats. The impacts on a broader geographic scale are discussed below.

Fragmentation of foraging habitat and commuting routes and areas used by bats for other non-roosting activities[69]

Given that there is evidence of bats crossing the proposed road development in multiple locations, and that all parts of the proposed road development are within the theoretical or proven CSZ of at least one bat roost, there is the potential for the proposed road development to act as a barrier to flight paths for all species (except Leisler's bats which have been shown to fly at greater altitudes so as not to be affected by ground level features) and in all locations.

The barrier effect can manifest itself as soon as the site clearance phase commences and the barrier itself is in the form of the cleared lands. Removal of hedgerows, treelines, woodland and scrub will take place across the length of the proposed road development. Whilst it is not proposed to remove all the vegetation within the proposed development boundary, it has been assumed that intervention of some kind in the landscape may occur within the boundary to the extent that it could affect bat behaviour, thereby assessing the worst-case scenario.

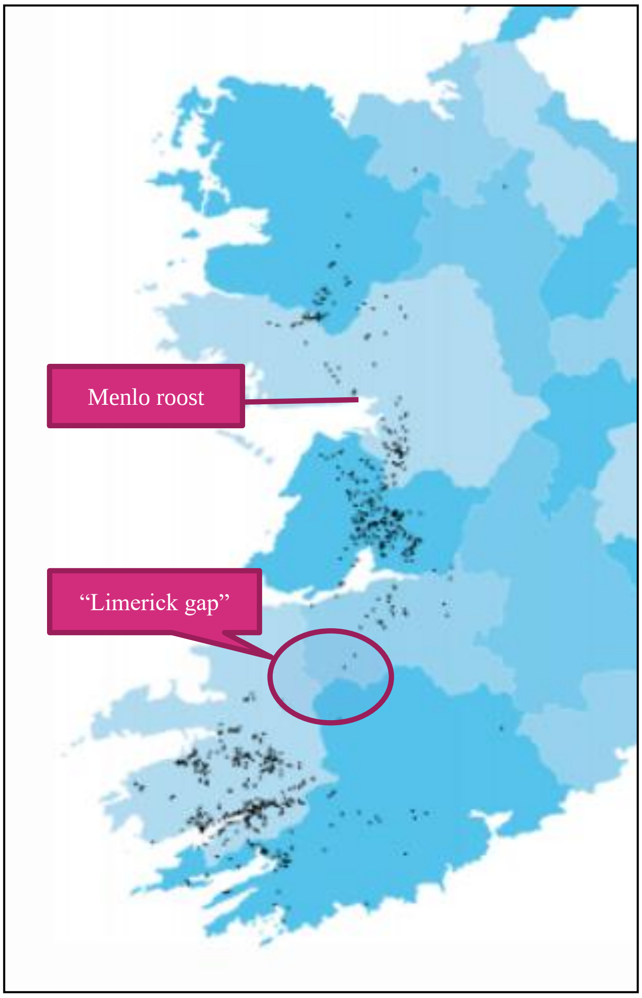
[68] This differs from the 98ha of land within the proposed development boundary which is within the 2925ha of CSZ for the roost at Menlo Castle, based on the MCPs for bats tracked in 2014 and 2015.
[69] As fragmentation of feeding habitat has the potential to disturb normal bat behavioural patterns, and thus adversely affect the ability of local bat populations to persist and reproduce, impacting on their local distribution and/or abundance and thereby conflicting with Regulation 51(b) of S.I. 477.

Interpretation of the patterns of bat activity records has indicated that potential barrier effects would be most significant at the following locations:

1. Bats flying to/from Bearna Woods – The woods were one of the few sites where Natterer's bats were recorded and also support a small/dispersed population of Lesser horseshoe bats. The relatively open, heathy landscape to the north of the woods would be regarded to offer less suitable opportunities for bat foraging so the woods are likely to be important for local populations of several bat species.
2. Aughnacurra (including Chestnut Lane and Upper Dangan) – the potential barrier effect posed by the proposed road development here is somewhat reduced by the proximity of the River Corrib which bats use as a flight corridor. The barrier effect would be likely to supress movements at a very localised scale.
3. Barrier effects in the area spanned by Menlough Castle-Coolagh-Castlegar are potentially the most significant as it is the known core foraging area/CSZ for the nationally-important Menlo Castle population of Lesser horseshoe bats as well as for roosts of other bat species close to the proposed development boundary. Severance of Lesser horseshoe flight paths between Menlo Castle and Cooper's Cave in particular could have significant effects on the ability of the breeding population to mate and hibernate in suitable roosts. Severance of flight paths between day and night roosts also could affect the ability of bats to reach suitable foraging areas further away by using the night roosts as stepping-stones.
4. The location of the Menlo Castle roost is regarded to be at a key location in the national distribution of Lesser horseshoe bats. The main strongholds for this species are in south Mayo, mid-Clare/south Galway, Kerry and West Cork but the species is present all along the west coast counties from Cork to Leitrim. Analysis of the genetic and echolocation differences has revealed that the Irish population is made up of differentiated north and south populations (Dool et al, 2016[70]). Factors such as habitat connectivity were identified as being one of the reasons why this species is subject to population fragmentation at a national scale. Dool et al (2016) describe the "Limerick gap" as an area where there has been a separation of lesser horseshoe bat populations, leading to genetic isolation in these areas. As can be seen in **Plate 8.2**, the Menlo Castle roost is in an area of similarly low densities of roost records and the loss of the population could create a new gap in in the natural range of the species in Ireland.

[70] Dool S.E., Puechmaille S.J., Kelleher C., McAney K., and Teeling E. (2016) *The effects of human-mediated habitat fragmentation on a sedentary woodland-associated species (Rhinolophus hipposideros) at its range margin.* Acta Chiropterologica, 18(2): 377–393, 2016.

Plate 8.2: Lesser horseshoe bat population distribution (taken from Bat Conservation Ireland distribution maps)



5. Based on the distribution of maternity roosts in the range of this species in Ireland, the Menlo Castle maternity roost and the local population it supports are of national importance, as defined in NRA (2009) “a smaller population may qualify as nationally-important where the population forms a critical part of a wider population or the species is at a critical phase of its life cycle”. However, the roost size falls well below the threshold for designation as a Special Area of Conservation (100 bats in maternity roost) and it has been confirmed by the NPWS as not being part of the Lough Corrib cSAC’s qualifying interest population.

6. There are only six known maternity roosts in and around Lough Corrib, with the majority of roosts concentrated on the northern shores near Cong. Only two roosts are located on the southern end: Ross Lake Gatehouse and Menlo Castle. These southern roosts may be stepping-stones for long-term movements and gene flow between bats at the northern shore of Lough Corrib, Lough Mask and Lough Carra and populations in South Galway and Clare. Recent counts from Ross Lake Gatehouse have shown that this roost has undergone significant deterioration resulting in decline in numbers from 150 bats in 1994 to five bats in 2011 (Rebecca Teesdale pers. Comm., 2014 and p44 in Roche et al, (2015)). A decline in the Ross Lake roost could potentially

increase the relative importance of the roost at Menlo Castle as a stepping stone roost, as it would be the only significant maternity colony at the southern end of Lough Corrib. Menlo Castle itself would not appear to be in a structurally-stable condition and the bat roost is vulnerable to rock fall, vandalism and blockage within the chimney flue. If bats were not able to reach the foraging areas and Cooper's Cave due to a barrier effect, then it would add another impact which might put the viability of this population at risk. Such impacts have the potential to result in a significant negative effect at the national geographic scale for the Lesser horseshoe bat. There is no evidence to suggest that Menlo Castle Lesser horseshoe bat population is connected to the Eborhall Lesser horseshoe bat population, which is the qualifying interest (QI) population for Lough Corrib cSAC. Any predicted impacts on Lesser horseshoe bats associated with the proposed road development will not affect the conservation objectives of the Lough Corrib cSACs QI Lesser horseshoe bat population, nor the QI Lesser horseshoe bat populations of any other European sites.

The numbers of Lesser horseshoe bats recorded using Cooper's Cave for hibernation has been relatively small (around 10% of the estimated roost size at Menlo Castle) but much of the cave is not accessible and there may be higher numbers present. The only other hibernation site known for this population is Menlo Castle and the roost site is not accessible for counting. A wildlife overpass has been included as part of the design of the proposed road development to allow bats to reach the cave for hibernation and to avoid them being forced to use less suitable locations. While Cooper's Cave is under ongoing pressures from fly tipping and disturbance, it is likely that bats will continue to use it unless the entrance is blocked altogether.

The western portion of the proposed road development (from Bearna to Upper Dangan) has a lower distribution density of bats and has less-suitable habitats for foraging but a barrier effect is still predicted in the absence of any effective mitigation. Such potential impacts are likely to result in a significant negative effect at a local geographic scale as the bat populations have been valued as being important at a local geographic scale, there are few roosts known in this area, and no important landscape features (such as major watercourses, areas of woodland or hedgerow networks) are predicted to be severed.

Mitigation to preserve flight paths across construction areas are detailed in **Section 8.6.7.2.1**.

Installation of temporary working and site compound lighting which may cause indirect disturbance of flight patterns

As construction works will typically be undertaken during normal daylight working hours, the requirement for lighting for construction works during night time will be limited.

Over the expected 36-month construction phase there will be up to a total of 10 weeks of night time working. Temporary night-time closure of existing local roads may be required where overbridges are to be constructed at locations such as the Rahoon Road, Letteragh Road, N59 Moycullen Road, Menlo Castle Bóithrín, Bóthar Nua, Seanbóthar, N84 Headford Road, N83 Tuam Road, Briarhill Business Park Road and R339 Monivea Road.

Night-time working requiring the use of floodlighting to permit safe working have the potential to displace bats from the illuminated area. This will be particularly sensitive at the following locations:

- N59 Moycullen Road near the Aughnacurra satellite roost (PBR178) and a proposed replacement roost structure
- Menlo Castle Bóithrín which is an important flight path for Lesser horseshoe bats and other bat species
- Bóthar Nua which is an important flight path for Lesser horseshoe bats and other bat species
- Seanbóthar which is an important flight path for Lesser horseshoe bats and other bat species
- N84 Headford Road which is an important crossing point for Lesser horseshoe bats and close to known night/occasional day roosts for this species and is also close to a proposed replacement roost structure

In all cases where lighting may cause disturbance, it will be temporary in nature but may last over several consecutive nights and this could result in temporarily lower bat diversity in these areas. Such displacement (which would be a matter of metres) could prevent bats from accessing foraging areas or roosts, or result in bats taking more circuitous routes to get to foraging areas and hence potentially depleting energy reserves. It cannot be predicted precisely when these works will take place during the year but it could be a significant disturbance if affecting bats pre-parturition (birth) or pre-hibernation when energy reserves are essential for survival. However, the potential impact only arises during months when bats are most active (April to September) and during these months the need for night lighting is likely to be limited as daylight hours are longer. Such potential impacts have the potential to result in a significant negative effect at a local geographic scale.

8.5.6.2.2 Operational Phase Impacts

Direct mortality through collisions

Research (Butchkowski and Hassinger, 2002; Dodd et al., 2004; Capo et al., 2006; Choquene, 2006; Glista and DeVault, 2008; Hein et al.,2009; Russell et al., 2009; Sparks and Choate, 2000; Whitaker and Mumford, 2009) has provided evidence that mortality of bats due to road collisions can reach an annual mortality of 5% of the bats in local roosts. Altringham (2008) arrived at a similar estimate, based on conservative calculations for a road in the UK crossed by lesser horseshoe bats from a large roost (data from Billington, 2001-2006).

Theoretical studies (e.g. Lande 1987, With and King 1999, Carr and Fahrig 2001) *"*show that populations of animal species with low reproductive rates and high intrinsic mobility, such as bats, are more susceptible to decline and ultimately extinction by the additional mortality caused by roads" (taken from Appendix A, WC1060 main report).

Lesiński (2007) recorded mortality highest where roads approached tree stands (up to 6.8 per km/year) or crossed a forest (2.7 per km/year) and lowest within densely built-up areas (0.3 ind./km/year). If the highest rates were applied to the Lesser horseshoe bat roost at Menlo Castle (PBR06) then this could equate to 34 deaths per year based on the maximum roost foraging area being bisected by c. 5km of the proposed road development (based on radio-tracking in 2014). The lower rate for mortality near forests would result in 13 deaths per year. Whilst the long-term population fluctuations are not known for this population, in a worst-case scenario such mortality rates could cause the entire roost to become extinct in less than two years assuming that all of the bats in the roost are exposed to the same level of mortality risk and that all of the bats killed per km were of this species. The loss of this roost would be regarded to be a significant potential effect at a national geographic scale, assuming a worst-case scenario and in the absence of any mitigation.

Similar mortality rates could be applied to similar low-flying gleaning species of bats such as Brown long-eared bats and some *Myotis* species such as Daubenton's bats. Since this would have significant negative effect on these species, a complex mitigation strategy has been developed and is presented in **Section 8.6.7.2.2**.

Barrier/Severance effects

The effects of the proposed road development on the movements of bats across the landscape after completion have been studied more frequently than the effects during the construction phase. Monitoring of bat activity around road schemes have shown the effects of traffic disturbance, lighting, loss of connecting landscape features and foraging habitats can result in depreciation in bat activity up to 1.6km from the road itself in certain landscapes (Berthinussen and Altringham (2012b, 2015), Elmeros et al (2016). The research is still in progress and the effects of different habitat types at the edge of the road carriageway is yet to be fully understood. In the absence of fully applicable research, it is predicted that potential significant impacts caused by the proposed road development acting as a barrier to landscape-scale movements may occur in the following location and on the following species:

- Movements of bats to Bearna Woods: As described in the context of impacts on PBR241, the proposed road development may impact on the movements of bats using north-south trajectory. Bearna Woods was noted as an area of relatively high bat diversity and abundance and is one of the few areas of continuous woodland in this part of the study area. A barrier effect may limit populations mixing outside of the Bearna Woods area and potentially lead to decline in reproductive rates. There are seven confirmed roosts south of the proposed road development near Bearna which could persist in the presence of the proposed road development but will have more limited access to foraging areas north of the proposed road development. The survey results have suggested widespread bat activity along the roads aligned north-south. Some of these may continue to be used by bats and cross the narrower parts of the mainline of the proposed road development but there are no junctions in this location that allow bats to pass under the proposed road development

- Movements of bats along banks of the River Corrib: Currently, bats move up and down the River Corrib corridor unhindered by lighting or physical obstacles. It is possible that existing lighting within the NUIG campus and at Quincentenary Bridge may be a deterrent to light-sensitive bats such as Lesser horseshoe bats. The proposed road development will introduce embankments for the bridge on both banks which could present a physical barrier to such movements. While bats will be able to fly around the toe of the abutments on each bank and under the elevated deck of the proposed River Corrib Bridge and have free movement over the river itself, such re-routing of flight paths could add to the energy requirements for individual bats. On the west bank, assuming that bats are commuting north-south in the area from the N59 Moycullen Road to the river (750m wide corridor), the proposed abutments would reduce the flight corridor to 420m and lead to an additional c. 500m of flight to get around the abutment in the Aughnacurra area. Assuming a flight speed of 3.5m/s (Lesser horseshoe bat) this would mean that a flight of 60m across the proposed road development that would normally take 17s will take 142s when the proposed River Corrib Bridge is in place. On the eastern bank, bats will be able to fly either around the western toe of the bridge abutment or under the road at the Menlo Castle Bóithrín with the barrier stretching between the two points for a distance of 210m
- Movement of bats in the area around Menlough-Coolough Road-Ballindooley-Castlegar area: this area is regarded to be important for Lesser Horseshoe bats, Brown long-eared and Pipistrelle bats. The movement of Lesser horseshoe bats has been confirmed by radio-tracking individuals in 2014 and 2015. This data suggests that the majority of flights across the proposed road development are in the section Ch. 9+500 – Ch. 10+150 between the River Corrib and the Coolough Road. The embankment section will either provide a barrier to bats or force them up and over the proposed road development bringing them across the flow of traffic and risking collision with vehicles. Similar potential barrier effects are predicted at the N84 Headford Road and further east at Ch. 12+200 – Ch. 12+450 and at locations north of Castlegar Village. Static detectors placed at Ch. 12+600 and Ch. 12+750 in 2015 recorded relatively high levels of activity for Lesser horseshoe bats, Common and Soprano pipistrelle bats and Leisler’s bats suggesting that they would be affected by a barrier to movement in this location (Leisler’s bats less so due to their tendency to fly at height).

Barrier effects in the absence of mitigation are likely to result in a significant negative effect at a local geographic scale for all chainages along the route of the proposed road development and at a national geographic scale for effects in the section Ch. 8+500 (N59 Moycullen Road) to Ch. 13+150 (School Road, Castlegar).

Mitigation to reduce barrier effects within the design and operation of the proposed road development are detailed in **Section 8.6.7.2.2**.

Indirect disturbance of flight patterns due to operational lighting

The barrier effect can be compounded by light spill associated with the illumination of the corridor of the proposed road development. Examination of light spill modelling has identified potential light spill impacts on bats (where light levels exceed 1 lux) at the following locations:

- Ch. 2+850: Lighting at the Bearna East Roundabout may impact on the movement of bats in the locality and prevent them using the proposed culvert CO2/01b. However, proposed landscape planting near the mouth of the culvert entrances will help in shading the flight paths approaching the culvert at this location to allow bats to fly through
- Ch. 4+300 - Ch. 4+550: Lighting at the Cappagh Road junction is close to PBR139 and PBR146 (both Leisler's bat roosts) and Soprano pipistrelle activity has been recorded nearby. Localised displacement may occur in this area although the presence of roadside scrub and garden shrubs and trees will provide shaded area which may be used by bats to avoid lit areas
- N59 Link Road North and South: This will be illuminated over a length of 2.4km across open agricultural and heath landscape. Light spill may cause a localised barrier to movements in an east-west direction although there are only two roosts (PBR49 and PBR237) which are parallel to this link road and neither are in the light spill of the proposed lighting design
- Ch. 9+150 – Ch. 9+250: Lighting will be provided as part of the proposed NUIG Sports Pitches. Whilst there is planning permission to floodlight the existing pitches adjacent to the river, they are currently unlit. There are a number of roosts in this general area (for Lesser horseshoe bat, Daubenton's bat, Soprano pipistrelle bat and Brown long-eared bats) however none of them are located within the area of light spill from the proposed lighting. The closest roost is Menlo Castle PRB06 which is approximately 375m from the proposed sports pitches at their closest point. No roosts will be directly impacted. The light spill will not impede bats from using the River Corrib for feeding or commuting. There may be a displacement effect locally from the sports pitches themselves and for an area around the sports pitches due to light spill, however the bat survey results did not record significant levels of usage of these fields by any species.
- Ch. 11+050 – Ch. 11+150: Lighting at western entrance to Lackagh Tunnel. This will be localised and will not affect roosts but is likely to have a displacement effect on bats over an area of circa 150m x 50m where light levels exceed 1 lux. Whilst there is little bat activity data collected for this location, it is likely to be used by several species of bats for feeding and commuting
- Ch. 11+380 – Ch. 11+500: Lighting at eastern entrance to Lackagh Tunnel. This will be localised and will not affect roosts but is likely to have a displacement effect on bats over an area of circa 150m x 50m where light levels exceed 1 lux. There is bat activity data collected for this location including feeding and resting Lesser horseshoe bats and it is likely to be used by several other species of bats for feeding and commuting

- Ch. 11+975 – Ch. 14+500: The N84 Headford Road at this location is currently unlit and the proposed new lighting will introduce approximately 8ha of illuminated area. This area is used by several species including Lesser horseshoe bats and will result in a displacement from this area. PBR154 (a Lesser horseshoe bat night roost and occasional day roost) will be impacted upon by light spill to the roost. However, the entry to the roost will still remain unlit and well shielded from the lighting as it faces to the east and is at a lower elevation than the N84 Headford Road and the proposed road development. Light spill from lighting columns in the area of Ballindooley-Castlegar (Ch. 12+600 to Ch. 13+600) will generally be contained within the immediate vicinity of the proposed road development which, at this location, is sunken below the level of the surrounding landscape. Light spill here will help to deter bats from crossing the road and reduce the risk of vehicle collision, whilst the Castlegar Wildlife Overpass will be in darkness and provide a safe crossing point.
- Lighting in the area around the N83 Tuam Road Junction, the City North Business Park Link and the Parkmore Link Road will alter and may have localised impacts on the flight paths of Pipistrelle species recorded nearby
- Ch. 14+850 – Ch. 15+000: Eastern end of Galway Racecourse Tunnel entrance. This will be localised and will not affect roosts but is likely to have a displacement effect on bats over an area of circa 150m x 50m where light levels exceed 1 lux. This may lead to localised impacts on the flight paths of Pipistrelle species recorded nearby
- Ch. 15+150 – Ch. 15+300: Western end of Galway Racecourse Tunnel entrance. This will be localised and will not affect roosts but is likely to have a displacement effect on bats over an area of circa 150m x 50m where light levels exceed 1 lux. This may lead to localised impacts on the flight paths of Pipistrelle species recorded nearby
- Ch. 15+500 – Ch. 17+483 (end of proposed road development): Scattered records of Pipistrelle species and Leisler’s bats in this location suggest that the widened illuminated corridor in this location will result in localised displacement. This impact is not regarded to be significant as most of the bat records suggest activity is focused to the north east away from the proposed road development

The potential impact of vehicle lighting has been assessed in the context of the potential illumination of Menlo Castle (PBR06). This would have particularly high sensitivity due to the absence of any notable lighting at present and the presence of both a maternity roost and hibernacula for Lesser horseshoe bats, a maternity roost for Daubenton’s bat and a former Brown long-eared roost; all species which would be susceptible to lighting impacts. In a worst case scenario, the cumulative impact of many vehicles on the River Corrib Bridge on Menlo Castle is less than 0.01 lux and this would only result on the top section of the castle. Given that the Lesser horseshoe bats generally flew at heights of 1-3m above the ground at and near the roost location this is not predicted to affect their flight paths. This level of illumination is also well within the tolerance range for this species.[71].

There are no roosts that will be directly illuminated by the proposed operational lighting to the extent that any likely significant effects are predicted.

8.5.6.3 Badger

8.5.6.3.1 Construction Phase Impacts

There were a total of 17 badger setts recorded across the study area. Three of these setts (S9, S11 and S14) were within the proposed development boundary. Two setts (S3 and S10) were within the ZoI of general construction activities (i.e. within 50m) based upon the impact distance bands described in the TII guidance (National Roads Authority, 2006c). A further seven setts (S2, S4, S8, S13, S15, S16 and S17) were within the ZoI of any potential pile driving or blasting works—i.e. within 150m. The remaining setts (S1, S5, S6, S7 and S12) are beyond the ZoI of any construction activities.

Although it cannot be predicted if Badger will establish new setts within the ZoI of the proposed road development before construction works commence, it is a possibility and this scenario has been taken into account in the mitigation strategy (refer to **Section 8.6.7.3**).

Based on interpretation of the survey results, the directly affected badger setts (S9, S11 and S14) were considered to be within the territories of two badger groups. S9 and S11 are considered to be part of one badger group to the east of Lackagh Quarry (hereafter, referred to as the Lackagh badger group). S14 is considered to be part of a separate badger group west of the N83 Tuam Road Junction at Cappanabornia (hereafter, referred to as the Cappanabornia badger group).

Loss of Foraging Habitat

Construction will result in the permanent loss of foraging habitat within the territories of up to ten badger groups across the study area[72]. The loss of habitat is likely to affect each of the badger groups to some degree, at least temporarily, as it will reduce the foraging area and feeding resource available within their existing territories. This is also likely to have a knock-on consequence of increased conflict with neighbouring Badger groups in competition for resources - although this territorial behaviour is a natural dynamic between neighbouring Badger groups in response to many other factors that affect population numbers, territorial behaviour, and dispersion of individuals.

[71] Average light levels recorded along preferred commuting routes of *Rhinolophus hipposideros* under natural unlit conditions were 0.04 lux across eight sites. Stone E.L. (2011) *Bats and development: with a particular focus on the impacts of artificial lighting.* (Ph.D. Thesis) University of Bristol, UK (2011).

[72] This territory number estimate is based upon an interpretation of the survey results – sett locations, sett types, and the distribution of signs such as tracks, foraging and latrine sites

There is an abundance of alternative suitable foraging habitat locally which is likely to be sufficient to maintain the local population in the long-term. Although the actual effect of foraging habitat loss cannot be quantified in terms of any threshold value that could be predicted, each of the affected Badger groups would be expected to adapt to the changed landscape. It is therefore predicted that, despite any temporary effects, the loss of foraging habitat associated with the proposed road development is unlikely to affect the conservation status of the local badger population and will not result in a likely significant negative effect, at any geographic scale.

Loss of breeding/resting sites

The proposed road development will result in the permanent loss of three badger setts, affecting two badger groups: the main sett (S9) and a subsidiary sett (S11) of the Lackagh Quarry badger group; and, a subsidiary sett (S14) of the Cappanabornia Badger group.

The significance of sett loss in relation to any badger group is based upon consideration of the type of sett, its importance to the badger group, and the availability of either alternative setts for affected badgers to relocate to or the availability of alternative suitable sett building habitat within the territory. Locally, given the underlying karst nature of the area, limestone is generally overlain by thin soils and frequently outcrops locally as limestone pavement; offering limited opportunities for sett building habitat. As a consequence, the significance of sett loss with respect to both badger groups is largely dependent on the presence of existing alternative setts within their territories. As discussed above in relation to loss of foraging habitat, sett loss may also lead to increased conflict with neighbouring Badger groups if alternatives, in the form of existing setts or suitable habitat to construct setts, are not available within the existing territory. There is also the potential for Badgers to be killed during site clearance works where setts are being removed.

The Lackagh Quarry badger group will lose two out of three setts (S9 and S11) recorded within their territory — including the main sett. The remaining subsidiary sett (S10) lies within the ZoI of what will likely be significant disturbance effects resulting from rock breaking and blasting associated with excavating the eastern approach to Lackagh Quarry, from the N59 Moycullen Road. Considering those factors and that there is little alternative suitable sett building habitat in the immediate vicinity, the proposed road development may have a long-term effect on this Badger group. On that basis, it is considered that the proposed road development has the potential to negatively affect the conservation status of this badger group and result in a likely significant negative effect, at a local geographic scale.

In relation to the Cappanabornia badger group, the proposed road development will result in the loss of a single subsidiary sett (S14) within its territory. There are two other Badger setts nearby, S13 and S15, both of which were also classified as subsidiary setts. Whilst it is not known whether all three setts are used by the same Badger group, based on their relative locations and distance from one another, it's probable that at least one of those setts is and would therefore provide a suitable alternative to S14. Given there are alternative setts, and alternative suitable sett building habitat, available beyond the ZoI of general construction activities the loss of sett S14 is not likely to affect the species ability to maintain itself on a long-term basis locally, will not affect its conservation status locally, and will not result in a likely significant negative effect, at any geographic scale.

Given the legal protection afforded to Badgers under the Wildlife Acts, which prohibits their intentional killing or injury, or the wilful interference with their breeding or resting places, a mitigation strategy has been developed (see **Section 8.6.7.3.1**).

Disturbance/displacement

In conjunction with any displacement effects associated with habitat loss, increased human presence and/or noise and vibration associated with construction works, has the potential to displace badgers from both breeding/resting places and from foraging habitat. As construction works will typically be undertaken during normal daylight working hours and badgers are nocturnal in habit, displacement of badgers from foraging areas (outside of areas where foraging habitat will be lost as a result of the proposed road development) is extremely unlikely to affect the local badger population and will not result in a likely significant negative effect, at any geographic scale.

Two badger setts (S3 and S10) outside the proposed development boundary were within 50m of construction works and therefore, likely to be subject to temporary disturbance/displacement effects. Any disturbance/displacement impact is likely to be more significant during the badger breeding season (December to June inclusive) if the sett is in use at that time. A further seven setts were located within 150m of the proposed development boundary and therefore, likely to be subject to temporary disturbance/displacement construction effects associated with any rock breaking, blasting or pile driving works that may be required. If undertaken during the breeding season, this could result in the displacement of badgers from occupied setts, potentially affecting breeding success.

On a precautionary basis, disturbance/displacement effects during construction have the potential to negatively affect the conservation status of local badger groups/populations (at least in the short-term) and could result in a likely significant negative effect, at a local geographic scale.

Given the legal protection afforded to Badgers under the Wildlife Acts, which prohibits their intentional killing or injury, or the wilful interference with their breeding or resting places, a mitigation strategy has been developed (see **Section 8.6.7.3.1**).

Severance/barrier effect

It is considered near-certain that the physical disturbance to the existing landscape during site-clearance and construction will result in some initial temporary severance of Badger territories through which the proposed road development traverses; most notable where it severs the network of setts within a given territory (as is the case with the Cappanabornia Badger group), or setts from foraging areas (as in the case of the Lackagh Badger groups).

However, given that Badgers are nocturnal in habitat and works will be carried out during normal daylight working hours, affected Badger groups would be expected to habituate to the altered landscape. The severance/barrier effect of construction works will be temporary in nature and is not likely to affect the local population, over even the short-term, and will not result in a likely significant negative effect, at any geographic scale.

8.5.6.3.2 Operational Phase Impacts

Habitat Severance/Barrier Effect

The presence of a new road along the offline sections of the proposed road development, where it severs existing Badger territories, has the potential to act as a permanent barrier to Badger movements: either acting as a physical barrier or through traffic deterring Badgers from attempting to cross.

However, some sections of the proposed road development will be either elevated above ground level on piers or will pass through a subterranean tunnel (e.g. the proposed River Corrib Bridge, Menlough Viaduct and the proposed Lackagh Tunnel). In these locations, an accessible link will be maintained across the proposed road development either beneath viaduct/bridge structures or above tunnels, which will serve to maintain habitat connectivity within each affected Badger territory (Eldridge & Wynn, 2011).

Nevertheless, there will be extensive lengths of the proposed road development that may act as a barrier to Badger movements within the study area. This has the potential to have a long-term impact on local Badger population dynamics, affecting both local foraging behaviour and competition for resources and larger scale movements associated with dispersal and/or with breeding behaviour and genetic exchange between populations.

The habitat severance/barrier effect to Badgers associated with the proposed road development has the potential to affect local Badger populations over the long-term and result in a likely significant negative effect, at a local geographic scale. Mitigation measures have been designed to reduce the effects of this impact (**see Section 8.6.7.3.2**).

Mortality Risk

The introduction of the proposed road development into a rural landscape will permanently increase the risk of road traffic collisions with Badger, across the study area. The risk is likely to be higher in areas where the proposed road development is in close proximity to Badger setts, is severing Badger territories, or is passing through habitats where high levels of Badger activity were recorded (see **Figures 8.3.1** to **8.3.14**).

Although it is not possible to quantify the magnitude of the effect, the increased collision risk would likely result in a long-term suppression of the local Badger population in these areas and would negatively affect the conservation status of the local Badger population.

Collision risk to Badgers associated with the proposed road development is predicted to result in a likely significant negative effect, at a local geographic scale. Mitigation measures have been designed to avoid this potential impact (see **Section 8.6.7.3.2**).

Light Spill

Nocturnal mammals, such as the badger, are likely to be disturbed by the introduction of artificial light into established breeding and foraging areas (Rich & Longcore, 2005). Along the proposed road development lighting is proposed only at the Bearna West Roundabout, the Bearna East Roundabout, the Cappagh Road Junction, the Ballymoneen Road Junction, the N59 Link Road North and South, the western and eastern portals to the Lackagh Tunnel, the proposed NUIG Sports Pitches, the N84 Headford Road Junction to the N83 Tuam Road Junction including the junctions at the Galway Racecourse Tunnel and the Coolagh Junction. The majority of the proposed road development will remain unlit, minimising the potential for light spill to affect fauna species. The lighting design of the proposed road development controls light emissions such that along the majority of the alignment light spill does not extend beyond the proposed development boundary and where it does, this is at tie-ins with the existing road network or at residential properties (**Figures 5.4.01** to **5.4.14**). There are no badger setts, or areas of high badger activity, beyond the proposed development boundary that are located within the modelled light spill zone for the proposed road development.

Therefore, lighting associated with the proposed road development will not disturb or displace Badgers from habitat areas beyond the proposed development boundary, will not affect the species conservation status in that regard and will not result in a likely significant negative effect, at any geographic scale.

8.5.6.4 Other Mammal Species

8.5.6.4.1 Construction Phase Impacts

Habitat Loss

Road construction will result in the permanent loss of mammal habitat within the boundary of the proposed road development. Given the relatively low numbers of individuals of each species that are likely to be affected (Pine marten, Wood mouse, Red squirrel, Irish stoat, Hedgehog, Pygmy shrew, Fox, Rabbit, Mink and Bank vole), and the abundance of alternative suitable habitat available locally, the effects of habitat loss associated with construction works are unlikely to affect the long-term viability of their local populations. Therefore, habitat loss is unlikely to affect the species' conservation status or result in a significant negative effect, at any geographic scale.

Mortality Risk

Site clearance works have the potential to result in the mortality of mammal species. The potential for impact would be expected to be greater during the breeding season when juveniles would be present in nests, or in the case of Hedgehog impacts may be greater during their hibernation period. Given the relatively low numbers of individuals of each species that are likely to be affected, and that they are highly mobile species, site clearance is unlikely to result in a level of mortality that would affect the species' conservation status, and result in a significant negative effect, even at a local geographic scale.

Habitat Severance/Barrier Effect

As discussed above in relation to Badgers, the presence of a new road along the offline sections of the proposed road development has the potential to act as a permanent barrier to many other terrestrial mammal species. Either acting as a physical barrier or through traffic deterring mammals from attempting to cross.

Sections of the proposed road development elevated on piers and above tunnels will serve to maintain habitat connectivity. Nevertheless, there will be extensive lengths of the proposed road development that may act as a barrier to the movements of other terrestrial mammal species within the study area. This has the potential to have a long-term impact on local mammal population dynamics, affecting both local foraging behaviour and competition for resources and larger scale movements associated with dispersal and/or with breeding behaviour and genetic exchange between populations.

The habitat severance/barrier effect to these other terrestrial mammal species associated with the proposed road development has the potential to affect local mammal populations over the long-term and result in a significant negative effect, at a local geographic scale. Mitigation measures have been designed to minimise the long-tern effects of any barrier effect posed by the proposed road development (see **Section 8.6.7.4.1**).

Disturbance/displacement

In conjunction with any displacement effects associated with habitat loss, increased human presence and/or noise and vibration associated with construction works, has the potential to displace mammal species from both breeding/resting places and from foraging habitat.

However, as disturbance will be intermittent and temporary (in the majority of locations) it is extremely unlikely to result in any long-term effects on the local mammal population or their conservation status. Therefore, disturbance / displacement during construction is unlikely to result in a significant negative effect, at any geographic scale.

Habitat degradation - water quality

During construction, contaminated surface water runoff and/or an accidental spillage or pollution event into any surface water feature has the potential to have a significant negative impact on water quality in Galway Bay and consequently an impact upon marine mammals; either directly (e.g. acute or sub-lethal toxicity from pollutants) or indirectly (e.g. affecting their food supply or supporting habitats).

However, it is considered unlikely that a pollution event of such a magnitude would occur during construction that would have any perceptible effect on water quality in the marine environment, or be any more than temporary in nature. Nevertheless, a precautionary approach is being taken in assuming a level of risk of water quality impacts and detailed mitigation measures have been designed to further minimise the risk of the proposed road development having any perceptible effect on water quality during construction or affecting the conservation status of the marine mammal species in Galway Bay (see **Section 8.6.4**).

8.5.6.4.2 Operational Phase Impacts

Habitat Severance/Barrier Effect

The presence of a new road along the offline sections of the proposed road development, would be certain to act as a permanent barrier to mammal movements locally, either through acting as a physical barrier or as a consequence of road traffic acting as a crossing deterrent.

As discussed above for Badger, elevated sections of the proposed road development (e.g. the proposed River Corrib Bridge and the Menlough Viaduct structures) will serve to maintain a degree of habitat connectivity within each affected Badger territory (Eldridge & Wynn, 2011).

Nevertheless, there will be extensive lengths of the proposed road development that will act as a barrier to species movements within the study area. This has the potential to have a long-term impact on population dynamics, affecting both local foraging behaviour and competition for resources and larger scale movements associated with dispersal and/or with breeding behaviour and genetic exchange between populations.

The habitat severance/barrier effect associated with the proposed road development has the potential to affect local mammal populations over the long-term and result in a significant negative effect, at a local geographic scale. Mitigation measures have been designed to minimise the long-tern effects of any barrier effect posed by the proposed road development (see **Section 8.6.7.4.2**).

Disturbance/displacement

The operation of the proposed road development is likely to have some level of long-term effects on mammal usage of habitat in the vicinity of the proposed road development (Benítez-López et al. 2010). However, this is not likely to affect the species’ conservation status nor result in a likely significant negative effect, at any geographic scale.

Habitat degradation - water quality

There will be outfall points to surface water features from the proposed road drainage network during operation and therefore, a potential impact pathway to affect water quality in Galway Bay. This in turn could affect the marine mammal species therein. The proposed drainage design for the mainline of the proposed road development incorporates pollution control measures (this includes petrol interceptors, wetland and other measures, such as SuDS) followed by either infiltration ponds (where discharging to ground) or attenuation ponds (where drainage will be discharged to the existing surface water/storm sewer), as described in detail in **Chapter 5, Description of Proposed Road Development**.

Those sections of the proposed road drainage that are to be discharged to ground, pose no risk to surface water quality. It is extremely unlikely that the normal operating water quality of the drainage outfalls discharging to the existing surface water/drainage network, even in the unlikely event of a pollution incident, would have any perceptible impact on water quality in receiving watercourses. The functioning and effectiveness of both elements of the road drainage network are discussed in more detail in **Chapter 11, Hydrology**.

Habitat degradation as a result of effects on water quality in Galway Bay during operation is not likely to have any effect on the marine mammal populations or their conservation status, and therefore will not result in a likely significant negative effect, at any geographic scale.

Mortality Risk

The proposed road development will permanently increase the risk of road traffic collisions with mammal species[73]. For some species, such as rodents, the risk may be higher as many such species forage in rough grassland and scrub habitats and may be attracted to foraging along the road margins. However, the hard surfaces of the road infrastructure offer little in the way of potential foraging habitat for mammal species, other than opportunistic scavenging by larger mammal species. The rates of mammal fatality recorded by Haigh (2012) were low (1.2 per 100km) although the presence of dedicated mammal passage facilities were present on sections of the studied roads which is likely to have positively influenced this figure. In the absence of being able to fully quantify the impact on an unmitigated road scheme, a precautionary approach is to conclude that the proposed road development does have the potential to affect the local mammal populations in the long-term, if even only in a local context. Therefore, the proposed road development has the potential to affect the local conservation status of many mammal species, and result in a significant negative effect, at the local geographic scale. Mitigation measures have been designed to reduce this potential impact (see **Section 8.6.7.4.2**).

8.5.7 Invertebrates

8.5.7.1 White-clawed crayfish

As the White-clawed crayfish is not present within the ZoI of the proposed road development, no impacts are predicted.

8.5.7.2 Freshwater pearl mussel

As the Freshwater pearl mussel is not present within the ZoI of the proposed road development, no impacts are predicted.

[73] Haigh (2012) recorded the following mammal road kill species in a study undertaken along the road network between Bandon in County Cork and Caherlistraine in Co. Galway: Rabbit, Hedgehog, Badger, Fox, rodents, Mink, Hare, Otter, Pine marten and Stoat. However, in terms of the protected mammal species discussed in this section, all bar Hedgehog and rodents were infrequently recorded.

Although no freshwater pearl mussel were present with the ZoI of the proposed road development, impacts to salmonid fish species could indirectly affect the Freshwater pearl mussel population in Lough Corrib cSAC; the QI population is in the Owenriff River, c.23km to the north – see **Section 8.5.11** below for impacts on fish species.

8.5.7.3 Marsh whorl snail

8.5.7.3.1 Construction Phase Impacts

Habitat Degradation – Surface Water Quality

An accidental spillage or pollution event affecting the River Corrib, the Coolagh Lakes and surrounding drainage features and springs, and Ballindooley Lough has the potential to negatively impact upon water quality and consequently on the fringing wetland habitat that supports the Marsh whorl snail.

The magnitude and significance of such an impact would be entirely dependent on the nature, scale and duration of the pollution event. Although unlikely, in a worst case scenario this could potentially result in extensive degradation of fringing aquatic habitat in receiving watercourses/waterbodies such that it could, at least in the short-term, no longer support the species. There is the potential for such impacts to have long-term effects on the local Marsh whorl snail population, potentially resulting in localised extinctions. Habitat degradation therefore, has the potential to affect the species' conservation status and result in a significant negative effect, at the local geographic scale. Mitigation measures have been designed to protect water quality during construction (see **Section 8.6.4**).

Habitat Degradation – Groundwater

Any effects on the existing hydrogeological regimes at the Coolagh Lakes and Ballindooley Lough have the potential to negatively impact upon the fringing wetland vegetation that supports the Marsh whorl snail.

Based on the findings of the hydrogeological impact assessment in **Chapter 10, Hydrogeology**, the proposed road development does not pose a risk to the groundwater supply to Ballindooley Lough. The proposed road development does however, have the potential to affect the quantity and quality of groundwater supplying the Coolagh Lakes. Although the magnitude of the impact cannot be fully quantified, on a precautionary basis it is assessed as having has the potential to affect the species' conservation status and result in a likely significant negative effect, at the local geographic scale. Mitigation measures have been designed to protect the existing hydrogeological regime during construction (see **Section 8.6.5**).

Habitat Loss & Mortality Risk

Two wetland habitat areas that will be directly impacted by the proposed road development supported the Marsh whorl snail: at Ballindooley Lough (Ch. 12+350) and a marsh area at Castlegar (Ch. 13+000).

Overall, the Marsh whorl snail was relatively common locally: recorded at 33 sampling sites out of a total of 120. The relatively minor loss of habitat at

Ballindooley Lough and at the Castlegar marsh will not reduce the local wetland habitat resource for the species such that it would be likely to affect its ability to maintain the local population on a long-term basis. Similarly, although there is likely to be some level of mortality associated with construction works at these locations, the species' conservation status locally is not likely to be affected.

Habitat loss and mortality risk during construction are not likely to affect the species' conservation status and will not result in a likely significant negative effect at any geographic scale.

8.5.7.3.2 Operational Phase Impacts

Habitat Degradation – Surface Water & Groundwater

There will be drainage outfall points to two surface water features supporting the Marsh whorl snail: the River Corrib and Ballindooley Lough. Therefore, there is a risk that discharges from the proposed road drainage network could affect water quality and consequently impact upon the Marsh whorl snail or its supporting habitat.

The proposed drainage design consists of a petrol interceptor followed by either attenuation and infiltration ponds (where discharging to ground) or attenuation and constructed wetland (where drainage will be discharged to the existing surface water/drainage network) — as described in detail in **Chapter 11, Hydrology**.

Those sections of the proposed road drainage that are to be discharged to ground, pose no risk to surface water quality. It is extremely unlikely that the normal operating water quality of the drainage outfalls discharging to the existing surface water/drainage network, even in the unlikely event of a pollution incident, would have any perceptible long-term effect on water quality in receiving watercourses. The functioning and effectiveness of both elements of the proposed road drainage network are discussed in more detail in **Chapter 11, Hydrology**.

Although the drainage design will ensure that groundwater quality will be maintained during operation, it is important that infiltration basins are inspected to ensure that karst features do not affect the functioning of them during operation. If this is identified during routine inspections of the infiltration basins then mitigation is required to ensure any issues are addressed so that they continue to function as designed for the operational lifespan of the proposed road development.

Habitat degradation as a result of effects on surface water quality during operation is not predicted to affect the conservation status of the Marsh whorl snail and will therefore, not result in a likely significant negative effect, at any geographic scale.

Habitat degradation as a result of effects on groundwater during operation has the potential to affect the conservation status of the Marsh whorl snail locally and therefore, has the potential to result in a significant negative effect, at the local geographic scale.

8.5.7.4 Marsh fritillary butterfly

The Marsh fritillary butterfly exists in a metapopulation structure — i.e. individual colonies, or populations, that are spatially separated yet interact with one another on some level. Survival and persistence of the metapopulation relies on there being a sufficient network and density of interconnected suitable habitat areas, such that the individual colonies can readily interact and recolonise new habitat patches in response to (what can be) frequent local extinctions. These local extinction events occur in response to factors such as changes in habitat management and condition, weather, resources and intraspecific competition, and/or parasite infestations. In assessing the impacts on the Marsh fritillary butterfly, given the species' population structure, areas of suitable habitat are equally as important to consider as areas where larval webs were recorded.

The natural fluctuations and variations in Marsh fritillary populations are reflected in the larval web records across the four survey years. Comparing the results of the 2013 and 2014 surveys (as both years covered the larger scheme study area): in 2013, only a single habitat patch supported larval webs yet in 2014, 111 larval webs were recorded across the network of suitable habitat patches[74]. This pattern suggests that there was a core population (either in an area within the scheme study area that was not surveyed, or beyond it) which, despite the apparent population crash in 2013, was robust enough to recolonise the locality in 2014. Even comparing the 2015 and 2016 surveys, which both covered a smaller, more targeted survey area focussed on the proposed road development and lands in the immediate vicinity, the number of larval webs recorded increased from 12 in 2015, to 56 in 2016. The same area in 2014 held 39 webs.

The area of suitable habitat mapped for the species across the scheme study area in 2014 totalled approximately 110ha, spread over 139 distinct habitat patches—the densest clusters of which were concentrated around the bog/heath/scrub/wet grassland habitat mosaics at Na Foraí Maola, Lough Inch, An Chloch Scoilte, Ballard, Na hAille, Cappagh and Tonabrocky. Of the suitable habitat patches in these areas, larval webs were recorded in 39 (in total covering an area of c.60ha).

8.5.7.4.1 Construction Phase Impacts

Habitat Loss

The proposed road development will result in the permanent loss of suitable Marsh fritillary habitat, including habitat patches supporting larval webs. The resulting impact will increase habitat fragmentation, not only within individual suitable habitat patches, but also amongst the local network of suitable habitat areas supporting the local Marsh fritillary metapopulation.

In terms of habitat loss in areas where suitable habitat was recorded, and larval webs were present (during any of the surveys carried out between 2013 and 2016), the proposed road development will affect the Marsh fritillary butterfly in the western

74 The majority of the two core areas at Cappagh and Tonabrocky which supported significant numbers of larval webs in 2014 were not surveyed in 2013.

part of the study area; between Bearna and the River Corrib. The area of Marsh fritillary habitat directly affected is approximately 5.2ha.

It is noted in the literature (Bulman 2001; Fowles & Smith 2006) that within 16km^2 sample areas, it was estimated that a minimum area greater than 71ha (and probably 100ha) of suitable habitat was required to give a high degree of probability that a metapopulation would persist long-term. The total coverage of suitable habitat, across the western part of the scheme study area, approximates an area of 16km^2. Therefore, even with the loss of c.5.2ha, the remaining 104.8ha [75] present within the scheme study area is more than the quoted threshold and will probably be sufficient to maintain the local metapopulation in the long-term.

This is evident in the findings of the surveys which demonstrate that even despite localised “crashes” in the local population year on year, there is a sufficient habitat network, and a persisting core colony or population within recolonization range, to allow the metapopulation to recover. Also of note in that regard is that the larger and consistently more densely populated habitat complexes at Lough Inch, Cappagh, and Tonabrocky will remain unaffected by the proposed road development.

Therefore, habitat loss associated with the proposed road development is not likely to affect the species conservation status or result in a likely significant negative effect, at any geographic scale.

Habitat Fragmentation/Severance

Key to Marsh fritillary being able to recolonise or relocate to alternative habitat areas is the spatial relationship between areas of suitable habitat in a network of suitable habitat sites; and principally, their proximity to one another. Therefore, the loss of suitable habitat patches, regardless of their size or whether the species has been recorded there previously, has the potential to result in fragmentation, or habitat isolation, that could potentially affect the long-term viability of the local Marsh fritillary metapopulation.

The Marsh fritillary butterfly is generally a sedentary species. Many studies have reported that the maximum distances over which the species will readily colonise/disperse between habitat areas is 1-2km (Betzholtz et al. 2007; Fowles and Smith 2006); although longer distance movements have been recorded, they are likely to be more infrequent (Warren 1994; Hula et al. 2004; Zimmermann et al. 2011). In applying the more conservative 1km threshold to considering how habitat loss could affect the future prospects of the affected Marsh fritillary metapopulation to colonise suitable habitat areas, the resulting fragmentation would not result in

75 The total area of suitable Marsh fritillary habitat recorded within the scheme study area is likely to only represent a proportion of the actual coverage of suitable habitat available to support the local metapopulation. Although no surveys were undertaken for this project beyond the scheme study area, based on a review of recent orthophotography it would appear that a similar habitat mosaic to that within the scheme study area, extends to the west and north. This, along with the rapid recolonization of the scheme study area between the “crash” year of 2013 and 2014, suggests that a core colony persisted in suitable habitat, within close proximity. Therefore, the quoted area of available habitat, post-construction, is probably a very conservative underestimate.

any of the unaffected suitable habitat areas being permanently isolated by this distance, or greater.

The fragmentation of an individual suitable habitat patch by the proposed road development may also render the remaining fragments unsuitable for the species, due to their small size or due to increased edge effects. Bulman (2001) found that Marsh fritillary did not breed in habitat patches less than 0.1ha in area and this minimum area is considered to be the threshold below which isolated habitat patches would become unusable by the species. This is reflected in the findings of the surveys where all, bar two, of the 39 suitable habitat patches where larval webs had been recorded were greater than 0.1ha in area. Therefore, any remaining suitable habitat fragments below this threshold have been included in the habitat loss calculation. Small, isolated habitat patches are likely to be more susceptible to edge effects and scrub encroachment/succession which could, over the longer-term, result in them becoming unsuitable to support the species. However, even if all such areas were to ultimately become unavailable to the local Marsh fritillary butterfly as a consequence of the habitat fragmentation impact, the areas involved only total c.2ha. In the context of the area of suitable habitat that will be available post-construction (104.8ha) and the additional areas of suitable habitat likely to be present beyond the scheme study area, given the mosaic of heath, bog and wet grassland evident from the orthophotography, this loss is extremely unlikely to affect the long-term viability of the local population or metapopulation.

Therefore, habitat fragmentation/severance is not likely to affect the species conservation status or result in a likely significant negative effect, at any geographic scale.

Mortality Risk

Site clearance works have the potential to result in the mortality of Marsh fritillary butterflies and/or disturb their breeding/resting places; either adults, eggs or larvae, depending on the time of year works are undertaken. The magnitude of the potential impact would be dependent on the species' distribution and abundance across the area in any given year.

Given the distribution of breeding sites across the study area over the survey period, and the resilient nature of the species' natural response to frequent local extinction events, any mortality or disturbance that may result from construction works will most likely be confined to the season within which site clearance works are undertaken and is likely to only affect the local population[76]. Although unlikely, it is possible that the suitable habitat patches affected by the proposed road development could support a significant proportion of the local metapopulation in a given year. If this were to occur, it could potentially affect the species' conservation status locally and result in a significant negative effect, at the local geographic scale. Given the current distribution of the Marsh fritillary butterfly at the county scale (c.46 10km squares), and considering the scale and short-term nature of the predicted impact and the resilient nature of the species' natural response to frequent local extinction events, it would not be likely to affect the

[76] The current distribution for the species within, or adjacent to, the County Galway border covers c.46 10km squares (NPWS, 2013c)

species' conservation status at the county geographic scale, at which the local Marsh fritillary population has been valued.

Mitigation measures to avoid this impact are detailed in **Section 8.6.8.2.1**.

8.5.7.4.2 Operational Phase Impacts

Barrier Effect

From the available literature, there is no definitive evidence to conclude whether the construction or operation of the proposed road development will create a permanent barrier to Marsh fritillary movements. Along the length of the proposed alignment, there are two locations where the proposed road development will sever areas of Marsh fritillary habitat: in the western part of the study area, between Ch. 0+750 and Ch. 8+000; and at the Galway Racecourse where the proposed road development surrounds it on three sides.

The Marsh fritillary butterfly is a species capable of long-distance dispersal movements (Warren 1994; Hula et al. 2004; Zimmermann et al. 2011). It has also evidently crossed the existing road network in the past to colonise habitat at the Galway Racecourse. Considering the above and also that (at least in the western part of the study area) the proposed road development consists of a relatively narrow single carriageway (c.20m), the proposed road development would not be expected to pose a physical barrier to Marsh fritillary movements between the existing network of suitable habitat patches such that it would affect the long-term prospects for either the local populations or the greater metapopulation. Even taking a very precautionary approach, and assuming that the full area of suitable habitat south of the proposed road development would become unavailable, the loss of 7.6ha is not likely to reduce the area of suitable habitat that the local metapopulation is likely to require to ensure it persists over the long-term (see discussion on habitat area requirements above, under the heading of construction phase impacts).

Therefore, any barrier effect associated with the proposed road development is not likely to affect the species' conservation status or result in a significant negative effect, at any geographic scale.

Mortality Risk

It is likely that during operation the proposed road development will result in some level of mortality risk to Marsh fritillary butterfly crossing the proposed road carriageway; although from the available published literature, it is not possible to quantify what that level of risk might be. Of the c.105ha of suitable Marsh fritillary habitat that will remain post-construction, only 7.6ha lies to the south of the proposed road carriageway. The majority (c.97.4ha), which includes the core areas at Cappagh and Tonabrocky, lies to the north. This limits the potential, or need, for Marsh fritillary butterflies to cross the proposed road carriageway and it is not likely that there would be frequent movement of Marsh fritillary butterflies across the proposed road development.

Therefore, it is not likely that any population level effects would arise as a consequence of road mortality that would affect the species' conservation status or result in a significant negative effect, at any geographic scale.

8.5.8 Birds

8.5.8.1 Breeding Birds

The assessment carried out in the NIS for the proposed road development considered the potential for the proposed road development to affect the bird species listed as SCIs of Lough Corrib SPA and Inner Galway Bay SPA for their breeding populations: Black-headed gull, Cormorant and Common tern. That assessment concluded that the proposed road development would not affect their breeding colonies or have any long-term effects on the local breeding populations—which for the purposes of that assessment took a precautionary approach in assuming that all SCI bird species recorded within the scheme study area formed part, or were linked to, the SPA populations. Therefore, for these species, the proposed road development will not affect the conservation status of the breeding populations and will not result in a likely significant negative effect at any geographic scale.

8.5.8.1.1 Construction Phase Impacts

Habitat Loss & Loss of Breeding/Resting Sites

The proposed road development will result in the loss of breeding bird nesting and foraging habitat across the study area. The areas of habitat loss along route of the proposed road development are given in **Section 8.5.4.3** and tabulated in **Table 8.27** for KER habitat types[77]. In the western part of the study area, this is predominantly habitat blocks comprised of mosaics of bracken, scrub, heath and wet grassland. There are sections where the proposed road development crosses more intensively managed agricultural lands, with little vegetation cover for nesting breeding birds, and habitat loss in these areas will have a much lower effect on local bird populations than the more semi-natural habitat mosaics. From the N59 Moycullen Road through to Lackagh Quarry, the habitats affected are amenity grassland and small agricultural fields and a mix of amenity planted woodland (at NUIG) and semi-natural Ash and Hazel woodland (east of the River Corrib). East of Lackagh Quarry a small area of scrub and wet grassland will be lost at Ballindooley Lough. At Castlegar a small area of scrub surrounding a marsh will be affected, near the N83 Tuam Road a small area of Ash/Hazel woodland, and some scrub around the existing N6 Junction. Aside from these areas, the majority of the proposed road development, east of Lackagh Quarry, will largely result in the loss of improved agricultural grassland fields or artificial surfaces associated with the existing road network, business parks and Galway Racecourse.

The primary consequence of habitat loss will be increased competition for resources (e.g. nesting habitat or prey/food source) both between and amongst breeding bird species. The magnitude of this effect will be largely defined by many unquantifiable factors such future land use changes and whether the local habitat resource has currently reached its carrying capacity or not in terms of breeding bird species. For

[77] The loss of these KER habitat types are those most likely to directly affect breeding birds – comprising more than 80ha of scrub, woodland, semi-natural grasslands, wetland habitats (e.g. fens, marsh and reed swamp) and heath habitats, along with almost 12km of hedgerows and treelines.

species with larger home ranges during the breeding season (such as Peregrine falcon, which hunt within 2km of the nest site) habitat loss at the scale of the proposed road development is not likely to have any perceptible effects on breeding success or population dynamics. Another example is Barn owl, which generally hunt within a kilometre of the nest site (Hardy et al., 2009). Within this distance of Menlo Castle, most of the habitats affected are woodland or residential development and not the favoured permanent rough grassland foraging habitat.

The habitat areas that will be lost as a result of the proposed road development form a relatively small part of what are much larger expanses of similar habitat types and mosaics nearby. In that regard, none of the habitat areas that will be lost are unique in the sense that they are not the only areas of that habitat type locally and, either individually or collectively, are not likely to support a significant proportion, or the only population, of any given breeding bird species locally. Although a decline in overall breeding bird abundance could potentially occur at a local level, this is unlikely to affect the local range of the breeding bird species present nor is it likely to affect the ability of these breeding bird populations to maintain their local populations in the long-term. Mitigation measures will be implemented to reduce the effects of habitat loss on breeding birds species locally (see **Section 8.6.9.1.1**).

Mortality Risk

If site clearance works were to be undertaken during the bird breeding season (March to August, inclusive) it is likely that nest sites holding eggs or chicks will be destroyed and birds killed.

Mortality of birds at the scale of the proposed road development, over what is likely to be a single breeding bird season in terms of completing site clearance works, will probably have a short-term effect on local breeding bird population abundance. However, in the longer-term this would be unlikely to affect the ranges of the breeding bird species recorded in the study area nor would it be likely to affect the long-term viability of the local populations.

Mortality of birds during site clearance works is not predicted to affect the conservation status of any of the breeding bird species present within the study area.

Disturbance/displacement

The noise, vibration, increased human presence and the visual deterrent of construction traffic associated with site clearance and construction will disturb breeding bird species and is likely to displace breeding birds from habitat areas adjacent to the proposed development boundary. The magnitude of the impact will be dependent on the type of construction works and their duration; general construction activities will have a less pronounced affect than blasting, in terms of its ZoI, but will be on-going from periods of several months to several years and breeding seasons. Although it is not possible to quantify the magnitude of this potential impact (or the potential effect zone) it could potentially extend for several hundred metres from the proposed road development.

In terms of nesting sites, the most sensitive in terms of disturbance effects (given their low numbers locally, conservation status and proximity of nest sites to the construction works) are Barn owl and Peregrine falcon.

The Barn owl nest site at Menlo Castle is c.140m from the main construction works with landscape planting and installation of a boundary fence proposed adjacent to the castle. The main construction works are likely to be sufficiently removed from Menlo Castle that the resident Barn owl pair will not abandon the nest site and as a consequence no long-term effects on the local population are likely in this regard.

The Peregrine falcon nest site at Lackagh Quarry is immediately adjacent to the proposed road development and construction activities here include rock breaking and rock blasting, and the installation of rock bolts on the exposed cliff faces (for more detail refer to **Chapter 7, Construction Activities**). There is therefore a high risk that the resident pair of Peregrine falcons will abandon the quarry, if works commence part way through the breeding season. As works will be ongoing in the vicinity for a period of c.3 years, this has the potential to have long-term effects on recruitment within the local Peregrine falcon population if the pair repeatedly fail to breed.

Given the temporary to short-term nature of the construction works, disturbance or displacement effects will also be over the short-term and are therefore not likely to affect the conservation status of the majority of affected breeding bird species and will not result in a likely significant negative effect, at any geographic scale.

However, there is the potential for long-term effects on the local Peregrine falcon population and significant negative effects at a county geographic scale. Mitigation measures will be implemented to reduce the effects of construction related disturbance on nesting Peregrine falcon (see **Section 8.6.9.1.1**).

8.5.8.1.2 Operation Phase Impacts

Mortality Risk & Disturbance/Displacement

Road traffic, has been shown to negatively influence local bird populations (Reijnen & Foppen, 2006; Summers et al., 2011): new roads increase mortality risk, road traffic acts as a visual deterrent, and noise associated with road traffic has a negative impact upon bird abundance and occurrence. The magnitude of the potential impact is related to the interaction between a multitude of factors such as species and traffic density (which influences noise levels and mortality risk) and is also influenced by habitat type. Roadside habitat can have a positive effect on bird abundance (e.g. the provision of scrub, either through planting or as a result of edge effects, wetland habitat, or rank grassland habitat). Although any benefits associated with this type of habitat creation are generally on quiet, low-traffic roads and the impacts associated with high density traffic on bird densities generally outweigh any potential benefits.

It is likely that the abundance of breeding bird species will permanently decline near to the proposed road development as a consequence of increased disturbance and mortality from road traffic; the effects of which will reduce to a neutral impact with increasing distance from the proposed road development. Although it is not possible to quantify the magnitude of the potential impact (or the potential road effect zone) based upon the available literature for most breeding bird species, in general it could potentially extend for several hundred metres from the proposed road development. However, where the proposed road development crosses a landscape which is already highly disturbed (i.e. where it will be constructed alongside the existing road network) or of low habitat quality for breeding birds (e.g. the business parks at Ballybrit and Parkmore), the road effect zone will be minimal.

The road effect zone may also act as a population sink during good breeding bird years; where fecundity and juvenile survival rates are high. Less experienced juveniles may be attracted in to the poorer quality habitat affected by road traffic disturbance and with a relatively higher associated mortality risk due to the proximity of the proposed road development. This in turn is likely to affect their breeding success and survival. Another likely consequence of the displacement of breeding birds from the road effect zone is increased competition for resources (e.g. nesting habitat or prey/food sources) both between and amongst breeding bird species.

One exception to this predicted road effect zone is the Barn owl which is likely to be affected at a much greater distance and is discussed separately below. Another, is the Peregrine falcon; a species which is relatively tolerant of human disturbance and road traffic.

Although the proposed road development is predicted to have a long-term effect on local breeding bird populations, even at a local level this is not predicted to affect the ability of almost all local breeding bird species to persist within their current ranges or to maintain their populations long-term — the exception being the Barn owl.

Therefore, the proposed road development is not likely to affect the conservation status of breeding bird species generally (excluding Barn owl and Peregrine falcon, which are discussed separately below) and will not result in a likely significant negative effect, at any geographic scale.

Barn owl

Available published material relating to the potential impacts of road development on Barn owl concludes that the presence of major roads within 2.5km of an active nest site is likely to result in a severe depletion of the local population (Ramsden, 2003). The risk of such effects is likely to be extremely high in the case of the Menlo Castle nest site as it lies c.150m from the proposed road carriageway. Although only a single nest site is within the predicted road effect zone, it is not likely that there will be large numbers of nest sites at a county scale and a long-term decline of the population level at a county scale is likely.

It is unlikely that operational noise levels will result in any disturbance to nesting Barn owl at Menlo Castle (L_{den} 50-60dB). Barn owl are a nocturnal species and therefore, disturbance from road traffic at night (particularly from headlights) and from artificial lighting along the proposed road development is likely to result in some level of displacement of Barn owl from foraging habitat near the proposed road development. However, given the relatively small impact zone of the lighting when compared with the home range of the species (up to 5,000ha in the winter and up to 350ha in the summer (Hardy et al., 2009)), disturbance during operation is not likely to result in any decline in the local Barn owl population or affect its ability to maintain itself over the long-term.

Overall, mortality risk associated with the proposed road development is likely to affect the conservation status of Barn owl and result in a significant negative effect at the county geographic scale. Mitigation measures will be implemented to reduce the mortality risk to Barn owl posed by the proposed road development (see **Section 8.6.9.1.2**).

Peregrine falcon

Although the nest site at Lackagh Quarry used between 2015 and 2017 will not be lost, the nest site used by the breeding pair of Peregrine falcon in 2018 will likely be directly impacted, Despite the retention of the 'traditional' nesting ledge, the presence of a new road at such close proximity and elevated above the existing ground levels, has the potential to permanently displace nesting Peregrine falcon from that nest site. The absence of any alternative suitable nesting sites within the quarry may result in the permanent loss of the quarry as local Peregrine falcon nest site. There are two other quarry sites present locally which are currently not occupied by a Peregrine falcon pair. However, it cannot be predicted with any degree of certainty that Peregrine displaced from Lackagh Quarry would take up residence at these other sites, even with interventions such as creating suitable nesting ledges. The potential loss of one out of three local Peregrine falcon nest sites has the potential to have long-term effects on the local population, affecting the species conservation status locally.

The potential loss of this nesting site is also significant at the county geographic scale. The actual number of nest sites known across counties Galway and Clare is not known[78] but current estimates are on the region of 60-70 nest sites. The loss of one site, that has been regularly in use for many years, is significant in that context.

The potential loss of the nest site at Lackagh Quarry has the potential to result in a likely significant negative effect, at the county geographic scale.

Habitat Degradation – Water Quality

There will be drainage outfalls to all river/stream catchments crossed by the proposed road development. Therefore, there is a risk that discharges from the proposed road drainage network could affect water quality, potentially over the long-term, and consequently impact upon aquatic habitats and bird species, and their prey. In a worst-case-scenario, this could result in a long-term decline in aquatic/wetland bird species abundance and distribution on affected rivers or streams.

The proposed drainage design for the mainline of the proposed road development incorporates pollution control measures (this includes petrol interceptors, wetland and other measures, such as SuDS) followed by either infiltration ponds (where discharging to ground) or attenuation ponds (where drainage will be discharged to the existing surface water/storm sewer), as described in detail in **Chapter 5, Description of Proposed Road Development**.

Those sections of the proposed road drainage that are to be discharged to ground, pose no risk to surface water quality. It is extremely unlikely that the normal

[78] At the time of writing, a national Peregrine falcon census is underway but the results are not yet known.

operating water quality of the proposed drainage outfalls discharging to the existing surface water/drainage network, even in the unlikely event of a pollution incident, would have any perceptible long-term effect on water quality in receiving watercourses. The functioning and effectiveness of both elements of the proposed road drainage network are discussed in more detail in **Chapter 11, Hydrology**).

Habitat degradation is not predicted to affect the conservation status of aquatic or wetland bird species because of effects on surface water or groundwater during operation and will therefore, not result in a likely significant negative effect, at any geographic scale.

8.5.8.2 Wintering Birds

This section of the impact assessment deals with wintering bird species — i.e. those bird species which are SCIs of SPAs for their wintering populations, or are listed on either the BoCCI Red or Amber lists for their wintering populations.

Local bird population figures are based on the sum of the mean populations from I-WeBS summary data for Lough Corrib and Inner Galway Bay (accessed December 2015). However, local bird population figures are likely to be an underestimate of the actual local population due to patchy/incomplete I-WeBS counts and that only two wetland areas are covered in the local area (Inner Galway Bay and Lough Corrib).

8.5.8.2.1 Construction Phase Impacts

Habitat Loss

The proposed road development will result in the loss of suitable wintering bird habitat area from nine of the wintering bird sites surveyed over the winter of 2014/15.

The proposed road development will result in the loss of a mosaic of wet grassland/heathland/scrub habitat at An Chloch Scoilte WB07 (c.2.2ha), Cappagh WB03 (c.4.2ha) and Ballagh WB10 (c.2.8ha). In all cases the habitat loss is along the southern margins of those habitat blocks and will therefore, not result in any fragmentation. Although these sites supported Curlew (on the BoCCI Red List for its wintering population) the numbers were low across all three sites in any of the positive survey months—eight in September 2014, seven in October 2014 and 2 in November 2014. These sites also supported wintering bird species on the BoCCI Amber List. Single Cormorant and Common gull were recorded on only one occasion at survey sites WB07 and WB10, respectively. A single Teal was also only recorded once at WB10. Snipe were recorded frequently across all three survey sites but in relatively low numbers (between one and nine individuals, with almost half being one or two birds). Given that the majority of each habitat block will be unaffected by habitat loss, or fragmentation, and the numbers of wintering birds were low and/or infrequently recorded across the affected wintering bird sites, long-term effects on local wintering bird populations of conservation concern are not likely. There is a small overlap with survey site WB08 at Na Foraí Maola Thoir (c.0.04ha) but this part of the site has been built on and is not of importance for wintering bird species.

At the NUIG Sporting Campus, (WB45) c.3.7ha of the amenity grassland habitat used by wintering birds will be affected by construction phase (for c.18 months). Of this, c.2.8ha will be permanently lost to the proposed Sports Pitches. Considering the availability of alternative amenity grassland habitat on the complex, and elsewhere in Galway City, long-term effects on local wintering bird populations at this site are not likely as a consequence of the habitat loss.

The proposed road development will potentially result in the permanent loss of c.0.9ha of wet grassland habitat from the southern end of the Ballindooley Lough survey site (WB02). This represents approximately 0.7% of the lake and wetland complex. As this portion of habitat was not recorded as being used by wintering birds during the surveys, and the loss of habitat will not fragment the wetland complex, the habitat loss associated with the proposed road development at Ballindooley Lough is not likely to affect the local wintering bird populations using the site.

At Galway Racecourse (WB23), c.0.5ha (or c.1%) of the habitat area within that survey site will be lost. No wintering bird species were recorded using the affected habitat area and as it is on the western edge, the proposed road development will not fragment the site. In terms of wintering birds of conservation concern, the Galway Racecourse site infrequently supported small numbers of Black-headed gull (three, on a single occasion), Common gull (also three on a single occasion), Oystercatcher (one individual on one occasion). More notable is that Curlew were recorded on three occasions (three in October 2014, two in November 2014, and 37 in January 2015) but always in the south-western corner of the survey site, where the proposed road development will not result in any habitat loss.

In WB01, which includes the lands around Ardaun and Doughiska, only small numbers of Black-headed gull were recorded on two occasions. Given the infrequent and low numbers recorded, and that there is an abundance of alternative agricultural grassland habitat locally that will remain unaffected by the proposed road development, the loss of habitat at this survey site is not likely to affect the local Black-headed gull wintering population.

At Lackagh Quarry(WB16), Kestrel were the only wintering bird of conservation concern recordedover the winter of 2014/15 — three were recorded overflying the site in February 2015. Although not confirmed, it is likely that the Menlough/Coolough area is a winter home range for a local pair recorded nesting at Angliham Quarry in 2014, 2015 and 2016. Lackagh Quarry has not been recorded as a roosting site for the species and offers little in the way of foraging habitat for the species. Considering this, and given the availability of alternative foraging habitat within the local area (e.g. open wet grassland and peatland habitats at Coolanillaun), the loss of habitat to the proposed road development is not likely to have any perceptible effect on local wintering Kestrel.

Peregrine falcon nest/roost at Lackagh Quarry during the breeding season and, although not recorded during the winter bird surveys, are also likely to be resident during the winter. With a large hunting range (2-6km from nest site – Hardy *et al.* 2009), and given the availability of alternative foraging habitat within the local area for such an adaptable species in terms of habitat preference, the loss of habitat to the proposed road development is not likely to have any perceptible effect on local wintering Peregrine falcon.

Overall, and considering the cumulative effect of habitat loss across all affected winter bird survey sites, habitat loss is not likely to affect the conservation status of wintering bird species and will not result in a likely significant negative effect, at any geographic scale.

Disturbance/displacement

As the majority of works will be carried out during normal working daylight hours, the potential for construction to disturb wintering birds at night, either foraging or roosting, will not arise. Therefore, the discussion below is focussed on daytime disturbance.

For the purposes of impact assessment and defining disturbance effect distances, construction related disturbance is considered in relation to general construction activities (e.g. visual impact of construction workers and machinery and the associated vibration and more constant/continuous noise levels) and impulse noise disturbance from infrequent noise sources with a high noise level, such as blasting.

General Construction Activity Disturbance

In a report prepared for Humber INCA, Cutts *et al.* (2009) investigated the effects of disturbance on foraging and roosting waterbirds. Based on the findings of that study, in terms of a response to third party disturbance (e.g. human presence), minimal effects would be expected beyond 300m. In terms of construction noise, levels below 50dB would not be expected to result in any response from foraging or roosting birds. Noise levels between 50dB and 70dB would provoke a moderate effect/level of response from birds — i.e. birds becoming alert and some behavioural changes (e.g. reduced feeding activity)—but birds would be expected to habituate to noise levels within this range. Noise levels above 70dB would likely result in 8.31 birds moving out of the affected zone, or leave the site altogether. This is supported by the findings of Wright et al. (2010) which found that average noise levels above 60dB resulted in behavioural responses, with birds abandoning the site in response to noise levels above 70dB.

Noise levels associated with typical construction activity have been calculated in accordance with the methodology set out in BS 5228: Part 1. This standard sets out sound power levels for plant items normally encountered on construction sites, which in turn enables the prediction of noise levels. A variety of items of plant will be in use during the construction works. These will include breakers, excavators, dump trucks, and generators in addition to general road surfacing and levelling equipment. The key phases of works will involve ground breaking, excavation works, fill works, piling of structures, and general road works.

Calculations of indicative noise levels for typical noise sources associated with road construction works at set distances from the construction activity were calculated using the source data from BS 5228:2009 Code of Practice for Noise and Vibration Control on Construction and Open Sites – Part 1 Noise. The calculations assume that plant items are operating for 66% of the time to obtain an LAeq, 1 hour value. Noise levels are presented in **Table 8.33** for the individual items of plant at specific distances in addition to a cumulative level assuming all plant items associated with the individual phases are operating simultaneously, and at the same distance, for any one scenario. The calculations do not take account of any screening afforded by intervening structures, construction site hoarding etc. and therefore represent a "worst case" scenario.

None of the construction activities listed above would be expected to result in any more than a moderate level of disturbance effect on waterbirds at distances beyond 150m. At 300m, noise levels are below 60dB or, in most cases, are approaching the 50dB threshold. Low, or no, effects would be expected for those noise levels. Any landscape features, vegetation cover or buildings between the construction site and winter bird sites would contribute to further reducing the ambient noise at any given distance. Therefore, 300m is considered to be a precautionary buffer in defining the ZoI of disturbance effects.

Impulse Noise Disturbance

In terms of noise levels associated with blasting, behavioural response thresholds would be expected to be similar to those described above for general construction related disturbance — i.e. greater than 60dB. However, calculating a distance whereby blasting would attenuate to below 60dB is less certain given the large number of variables that would influence that calculation (e.g. size of charge used).

Rees et al. (2005) found that impulsive noise disturbance (e.g. airport bird scaring) alerted Whooper swans at distances of up to c.800m. As a precautionary approach, this distance is the zone within which some level of disturbance would be expected from rock blasting. However, it is worth noting that in that study less than a third of birds were alerted and disturbance events were also temporary, with birds resuming undisturbed behaviour within minutes. Therefore, the magnitude of any disturbance effects is likely to be greatest where blasting is occurring regularly, over a prolonged period, and probably at distances less than 800m. The only location along the proposed road development where regular, prolonged blasting is likely to occur in the vicinity of an important wintering bird site (i.e. with high numbers of birds, frequently present) is in the zone between the western approach to Lackagh Tunnel and the proposed N83 Tuam Road Junction. Therefore, Ballindooley Lough is the only winter bird site where blasting may have a significant negative effect on wintering bird species and this is reflected in the discussions below, under the individual species headings.

Impacts on Winter Bird Species of Conservation Concern

In terms of effects on each of the wintering bird species recorded within the ZoI of the proposed road development, the NIS for the proposed road development presents a detailed assessment of those species listed as SCIs of either Lough Corrib SPA or Inner Galway Bay SPA. Based on the abundance and frequency of these bird species recorded at each affected winter bird site, and the assessment methodology relating to disturbance outlined above, it was concluded that there would not be any population level effects. Therefore, for these species disturbance/displacement from construction works will not affect the species' conservation status or result in a likely significant negative effect, at any geographic scale.

The non-SCI wintering bird species of conservation concern present within the ZoI of the proposed road development were: Bittern, Great crested grebe, Little grebe, Merlin, Mute swan, Oystercatcher, Peregrine falcon and Snipe. The potential impact of the proposed road development on the wintering populations of each of these species are discussed below.

Bittern

A single Bittern was recorded at the Coolagh Lakes (WB04) in February 2015, initially in flight and landing in reed beds on the eastern side of the larger northern lake. Bittern is a scarce winter visitor to Ireland and is not included within the BoCCI lists. Ad hoc observations of Bittern in County Galway suggest it was last recorded near Lough Corrib in December 2011[79]; with only two records in the county in the 5 years up to winter 2015. It is likely that construction works will take place over the winter period within 300m of the Coolagh Lakes and therefore, there is the potential for disturbance and displacement of wintering birds, including Bittern. However, only the very northern end of the wetlands at the Coolagh Lakes falls within the ZoI of general construction related disturbance. Blasting may be required during construction within 800m of the Coolagh Lakes, but the requirements are likely to be minimal: i.e. likely to be carried out over periods of days, or a few weeks, with infrequent blasting events at any given location. Thus, displacement from any blasting is unlikely to cause any more than a brief effect at any instance. Given the extensive woodland cover that lies between the wetland/lake habitats and the proposed road development the disturbance effects during construction are likely to be significantly reduced from the 300m and 800m distances related to the construction effects described. Even if Bittern were temporarily displaced from the area, there is an abundance of alternative suitable habitat available to accommodate the species, both surrounding the Coolagh Lakes and to the north of Menlo Castle. Therefore, disturbance from construction works

[79] According to www.irishbirding.com 'Sightings' records Accessed 18th December 2015

is not likely to affect the species' conservation status and will not result in a likely significant negative effect, at any geographic scale.

Great crested grebe

Two Great crested grebe were recorded on a single occasion during the winter bird surveys on the River Corrib corridor (WB12), near the Glenlo Abbey Hotel's boat landing stage. This is estimated at approximately 3.4% of the local population. In the area between the Glenlo Abbey Hotel and Menlo Pier, the River Corrib is within the ZoI of general construction works. Any disturbance effects associated with construction works in this area are likely to be temporary given that it is a pipeline, attenuation facilities and a drainage outfall, and that only a small proportion of the works are within 300m of the River Corrib. Given the scarce records for the species from that part of the River Corrib within the ZoI of the proposed road development, and the temporary nature of the works in the vicinity, there is a low risk of any disturbance or displacement effects. The majority of the river corridor (locally) is beyond the ZoI of any disturbance effects and would be available to accommodate displaced grebes. Therefore, disturbance from construction works is not likely to affect the species' conservation status and will not result in a likely significant negative effect, at any geographic scale.

Little grebe

Little grebe were recorded at four winter bird sites within the ZoI of general construction works and potentially prolonged blasting at Lackagh Quarry: Ballindooley Lough (WB02), the Coolagh Lakes (WB02), west of Lough Inch (WB08) and along the River Corrib corridor (WB12).

Lough Inch is c.740m from the proposed road development, at its nearest point. At this distance, and given that the nearest potential blasting location is c.800m from the lake shore, construction works are not likely to have any perceptible disturbance effects at this site.

Little grebe were recorded frequently at Ballindooley Lough, Coolagh Lakes and on the River Corrib; although five was the maximum number recorded at any one location or on any given survey visit (estimated to be c.4.3% of the local population). As discussed above in relation to Bittern, construction related disturbance at the Coolagh Lakes is not likely to displace wintering birds from most of the lake habitat—even as a consequence of any blasting that might be required, and the effects of which would be of a brief duration.

On the River Corrib, Little grebe were recorded along the river corridor from Galway City to Menlough; the majority of records were from upstream of the NUIG Sporting Campus and between the Coolagh Lakes and Waterside in the city. Both locations are beyond the ZoI of general construction activities and any blasting requirements that may be associated with works within 800m of the River Corrib are likely to be minimal and with only a brief disturbance effect. Construction works near the River Corrib will probably result in some level of construction related disturbance but this will be short-term (c.18 months). Considering that most of the river habitat will be beyond the ZoI of construction related disturbance, and given the low numbers of Little grebe potentially affected along the river, any disturbance/displacement will not have any long-term effects on the species.

As Ballindooley Lough is within the ZoI of (potentially) long-term blasting activity between Lackagh Quarry and the N83 Tuam Road Junction there is the potential for construction works to displace wintering birds from Ballindooley Lough over several winter seasons (estimated/predicted to be three). This could potentially have long term effects on the local population and result in a likely significant negative effect, at the local geographic scale. Mitigation measures will be implemented to limit noise related disturbance during construction (see **Section 8.6.9.2.1**).

Merlin

A single Merlin was recorded in the area west of Lough Inch (WB08) in December 2014; flying to the south of the site. The area covered by the winter bird surveys here that lies within the ZoI of construction works, represents only a small proportion of what is an extensive upland habitat complex extending for more than 50km to the north west, including the Connemara Bog Complex SPA, c.9km away, for which Merlin is a SCI species. Given the scarce presence of the species in habitats near to the proposed road development, and the temporary nature of the works and any potential for disturbance, construction works are not likely to have any long-term effects on the species.

Therefore, disturbance from construction works is not likely to affect the species' conservation status and will not result in a likely significant negative effect at any geographic scale.

Mute swan

Mute swans were recorded at five winter bird sites within the ZoI of general construction works and potentially prolonged blasting at Lackagh Quarry: Ballindooley Lough (WB02), the Coolagh Lakes (WB02), west of Lough Inch (WB08) and along the River Corrib corridor (WB12).

As discussed above, Lough Inch is beyond the disturbance ZoI of the proposed road development and at the Coolagh Lakes disturbance/displacement effects are likely to be minimal and short-term.

On the River Corrib, Mute swan were frequently recorded but, bar a single record of 14 birds in February 2014 (estimated to be c.2.9% of the local population), numbers present ranged from four to eight individuals.

Construction works near the River Corrib will probably result in some level of construction related disturbance but this will be short-term (c.18 months). Considering this, that most of the river habitat will be beyond the ZoI of construction related disturbance, and given the low numbers of Mute swan potentially affected along the river, any disturbance/displacement will not have any long-term effects on the species.

Therefore, disturbance from construction works is not likely to affect the species' conservation status and will not result in a likely significant negative effect, at any geographic scale.

Oystercatcher

Oystercatcher were recorded widely across the study area: the River Corrib corridor (WB12), Merlin Park (WB21), Galway Racecourse (WB23), Ballybane Playing Fields (WB24), NUIG Sporting Campus (WB45), Gort na Bró Playing Fields (WB48) and the Bearna Woods Playing Fields (WB50).

The Merlin Park and Ballybane sites have a significant buffer of urban development between them and the proposed road development, and works in these areas are predominantly on-line. Therefore, no disturbance effects at those sites are likely because of construction works.

Although Galway Racecourse grounds lie within the potential disturbance ZoI, Oystercatcher were only recorded here on one occasion (and only a single individual). In WB12, the species was only recorded on a single occasion and in low numbers (in lands at Menlo Castle where seven individuals were recorded in February 2014). At the Bearna Woods Playing Fields, numbers recorded were also low — one in November 2014, two in December 2014 and five in February 2015. The frequency of use and numbers recorded were similar at the Gort na Bró site—five in both November 2014 and January 2015, three in February 2015 and 20 in March 2015. Therefore, any temporary displacement at these sites during construction will not affect the local population which is estimated to be c.740.

Oystercatcher were recorded at the NUIG Sporting Campus on nine separate occasions over the winter of 2014/15 and it was the most frequently used of the winter bird survey sites by the species. The majority of records ranged between three and 22 individuals; the exception being a record of 34 in December 2014 which is estimated to represent c.4.6% of the local population. It was noted during the surveys at this site that birds were regularly disturbed and temporarily displaced from the playing fields by users of the sports facilities, returning to the same field or to another nearby. This would suggest that Oystercatcher using this site have adapted to a certain degree of habitual disturbance and despite this, frequently use the playing fields. Construction works at the NUIG Sporting Campus will result in some level of construction related disturbance but this will be short-term (c.18 months). Considering this, that there are alternative sites available locally beyond the ZoI of construction related disturbance, and given the relatively low numbers of Oystercatcher potentially affected here, any disturbance/displacement will not have any long-term effects on the species.

Therefore, disturbance from construction works is not likely to affect the species' conservation status and will not result in a likely significant negative effect, at any geographic scale.

Peregrine falcon

During the winter of 2014/15, Peregrine falcon were recorded at one winter bird survey site within the potential ZoI of construction works—the Roadstone Quarry (WB17)—on three occasions in December, February and March when a single bird was observed. The results of the Peregrine falcon survey carried out in 2016 confirmed the presence of three local breeding pairs, and it would be expected that they would maintain a local presence over the winter period.

Peregrines are highly adaptable species and not highly sensitive to construction related disturbance away from the nest site; as evidenced by the species regularly breeding in active quarry sites and in the urban environment. Therefore, construction works are not likely to have any perceptible effect on the local population during the winter period, is not likely to affect the species' conservation status and will not result in a likely significant negative effect, at any geographic scale.

Snipe

Snipe were distributed widely across the study area: recorded at eight of the winter bird survey sites. Although Snipe were frequently recorded across these sites, the numbers were generally low (<10 birds). The exception being records of 28 and 34 at Ballindooley Lough in December 2014 and March 2015, respectively.

In the western part of the study area, four winter bird sites within the ZoI of construction related disturbance supported wintering Snipe — Cappagh (WB03), An Chloch Scoilte (WB07), west of Lough Inch (WB08) and Ballagh (WB10). The areas within those sites potentially affected by disturbance during construction represent only a small proportion of the locally available habitat resource for the species during the winter (i.e. rough wet grassland/heath habitat offering good ground cover). Given the low numbers potentially affected at these sites, and the temporary nature of any construction related disturbance, disturbance/displacement effects are not likely to affect the local Snipe population in the long-term.

Where the proposed road development crosses the River Corrib (WB12), there is little habitat suitable for the species within the disturbance ZoI. As discussed above for Bittern, Little grebe and Mute swan, at Coolagh Lakes disturbance/displacement effects are likely to be minimal and short-term at most. Therefore, even temporary effects during construction are unlikely to affect the local population.

The Terryland River Valley (WB14) is beyond the ZoI of general construction works with a buffer of residential development between it and the proposed road development. Even if prolonged blasting in this area were required during construction, the effects would remain brief and most of this winter bird site would remain unaffected by disturbance.

As Ballindooley Lough is within the ZoI of (potentially) long-term blasting activity between Lackagh Quarry and the N83 Tuam Road Junction there is the potential for construction works to displace wintering birds from Ballindooley Lough over several winter seasons (estimated/predicted to be three). This could potentially have long term effects on the local population and result in a significant negative effect, at the local geographic scale. Mitigation measures will be implemented to limit noise related disturbance during construction (see **Section 8.6.9.2.1**).

<u>Impacts on Important Winter Bird Sites</u>

Given their SPA status, Lough Corrib SPA and Inner Galway Bay SPA are the most sensitive sites for wintering birds locally. A detailed assessment of the potential for the proposed road development to affect both Lough Corrib SPA and Inner Galway Bay SPA is presented in the NIS. This assessment concluded that the proposed road development would not result in an adverse effect on the integrity of either SPA.

However, this conclusion was dependant on the implementation of mitigation measures relating to the protection of surface water, groundwater and disturbance—which are also reflected in the mitigation strategy presented in **Section 8.6** of this chapter.

Ballindooley Lough is also considered to be a locally important wintering bird site given the diversity of bird species of conservation concern for their wintering populations recorded there; fourteen in total, which included species listed as SCIs for Lough Corrib SPA and Inner Galway Bay SPA. The site regularly supported Coot, Curlew, Teal, Tufted duck and Shoveler—all species listed as SCIs for the nearby Lough Corrib SPA and Inner Galway Bay SPA. Although recorded less frequently and/or in low numbers, other SCI bird species recorded over the winter period were Bar-tailed godwit, Black-headed gull, Cormorant, Grey heron, Lapwing and Wigeon. The BoCCI Amber listed wintering species Little grebe, Mute swan and Snipe were also regularly recorded at Ballindooley Lough. As Ballindooley Lough is within the ZoI of (potentially) long-term blasting activity between Lackagh Quarry and the N83 Tuam Road Junction there is the potential for construction works to displace wintering birds from Ballindooley Lough over several winter seasons (estimated/predicted to be three). This could potentially have long term effects on the local population and result in a significant negative effect, at the local geographic scale. Mitigation measures will be implemented to limit noise related disturbance during construction (see **Section 8.6.9.2.1**).

The River Corrib corridor (including the NUIG Sporting Campus) and Coolagh Lakes were also important sites for wintering birds of conservation concern. Between them they supported three BoCCI Red list species (Black-headed gull, Curlew and Redshank) and ten Amber listed species—Cormorant, Coot, Great-black backed gull, Little grebe, Mute swan, Snipe, Teal, Common gull, Great crested grebe and Oystercatcher. The areas where most of these species were most frequently recorded (and recorded in the greatest numbers) are generally in the lower parts of the river between Coolagh Lakes and the Salmon Weir, or upstream of Menlo Castle. The exception being Oystercatcher who were frequently recorded at the NUIG Sporting Campus but there are alternative amenity grassland areas available to the species elsewhere in the complex.

As discussed above, and in the NIS, in relation to the species recorded at each of these sites, the potential impacts associated with the proposed road development, either at each site or cumulatively, are not likely to affect the conservation status of the local wintering populations at these winter bird sites and will not result in a likely significant negative effect, at any geographic scale.

Habitat Degradation – Surface Water Quality

During construction, contaminated or heavily silted surface water runoff, pump discharges and/or an accidental spillage or pollution event into any surface water feature has the potential to have a significant negative impact on water quality and consequently on aquatic habitats and species supporting the wintering bird populations. This could be either directly (e.g. bird species coming into direct contact with pollutants) or indirectly (e.g. acute or sub-lethal toxicity from pollutants affecting their food supply or supporting habitats).

The effects of frequent and/or prolonged pollution events in lake systems could potentially have significant long-term effects. It is considered unlikely that a pollution event of such a magnitude would occur during construction, or be any more than temporary in nature. Nevertheless, a precautionary approach is being taken in assuming a level of risk of water quality impacts and detailed mitigation measures are required to further minimise the risk of the proposed road development having any perceptible effect on water quality during construction.

Habitat degradation as a result of effects on surface water quality during construction has the potential to affect the conservation status of affected wintering bird species and result in a likely significant negative effect, at a local geographic scale. Mitigation measures have been designed to protect water quality during construction (see **Section 8.6.4**).

Habitat Degradation – Groundwater

Any effects on the existing hydrogeological regimes at Coolagh Lakes and Ballindooley Lough have the potential to negatively impact upon the aquatic habitats and wintering bird species they support.

Based on the findings of the hydrogeological impact assessment in **Chapter 10, Hydrogeology**, the proposed road development does not pose a risk to the groundwater supply to Ballindooley Lough. The proposed road development does however, have the potential to affect the quantity of groundwater supplying the Coolagh Lakes. Although the magnitude of the impact cannot be fully quantified, on a precautionary basis it is assessed as having has the potential to affect winter bird usage of the Coolagh Lakes and result in a likely significant negative effect, at the local. Mitigation measures have been designed to protect the existing groundwater regime during construction (see **Section 8.6.5**).

8.5.8.2.2 Operation Phase Impacts

Disturbance/displacement

During operation, the proposed road development has the potential to disturb and displace wintering bird species from habitat near the proposed road development because of the noise and visual disturbance associated with road traffic. The focus of research, and attempting to quantify, the effect of operational roads on bird populations has been largely focussed on breeding populations. Although the operational disturbance/displacement effect cannot be quantified it would be expected to be much less than the 300m ZoI associated with construction works. Most species of wintering birds are likely to habituate to the presence of a new road, particularly when there is a barrier in place, as is the case for the proposed road development in the form of the boundary fencing or where the proposed road is in a deep cutting. Also, background noise levels are predicted to increase in the western part of the study area from a current range of 45-55dB to between 50 and 60dB during operation—a noise level at which birds would not be expected to be displaced from the area. In the zone between the N83 Tuam Road and the existing N6, background noise levels are currently in the 50-60dB range and any operational noise/traffic is not likely to alter the existing baseline effect on wintering birds using habitats locally.

Although there is still likely to be some level of displacement effect, a perceptible effect would be expected to be limited to habitats immediately adjacent to the proposed road development. Although it is likely to add to the effect of habitat loss, in terms of additional habitat area unavailable or unlikely to be used by wintering birds, it is not predicted to have a detrimental population level effect—particularly given the relatively infrequent and/or low numbers of wintering birds generally recorded at affected winter bird sites.

Therefore, any displacement of birds from habitat areas during operation of the proposed road development is not likely to affect the conservation status of wintering bird species and will not result in a likely significant negative effect, at any geographic scale.

Mortality Risk

The proposed River Corrib Bridge poses a collision risk to birds commuting along the river corridor. The risk of birds colliding with a bridge is dependent on many factors such as bridge design, visibility (bridge strikes are more likely during poor weather conditions or at night), the structure of the surrounding habitat, the bird species present, their frequency of occurrence within the impact zone (and flight height relative to the bridge structure), and their relative susceptibility to colliding with structures.

Surveys carried out in 2005/2006 as part of the 2006 Galway City Outer Bypass Scheme (RPS, 2006) recorded the following SCI species flying through the proposed bridge site for that scheme over the survey period (52 surveys encompassing 104 hours of observations): Hen harrier, Coot, Black-headed gull, Common gull, and Common tern. The most frequently recorded of these were Black-headed gull, Common gull and Cormorant; Hen harrier and Coot were only recorded once, Common tern were observed crossing the bridge site on only 43 occasions and generally low over the water (<5m).

The bridge structure is clear-span with no supporting cable structures and as such, poses a minimal risk to wintering birds passing along the river corridor. Given the bird numbers and crossing frequencies observed during the 2006 surveys, a bridge such as that proposed in the design (refer to **Section 5.5.4.6** of **Chapter 5, Description of Proposed Road Development**) would not be expected to pose a collision risk of a magnitude that it would result in long-term effects on local bird populations.

Nor would the presence of the proposed road development outside of the River Corrib corridor be expected to pose any significant collision risk to winter birds moving between the coast, Lough Corrib or any of the other winter bird survey sites at which they were recorded. Particularly given that to move between sites outside of the river corridor at present birds must fly over the existing road network and urban infrastructure in Galway City.

Therefore, any collision risk posed by the proposed road development is not likely to affect the conservation status of wintering bird species and will not result in a likely significant negative effect, at any geographic scale.

Habitat Degradation – Surface Water

There are proposed drainage outfalls to all river/stream catchments crossed by the proposed road development. Therefore, there is a risk that discharges from the proposed road drainage network could affect water quality, potentially over the long-term, and consequently impact upon the aquatic environment and supported bird species. In a worst-case-scenario, this could result in a long-term decline in aquatic/wetland bird species abundance and distribution on affected rivers or lakes.

The proposed drainage design for the mainline of the proposed road development incorporates pollution control measures (this includes petrol interceptors, wetland and other measures, such as SuDS) followed by either infiltration ponds (where discharging to ground) or attenuation ponds (where drainage will be discharged to the existing surface water/storm sewer), as described in detail in **Chapter 5, Description of Proposed Road Development**.

Those sections of the proposed road drainage that are to be discharged to ground, pose no risk to surface water quality. It is extremely unlikely that the normal operating water quality of the drainage outfalls discharging to the existing surface water/drainage network, even in the unlikely event of a pollution incident, would have any perceptible long-term effect on water quality in receiving watercourses. The functioning and effectiveness of both elements of the proposed road drainage network are discussed in more detail in the hydrology chapter (**Chapter 11, Hydrology**).

Habitat degradation because of effects on surface water or groundwater during operation are not predicted to affect the conservation status of aquatic or wetland bird species and will therefore, not result in a likely significant negative effect, at any geographic scale.

8.5.9 Amphibians

8.5.9.1 Construction Phase Impacts

Habitat Loss

The construction of the proposed road development will result in the permanent loss of both confirmed and potentially suitable amphibian habitat within the proposed development boundary. The presence of potentially suitable amphibian breeding habitat is of note as, even though both Common frog and Smooth newt were only confirmed at a small number of sites within the proposed development boundary (see **Figures 8.10.1** to **8.10.8**), it is possible that any wetland/peatland habitat or drainage ditches could be colonised and used by this species at the time of construction.

Given the low number of habitat features supporting amphibian species directly impacted by the proposed road development, and that these areas supported relatively few individuals, and the abundance of alternative suitable habitat available locally, the effects of habitat loss associated with construction works are unlikely to affect the ability of the local frog or newt populations to maintain themselves in the long-term.

Therefore, habitat loss associated with the proposed road development is not likely to affect the species' conservation status or result in a likely significant negative effect, at any geographic scale.

As amphibian breeding habitat will be directly impacted by the proposed road development, and given the legal protection afforded to amphibian species under the Wildlife Acts (which prohibits wilful destruction or interference with an amphibian breeding or resting places), a mitigation strategy has been developed (see **Section 8.6.10.1**).

Disturbance & Mortality Risk

Site clearance works also have the potential to result in disturbance to, and the direct mortality of, Common frog and Smooth newt. The potential for direct mortality to occur, and the magnitude of any effects, would be expected to be greater where (a) suitable habitat exists and either Common frog and/or Smooth newt have been previously recorded (b) works affecting suitable habitat are undertaken during the breeding season, when adults and/or frog spawn/newt eggs may be present, or during the winter hibernation period when individuals are in refugia. Based on the survey results, the number of individuals that would potentially be at risk is low and would be unlikely to affect the local populations in the long-term.

Therefore, the proposed road development is not likely to affect the species' conservation status in that regard or result in a likely significant negative effect, at any geographic scale.

Amphibian species have been confirmed using habitat areas within, and immediately adjacent to, the proposed road development that have the potential to be killed, injured, or affected by construction related disturbance. Given the legal protection afforded to amphibian species under the Wildlife Acts, which prohibits their intentional killing or injury, or the wilful interference with an amphibian breeding or resting places, a mitigation strategy has been developed (see **Section 8.6.10.1**).

Habitat Severance/Barrier Effect

The temporary to short-term physical disruption of the existing landscape during site clearance and construction will fragment wetland and peatland habitats used by amphibian species. As a temporary to short-term impact, this is unlikely to present a significant barrier to the movement of amphibian species such that it would affect the local Common frog or Smooth newt populations in the long-term. Therefore, habitat severance during construction and any associated barrier effect are not predicted to result in a likely significant negative effect to amphibian species, at any geographic scale.

Habitat Degradation – Surface Water Quality

An accidental spillage or pollution event into a surface water feature supporting Common frog or Smooth newt will probably have a negative impact. The magnitude and significance of such an impact would be entirely dependent on the nature, scale and duration of the pollution event. Although unlikely, in a worst case scenario this could result in extensive degradation of amphibian habitat and/or the mortality of amphibians in affected habitats. There is the potential for such impacts to have long-term effects on the local populations of both the Common frog and the Smooth newt and result in a likely significant negative effect, at the local geographic scale. Habitat degradation therefore, has the potential to affect the species' conservation status and result in a likely significant negative effect, at the local geographic scale. Mitigation measures have been designed to protect water quality during construction (see **Section 8.6.4**).

8.5.9.2 Operational Phase Impacts

Habitat Severance/Barrier Effect

The presence of the proposed road development will create a permanent barrier in the landscape to the movement of Common frog and Smooth newt. This is likely to affect foraging behaviour and dispersal corridors, e.g. the movement of species between breeding and hibernation sites. Populations on the fringes of Galway City may be isolated from habitat areas and populations beyond, having long-term effects on genetic diversity and gene flow, at a local geographic scale.

Habitat severance and barrier effect has the potential to have long-term effects on the local populations of both the Common frog and the Smooth newt, affect the species' conservation status and result in a likely significant negative effect, at the local geographic scale. Mitigation measures have been designed to minimise the long-tern effects of any barrier effect posed by the proposed road development (see **Section 8.6.10.2**).

Mortality Risk

Amphibians species are vulnerable to road mortality and the presence of the proposed road development will pose a permanent mortality risk to Common frog and Smooth newt. Although it is not possible to quantify the magnitude of this impact, it is unlikely to have long-term effects that would result in a decline of the local Common frog and Smooth newt populations. Particularly, given the high degree of permeability across the proposed road development included within the design which will minimise the potential interaction of amphibians with the proposed road carriageway.

Therefore, mortality risk is not likely to affect the species' conservation status or result in a likely significant negative effect, at any geographic scale.

Habitat Degradation – Surface Water Quality

There will be outfall points to surface water features from the proposed road drainage network during operation. Therefore, there is a risk that discharges from the proposed road drainage network could affect water quality in receiving surface water features and consequently impact upon amphibian habitat.

The proposed drainage design for the mainline of the proposed road development incorporates pollution control measures (this includes petrol interceptors, wetland and other measures, such as SuDS) followed by either infiltration ponds (where discharging to ground) or attenuation ponds (where drainage will be discharged to the existing surface water/storm sewer), as described in detail in **Chapter 5, Description of Proposed Road Development**.

Those sections of the proposed road drainage that are to be discharged to ground, pose no risk to surface water quality. It is extremely unlikely that the normal operating water quality of the drainage outfalls discharging to the existing surface water/drainage network, even in the unlikely event of a pollution incident, would have any perceptible long-term effect on water quality in receiving watercourses. The functioning and effectiveness of both elements of the proposed road drainage network are discussed in more detail in **Chapter 11, Hydrology**.

Habitat degradation as a result of effects on surface water quality during operation is not predicted to affect the conservation status of amphibian species and will therefore, not result in a likely significant negative effect, at any geographic scale.

8.5.10 Reptiles

8.5.10.1 Construction Phase Impacts

Habitat Loss

Construction of the proposed road development will result in the permanent loss of Common lizard habitat within the proposed development boundary (see **Figures 8.10.1** to **8.10.8**). There are three distinct areas, where Common lizard were recorded, that are affected directly by the proposed road development: a mosaic of heath, scrub, bracken and wet grassland at Na Foraí Maola/An Chloch Scoilte (Area A); a similar habitat mosaic between Bearna Woods and na hAille (Areas B & C); and, at Ballagh (Areas E & F). This is consistent with the species favouring structurally diverse habitat mosaics to provide foraging areas, refuges and hibernacula, and basking sites within their territories.

In all areas, only single individual Common lizard were recorded on any given visit. Given the relatively low numbers of Common lizard that are likely to be affected, and the abundance of alternative suitable habitat available locally, the effects of habitat loss associated with construction works are unlikely to affect the long-term viability of the local Common lizard population. Therefore, habitat loss is not likely to affect the species' conservation status or result in a likely significant negative effect, at any geographic scale.

As Common lizard habitat will be directly impacted by the proposed road development, and given the legal protection afforded to the species under the Wildlife Acts (which prohibits wilful destruction or interference with their breeding or resting places), a mitigation strategy has been developed (see **Section 8.6.11.1**).

Disturbance & Mortality Risk

Site clearance works have the potential to result in disturbance to, and the direct mortality of, Common lizard. The potential for direct mortality to occur, and the magnitude of any effects, would be expected to be greatest where (a) suitable habitat exists and Common lizard have been previously recorded (b) works affecting suitable habitat are undertaken during the winter hibernation period (October to mid-March) and affect potential hibernacula (e.g. stone walls), when lizards are less active and therefore less able to escape any works being undertaken.

Based on the survey results, the number of individuals that would potentially be at risk is low and would be unlikely to affect the local populations in the long-term. Therefore, disturbance or mortality risk are not likely to affect the species' conservation status or result in a likely significant negative effect, at any geographic scale.

Common lizard have been confirmed using habitat areas within, and immediately adjacent to, the proposed road development and there is therefore, the potential for individuals to be killed, injured, or affected by construction related disturbance. Given the legal protection afforded to the Common lizard under the Wildlife Acts (which prohibits their intentional killing or injury, or the wilful interference with their breeding or resting places) and a mitigation strategy has been developed (see **Section 8.6.11.1**).

Habitat Severance/Barrier Effect

The temporary to short-term physical disruption of the existing landscape during site clearance and construction will fragment habitat used by Common lizard. As a temporary to short-term impact, this is unlikely to present a significant barrier to the movement of the species such that it would affect the local Common lizard population in the long-term. Therefore, habitat severance during construction and any associated barrier effect are not likely to affect the species' conservation status and are not predicted to result in a likely significant negative effect to the Common lizard, at any geographic scale.

8.5.10.2 Operational Phase Impacts

Habitat Severance/Barrier Effect

The presence of the proposed road development will create a permanent barrier in the landscape to the movement of Common lizard. This is likely to affect foraging behaviour and dispersal corridors, e.g. the movement of individuals within their territories and between breeding and hibernation sites. Populations on the fringes of Galway City may be isolated from habitat areas and populations beyond, having long-term effects on genetic diversity and gene flow, at a local geographic scale.

Habitat severance and barrier effect has the potential to have long-term effects on the local Common lizard population, affect the species' conservation status and result in a likely significant negative effect, at the local geographic scale. Mitigation measures have been designed to minimise the long-tern effects of any barrier effect posed by the proposed road development (see **Section 8.6.11.2**).

Mortality Risk

Common lizard are vulnerable to road mortality and the presence of the proposed road development will pose a permanent mortality risk to the species. Although it is not possible to quantify the magnitude of this impact, it is unlikely to have long-term effects that would result in a decline of the local Common lizard population. Particularly, given the high degree of permeability across the proposed road development included within the proposed design which will minimise the potential interaction of lizards with the proposed road carriageway.

Therefore, mortality risk is not predicted to affect the species' conservation status or result in a likely significant negative effect to amphibians, at any geographic scale.

8.5.11 Fish

8.5.11.1 Construction Phase Impacts

Habitat Loss

The proposed road development will result in the permanent loss of fisheries habitat where it crosses Sruthán na Líbeirtí, the Trusky Stream, the Bearna Stream (and tributary), the Tonabrocky Stream, the Knocknacarra Stream. A reduction in habitat availability could potentially have long-term effects on fish populations within a given river/stream catchment.

Sruthán na Líbeirtí

Sruthán na Líbeirtí is crossed by the proposed road development at two locations: between Ch. 0+650 and Ch. 0+750 (refer to **Figure 5.1.1**) where the length of channel directly affected is c.130m, and between Ch. 0+850 and Ch. 1+000 where c.120m will be lost. There is an additional 240m of the watercourse that lies within, or along, the proposed development boundary and is likely to be affected to some degree by construction, construction works could potentially result in further habitat loss. Construction works to install the proposed drainage outfall and road carriageway near where the stream passes beneath the R336 has the potential to result in further habitat loss, although the areas involved are likely to be small (<10m^2). The impact associated with the loss of instream habitat will be offset slightly by the creation of a new section of river channel, c.40m in length.

Sruthán na Líbeirtí is a seasonal watercourse with low fisheries value in the upper reaches, where it is impacted by the proposed road development. Considering this and the design requirements relating to new crossing structures and the proposed realigned channel, the loss of habitat is predicted not to affect the conservation status of the fish species within that catchment and will not therefore, result in a likely significant negative effect, at any geographic scale.

Trusky Stream

Approximately 160m of instream habitat will be lost on the Trusky Stream (Ch. 2+750 to Ch. 2+900 - refer to **Figure 5.1.1** and **Figure 5.1.2**) with a new channel, c.60m in length, being constructed in its place. There is also an additional 65m of the watercourse that lies within the proposed development boundary and is likely to be affected to some degree by construction works, e.g. the construction of the proposed drainage outfall will require installing a permanent structure on the stream bank.

The Trusky Stream is a seasonal watercourse with low fisheries value in the upper reaches, where it is impacted by the proposed road development. Considering this, the loss of habitat is not likely to affect the conservation status of the fish species within that catchment and will not therefore, result in a likely significant negative effect, at any geographic scale.

Bearna Stream

The Bearna Stream is crossed by the proposed road development at Ch. 4+125 (refer to **Figure 5.1.3**) where c.40m of existing instream habitat will be lost. There is an additional 285m of the watercourse that lies within, or along, the proposed development boundary and is likely to be affected to some degree by construction. Construction works could potentially result in further habitat loss such as that associated with installing the drainage outfall from the attenuation ponds. At Ch. 3+950, approximately 40m of instream habitat in a small tributary of the Bearna Stream will be lost; there is also c.110m of additional stream channel within the proposed development boundary with the same potential construction impacts as outlined above for the main channel of the Bearna Stream.

The main channel of the Bearna Stream is more than 4km in length. Considering that the linear length of stream channel that will be lost represents less than 1% of the total, the habitat loss is not likely to be of a magnitude to affect the conservation status of the fish species within that catchment and will not therefore, result in a likely significant negative effect, at any geographic scale. The unnamed tributary of the Bearna Stream is a seasonal watercourse with a relatively lower fisheries value in the upper reaches, where it is crossed by the proposed road development. Considering this, the loss of habitat is not likely to affect the conservation status of the fish species within that catchment and will not therefore, result in a likely significant negative effect, at any geographic scale.

Tonabrocky Stream

Approximately 450m of the Tonabrocky Stream channel will be lost as a result of the proposed road development between Ch. 4+850 and Ch. 5+225 (refer to **Figure 5.1.4**). As with many of the other watercourses crossed by the proposed road development, a further c.80m of the stream channel lie within the proposed development boundary and may also be directly impacted by construction works. A new section of stream channel, c.250m in length, which will offset the habitat loss to a degree.

The main channel of the Tonabrocky Stream is more than 5km in length. Although the linear length of stream channel that will be lost represents c.9% of the total, when the new length of stream channel is considered (reducing the permanent loss to c.4%) the habitat loss is not likely to be of a magnitude to affect the conservation status of the fish species within that catchment, particularly given that the impacted area is in the upper reaches of the catchment where the fisheries value was assessed as low. Habitat loss on the Tonabrocky Stream will not therefore, result in a likely significant negative effect, at any geographic scale.

Knocknacarra Stream

As a seasonal stream with a low fisheries value (where impacted by the proposed road development), the loss of habitat is predicted not to affect the conservation status of the fish species within that catchment and will not therefore, result in a likely significant negative effect, at any geographic scale.

River Corrib

There are no instream works proposed at the River Corrib. Habitat loss here will be restricted to the permanent loss of riparian/bankside habitat to install the drainage outfalls; one on each bank of the river which will affect c.3m of riparian habitat (refer to **Figure 5.1.7** and for habitats **Figures 8.14.7** and **8.15.7**). In the context of the River Corrib, where there is no spawning habitat or habitat suitable to support lamprey ammocoetes present in the immediate vicinity of the proposed River Corrib Bridge, this level of habitat loss is not likely to have any perceptible impact upon the fish species using the river. Therefore, habitat loss is not likely to have any long-term effect on the fish populations of the River Corrib or their conservation status, and therefore will not result in a likely significant negative effect, at any geographic scale.

Even though habitat loss is not predicted to result in any likely significant negative effect on affected watercourses/catchments, mitigation measures are proposed to minimise the loss of fisheries habitat, to protect that which is being retained within the proposed development boundary, and through the design of new channels and the culverts, minimise its effects on the local fish populations.

Coolagh Lakes, Ballindooley Lough and Galway Bay

There will be no habitat loss associated with the proposed road development at the Coolagh Lakes, Ballindooley Lough or in Galway Bay.

Habitat Degradation – Surface Water Quality

During construction, contaminated or heavily silted surface water runoff, pump discharges and/or an accidental spillage or pollution event into any surface water feature has the potential to have a significant negative impact on water quality and consequently on aquatic habitats and fish species, and potentially also in the marine environment downstream. This could be either directly (e.g. acute or sub-lethal toxicity from pollutants or siltation events damaging spawning habitat downstream) or indirectly (e.g. affecting their food supply or supporting habitats).

The effects of frequent and/or prolonged pollution events in a river system have the potential to be extensive and far-reaching and could potentially have significant long-term effects. It is considered unlikely that a pollution event of such a magnitude would occur during construction, or be any more than temporary in nature. Nevertheless, a precautionary approach is being taken in assuming a level of risk of water quality impacts and detailed mitigation measures are required to further minimise the risk of the proposed road development having any perceptible effect on water quality during construction.

Habitat degradation as a result of effects on surface water quality during construction has the potential to affect the conservation status of affected fish species and result in a likely significant negative effect, at a local geographic scale. Mitigation measures have been designed to protect water quality during construction (see **Section 8.6.4**).

Habitat Degradation – Groundwater

Any effects on the existing hydrogeological regimes at the Coolagh Lakes and Ballindooley Lough have the potential to negatively impact upon the aquatic habitats and the fish species they support.

Based on the findings of the hydrogeological impact assessment in **Chapter 10, Hydrogeology**, the proposed road development does not pose a risk to the groundwater supply to Ballindooley Lough. The proposed road development does however, have the potential to affect the quantity and quality of groundwater supplying the Coolagh Lakes. Although the magnitude of the impact cannot be fully quantified, on a precautionary basis it is assessed as having the potential to affect fish species' conservation status in the Coolagh Lakes and result in a likely significant negative effect, at the local geographic scale. Mitigation measures have been designed to protect the existing hydrogeological regime during construction (see **Section 8.6.5**).

Mortality Risk

Construction works to install culverts on Sruthán na Líbeirtí, the Trusky Stream, the Bearna Stream (and tributary), the Tonabrocky Stream, the Knocknacarra Stream and the River Corrib will require instream works, and in some cases realignment of a section of the stream channel. Instream works, or works associated with channel diversions, stream realignments or general construction activities (e.g. dewatering channels or water abstraction for dust control), have the potential to result in the direct mortality of fish species. This section assesses the risk associated with mortality due to species interacting with construction vehicles, machinery such as pumps, or as a result of dewatering. The potential effects of accidental pollution events, which can also result in fish mortality, are discussed separately under the heading of *Habitat Degradation – Surface Water*.

Given the seasonal nature of the upper reaches of many of the streams, where the proposed road development will be impacting upon the channel, and the low numbers of fish species recorded there during the electrofishing surveys, the mortality risk posed by the construction works is unlikely to affect the conservation status of any of the fish species present in the catchments of Sruthán na Líbeirtí, the Trusky Stream, the Bearna Stream (and tributary), the Tonabrocky Stream, or the Knocknacarra Stream.

Instream works on the River Corrib are limited to construction of the drainage outfalls (one on each river bank) which will require the installation of a head wall and concrete base. Given the scale of the works, they do not pose a risk of fish mortality such that it is likely to affect the conservation status of any of the fish species present in the River Corrib catchment.

The mortality risk from construction works is not likely to have any long-term effect on the local fish populations or their conservation status, and therefore will not result in a likely significant negative effect, at any geographic scale.

Given the legal protection afforded to fish species under the Fisheries Acts, a mitigation strategy has been developed to avoid an offence being committed during construction works (see **Section 8.6.12.1**).

Disturbance/Displacement

Increased human presence, and noise and vibration associated with the construction works (e.g. the installation of culverts and piles) is likely to result in the displacement of fish species from the area. long-term disturbance/displacement effects on the local fish populations are not likely given the temporary nature of any vibration associated with the pile driving, and the short-term nature of general construction works (which if carried out during normal working hours, would be of a limited duration each day), that there are no spawning grounds near any of the proposed watercourse crossings.

Disturbance/displacement during construction is not predicted to affect the conservation status of the local fish populations and therefore, will not result in a likely significant negative effect, at any geographic scale.

Habitat Severance/Barrier Effect

Instream construction works have the potential to sever fisheries habitat and result in a barrier to fish passage, at least temporarily. Restricting fish access to food resources, or spawning grounds, could have long-term effects on the local fish populations.

The habitat affected by, and upstream of, the proposed road development in the catchments of Sruthán na Líbeirtí, the Trusky Stream, the Bearna Stream (and tributary), the Tonabrocky Stream, and the Knocknacarra Stream were considered to be of a low fisheries value – most being seasonal in nature with few, or no, fish species recorded during the fisheries surveys. Therefore, any temporary severance or barrier effect during construction is not likely to result in long-term effects on the local fish populations in these catchments.

As the proposed River Corrib Bridge is a clear span bridge structure with no instream structures or works with the potential to block the river channel, no habitat severance or barrier effect will occur on the River Corrib.

Overall, habitat severance and barrier effect during construction is not likely to have any long-term effect on the local fish populations or their conservation status, and therefore will not result in a likely significant negative effect, at any geographic scale.

8.5.11.2 Operation Phase Impacts

Habitat Degradation – Surface Water

There will be drainage outfalls to all river/stream catchments crossed by the proposed road development. Therefore, there is a risk that discharges from the proposed road drainage network could affect water quality, potentially over the long-term, and consequently impact upon aquatic habitats and fish species. In a worst-case-scenario, this could result in a permanent decline in fish species abundance and distribution.

The proposed drainage design for the mainline of the proposed road development incorporates pollution control measures (this includes petrol interceptors, wetland and other measures, such as SuDS) followed by either infiltration ponds (where discharging to ground) or attenuation ponds (where drainage will be discharged to the existing surface water/storm sewer), as described in detail in **Chapter 5, Description of Proposed Road Development**.

Those sections of the proposed road drainage that are to be discharged to ground, pose no risk to surface water quality. It is extremely unlikely that the normal operating water quality of the drainage outfalls discharging to the existing surface water/drainage network, even in the unlikely event of a pollution incident, would have any perceptible long-term effect on water quality in receiving watercourses. The functioning and effectiveness of both elements of the proposed road drainage network are discussed in more detail in the hydrology chapter (**Chapter 11, Hydrology**).

Habitat degradation because of effects on surface water or groundwater during operation is not predicted to affect the conservation status of fish species and will therefore, not result in a likely significant negative effect, at any geographic scale.

Habitat Severance/Barrier Effect

The structures have been designed in consultation with IFI and the design criteria set out in *Guidelines for the Crossing of Watercourses during the Construction of National Road Schemes* (National Roads Authority, 2005) and the *Guidelines on Protection of Fisheries During Construction Works in and Adjacent to Waters* (IFI, 2016). This will maintain fish passage during the operation of the proposed road development and therefore, will result in a neutral impact to fish species.

8.5.12 Local Biodiversity Areas

The Coast Road (R336) to the N59 Moycullen Road (which includes the Cappagh – Ballymoneen and the Ballagh – Barnacranny Hill local biodiversity areas from the draft Galway City Biodiversity Action Plan 2014-2024)

In terms of biodiversity effects, the proposed road development will result in habitat loss across this area, including the loss of areas of the Annex I habitats Wet heath, Dry heath and Molinia meadow (see **Section 8.5.4** above for habitat impacts). It will also impact upon mammal species including Otter and Badger (see **Section 8.5.6** above), bat species (see **Section 8.5.6.2** above), the Marsh fritillary butterfly (see **Section 8.5.7.4**), breeding and wintering birds (see **Section 8.5.8** above), the Common frog and Smooth newt (see **Section 8.5.9**), the Common lizard (see **Section 8.5.10** above), and fish species in Sruthán na Líbeirtí, the Trusky Stream, the Bearna Stream, the Tonabrocky Stream and the Knocknacarra Stream (see **Section 8.5.11** above).

Rusheen Bay – Barna Woods – Illaunafamona

The proposed road development has the potential to affect habitats and species in Rusheen Bay if it were to result in a deterioration in water quality in the receiving surface water network, which discharges to Rusheen Bay (the Bearna Stream, the Tonabrocky Stream and the Knocknacarra Stream). For example, this is discussed above in **Section 8.5.4.1** in relation to habitats (including watercourses), in **Section 8.5.6.1.1** in relation to Otter, and in **Section 8.5.8.2.1** in relation to wintering birds. The proposed road development also has the potential to present a barrier to Otter movement in watercourses connected to Rusheen Bay (features that are important in supporting the local Otter populations), and road traffic has the potential to present a mortality risk to Otter (see **Section 8.5.6.1** above).

The River Corrib and the Coolagh lakes (which includes the River Corrib and adjoining wetlands local biodiversity areas from the draft Galway City Biodiversity Action Plan 2014-2024)

In terms of biodiversity effects, the proposed road development will result in habitat loss in the vicinity of the proposed River Corrib crossing, has the potential to affect water quality in the receiving environment, has the potential to affect groundwater quality and quantity supplying the Coolagh Lakes, to disturb species using the River Corrib corridor and the Coolagh Lakes (e.g. aquatic species and breeding/wintering birds). These impacts have the potential to affect both habitats and the assemblage of fauna species supported by those habitats; which include Otter, fish species, wintering and breeding birds, bats (including the Lesser horseshoe bat) and mollusc species. Construction of the River Corrib Bridge has the potential to affect aquatic species through the risk of construction materials dropping into the river, with operation of the proposed road development posing a mortality risk to Otter.

The effects on the River Corrib and the Coolagh Lakes are discussed briefly in **Section 8.5.3.1** in relation to Lough Corrib cSAC and in Section **8.5.3.2.2** in relation to Lough Corrib pNHA. However, a more detailed assessment is presented in the NIS in the context of impacts on the River Corrib/Coolagh Lakes and Lough Corrib cSAC, which considers all of the aforementioned potential impacts, as the cSAC designation includes the River Corrib and the Coolagh Lakes. This area is also included within the Lough Corrib pNHA.

Menlough to Coolough Hill (including Lackagh Quarry)

In terms of biodiversity effects, the proposed road development will result in habitat loss across this area, including semi-natural grasslands, woodland, scrub, calcareous springs and exposed limestone rock – this includes the loss of areas of the Annex I habitats Petrifying springs, Limestone pavements, Calcareous grasslands and Residual alluvial forests. There is also the potential for groundwater impacts to affect a Turlough feature (see **Section 8.5.4** above for habitat impacts). It will also impact upon mammal species including Badger (see **Section 8.5.6** above), bat species (and in particular the Lesser horseshoe bat and the maternity roost at Menlo Castle, see **Section 8.5.6.2** above), breeding birds (including Barn owl, see **Section 8.5.8** above), and potentially amphibian species (see **Section 8.5.9**).

A portion of this area also lies within Lough Corrib cSAC, this is discussed briefly in **Section 8.5.3.1** in relation to Lough Corrib cSAC. However, a more detailed assessment is presented in the NIS in the context of impacts on that portion of this area that lies within Lough Corrib cSAC

Ballindooley – Castlegar (which is linked to the River Corrib by the Terryland River valley)

In terms of biodiversity effects, the proposed road development will result in habitat loss at Ballindooley Lough, including the loss of an area of *Molinia* meadow, and also has the potential to affect surface water quality in the lakes during construction (see **Section 8.5.4** above for habitat impacts). These impacts will also likely impact upon mammal species generally (see **Section 8.5.6** above), bat species including the Lesser horseshoe bat (see **Section 8.5.6.2** above), breeding and wintering birds (see **Section 8.5.8** above), fish species in the lakes (see **Section 8.5.11** above), and potentially amphibian species (see **Section 8.5.9**).

Galway Racecourse, Ballybrit

The semi-natural habitats present at this site are not directly impacted or likely to be affected in any way by the proposed road development.

Doughiska

In terms of biodiversity effects, the proposed road development will result in habitat loss within this area, including the loss of areas of the Annex I habitats Calcareous grassland and Limestone pavement (see **Section 8.5.4** above for habitat impacts). It is also likely to impact upon mammal species generally (see **Section 8.5.6** above), bat species (see **Section 8.5.6.2** above) and breeding and wintering birds (see **Section 8.5.8** above).

Galway Bay (which includes the Mutton Island and Nearby Shoreline local biodiversity areas from the draft Galway City Biodiversity Action Plan 2014-2024)

The proposed road development has the potential to affect habitats and species in Galway Bay if it were to result in a deterioration in water quality in the receiving surface water network, which discharges to Galway Bay. The proposed road development also has the potential to present a barrier to Otter movement in watercourses connected to Galway Bay (features that are important in supporting the local Otter populations), and road traffic has the potential to present a mortality risk to Otter.

8.5.13 Summary of Potential Impacts

Table 8.34 below presents an overall summary of the likely significant effects of the proposed road development on biodiversity, in the absence of mitigation measures.

Table 8.34: Summary of Likely Significant Effects of the Proposed Road Development on Biodiversity (pre-mitigation)

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance
Designated Areas for Nature Conservation			
Lough Corrib cSAC (including Lough Corrib pNHA)	International (National)	**Construction** Habitat loss Habitat degradation – tunnelling/excavation Habitat degradation – hydrogeology	Likely significant effect at the international geographic scale

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance
		Habitat degradation – hydrology Habitat degradation – air quality Habitat degradation – non-native invasive plant species Mortality risk **Operation** Habitat degradation – hydrogeology Habitat degradation – non-native invasive plant species Mortality risk	
Galway Bay Complex cSAC (including Galway bay Complex pNHA)	International (National)	**Construction** Habitat degradation – hydrology Habitat degradation – non-native invasive plant species Barrier effect Mortality risk	Likely significant effect at the international geographic scale
Lough Corrib SPA (including Lough Corrib pNHA)	International (National)	**Construction** Habitat degradation – hydrogeology Habitat degradation – hydrology Disturbance/displacement **Operation** Habitat degradation – hydrogeology	Likely significant effect at the international geographic scale
Inner Galway Bay SPA including Galway bay Complex pNHA)	International (National)	**Construction** Habitat degradation – hydrogeology Habitat degradation – hydrology Disturbance/displacement **Operation** Habitat degradation – hydrogeology	Likely significant effect at the international geographic scale
Moycullen Bogs NHA	National	**Construction** Habitat degradation – air quality Habitat degradation – non-native invasive plant species Habitat degradation – hydrology **Operation** Habitat degradation – non-native invasive plant species	Likely significant effect at the national geographic scale
Habitats (outside of designated areas for nature conservation)			
Limestone pavement [*8240]	International Importance	**Construction** Habitat loss Habitat degradation – air quality	Likely significant effect at the international geographic scale

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance
		Habitat degradation – non-native invasive plant species **Operation** Habitat degradation – non-native invasive plant species	
Petrifying springs [*7220]	International Importance	**Construction** Habitat loss	Likely significant effect at the county geographic scale (see **Section 8.5.4.3** under petrifying springs)
Calcareous grassland [*6210/6210]	International/ National Importance	**Construction** Habitat loss Habitat degradation – air quality Habitat degradation – non-native invasive plant species **Operation** Habitat degradation – non-native invasive plant species	Likely significant effect at the national geographic scale (No *6210 affected – see **Section 8.5.4.3** under Calcareous grassland))
Dry heath [4030]	National Importance	**Construction** Habitat loss Habitat degradation – air quality Habitat degradation – non-native invasive plant species **Operation** Habitat degradation – non-native invasive plant species	Likely significant effect at the national geographic scale
Wet heath [4010][80]	National Importance	**Construction** Habitat loss Habitat degradation – air quality Habitat degradation – groundwater **Operation** Habitat degradation – groundwater	Likely significant effect at the national geographic scale
Molinia meadow [6410]	National Importance	**Construction** Habitat loss Habitat degradation – air quality Habitat degradation – non-native invasive plant species **Operation** Habitat degradation – non-native invasive plant species	Likely significant effect at the national geographic scale

[80] Including areas of Wet heath/Dry heath/*Molinia* meadow [4010/4030/6410] mosaic

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance
Residual alluvial forest [*91E0]	International Importance	**Construction** Habitat loss Habitat degradation – air quality Habitat degradation – non-native invasive plant species **Operation** Habitat degradation – non-native invasive plant species	Likely significant effect at the international geographic scale
Turloughs [*3180]	International Importance	**Construction** Habitat loss Habitat degradation – surface water quality Habitat degradation – groundwater Habitat degradation – air quality Habitat degradation – non-native invasive plant species **Operation** Habitat degradation – groundwater Habitat degradation – non-native invasive plant species	Likely significant effect at the international geographic scale
Hard water lakes [3140]	National Importance	**Construction** Habitat degradation – surface water quality (Ballindooley Lough)	Likely significant effect at the national geographic scale
Mesotrophic lakes (FL4) *Part of Ballindooley complex*	County Importance[81]	**Construction** Habitat degradation – surface water quality	Likely significant effect at the county geographic scale
Eutrophic lakes (FL5) *Part of Ballindooley complex*	County Importance[82]	**Construction** Habitat degradation – surface water quality Habitat degradation – groundwater	Likely significant effect at the county geographic scale
Calcareous springs (FP1) Non-Annex I habitat type	Local Importance (Higher Value)	**Construction** Habitat loss	Likely significant effect at the local geographic scale
Cladium fen [*7210]	International Importance	**Construction** Habitat degradation – surface water quality (Ballindooley Lough)	Likely significant effect at the international geographic scale

[81] On the basis that it forms part of the wetland complex at Ballindooley Lough
[82] On the basis that it forms part of the wetland complex at Ballindooley Lough

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance
Hydrophilous tall herb [6430]	International Importance	(see Lough Corrib cSAC above) **Construction** Habitat degradation – hydrogeology Habitat degradation – hydrology **Operation** Habitat degradation – hydrogeology	Likely significant effect at the international geographic scale
Alkaline fens [7230]	National Importance	**Construction** Habitat degradation – surface water quality (Ballindooley Lough)	Likely significant effect at the national geographic scale
Reed and large sedge swamps (FS1) Non-Annex I habitat type	Local Importance (Higher Value)	**Construction** Habitat degradation – surface water quality	Likely significant effect at the local geographic scale
Tall-herb swamps (FS2) Non-Annex I habitat type	Local Importance (Higher Value)	None	No likely significant effect at any geographic scale
Eroding/upland rivers (FW1)	Local Importance (Higher Value)	**Construction** Habitat degradation – surface water quality	Likely significant effect at the local geographic scale
Depositing /lowland rivers (FW2) River Corrib	International Importance	The River Corrib forms part of see Lough Corrib cSAC (see above and NIS)	Likely significant effect at the international geographic scale
Terryland River	Local Importance (Higher Value)	None	No likely significant effect at any geographic scale
Drainage ditches (FW4)	Local Importance (Higher Value)	None	No likely significant effect at any geographic scale
Marsh (GM1)	Local Importance (Higher Value)	None	No likely significant effect at any geographic scale
Dry calcareous and neutral grassland (GS1) Non-Annex I habitat type	Local Importance (Higher Value)	None	No likely significant effect at any geographic scale

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance
Dry meadows and grassy verges (GS2) Non-Annex I habitat type	Local Importance (Higher Value)	None	No likely significant effect at any geographic scale
Dry-humid acid grassland (GS3) Non-Annex I habitat type	Local Importance (Higher Value)	**Construction** Habitat loss Habitat degradation – air quality Habitat degradation – non-native invasive plant species **Operation** Habitat degradation – non-native invasive plant species	Likely significant effect at the local geographic scale
Wet grassland (GS4) Non-Annex I habitat type	Local Importance (Higher Value)	None	No likely significant effect at any geographic scale
Rich fen and flush (PF1) Non-Annex I habitat type	County Importance	**Construction** Habitat degradation – surface water quality Habitat degradation – air quality	Likely significant effect at the county geographic scale
Poor fen and flush (PF2) Non-Annex I habitat type	Local Importance (Higher Value)	**Construction** Habitat loss Habitat degradation – air quality **Operation** Habitat degradation – groundwater	Likely significant effect at the local geographic scale
(Mixed) broadleaved woodland (WD1)	Local Importance (Higher Value)	**Construction** Habitat loss Habitat degradation – air quality Habitat degradation – non-native invasive plant species **Operation** Habitat degradation – non-native invasive plant species	Likely significant effect at the local geographic scale
Mixed broadleaved/conifer woodland (WD2)	Local Importance (Higher Value)	None	No likely significant effect at any geographic scale
(Mixed) conifer woodland (WD3)	Local Importance (Higher Value)	None	No likely significant effect at any geographic scale

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance
Hedgerows (WL1)	Local Importance (Higher Value)	**Construction** Habitat loss Habitat degradation – air quality Habitat degradation – non-native invasive plant species **Operation** Habitat degradation – non-native invasive plant species	Likely significant effect at the local geographic scale
Treelines (WL2)	Local Importance (Higher Value)	**Construction** Habitat loss Habitat degradation – air quality Habitat degradation – non-native invasive plant species **Operation** Habitat degradation – non-native invasive plant species	Likely significant effect at the local geographic scale
Oak-ash-hazel woodland (WN2) Non-Annex I habitat type	Local Importance (Higher Value)	**Construction** Habitat degradation – air quality Habitat degradation – non-native invasive plant species	Likely significant effect at the local geographic scale
Scrub (WS1) Non-Annex I habitat type	Local Importance (Higher Value)	None	No likely significant effect at any geographic scale
Fauna Species			
Badger	Local Importance (Higher Value)	**Construction** Loss of breeding/resting sites Disturbance/displacement **Operation** Habitat severance/barrier effect Mortality risk	Likely significant effect at the local geographic scale
Otter	International Importance	**Construction** Habitat degradation - water quality **Operation** Habitat severance/barrier effect Mortality risk	Likely significant effect at the local geographic scale
Other mammal species protected under the Wildlife Acts	Local Importance (Higher Value)	**Construction** Habitat degradation - water quality **Operation** Habitat severance/barrier effect	Likely significant effect at the local geographic scale

All other wintering bird species (non-SCI)	Local Importance (Higher Value)	**Construction** Disturbance/displacement (Ballindooley Lough) Habitat degradation – surface water quality Habitat degradation – groundwater	Likely significant effect at the local geographic scale

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance
Smooth newt Common frog	Local Importance (Higher Value)	**Construction** Habitat loss Disturbance & mortality risk Habitat degradation – surface water quality **Operation** Habitat severance/barrier effect	Likely significant effect at the local geographic scale
Common lizard	Local Importance (Higher Value)	**Construction** Habitat loss Disturbance & mortality risk **Operation** Habitat severance/barrier effect	Likely significant effect at the local geographic scale
Atlantic salmon European eel	International Importance	**Construction** Habitat degradation – surface water quality Habitat degradation – groundwater	Likely significant effect at the local geographic scale
All other fish species recorded	Local Importance (Higher Value)	**Construction** Habitat degradation – surface water quality Habitat degradation – groundwater	Likely significant effect at the local geographic scale
Local Biodiversity Areas			
Local biodiversity areas	The value of the biodiversity receptors recorded in the vicinity of the proposed road development, across the local biodiversity areas, range from Local Importance (Lower Value) to Internationally Important	Combinations of all of the potential impacts noted above. The specific impacts are related to and dependent upon the potential impacts of the proposed road development on each of the individual ecological receptors that make up the biodiversity resource within a given local biodiversity area	Likely significant effects from local up to the international geographic scale

8.6 Mitigation Measures

This section presents the mitigation measures to avoid or reduce the potential impacts of the proposed road development on biodiversity. **Section 8.6.1.1** summarises the mitigation measures that relate to the protection of European sites. All other mitigation measures are described in **Sections 8.6.2** to **8.6.12** below. All of these mitigation measures are included in the Schedule of Environmental Commitments which will be implemented by the contractor under supervision of both the Project Ecologist (employed by the Employer) and the Ecological Clerk of Works (employed by the Contractor).

8.6.1 Designated Areas for Nature Conservation

8.6.1.1 European Sites

The mitigation measures that are specifically required to ensure that the proposed road development will not result in a likely significant effect (i.e. adversely affect the integrity of) on the European sites within its ZoI (Lough Corrib cSAC, Lough Corrib SPA, Galway Bay Complex cSAC and Inner Galway Bay SPA) are presented in Section 10 of the NIS. Following a consideration and assessment of the proposed road development on the identified relevant European sites, mitigation measures were developed to address the following potential impacts that were identified:

- Habitat loss/fragmentation: mitigation measures to minimise habitat loss in Lough Corrib cSAC and to avoid loss of QI habitats within Lough Corrib cSAC during construction
- Habitat degradation – tunnelling/excavation: mitigation measures to maintain the structural integrity of rock mass supporting QI habitats in Lough Corrib cSAC during the construction of the proposed Lackagh Tunnel (and its western approach)
- Habitat degradation – hydrogeology: mitigation measures to avoid habitat degradation in Lough Corrib cSAC as a result of potential hydrogeological impacts during construction and operation
- Habitat degradation – hydrology: mitigation measures to protect water quality in receiving watercourses during construction
- Habitat degradation – air quality: mitigation measures to control dust emissions during construction to prevent impacts on vegetation in Lough Corrib cSAC
- Habitat degradation – non-native invasive plant species: mitigation measures to avoid the introduction or spread of non-native plant invasive species to European sites during construction or operation
- Disturbance/displacement: mitigation measures to avoid/reduce the disturbance/displacement effects of blasting on wintering birds using Ballindooley Lough
- Barrier effect: mitigation measures to avoid the proposed road development restricting Otter movement within the Bearna Stream catchment

- Mortality risk: mitigation measures to avoid mortality of the QI species of Lough Corrib cSAC. These include both measures to ensure that construction materials are not introduced into the River Corrib and to remove the risk of Otter being killed/injured due to collisions with road traffic

8.6.1.2 Natural Heritage Areas and proposed Natural Heritage Areas

As discussed in **Section 8.5.3.2**, the potential for the proposed road development to significantly affect Lough Corrib pNHA or Galway Bay Complex pNHA is as per the corresponding European sites (Lough Corrib cSAC and Lough Corrib SPA in relation to Lough Corrib pNHA, and Galway Bay Complex cSAC and Inner Galway Bay SPA in relation to Galway Bay Complex pNHA). Therefore, the mitigation measures outlined above in **Section 8.6.1.1**, and as detailed in Section 10 of the NIS, will prevent the proposed road development resulting in a significant negative effect on Lough Corrib pNHA or Galway Bay Complex pNHA at the national geographic scale.

The mitigation measures that are required to ensure that the proposed road development will not significantly affect Moycullen Bogs NHA are as follows:

- Measures to control dust emissions during construction to prevent impacts to vegetation/habitats within Moycullen Bogs NHA at Tonabrocky – see **Section 8.6.2** below and **Chapter 16, Air Quality and Climate**. These include control measures such as spraying of exposed earthwork activities and site haul roads during dry weather, wheel washes, control of site vehicle speeds, road sweeping and dust screens
- Measures to avoid the introduction or spread of non-native invasive plant species to Moycullen Bogs NHA during construction or operation. These are detailed in the Non-native Invasive Species Management Plan which forms part of the Construction Environmental Management Plan (CEMP) – (**Appendix A.7.5**)
- Measures to control surface water runoff from the construction site to prevent an accidental pollution event affecting peatland habitats within Moycullen Bogs NHA at Tonabrocky – see **Section 11.6.2** of **Chapter 11, Hydrology**

8.6.2 Habitats

8.6.2.1 Mitigation Measures to Minimise Habitat Loss

To minimise the loss of Annex I habitat, areas of these habitat types within the proposed development boundary but which are not required to construct the proposed road development will be retained and fenced off for the duration of construction. These areas will also not be directly impacted during the operation of the proposed road development. These are shown on **Figures 8.23.1** to **8.23.14**.

To minimise the loss of habitat associated with the proposed road development, there are also areas within the proposed development boundary which are included for mitigation planting where general construction works will not be undertaken. These are shown on **Figures 8.23.1** to **8.23.15**.

Where possible, woodland, scrub, treelines and hedgerows which lie within, or along the boundary of the proposed road development, that are not directly impacted by the proposed road alignment or drainage will be retained. These areas will be protected for the duration of construction works and fenced off at an appropriate distance. Vegetation to be retained is shown on **Figures 8.23.1** to **8.23.15** and on **Figures 12.2.01** to **12.2.15**.

Where possible, areas of river channel and bankside vegetation which lie within, or along the boundary of the proposed road development, that are not directly impacted by the proposed road alignment or drainage will be retained. These areas will be protected for the duration of construction works and fenced off at a distance of 5m from the stream/river bank.

The Petrifying spring feature present in Lackagh Quarry, which lies c.25m to the north of the mainline of the proposed road development at Ch. 11+400, will be retained and shotcrete[83] will not be used as part of the quarry face stabilisation measures at the spring site.

8.6.2.2 Measures to Reduce the Potential for Impacts on Vegetation to be retained

Any vegetation (including trees, hedgerows or scrub adjacent to, or within, the proposed development boundary) which is to be retained shall be afforded adequate protection during the construction phase in accordance with the Guidelines for the Protection and Preservation of Trees, Hedgerows and Scrub Prior to, During and Post Construction of National Road Schemes (National Roads Authority, 2006b), as follows:

- All trees along the proposed development boundary that are to be retained, both within and adjacent to the proposed development boundary (where the root protection area of the tree extends into the proposed development boundary), will be fenced off at the outset of works and for the duration of construction to avoid structural damage to the trunk, branches or root systems of the trees. Temporary fencing will be erected at a sufficient distance from the tree so as to enclose the Root Protection Area (RPA) of the tree. The RPA will be defined based upon the recommendation of a qualified arborist
- Where fencing is not feasible due to insufficient space, protection for the tree/hedgerow will be afforded by wrapping hessian sacking (or suitable equivalent) around the trunk of the tree and strapping stout buffer timbers around it
- The area within the RPA will not be used for vehicle parking or the storage of materials (including soils, oils and chemicals). The storage of hazardous

[83] A concrete product which is sprayed at high velocity into a rock face as a structural/stabilising component.

materials (e.g. hydrocarbons) or concrete washout areas will not be undertaken within 10 m of any retained trees, hedgerows and treelines

- A qualified arborist shall assess the condition of, and advise on any repair works necessary to, any trees which are to be retained or that lie outside of the proposed development boundary but whose RPA is impacted by the works. Any remedial works required will be carried out by a qualified arborist
- A buffer zone of at least 5m will be maintained between construction works and retained hedgerows to ensure that the root protection areas are not damaged

8.6.3 Measures to Reduce the Potential for Air Quality Impacts during Construction

To control dust emissions during construction works standard mitigation measures shall include: spraying of exposed earthwork activities and site haul roads during dry and/or windy conditions; provision of wheel washes at exit points; control of vehicle speeds and speed restrictions (20km/h on any un-surfaced site road); covering of haulage vehicles; and, sweeping of hard surface roads. These procedures will be strictly monitored and assessed on a daily basis.

Dust screens will be implemented at locations where there is the potential for air quality impacts during the construction phase i.e. at locations where sensitive receptors are located within 100m of the works. In addition, a 2m dust screen will be provided at the locations in the areas of the overlap of the proposed road development and the Lough Corrib cSAC and adjacent to Moycullen Bogs NHA.

These measures are detailed further in **Section 16.6.2** of **Chapter 16, Air Quality and Climate** and in the CEMP in **Appendix A.7.5**.

8.6.4 Mitigation Measures to Reduce the Potential for Impacts to Water Quality in Receiving Watercourses

The mitigation measures to protect surface water during construction are detailed in **Section 11.6.2** of **Chapter 11, Hydrology**.

As is normal practice the Construction Environmental Management Plan (CEMP) included in **Appendix A.7.5** will be finalised by the Contractor in advance of the commencement of construction and the following will be implemented as part this plan:

- An Incident Response Plan detailing the procedures to be undertaken in the event of spillage of chemical, fuel or other hazardous wastes, logging of non-compliance incidents and any such risks that could lead to a pollution incident, including flood risks (Refer to Section 10 of the CEMP in **Appendix A.7.5**)
- A Sediment Erosion and Pollution Control Plan (Refer to Section 8 of the CEMP in **Appendix A.7.5**). This shall include water quality monitoring and method statements to ensure compliance with environmental quality standards specified in the relevant legislation (i.e. surface water regulations and Salmonid Regulations 1988)

Refer to Section **11.6.2** of **Chapter 11, Hydrology** for further mitigation measure details.

8.6.5 Measures to Protect Groundwater Quantity and Groundwater Quality

The mitigation measures to protect groundwater quantity and quality during construction and operation are detailed in **Section 10.6.2** (construction) and **Section 10.6.3** (operation) of **Chapter 10, Hydrogeology**.

Mitigation measures are included in **Section 9.6** of **Chapter 9, Soils and Geology** to restrict the use of fill material in areas where there is the potential for run off/infiltration to affect pH levels in adjoining peatland habitats within the operational hydrogeological ZoI.

8.6.6 Measures to Control and Prevent the Spread of Non-native Invasive Plant Species

The mitigation strategy in relation to non-native invasive plant species is based on the *Guidelines on the Management of Noxious Weeds and Non-native Invasive Plant Species on National Roads* (National Roads Authority, 2010) with the objectives of managing non-native invasive plant species within the working area and preventing the spread of any established populations present with the boundary of the proposed road development (a legal requirement for species such as Japanese knotweed).

A Non-native Invasive Species Management Plan has been prepared and included in the CEMP (see **Appendix A.7.5**) and will be implemented sufficiently far in advance of the proposed construction works commencing so as to allow time to adequately control all target non-native invasive plant species populations within the ZoI of the proposed road development, having regard to the specific timing/seasonal constraints that apply in relation to each individual species. The Non-native Invasive Species Management Plan will direct the construction contractor in implementing the specific mitigation measures required in relation to individual non-native invasive plant species.

As species may have spread, or their distribution may have changed, between the habitat surveys carried out for this EIAR and the commencement of construction works, the implementation of the Non-native Invasive Species Management Plan will include a pre-construction re-survey within the proposed development boundary. In accordance with the NRA guidance this survey will include accurate 1:5,000 scale mapping for the precise location of non-native invasive plant species. The pre-construction surveys will be undertaken by suitable experts with competence in identifying the species concerned.

In accordance with the National Roads Authority, 2010a guidelines, where cut, pulled or mown noxious weed or non-native invasive plant species material arises, its disposal will not lead to a risk of further spread of the plants. Care will be taken near watercourses as water is a fast medium for the dispersal of plant fragments and seeds. Material that contains flower heads or seeds will be disposed of either by composting or burial at a depth of no less than 0.5m in the case of noxious weeds, or by incineration (at a licenced facility having regard to relevant legislation) or disposal to licensed landfill in the case of non-native invasive plant species.

The taproots of docks and roots of creeping thistle are not suitable for composting or shallow burial, requiring disposal to landfill, incineration or burying at a depth of no less than 1.5m (practical only during the construction phase). Where burial is being used to dispose of Japanese knotweed, the material will be buried to a depth of 5m and overlain with a suitable geotextile membrane. All disposals will be carried out in accordance with the Waste Management Acts 1996-2011.

In relation to aquatic non-native invasive plant species all construction works, and any aquatic survey work that may be carried out (e.g. electrofishing), will comply with best practice biosecurity protocols for aquatic work – for example IFI's Biosecurity Protocol for Field Survey Work (IFI, 2010).

8.6.7 Mammals

8.6.7.1 Otter

Otter are listed on Annex II and Annex IV of the EU Habitats Directive. Otter are strictly protected under the Birds and Habitats Regulations. Otter, and their breeding and resting places, are also protected under the Wildlife Acts and it is an offence under that legislation to intentionally kill or injure an Otter or to wilfully interfere with or destroy their breeding or resting places (holts/couches).

8.6.7.1.1 Measures to Protect Otter during Construction

Habitat degradation - water quality

The mitigation measures relating to the protection of water quality in receiving watercourses during construction are outlined in **Section 8.6.4** and detailed in **Section 11.6.2** of **Chapter 11, Hydrology**.

Loss of breeding/resting sites

As in the future Otter could potentially establish new holt or couch sites within the ZoI of the proposed road development, a pre-construction check of all suitable Otter habitat will be required within 12 months of any constructions works commencing.

8.6.7.1.2 Measures to Protect Otter during Operation

Habitat Severance/Barrier Effect and Collision Risk

Otters use many of the watercourses crossed by the proposed road development. To avoid Otter road casualties, Otter passage facilities will be provided at all watercourses used by Otter (e.g. raised ledges within structures, or separate dry 600mm pipes installed adjacent to culverts). Mammal underpasses will be constructed in accordance with the *Guidelines for the Treatment of Otters prior to the Construction of National Road Schemes* (National Roads Authority, 2008c).

The locations where Otter passage facilities will be provided are listed below in **Table 8.36** and are shown on **Figures 8.23.1** to **8.23.14**.

Mammal-resistant fencing will be required to prevent Otter accessing the proposed road development and to guide Otters to the mammal underpasses. Mammal-resistant fencing will be installed in accordance with the specification outlined in *Guidelines for the Treatment of Otters prior to the Construction of National Road Schemes* (National Roads Authority, 2008c) and TIIs mammal resistant fencing specification (currently CC-SCD-00320/00319). The locations where mammal-resistant fencing is to be installed are shown on **Figures 8.23.1** to **8.23.14**.

In accordance with the recommendations described in the *Guidelines for the Treatment of Otters prior to the Construction of National Road Schemes* (National Roads Authority, 2008c), quarterly monitoring of the effectiveness of the mitigation measures will be undertaken in the first year after the completion of construction works (for example, fencing inspections to check for gaps and underpass inspection to check for blockages).

8.6.7.2 Bats

Bats are listed on Annex IV of the EU Habitats Directive and are therefore, strictly protected under the Birds and Habitats Regulations. Bats, and their breeding and resting places, are also protected under the Wildlife Acts and it is an offence under that legislation to intentionally kill or injure bats or to wilfully interfere with or destroy their breeding or resting places.

8.6.7.2.1 Measures to Protect Bats during Construction

Measures to Protect Bats during removal of Roosts

This assessment has identified that 14 properties that are confirmed bat roosts may be required to be removed as part of the proposed road development. A further 18 properties may be indirectly affected due to their proximity to the corridor or the proposed road development or are connected via known flight paths and in some cases disturbance to the roost may result.

All species and their roost sites are strictly protected under both European and Irish legislation including:

- Wildlife Act 1976 and Wildlife (Amendment) Act, 2000 (S.I. No. 38 of 2000)
- Council Directive on the Conservation of Natural Habitats and of Wild Flora and Fauna 1992 (Council Directive 92/43/EEC)
- European Communities (Birds and Natural Habitats) Regulations, 2011

It is an offence under Section 23 of the Wildlife Acts 1976-2017 and under Section 51 of the European Communities (Birds and Natural Habitats) Regulations, 2011 to kill a bat or to damage or destroy the breeding or resting place of any bat species. Under the European Communities (Birds and Natural Habitats) Regulations it is not necessary that the action should be deliberate for on offence to occur. This places an onus of due diligence on anyone proposing to carry out works that might result in such damage or destruction. Under Section 54 of S.I. 477 of 2011, a derogation may be granted by the Minister where there is no satisfactory alternative and the derogation is not detrimental to the maintenance of the populations of the species to which the Habitats Directive relates at a favourable conservation status in their natural range. Given the impacts on bats that are predicted for the proposed road development, a derogation licence under Section 54 of S.I. 477 of 2011 will be required. The Bat Derogation Licence application is included in **Appendix A.8.25**.

The following mitigation measures are proposed in relation to structures either confirmed as supporting bat roosts or considered to have the potential to support roosting bats:

- Prior to demolition of the 14 structures containing confirmed bat roosts, replacement artificial roosts will be in place to ensure that bats are able to access alternative resting places at the earliest opportunity
- Where possible, buildings with the confirmed bat roosts will not be demolished during the breeding period or hibernation period (April to mid-August and November-March) as the risk of accidental death or injury is higher at this time. Bats may use roosts in smaller numbers in winter but may nevertheless be present. Outside of these periods, the approach to demolition of bat roosts will be determined on a case-by-case basis and subject to relevant licence conditions
- Buildings confirmed as bat roosts proposed for demolition will be marked on the ground with agreed paint marking to permit identification by Contractors
- Prior to demolitions, all structures that were confirmed as either having bats or having high potential for bats will be re-examined immediately prior to demolition to assess whether bats are present at the time of demolition. This will be an all-night examination to determine if bats enter the building during the night or early morning. This will provide adequate information to proceed with demolitions unless weather conditions were unsuitable for feeding bats. If bats are present, then they will require exclusion from the property over several nights or if possible physical removal by hand by a licenced bat specialist to be placed in a bat box or similar for release in the evening after capture. For structures which have not been confirmed as bat roosts but regarded to have high potential for bats, a bat detector assessment of the property to be demolished will be carried out. If demolitions are proposed during the period May – August (note this time period will not be permitted in the case of the confirmed bat roosts to be demolished). This will be an all-night examination to determine if bats enter the building during the night or early morning. This will provide adequate information to proceed with demolition unless weather conditions were unsuitable for feeding bats. If bats are present, then they will require exclusion from the property over several nights or if possible physical removal by hand by a licenced bat specialist to be placed in a bat box or similar for release in the evening after capture
- Once structures containing roosts are deemed to be clear of bats, the bat specialist will be on site to supervise the demolition procedure until the structure is no longer deemed able to support a bat roost. Bats may re-enter a partially demolished structure overnight so the bat specialist may be required to be present during demolition works until they are completed

The following mitigation measures are proposed in relation to those trees identified as having high potential to support roosting bats. These include the two trees confirmed to have had bats present (PTR43, PTR48) or the 13 other trees to have high suitability, where either obvious potential roosting features are present, or where obscured by dense ivy cover, the tree is of an age and condition that there is a high chance that roosting features are present. **Figures 8.16.1** to **8.16.15** shows the locations of these trees but a more detailed drawing will be provided to the contractor prior to any felling works. Bats could occupy suitable roosting features at any time prior to the commencement of works. Therefore there is an inherent risk that bats could be affected by the proposed felling works. The following mitigation procedures will be followed:

- Felling of confirmed and potential tree roosts will be undertaken during the period September – October as during this period bats are capable of flight and may avoid the risks from tree felling if proper measures are undertaken, but also are neither breeding nor in hibernation
- Use of detectors alone may not be sufficient to record bat emergence and re-entry in darkness. Therefore, prior to felling of confirmed and potential tree roosts, an emergence survey using infra-red illumination and video camera(s) and bat detectors will be carried out on the night immediately preceding the felling operation to determine if bats are present
- Where it is safe and appropriate to do so for both bats and humans, such trees may be felled using heavy plant to push over the tree. In order to ensure the optimum warning for any roosting bats that may still be present, the tree will be pushed lightly two to three times, with a pause of approximately 30 seconds between each nudge to allow bats to become active. The tree should then be pushed to the ground slowly and should remain in place until it is inspected by a bat specialist
- Trees should only be felled “in section” or “soft felled” where the sections can be rigged to avoid sudden movements or jarring of the sections
- Where remedial works (e.g. pruning of limbs) is to be undertaken to trees deemed to be suitable for bats, the affected sections of the tree will be checked by a bat specialist (using endoscope under a separate derogation licence held by that individual) for potential roost features before removal. For limbs containing potential roost features high in the tree canopy, this will necessitate the rigging and lowering of the limb to the ground (with the potential roost feature intact) for inspection by the bat specialist before it is cut up or mulched. If bats are found to be present, they will be removed by a bat specialist licenced to handle bats and released in the area in the evening following capture

Prior to felling the two confirmed tree roosts (PTR43 and PTR48) replacement bat boxes will be in place to ensure that bats are able to access alternative resting places at the earliest opportunity. The location of the bat boxes in these instances will be within the proposed development boundary but the precise height and location will be decided by the bat specialist. If any additional bat tree roosts are confirmed, and will be removed by the proposed felling works, then appropriate alternative roosting sites will be provided in the form of replacement bat boxes.

Measures to preserve flight paths across Construction areas

It has been identified that during the construction phase, the removal of woodland and hedgerows and other intervention in the landscapes used by bats can open up habitats to the extent that bats will not want to risk crossing the new open space to reach other roosts and foraging areas on the other side. This severance of flight paths will continue throughout the construction phase.

The Report WC1060 *Development of a Cost-Effective Method for Monitoring the Effectiveness of Mitigation for Bats crossing linear infrastructure* includes best practice principles to address the general lack of evidence to show that many "conventional" mitigation measures work. These principles are reproduced below and have been adopted in the mitigation strategy for the proposed road development.

- *"Mitigation should be integrated into the scheme from the earliest opportunity*
  - *Mitigation should be considered during the planning and design stage of the infrastructure so that it can be incorporated effectively*
- *Crossing structures should be placed on the exact location of existing bat commuting routes*
  - *Attempts should not be made to divert bats from their existing commuting routes*
- *Crossing structures should not require bats to alter flight height or direction.*
  - *This will depend on the topography of the site. If the road is to be elevated above ground level an underpass may be used to preserve the commuting route below it, or if the road is in a cutting a green bridge may be used to carry the commuting route over the road*
- *Crossing structures should maintain connectivity with existing bat commuting routes*
  - *Connectivity must be maintained with undisturbed bat flight paths (e.g. treelines, hedgerows, woodland rides and streams), and bat habitat (e.g. woodland) within the surrounding landscape. Crossing structures should not be exposed or sited within open ground*
- *Over-the-road structures such as green bridges should be planted with vegetation*
  - *Vegetation should be continuous and connected (see above) and sufficiently mature before road construction (e.g. by planting either relatively mature trees or fast growing tree species in advance of construction commencing)*
- *Underpasses should be of sufficient height*
  - *Underpasses should be as spacious as possible with height being the critical factor. The minimum requirements for underpass height will be species-specific. Required heights will generally be lower for woodland-adapted species (~3 m) compared to generalist edge-adapted species (~6 m), but larger underpasses will accommodate more species.*
- *Green bridges should be of sufficient width*

  - *In addition to being vegetated, green bridges should be as wide as possible, to provide a large area for bats to commute across. Further research is needed to determine exact dimensions. We found a 30m wide green bridge to be effective in this study.*
- *Crossing structures should be unlit*
  - *The effects of light on bats are species-specific and lighting should be avoided*
- *Access and connectivity must be maintained*
  - *It is important that access to crossing structures is maintained (e.g. grilles should not be installed on underpasses) and that connecting vegetation is retained indefinitely or for as long as the mitigation structure is required*
- *Disturbance should be minimised during installation of mitigation structures*
  - *For example, by limiting noise and light pollution along the bat flight path, minimising vegetation clearance, installing suitable temporary crossing structures (which should also be subject to monitoring and evaluation), completing the installation as quickly as possible and ideally avoiding the summer months when bats are most active".*

The installation of temporary fencing across sites to replace connecting features has been used and appears to have only been monitored as part of one project in Switzerland (Britschgi et al, 2004)[84]. In this study, a 1m wide x 1.5-2m high artificial hedgerow was recorded to be followed by a proportion of the bats in a roost. It is proposed to apply similar measures in key locations to ensure that there are linear features to connect habitats across the construction footprint.

In order to inform siting of mitigation measures, including the temporary fencing described above during the construction phase, a series of infra-red/thermal camera surveys using a series of cameras and bat detectors along linear features in the following locations will be carried out in the optimum activity season. This will help to identify the preferred crossing points at the following sections:

Area 1: North of Bearna Woods

Area 2: Aughnacurra

Area 3: River Corrib to Coolough Road

Area 4: West of N84 Headford Road

Area 5: Ballindooley to Castlegar

Each area will be surveyed three times to record bats in flight in these locations with the precise vantage points for cameras to be determined during daytime surveys.

Any existing features that are identified as preferred crossing points and are scheduled for removal will be retained until the last moment and a portable artificial

[84] Britschgi A., Theiler A. & Bontadina F. (2004) *Wirkungskontrolle von Verbindungsstrukturen. Teilbericht innerhalb der Sonderuntersuchung zur Wochenstube der Kleinen Hufeisennase in Friedrichswalde-Ottendorf / Sachsen*.

crossing structure put alongside it prior to its removal, so at no stage there is a gap across the construction site at night. The use of the temporary fence as an artificial crossing structure will be monitored three times over two weeks following installation. If the artificial crossing structure is not at the same location as a proposed permanent crossing point (e.g. the wildlife overpass at Castlegar) then it shall be moved gradually over several nights to realign it with the permanent crossing point.

The nature of the artificial crossing structure may comprise lengths of camouflage netting, recycled Christmas trees roped together, portable planters or artificial plants that can be easily moved at morning and evening to ensure that the crossing is in place each night.

8.6.7.2.2 Measures to Protect Bats during Operation

Measures to reducing mortality risk and barrier effects within the design and operation of the proposed road development

The mitigation to address significant barrier effects has been designed to reflect current best practice. The last 10 years has seen an improvement in the monitoring of the effectiveness of bat mitigation measures for roads and there is considerable evidence that whilst bats may “use” measures designed to get them over or under a road, in the context of the overall population these measures may not be “effective” as they are often in the wrong place or simply not attractive to bats to use. Measuring bat mortality as a result of collisions has also been studied in greater detail in recent years.

The two main approaches employed for the proposed road development include underpasses of a suitable size where the design of the proposed road development is on embankment and a wildlife overpass where it is in cut. These two measures are the only options that have been demonstrated to be effective at a population level (CEDR, 2016, (Elmeros and Dekker, 2016, Abbot et al 2012a, 2012b).

Underpasses are proposed in important crossing point areas and are aligned with existing landscape features that are known to be used by bats as a result of the surveys. Underpasses in the Menlough - Bóthar Nua area and N84 Headford Road areas are regarded to be of critical importance for Lesser horseshoe bat and other bat movements across this landscape.

The section from the N84 Headford Road to N83 Tuam Road is almost entirely in cut and installing underpasses is not possible, therefore the only effective option is a wildlife overpass (referred to throughout this report as the Castlegar Wildlife Overpass).

The Castlegar Wildlife Overpass is a critical component of the strategy. It will allow bats to fly across the proposed road development between the roosts and foraging habitats on the north side and Coopers Cave and foraging areas to the south at this location.

From 2013-2015, bats were recorded using hedgerows at many locations in places between the N84 Headford Road and the N83 Tuam Road – a distance of 1750m. The western section of the proposed road development in this area includes for underpasses which would be used by Lesser horseshoe bats and other bat species in areas where they have been recorded, (approximately 400m in length) whilst the remainder of the proposed road development is in a cutting or it is not feasible to include such underpasses.

In the absence of the Castlegar Wildlife Overpass, it is possible that bats would attempt to cross the proposed road development at the location of the existing crossing points[85]. This would increase the risk of collisions with vehicles at this key location and for Lesser horseshoe bats this could have an adverse impact that could deplete the population to an unsustainably low level.

In the absence of the Castlegar Wildlife Overpass the Lesser horseshoe bats would not be able to use Cooper's Cave for mating in late summer and as a result they could be forced to use less suitable locations (no other mating roosts were recorded). Mating sites that are accessible to a geographically wide population and mixes of males and females from different roosts is an essential attribute to ensure genetic heterogeneity in the local bat population. At present, bats are able to get to Cooper's Cave from a variety of directions.

A potential worst case scenario barrier effect isolating the Menlo Castle roost would therefore lead to reduced genetic diversity and possible reduced reproductive rates in that population. Similarly, the bats using Cooper's Cave would be confined to sub-optimal habitats and it is not unreasonable to conclude that, in a worst-case-scenario, the cave would cease to be used by Lesser horseshoe bats.

The location of the Castlegar Wildlife Overpass is crucial to its success. Research published since 2008 by Berthinussen & Altringham (2015[86]) and evidence presented in the CEDR Safe Bat Paths reports (2016[87]) and Natural England (2015[88]) reports have identified that bats will cross a road along existing known flight paths in preference to new artificial crossings at alternative locations. Whilst this may be truer of species that are known to fly across open spaces such as Pipistrelle species, it is not known if Lesser horseshoe bats would also act in the same way. In the absence of data to the contrary the precautionary principle has been applied and the wildlife overpass has been located at known Lesser horseshoe bat crossing points. The proposed location at Ch. 12+690 – Ch. 12+720 ties in with records of Lesser horseshoe bats, Common and Soprano pipistrelle bats recorded by static bat detector in 2015. It will be essential to quantify the number of bats using each crossing point (especially the Castlegar Wildlife Overpass) immediately prior to construction in order to provide data against which post-construction surveys can be compared.

The width and design of the Castlegar Wildlife Overpass has followed simple assumptions that are based on the target species ecology and has followed best available knowledge and information as outlined below.

[85] Lighting of the proposed road development at this location may create a barrier effect, making crossing the proposed road development even more problematic for bats.
[86] *WC1060 Development of a Cost-Effective Method for Monitoring the Effectiveness of Mitigation for Bats crossing Linear Transport Infrastructure*. Final Report 2015. Anna Berthinussen & John Altringham. School of Biology, University of Leeds, Leeds LS2 9JT/
[87] http://bios.au.dk/om-instituttet/organisation/faunaoekologi/projekter/safe-bat-paths/documents/
[88] http://publications.naturalengland.org.uk/publication/6312886965108736

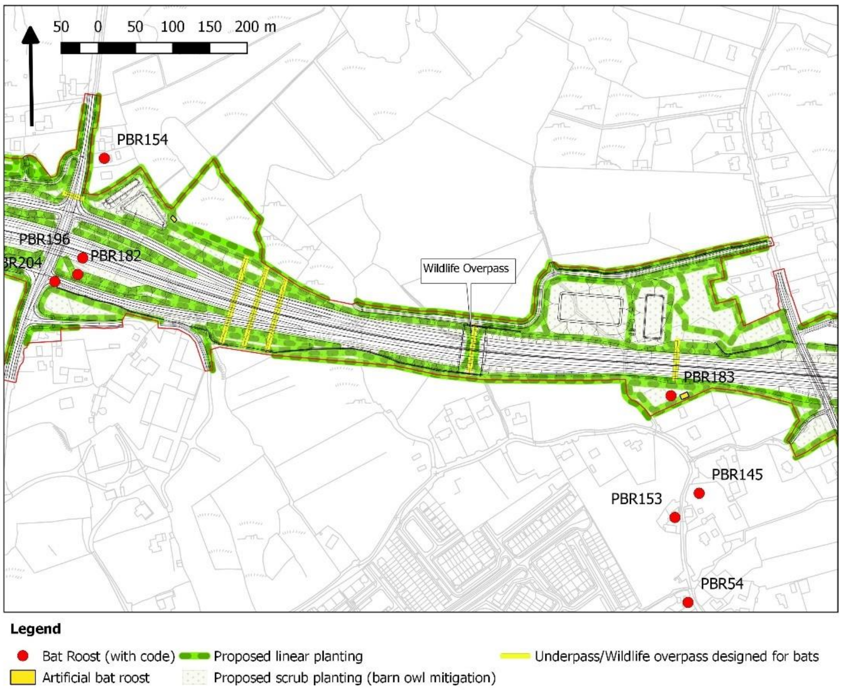
Guidance from Natural England (2015) can be summarised as follows:

- The COST 341 handbook (2003) identifies four types of 'over structure' to provide faunal passage; landscape bridges, wildlife bridges, modified bridges/ multi use bridges and tree top overpasses. A clear distinction between landscape bridges and wildlife bridges is not given, but in terms of design this appears to be based on scale aspects, with landscape bridges being larger structures over 80m wide and wildlife bridges being small in width with a recommendation of between 40 and 50m. The handbook does not use the term 'green bridge' to describe these structures
- Findings of the WC1060 Report (Berthinussen & Altringham, 2015) can be summarised as follows:
  - Although green bridges have the potential to be effective crossing structures for bats over infrastructure, there are other issues that also need to be considered such as the cost, the landtake required for construction of the bridge and the detrimental effects there may be on bats while it is being constructed. However, one expensive yet effective structure will always make more sense than cheaper structures that do not work: mitigation structures must be cost effective and functional. Green bridges may also provide mitigation for other wildlife. Eight mammal species have been found to use Scotney Castle landscape bridge, including deer, badger and breeding dormice (National Trust, 2012), and similar structures are commonly built throughout Europe and North America for large mammals. Combining mitigation for a range of wildlife may be a cost-effective solution, but would require careful planning, project management and monitoring
  - The two most widespread forms of wire bat bridge do not provide effective mitigation and should not be built, particularly since there is evidence that bats do not adapt to them with time. Our results suggest that green bridges and underpasses have the greatest potential but they must be designed correctly and many factors are important such as size, position, connectivity, topography, and the density and maturity of vegetation. Green bridges should be of sufficient width
  - Best practice principles for bat mitigation along linear transport infrastructure include that in addition to being vegetated, green bridges should be as wide as possible, to provide a large area for bats to commute across. Further research is needed to determine exact dimensions. A 30m wide green bridge was found to be effective in this study

A width below 20m is not recommended as although evidence shows that species will still use these bridges, the frequency of use is reduced. The proposed overpass bridge at Castlegar is 30m wide.

The proposed planting design comprises of a double hedgerow in the middle section of the overpass (to mimic a 4m wide bóithrín). Each of the hedgerows will then diverge out to create a "mouth" at the entrance to the overpass on both sides of the proposed road development to funnel bats in to the centre of the overpass. **Plate 8.3** shows the schematic design and location of the proposed overpass.

Plate 8.3: Castlegar Wildlife Overpass



No lighting will be provided at or on any of the structures which have been designed to provide bat passage, with the exception of S06/01 where lighting will be provided to allow for safe use by pedestrians. All of the bat underpasses (as well as artificial roosts) that are designed for Lesser horseshoe bats will have connecting woody vegetation features. Other bats species are not as reliant[89] on hedgerows and woodland edges. Whilst there are many existing landscape features outside of the proposed development boundary, the bat mitigation strategy cannot rely on these in the long term as they may be subject to interventions by third parties. In effect, what will be created is a hedgerow corridor leading up to underpasses in the section of the proposed road development between Aughnacurra and Castlegar. This planting provides a guaranteed green corridor connecting up the underpasses/overpasses and will allow bats to adapt more easily to any future landscape scale losses of connecting habitat features. The hedgerow planting leading up to underpasses will be maintained and the growth of the hedgerow monitored for 5 years following completion and remediation works undertaken if deemed necessary.

Table 8.35 below sets out the schedule of structures which provide bat passage and states the function that they serve in terms of mitigating the potential barrier effect. The size and location of the underpasses and culverts took into account the research carried out by Abbott (2012a, b) and the advice provided in the CEDR, COST341 and WC1060 reports. Design parameters included:

- Identifying where roosts are close to the proposed road development or where bat activity has been identified close to the proposed road development

[89] Although it is noted that Lesser horseshoe bats cross the River Corrib over 120m of open water at Menlo Castle.

- Identifying where the proposed vertical profile of the proposed road development (i.e. in cut, on fill or at grade) can permit bat passage underneath the proposed road development
- Where river culverts and minor roads pass under the proposed road development, it was considered if these can fulfil a role in conveying bats underneath the proposed road development
- New underpasses provided should be a minimum of 2.5m high to permit the passage of bats. Research by Abbott showed that this height would allow 90% of the bats to pass through an underpass 2.5m to 3.1m high as seen in the except from her research below

Plate 8.4: Results of surveys carried out by Abbott (2012c)

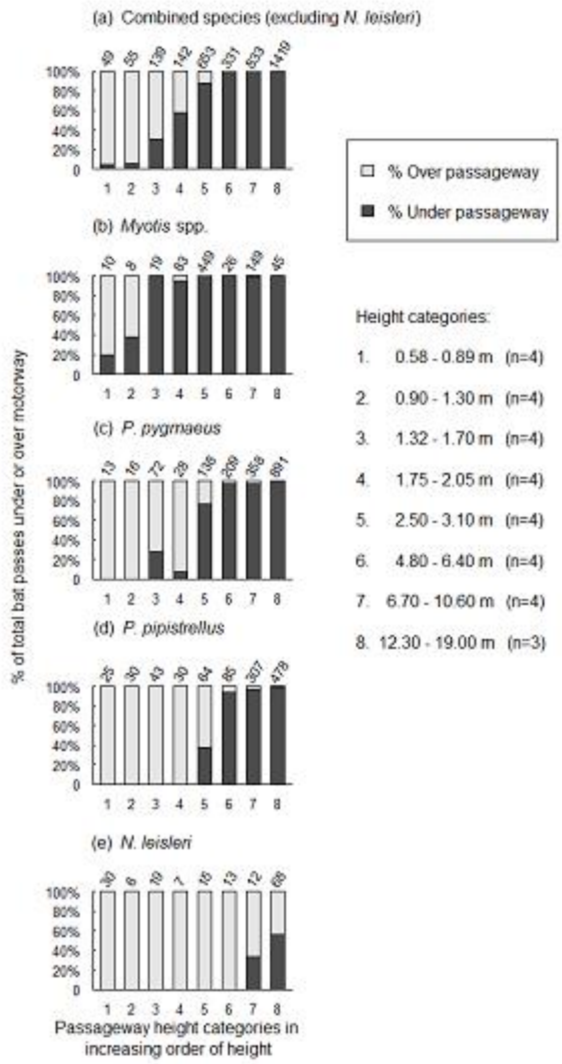


Fig. 4.17 Percentage of bat passes for **(a)** combined species (excluding *N. leisleri*), **(b)** *Myotis* spp., **(c)** *P. pygmaeus*, **(d)** *P. pipistrellus* and **(e)** *N. leisleri* (**b - e** in order of decreasing degree of clutter-adaptation) detected flying through underpasses (% Under) compared to flying over the traffic lanes of the motorway directly above underpasses (% Over) during simultaneously paired recordings. Bat pass counts (Over + Under) per height category (see legend) are shown above each bar for each species

Table 8.35: Schedule of structures designed to serve for bat passage

Structure	Description	Mitigation Function
Culvert C00/01	A 2.5m wide by 1.35m high culvert designed to provide bat passage beneath the proposed road development	Six species of bats recorded near this location. A combined hydraulic and wildlife culvert which will cater for Lesser horseshoe and Myotis species of bats which have been recorded here
Culvert C02/01b	A 2.5m wide by 2.5m high culvert designed to provide for bat passage beneath the proposed road development	A combined hydraulic and wildlife culvert which will cater for Pipistrelle species which were recorded nearby
Culvert C03/01	A 2.5m wide by 1.2m high culvert designed to provide for bat passage beneath the proposed road development	A combined hydraulic and wildlife culvert which will cater for Pipistrelle species which were recorded nearby
Culvert C03/03	A 2.5m wide by 2.5m high culvert designed to provide for bat passage beneath the proposed road development	Records of Pipistrelle, Lesser horseshoe and Myotis species of bats species nearby. A combined hydraulic and wildlife culvert which will cater for bats and will also cater for the commuting route for Lesser horseshoe bats to Bearna Woods
Culvert C03/04	A 2.5m wide by 2.5m high culvert designed to provide for bat passage beneath the proposed road development	Records of Pipistrelle, Lesser horseshoe and Myotis species of bats nearby. A combined hydraulic and wildlife culvert which will cater for bats and will also cater for the commuting route for Lesser horseshoe bats to Bearna Woods
Culvert C04/01	A 5m wide by 2.5m high culvert designed to provide for bat passage beneath the proposed road development	Records of Pipistrelle, Lesser horseshoe and Myotis species of bats nearby. A combined hydraulic and wildlife culvert which will cater for bats and will also cater for the commuting route for Lesser horseshoe bats to Bearna Woods.
Culvert C04/02	A 3.1m wide by 2.5m high culvert designed to provide for bat passage beneath the proposed road development	Records of Pipistrelle, Brown long-eared and Myotis species of bats nearby. A combined hydraulic and wildlife culvert which will cater for bats
Underbridge S06/01	Proposed road underbridge	The existing Rahoon Road will allow continued bat passage underneath the proposed road development. Records of Pipistrelle species of bat nearby. There will be lighting to allow safe pedestrian access
Culvert C06/00	A 2.5m wide by 2.5m high culvert designed to provide for bat passage beneath the proposed road development	Culvert will convey bats underneath proposed road development as the proposed road development severs the existing road which is used by Pipistrelle species. Records of Pipistrelle species of bat nearby, culvert

Structure	Description	Mitigation Function
		connects linear feature each side of the proposed road development
Culvert C06/01	A 2.5m wide by 2.5m high culvert designed to provide for bat passage beneath the proposed road development	Culvert allows passage across proposed road development in area of fill whereas there are no areas for underpasses to the west for c.500m. Connects to attenuation ponds which may be used for foraging
Culvert C07/00	A 2.5m wide by 2m high culvert designed to provide for bat passage beneath the proposed road development	Culvert will connect across landscape used by Pipistrelle and Brown long-eared bats. Roosts to the east which will be surrounded by the proposed road development will be reconnected via this culvert and also culverts to the north
Culvert C07/02A	A 2.5m wide by 2.5m high culvert designed to provide for bat passage beneath the proposed road development	Culvert will connect across landscape used by Pipistrelle and Brown long-eared bats. Roosts to the east which will be surrounded by the proposed road development will be reconnected via this culvert and also culverts to the north. The culvert carries a small stream and ties into a ditch and hedgerow on the eastern side and will join a proposed landscaped strip on the western side, to connect it to the existing Rahoon Road
Culvert C08/01A	A 2.5m wide by 2.5m high culvert designed to provide for bat passage beneath the proposed road development	This culvert is in an area of fill west of the N59 Moycullen Road and offers an opportunity for bats to cross under the proposed road development in this section. Pipistrelle and Lesser horseshoe bats have been recorded in the surrounding area
Culvert C08/05	2.5m wide by 2.5m high culverts will provide for bat passage beneath the proposed road development	These culverts are close to the artificial roost proposed to address the loss of the bat roosts at Aughnacurra (PBR178, 256, 255, 177, 210). As such it is essential to maximise permeability of the proposed road development in this section. Brown long-eared and Lesser horseshoe bats will be facilitated by this culvert. Proposed landscape planting strips will connect the culvert to retained vegetation at the perimeter
Culvert C08/04		
Culvert C08/02		
Culvert C09/01	A 5m wide by 4m high culvert will provide for bat passage beneath the proposed road development	Series of five culverts providing permeability underneath the proposed road development for Lesser horseshoe, Pipistrelle, Brown long-eared and other bat species. The culverts will open into the retained edges of Menlough woods with additional planting provided
Culvert C09/02	A 5m wide by 4m high culvert will provide for bat passage beneath the proposed road development	

Structure	Description	Mitigation Function
Culvert C09/03	A 5m wide by 4m high culvert will provide for bat passage beneath the proposed road development	
Culvert C09/04	A 5m wide by 4m high culvert will provide for bat passage beneath the proposed road development	
Culvert C09/05	A 5m wide by 4m high culvert will provide for bat passage beneath the proposed road development	
Road Underbridge S09/01	Proposed road underbridge (9.6m wide 5.3m high) Menlo Castle Bóithrín will provide for bat passage beneath the proposed road development	Key crossing point in the landscape for Lesser horseshoe bats permitting flights between Menlo Castle roost (and future new roost) and foraging areas near the Coolagh Lakes. Proven by radio-tracking data. The unlit existing road will allow continued bat passage underneath the proposed road development. Records of several species of bat nearby including being within the recorded foraging area for Lesser horseshoe bats and being in an important area for crossings
Culvert C09/06	A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development	This culvert connects woodland edges that will be retained at the edge of the culvert. Records of several species of bat nearby including being within the recorded foraging area for Lesser horseshoe bats and being in an important area for crossings
Culvert C09/07	A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development	In low area in local topography within the recorded foraging area for Lesser horseshoe bats and being in an important area for crossings
Underpass C10/01	A 18m wide by 2.35m high structure will provide for bat passage beneath the proposed road development	This structure connects woodland edges that will be retained at the edge of the culvert. Records of several species of bat nearby including being within the recorded foraging area for Lesser horseshoe bats and being in an important area for crossings as proven by radio-tracking data
Road Underbridge S10/02	Proposed road underbridge (9.6m wide by 5.3m high)	The proposed underbridge will allow continued bat passage beneath the proposed road development. Records of several species of bat nearby including Lesser horseshoe bats and being in an important area for crossings as proven by radio-tracking data

Structure	Description	Mitigation Function
Culvert C12/02	A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development	Series of 3 culverts, each 25m apart, connects lands north and south and allows bats to cross. A key crossing point for Lesser horseshoe bats, Brown long-eared bats and roosts for both species are nearby
Culvert C12/03	A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the road	
Culvert C12/04	A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the road	
Castlegar Wildlife Overbridge S12/02	The Castlegar Wildlife Overpass (60m long x 30m wide) will provide for bat passage over the proposed road development	Key crossing point in the landscape for Lesser horseshoe bats permitting flights between Castlegar and Ballindooley/Menlough areas. See text above this table for rationale for wildlife overpass location and design
Structure S08/04	River Corrib bridge will provide for bat passage over the proposed road development	An important crossing point for all bat species especially Lesser horseshoe and Daubenton's bats as proven by radio-tracking data. Roosts for both species are nearby

In addition to the structures specifically designed for bat passage, there are other structures such as where minor roads pass underneath the proposed road development which will be used by bats as safe crossing points.

8.6.7.2.3 Proposed monitoring programme

As the baseline level of bat activity and roost occupancy can change over time, pre-construction monitoring will be carried out in advance of construction works commencing to ensure that the data against which the post-construction monitoring will be compared to is as up-to-date as possible.

Monitoring of the effectiveness of the bat mitigation and compensation measures will also be undertaken during and post-construction. Where the monitoring identifies issues with either the mitigation or compensation measures (e.g. light spill affecting usage), these will be remediated to ensure that those measures will achieve their aims with respect to mitigating or compensating for impacts on the local bat populations.

Pre- construction monitoring

Pre-construction monitoring is required to provide data against which the post-construction monitoring can be compared. Parameters will include:

- Occupancy levels in roosts (Menlo Castle, proposed artificial roost buildings including retrofitted retained buildings, bat boxes)
- Bat passage structures (culverts, underpasses and the Castlegar Wildlife Overpass)

- Diversity of bat species and abundance of bat activity adjacent to the proposed road development

Occupancy levels in Menlo Castle will be measured by emergence surveys using infra-red video camera recording monthly from mid-April to September in the year of or immediately prior to construction commencing (whichever of the two is closer to the construction commencement).

Monitoring for bat usage of proposed bat passage structures will focus on recording bats using existing flight paths at proposed underpasses near Menlo Castle, the N59 Letteragh Junction and the proposed Castlegar Wildlife Overpass. Pre-construction baseline data is required on numbers of bats and flight height so that this can be compared to a post-construction scenario. Such data will be collected using focused infra-red camera and detector surveys carried out at least on three separate occasions at each location in the optimum survey period. In accordance with CEDR (2016) guidance it is proposed that this pre-construction monitoring involves a minimum of two separate surveys in the breeding season and two separate (in time) surveys in mid-August to late-September, to reflect periods of landscape-scale movements, and that these surveys take place for two bat activity seasons (May-August) following completion of the construction of the proposed road development.

The risk of adverse effects on bat diversity and abundance adjacent to the proposed road development can never be ruled out completely; but not all populations will be affected in the same location in the same way and therefore ongoing monitoring is regarded to be good practice to enhance our understanding of the effects of road developments and the effectiveness of mitigation measures. Diversity of bat species and abundance of bat activity adjacent to the proposed road development will be monitored using standardised survey transects from the edge of the proposed road development outwards as described by Berthinussen & Altringham (2015). These transects will be used to record bat activity across the lands flanking the corridor of the proposed road development. It is proposed that six transects are surveyed pre-construction in locations of high bat activity where underpasses or an overpass are proposed.

During and post-construction monitoring

<u>Roost monitoring</u>

Monitoring of occupancy of the artificial roost buildings (including retrofitted retained buildings) and bat boxes will commence immediately after their installation to determine how soon they are used. They will be installed prior to the main site clearance phase; therefore, all monitoring can be by visual inspection according to the following schedule:

- Emergence counts at Menlo Castle roost: emergence counts will be undertaken during the construction works and in 5 years following construction in May, July and August. These counts will be made using infra-red video camera recording at the same time as visual inspections of bats using the proposed new roost site adjacent to Menlo Castle in order to get an overall count of bats at this location

- Artificial roost buildings: Occupancy of the proposed artificial roost buildings (including retrofitted structures) during the works and post-construction will be undertaken in the 5 years following completion of construction. Surveys will be undertaken in mid-winter for hibernation use and in May and July for use during breeding season. Surveys will include checks for individuals and also for droppings (where necessary using DNA analysis). Droppings will be removed after each check to ensure that the subsequent survey only records usage in the interim period. The roosts will be monitored annually for Lesser horseshoe bats and counts sent to the NPWS as part of the national Lesser horseshoe bat monitoring programme. This monitoring may be undertaken by NPWS staff, Galway bat group or others to be decided by the local authority. Remote modes of monitoring using new technology may mean that visits to the roosts are not always required and that infra-red images inside the roost can be sent wirelessly. Should the monitoring of the roosts suggest that bats are not using them, additional focused surveys will be undertaken to try to understand bat movements in the locality and aim to address any issues. Any changes that may be deemed necessary will be coordinated and communicated to ensure that they do not conflict with any of the impact predictions or mitigation measures prescribed in this report. Temperature and humidity probes coupled with data loggers will be installed in the roosts for two years post construction of the roost and measures taken (e.g. fitting vents, increasing period of water tanks in the hibernation roost area) to address any issues arising
- Bat boxes: The authors are not aware of any minimum or recommended standard for bat box monitoring. After installation, boxes will be visually inspected quarterly per year for the first two years. Research into the effectiveness of mitigation measures has indicated that occupancy of bat boxes averages 50%[90] since bats may prefer existing alternative roost sites in the locality. Any boxes not showing signs of occupancy after that time may be relocated to alternative locations within the proposed development boundary nearby where they may be of benefit to the local bat population. In years 3-5 after installation the boxes will be checked in late March and September to record usage in winter and summer and to avoid disturbance during the sensitive hibernation times
- Bat boxes will be checked for a minimum of 5 years after erection

<u>Monitoring crossing points</u>

Monitoring will comprise acoustic detector and infra-red camera recording at the culverts at the five locations previously surveyed pre-construction, namely:

- Area 1: North of Bearna Woods
- Area 2: Aughnacurra
- Area 3: River Corrib to Bothár Nua
- Area 4: West of N84 Headford Road
- Area 5: Ballindooley to Castlegar, including the Castlegar Wildlife Overpass

[90] Paul Lynott, pers. comm 2017.

This will quantify the usage by bats compared to non-usage (e.g. using other flight paths). This will allow a determination as to whether the bat passage structures are being effective at a population level (where it is assumed that 90% of the bats are able to pass underneath the proposed road development). Monitoring will be repeated at all locations to provide a robust dataset. In the event that the proposed bat passage structures including the Castlegar Wildlife Overpass are not deemed to be effective, then further focused surveys will be required to determine the causes and address them in a reasonable manner where possible (for example, controlling lighting, addressing local landscape changes). Any changes that may be deemed necessary will need to be coordinated and communicated to ensure that they do not conflict with any of the impact predictions or mitigation measures prescribed in this report.

In accordance with CEDR (2016) guidance it is proposed that this post-construction monitoring involves a minimum of two separate surveys in the breeding season and two separate (in time) surveys in mid-August to late-September, to reflect periods of landscape-scale movements, and that these surveys take place for two bat activity seasons (May-August) following completion of the construction of the proposed road development.

The monitoring programme described above also relates to the compensation measures for bats described in **Section 8.9.2**.

<u>Diversity and abundance adjacent to the proposed road development corridor</u>

Transects of bat activity will be taken across the same locations as the pre-construction transects in order to identify any displacement effects caused by disturbance impacts during construction and operation. Whilst the application of the Berthinussen & Altringham (2015) methodology is not without its limitations as it has only been applied to open agricultural landscapes, it is nevertheless a foundation for a reproducible survey method that is appropriate to the proposed road development. If a displacement effect is detected (decreased abundance and diversity close to the proposed road development) then further focused surveys will be required to determine the causes and address them where possible (for example, controlling lighting, addressing local landscape changes through additional planting). Any changes that may be deemed necessary will need to be coordinated and communicated to ensure that they do not conflict with any of the impact predictions or mitigation measures prescribed in this report. It is proposed that monitoring takes place during construction and two bat activity seasons following completion of the construction of the proposed road development.

8.6.7.3 Badger

Badger, and their breeding and resting places, are protected under the Wildlife Acts and it is an offence under that legislation to intentionally kill or injure a Badger or to wilfully interfere with or destroy their breeding or resting places (setts).

A comprehensive suite of mitigation measures have been incorporated into the proposed road development to ensure that Badgers are not intentionally killed or injured and that any impacts to their breeding or resting places will not affect their conservation status, at any geographic scale, and will not give rise to any likely significant effects on the species.

The mitigation measures described below follow the recommendations set out in the *Guidelines for the Treatment of Badgers during the Construction of National Road Schemes* (National Roads Authority, 2006). These guidelines set out the best practice approach in considering and mitigating impacts on Badgers during construction works.

8.6.7.3.1 Measures to Protect Badger during Construction

A detailed summary of the mitigation measures as they relate to each of the Badger setts within the ZoI of the proposed road development is presented in **Appendix A.8.24**. The non-interference zones (30m, 50m and 150m), as they relate to each of the Badger setts within the ZoI of the proposed road development, are shown on **Figures 8.23.1** to **8.23.14**.

As the usage of setts by Badgers can change over time, a pre-construction check of the activity status of all setts will be required within 12 months of any constructions works commencing within the ZoI of the setts discussed below.

Disturbance/displacement

In order to prevent any disturbance to Badger setts not directly affected by the proposed road development, no heavy machinery shall be used within 30m of Badger setts at any time. No works shall be under taken within 50m of active setts during the breeding season. Lighter machinery (generally wheeled vehicles) shall not be used within 20m of a sett entrance. Neither blasting nor pile driving shall be undertaken within 150m of active setts during the breeding season (December to June inclusive).

Prior to works commencing, a non-interference zone of 30m will be established around each of the Badger setts within the ZoI of the proposed road development, as shown on **Figures 8.23.1** to **8.23.14**. If the sett is active, a non-interference zone will be extended to 50m during the breeding season (December to June inclusive). The fencing shall be as noted in **Chapter 7, Construction Activities** and of a sufficient durability to maintain the exclusion zone throughout the construction period or, if required, until such time as the sett in question is excluded/removed.

The mitigation measures, as they relate to each of the Badger setts within the ZoI of the proposed road development, are summarised in **Table 8.36** and illustrated on **Figures 8.23.1** to **8.23.14**.

Loss of breeding/resting sites

Where setts require exclusion and removal, or temporary exclusion for the duration of the construction period, this will be undertaken in accordance with the methodology detailed in the *Guidelines for the Treatment of Badgers during the Construction of National Road Schemes* (National Roads Authority, 2006):

- All Badger setts requiring exclusion and removal will require a monitoring period of at least five days to confirm activity status in advance of any construction works commencing

- If the sett is active, then it shall not be removed within the Badger breeding season (December to June inclusive). To exclude or remove an active Badger sett outside of this period, inactive entrances shall be soft and hard-blocked with one-way gates installed on active entrances. One-way gates will be tied open for three days before being set to exclude, and then monitored for a period of at least 21 days before the sett is deemed inactive and destroyed. If at any time during the monitoring period the sett becomes active, the exclusion process/programme must commence again from day 1 of the 21-day monitoring period
- For inactive setts, entrances will be soft-blocked (lightly blocked with vegetation and soil) and if all entrances remain undisturbed for a period of five days the sett should be destroyed immediately. This can be undertaken at any time of the year for inactive setts

An artificial sett is required to mitigate for the loss of the main sett (S9), in conjunction with a subsidiary sett (S11), of the Lackagh Badger group. The requirements relating to the provision and design of the artificial sett are set out in **Appendix A.8.24**. The location of the artificial sett is shown on **Figures 8.23.1** to **8.23.14**[91].

Inaccessible areas (see **Figures 8.3.1** to **8.3.14**) will require a pre-works survey for badger setts in advance of site clearance. If a sett is uncovered, works must cease and a non-interference zone of 30m established; extended to 50m during the breeding season if set is active (December to June inclusive). Sett removal will follow the process outlined above.

8.6.7.3.2 Measures to Protect Badger during Operation

Habitat Severance/Barrier Effect and Mortality Risk

Badgers typically follow the same pathways between setts, feeding areas and latrines. To avoid badger road casualties, mammal passage facilities will be provided at strategic locations along the route of the proposed road development. Mammal underpasses will be constructed in accordance with the *Guidelines for the Treatment of Badgers during the Construction of National Road Schemes* (National Roads Authority, 2006). Mammal underpasses which are at least 600mm in width, have adequate drainage, have good vegetation cover around the entrances and good habitat connectivity have been proven to be used by badgers (Eldridge & Wynn, 2011)[92].

---

[91] The closer an artificial sett is to the main sett being removed, the more likely it is to be used by the affected Badger group. Therefore, the artificial sett is proposed to be located approximately 60m to the north of S9. As the sett must be in place several months before works commence and the sett S9 is removed, the affected Badgers will have sufficient time to either adjust to the construction works in the vicinity of the artificial sett (which will involve blasting and rock breaking), relocate to another sett (e.g. S10), or construct a new sett elsewhere within their territory. Any disturbance from the construction works will be short-term and, even if the artificial sett is vacated during construction, its proximity to the operational road is not likely to deter badgers from occupying the sett at that time.

[92] Eldridge, B. & Wynn, J. (2011) Use of badger tunnels by mammals on Highways Agency schemes in England. *Conservation Evidence 8*. Pages 53-57

Where engineering constraints conflict with the recommended locations at construction, mammal underpasses may be moved to the nearest most suitable location, but not more than c.250 m away. The locations where Badger passage facilities will be provided are listed below in **Table 8.36** and are shown on **Figures 8.23.1** to **8.23.14**.

A number of the mammal passage structures lie within the modelled light spill zone and artificial lighting may affect their usage by Badger: structures C07/04, C07/01(b) and C12/01. Screening will be provided to ensure that the approaches and entrances to these structures are unaffected by light spill.

Table 8.36: Mammal passage facilities [93]

Ref. No.	Structure	Species and Description
C00/00	Pipe	Badger Dedicated 600mm concrete pipe will provide for mammal passage beneath the proposed road development
C00/01	Culvert	Bats A 2.5m wide by 1.35m high culvert will provide for bat passage beneath the proposed road development
C02/01b	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C03/01	Culvert	Bats A 2.5m wide by 1.2m high culvert will provide for bat passage beneath the proposed road development
C03/03	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C03/04	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C04/01	Culvert	Otter, Badger and Bats Raised mammal ledge, sited above flood water levels, incorporated into structure or a dedicated 600 mm concrete pipe on the east bank of the river/stream will provide for Otter and Badger passage A 5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C04/02	Culvert	Otter, Badger and Bats Raised mammal ledge, sited above flood water levels, incorporated into structure or a dedicated 600 mm concrete pipe on the east bank of the river/stream will provide for Otter and Badger passage

[93] Some of thes are also included in **Table 8.35** as part of the bat mitigation strategy but will also provide passage for many other mammal species

Ref. No.	Structure	Species and Description
		A 3.1m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C05/01	Pipe	Badger Dedicated 600mm concrete pipe will provide for mammal passage beneath the proposed road development
S06/01	Road Overbridge	Bats The unlit road overbridge will provide for bat passage across the proposed road development
C06/00	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C06/01	Culvert	Badger A 2.5m wide by 2.5m high culvert will provide for bat and badger passage beneath the proposed road development
C07/00	Culvert	Bats A 2.5m wide by 2m high culvert will provide for bat passage beneath the proposed road development
C07/02A	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C07/04	Pipe	Badger Dedicated 600mm concrete pipe will provide for mammal passage beneath the proposed road development
C07/01(b)	Pipe	Badger Dedicated 600mm concrete pipe will provide for mammal passage beneath the proposed road development
C08/01(a)	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C08/04	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C08/05	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C08/02	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development

Ref. No.	Structure	Species and Description
C09/01	Culvert	Bats and Badgers A 5m wide by 4m high culvert will provide for bat and badger passage beneath the proposed road development
C09/02	Culvert	Bats and Badgers A 5m wide by 4m high culvert will provide for bat and badger passage beneath the proposed road development
C09/03	Culvert	Bats and Badgers A 5m wide by 4m high culvert will provide for bat and badger passage beneath the proposed road development
C09/04	Culvert	Bats and Badgers A 5m wide by 4m high culvert will provide for bat and badger passage beneath the proposed road development
C09/05	Culvert	Bats and Badgers A 5m wide by 4m high culvert will provide for bat and badger passage beneath the proposed road development
S09/01	Road Overbridge	Bats and Badgers The road overbridge (9.6m wide by 5.3m high) will provide for bat and badger passage beneath the proposed road development
C09/06	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C09/07	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C10/01	Underpass	Bats and Badgers A 18m wide by 2.35m high underpass will provide for bat and badger passage beneath the proposed road development
S10/02	Road Overbridge	Bats The road overbridge (9.6m wide by 5.3m high) will provide for bat passage beneath the proposed road development
C10/02	Pipe	Bats and Badger Dedicated 1200mm concrete pipe will provide for mammal passage beneath the proposed road development
C12/01	Pipe	Badger Dedicated 600mm concrete pipe will provide for mammal passage beneath the proposed road development
C12/02	Culvert	Bats

Ref. No.	Structure	Species and Description
		A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C12/03	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
C12/04	Culvert	Bats A 2.5m wide by 2.5m high culvert will provide for bat passage beneath the proposed road development
S12/02	Green bridge	Bats and Badgers The Green Bridge (30m in width) will provide for bat and mammal passage over the proposed road development
C13/01	Culvert	Bats and Badger A 2.5m wide by 1.5m high culvert will provide for bat and badger passage beneath the proposed road development

Mammal-resistant fencing will be required to guide badgers to the underpasses and will be installed in accordance with the specification outlined in *Guidelines for the Treatment of Badgers prior to the Construction of National Road Schemes*, and TIIs mammal resistant fencing specification (currently CC-SCD-00320/00319), and will include badger proofing of emergency access roads and other similar access points, where located in areas where mammal-resistant fencing is to be installed. The locations where mammal-resistant fencing is to be installed are shown on **Figures 8.23.1** to **8.23.14**.

In accordance with the recommendations described in the *Guidelines for the Treatment of Badgers during the Construction of National Road Schemes* (National Roads Authority, 2006), quarterly monitoring of the effectiveness of the mitigation measures will be undertaken in the first year after the completion of construction works (for example, fencing inspections to check for gaps and underpass inspection to check for blockages).

8.6.7.4 Other Mammal Species

8.6.7.4.1 Measures to Protect Other Mammal Species during Construction

Habitat degradation - water quality

The mitigation measures relating to the protection of water quality in receiving watercourses during construction are outlined in **Section 8.6.4** and detailed in **Section 11.6.2** of **Chapter 11, Hydrology**.

8.6.7.4.2 Measures to Protect Other Mammal Species during Operation

Habitat Severance/Barrier Effect

The combination of the network of dedicated mammal passage facilities, along with the bridge and viaduct structures (the proposed River Corrib Bridge and the Menlough Viaduct), and the retained lands above the proposed Lackagh Tunnel and the Galway Racecourse Tunnel provide a high degree of landscape permeability along the route of the proposed road development for all of the other mammal species recorded, or likely to be present, within the study area. The locations are described above in **Table 8.36** and are shown on **Figures 8.23.1** to **8.23.14**.

Wildlife passage facilities have been shown to be used by small mammal species such as Hedgehog, Pygmy shrew and Wood mouse (Dolan 2006; Eldridge & Wynn 2011); although their effectiveness has not been tested. However, it is likely that the high permeability of the proposed road development will reduce the effects of any severance or barrier effect that may be associated with the proposed road development (Haigh, 2012) such that the species' conservation status would not be affected. Therefore, habitat severance and barrier effect are not likely to result in a significant negative residual effect, at any geographic scale.

Collision Risk

There are no practical or effective means of preventing small mammals or arboreal mammal species (such as the Pine marten and Red squirrel, which are highly skilled climbers) from accessing the proposed road development. As discussed above in relation to severance and barrier effect, the design of the proposed road development provides for a high degree of permeability across the proposed road development and this offers the most practical solution to minimise the potential interaction of small mammals with the proposed road development. Collision risk is therefore, not likely to affect the species' conservation status and not likely to result in a significant negative residual effect, at any geographic scale.

8.6.8 Invertebrates

8.6.8.1 Marsh whorl snail

8.6.8.1.1 Measures to Protect the Marsh whorl snail during Construction

Habitat Degradation – Surface Water Quality

The mitigation measures relating to the protection of water quality in receiving watercourses during construction are outlined in **Section 8.6.4** and detailed in **Section 11.6.2** of **Chapter 11**, **Hydrology**.

Habitat Degradation – Groundwater

The mitigation measures relating to the protection of the groundwater regime during construction are described in **Section 10.6.2** of **Chapter 10, Hydrogeology**.

8.6.8.1.2 Measures to Protect the Marsh whorl snail during Operation

Habitat Degradation – Groundwater

The mitigation measures relating to the protection of the groundwater regime during operation are described in **Section 10.6.3** of **Chapter 10, Hydrogeology**.

8.6.8.2 Marsh fritillary butterfly

8.6.8.2.1 Measures to Protect the Marsh fritillary butterfly during Construction

Mortality Risk

To avoid the destruction of Marsh fritillary eggs or the mortality of Marsh fritillary caterpillars, the following mitigation strategy will be implemented in relation to the site clearance works:

- All areas within the proposed development boundary, which have been identified as suitable habitat to support the Marsh fritillary butterfly, will be subject to a pre-construction larval web survey. This will be undertaken during the mid-August to the end of September window immediately preceding site clearance works
- If larval webs are present, they will be translocated to another area of suitable habitat; either outside of the proposed development boundary or, if within, to an area of suitable habitat that will remain unaffected by construction works for the duration
- Once all larval webs have been removed from the affected areas, or if no larval webs were recorded, the vegetation will be immediately cleared or cut to ground level to render the area unsuitable for the species to recolonise. The vegetation shall be maintained in this state until such time as the topsoil is removed.

8.6.9 Birds

8.6.9.1 Breeding Birds

8.6.9.1.1 Measures to Protect Breeding Birds during Construction

Habitat Loss, Disturbance and Destruction of Breeding Habitat

General

Where feasible, vegetation (*e.g.* hedgerows, trees, scrub and grassland) will not be removed, between the 1 March and the 31 August, to avoid direct impacts on nesting birds. Where the construction programme does not allow this seasonal restriction to be observed, then these areas will be inspected by a suitably qualified ecologist for the presence of breeding birds prior to clearance. Areas found not to contain nests will be cleared within 3 days of the nest survey, otherwise repeat surveys will be required.

Barn owl

To minimise the effects of current levels of disturbance to the Barn owl nest site at Menlo Castle, and thereby reduce any cumulative effect that construction activities nearby may have, alternative nesting sites will be provided in the vicinity. Three Barn owl nest boxes will be erected across the area shown on **Figures 8.23.1** to **8.23.14** and will consist of either nest boxes erected on suitable trees or pole-mounted nest boxes. Preference will be given to erecting nest boxes on suitable trees, where possible.

Tree mounted boxes will be erected at least 3m above ground level on a mature tree with few or no low branches to obscure the nest box. The selected tree shall be either isolated in a hedgerow or situated on a woodland edge with the access hole facing open ground.

Pole-mounted nest boxes will be erected at a minimum height of 4.5m above ground.

The nest box design (e.g. entrance hole size, floor area and depth from the bottom of the entrance hole to the nest) shall be in accordance with the design requirements published by The Barn Owl Trust (http://www.barnowltrust.org.uk/). Nest boxes will be inspected annually for defects/damage and cleaned out/repaired as required to ensure waterproofness and the internal box depth.

Peregrine falcon

To minimise the potential for construction works near Lackagh Quarry to disturb the Peregrine falcon nest site, works from the Lackagh Tunnel to the N84 Headford Road Junction will commence prior to mid-February. This will ensure that any construction related disturbance, if its magnitude displaces Peregrine from the quarry for the duration of construction works, can influence the selection of the nest site and will not impact upon an incubating female on the nest. The installation of rock bolts on the cliff faces in the vicinity of the nest site will be undertaken in a sensitive manner (as advised by a suitably experienced ecologist) so as to minimise any potential disturbance to the nest site during the breeding season, particularly if the nest site is occupied.

8.6.9.1.2 Measures to Protect Breeding Birds during Operation

Habitat loss, Habitat Severance/Barrier Effect and Mortality Risk

General

Planting of woodland, hedgerow and grassland habitats along the proposed road development as detailed in the landscape drawings (**Figures 12.2.01** to **12.2.15**) will provide compensatory habitat for some bird species. In some instances, such as in large areas of improved agricultural grassland with no vegetated field boundaries, this will improve the diversity of bird habitat.

Many species may not nest near a road development due to disturbance (e.g. drowning out of bird song by traffic noise). Whilst the planting is not likely to fully offset the loss of breeding habitat (due to the proximity of road traffic disturbance on the operational road) it is likely to provide additional foraging habitat for some species.

To further minimise the effects of breeding habitat loss, a total of 20 nest boxes will be erected by a qualified ecologist in suitable locations away from the busy junctions/roadways. The siting and type of nest boxes will be decided on by an ecologist at locations where trees will be planted or retained along the proposed road development; as shown on **Figures 12.2.01** to **12.2.15**.

Barn owl

Sections along the proposed road development will be planted with dense low growing scrub cover (e.g. blackthorn) to discourage Barn owls from foraging near the proposed road development. The planting will be of a density to minimise the lag time between planting and obtaining sufficient ground cover to deter foraging Barn owl.

In areas where there is a high probability that Barn owls may regularly attempt to cross the proposed road development (the section of embankment between Ch. 9+600 and Ch. 10+100), lines of closely spaced (approximately 2m centres) trees, greater than 3m in height, will be planted along the top of the embankments of the proposed road development; outside of the safety barrier and clear zone. The understorey will also be densely planted. This is to present a solid vegetated barrier to deflect Barn owl from these high-risk areas and/or force birds to fly over the proposed road development above the road traffic.

All mitigatory planting will be in place at the earliest feasible stage during construction to ensure that the mitigation is functioning as soon as possible, following the opening of the proposed road development.

The locations where planting will be used to reduce the risk of Barn owl mortality from road traffic are shown on **Figures 8.23.1** to **8.23.14** and on the landscape drawings (**Figures 12.2.01** to **12.2.14**).

Following implementation of all mitigation measures and completion of construction of the proposed road development, the following monitoring measures are proposed:

- Surveys will be undertaken of roadside planting schemes at the end of years one and two with the objective of identifying and replacing failed plantings
- A road casualty survey to record barn owl mortalities along the route of the proposed road development will be conducted once per week for a period of two years by a suitably qualified and experienced ornithologist. The proposed road development will be driven at a steady pace in both directions so that all sections and both sides of the route will be surveyed correctly. Where noted, all barn owl mortalities will be assigned to either the “breeding” season (March to July) or “non-breeding” season (August to January). Location details of the casualty will be recorded, including a 10-digit GPS co-ordinate, position on the route (central median, hard shoulder, or verge) and orientation (southbound,

northbound, eastbound, and westbound). The age class of the bird will be determined and classed as either "pre-breeding" if first or second calendar year recovered before March, or "adult" if the bird is second calendar year recovered later than March or older. The adjacent habitat feature will be noted. This methodology is in line with that utilised for *Barn Owl population status and the extent of road mortalities in relation to the Tralee Bypass* (O'Clery et al., 2016)

- Monitoring to determine activity and breeding status of all active sites within 5km of the proposed road development over two breeding seasons (March to July). This will be carried out concurrently with the road casualty survey, and will involve visits to known and potential nesting sites to determine brood size and breeding success. Where accessible, nests will be visited in order to ring owlets (subject to an appropriate licence from the NPWS)

A report summarising the findings of the above monitoring will be submitted at the end of year two to the NPWS. The report may include further recommendations pending survey outcomes.

8.6.9.2 Wintering Birds

8.6.9.2.1 Measures to Protect Wintering Birds during Construction

Construction noise will be kept to a minimum in accordance with BS 5228 (2009).

The contract documents will specify that the Contractor, undertaking the construction of the works, will be obliged to take specific noise abatement measures and will comply with the best practice outlined in British Standard BS 5228 – 1: 2009 +A1 2014: *Code of practice for noise and vibration control on construction and open sites – Noise* and the NRA (now TII) guidelines *Good Practice Guideline for the Treatment of Noise during the planning of National Road Schemes* (National Roads Authority, 2014).

Blasting associated with the eastern approach to Lackagh Quarry (Ch. 11+800 to Ch. 12+100) will be carried out between the months of April to September (inclusive) to minimise the exposure of wintering birds at Ballindooley Lough to blasting-related disturbance.

Blasting associated with the cutting at Castlegar (Ch. 12+550 to Ch. 13+650) will take approximately nine months to complete, with an estimated five blast events per week. To minimise the exposure of wintering birds at Ballindooley Lough to blasting-related disturbance, all of those nine months must be in the April to September period (inclusive) within consecutive years.

8.6.9.2.2 Measures to Protect Wintering Birds during Operation

Disturbance/Displacement

Despite the assessment conclusion that disturbance during operation of the proposed road development is not likely to result in any population level effects on wintering birds, hedgerow planting along the proposed development boundary (at the locations shown on the landscape drawings (**Figures 12.2.01** to **12.2.14**) will further minimise the potential disturbance to wintering birds from road traffic.

8.6.10 Amphibians

8.6.10.1 Measures to Protect Amphibians during Construction

Habitat Loss, Disturbance & Mortality Risk

If works to clear any of the habitat features suitable to support amphibian species are to begin during the season where frogspawn or tadpoles may be present (February – mid-summer), or where breeding adult newts, their eggs or larvae may be present (mid-March – September), a pre-construction survey will be undertaken to determine whether breeding amphibians are present.

In the case of Common frog, any frog spawn, tadpoles, juvenile or adult frogs present will be captured and removed from affected habitat by hand net and translocated to the nearest area of available suitable habitat, beyond the ZoI of the proposed road development.

In the case of Smooth newt, individuals will be captured and removed from affected habitat either by hand net or by trapping and translocated to the nearest area of available suitable habitat, beyond the ZoI of the proposed road development. If used, the type and design of traps shall be approved by the NPWS. This is a standard and proven method of catching and translocating Smooth nest.

If the size or depth of the habitat feature is such that it cannot be determined whether all amphibians have been captured, it will be drained under the supervision of a suitably experienced ecologist to confirm that no amphibian species remain before it is destroyed or infilled. Any mechanical pumps used to drain the habitat feature will have a screen fitted, and be sited, such that no amphibian species can be sucked into the pump mechanism.

Any capture and translocation works shall be undertaken immediately in advance of site clearance/construction works commencing.

Habitat Degradation – Surface Water Quality

The mitigation measures relating to the protection of water quality in receiving watercourses during construction are outlined in **Section 8.6.4** and detailed in **Section 11.6.2** of **Chapter 11, Hydrology**.

8.6.10.2 Measures to Protect Amphibians during Operation

Habitat Severance & Barrier Effect

The combination of the network of wildlife passage facilities, culverts, bridges and viaduct structures (e.g. the proposed River Corrib Bridge and the Menlough Viaduct) provide a high degree of landscape scale permeability along the proposed road development. This will serve to maintain connectivity at a local scale between sites used by amphibian species and is predicted to reduce any long-term severance or barrier effects associated with the proposed road development such that the conservation status of amphibian species is not likely to be negatively affected.

The locations of the wildlife passage facilities are described above in **Table 8.36** and are shown on **Figures 8.23.1** to **8.23.14**.

8.6.11 Reptiles

8.6.11.1 Measures to Protect Reptiles during Construction

Habitat Loss, Disturbance & Mortality Risk

Given the broad range of habitat types favoured by the Common lizard, and that the majority of the proposed road development passes through mosaics of such habitats, site clearance works at any time of year in suitable habitat are highly likely to encounter the species, cause disturbance and have the potential to kill or injure individuals.

In order to minimise the risk of site clearance and construction works disturbing, or causing the mortality of, Common lizard the following schedule of site clearance works will be followed in the areas highlighted on **Figures 8.10.1** to **8.10.8**, where the presence of Common lizard has been confirmed:

- grass, scrub or heath vegetation will be removed during the winter period, where possible, avoiding potential Common lizard hibernacula sites (dry sites which provide frost-free conditions e.g. stone walls, underground small mammal burrows, piles of dead wood or rubble)
- where this is not possible and clearance will be undertaken during the active season (March through to September, inclusive), vegetation will be cut first to approximately 15cm, and then to the ground, under supervision of an ecologist. This will allow the opportunity for lizards to be displaced by the disturbance and leave the affected area
- stone walls (or other potential hibernacula sites) will be removed during the active season (March through to September, inclusive) under the supervision of an ecologist, when they are less likely to be in use by torpid lizards

8.6.11.2 Measures to Protect Reptiles during Operation

Habitat Severance & Barrier Effect

The combination of the network of wildlife passage facilities, culverts, bridges and viaduct structures (e.g. the proposed River Corrib Bridge and the Menlough Viaduct) provide a high degree of landscape scale permeability along the proposed road development. This will serve to maintain connectivity at a local scale between sites used by reptile species and is predicted to reduce any long-term severance or barrier effects associated with the proposed road development such that the conservation status of reptile species is not likely to be negatively affected.

The locations of the wildlife passage facilities are described above in **Table 8.36** and are shown on **Figures 8.23.1** to **8.23.14**.

8.6.12 Fish

8.6.12.1 Measures to Protect Fish Species during Construction

Habitat Loss

The structures have been designed in consultation with IFI and in accordance with the design criteria set out in *Guidelines for the Crossing of Watercourses during the Construction of National Road Schemes* (National Roads Authority**,** 2005) and the *Guidelines on Protection of Fisheries During Construction Works in and Adjacent to Waters* (IFI, 2016). These measures, which include, in broad terms replicating the existing channel profile and substrate, will likely minimise the effects of habitat loss to a degree but it is acknowledged that this will be limited by the fact that they are artificial channels within a light limiting box structure.

To minimise the effects of habitat loss on fish species, all sections of river/stream channel within the proposed development boundary, but not within the footprint of the proposed road development and associated infrastructure, will be protected from site clearance and construction works. Rivers/streams will be fenced off at a minimum distance of 5m from the river bank and within this zone the natural riparian vegetation will be retained.

Habitat Degradation – Surface Water Quality

The mitigation measures relating to the protection of water quality in receiving watercourses during construction are outlined in **Section 8.6.4** and detailed in **Section 11.6.2** of **Chapter 11, Hydrology**.

Habitat Degradation – Groundwater

The mitigation measures relating to the protection of the groundwater regime during construction are described in **Section 10.6.2** of **Chapter 10, Hydrogeology**.

Mortality Risk & Disturbance/Displacement

To minimise the potential effects of construction works on fish species the following mitigation measures will be implemented:

- No instream works will be carried out between the months of October and June (inclusive) to avoid the most sensitive time for fish species and fish species movements
- Design of new sections of river channel shall be in accordance with the principles outlined in *Channels & Challenges. Enhancing Salmonid Rivers*. (O'Grady, 2006)
- Immediately prior to rivers/streams being diverted into a newly constructed river channel or culvert, they will be electrofished (if required) to capture and transfer fish from the original channel to the new one. Once the watercourse has been diverted this will be followed by a manual search of the original watercourse to transfer any remaining fish to the new river/stream channel

- Any water abstraction points required for dust suppression will be agreed with IFI and the suction head shall be screened to ensure that fish are not removed during the abstraction process

Habitat Severance/Barrier Effect

All temporary crossing structures used to cross watercourses during construction will be designed in accordance with the *Guidelines on Protection of Fisheries During Construction Works in and Adjacent to Waters* (IFI, 2016) and *Guidelines for the Crossing of Watercourses during the Construction of National Road Schemes* (National Roads Authority**,** 2005) to maintain fish and macroinvertebrate passage, and to prevent sedimentation and erosion.

8.6.13 Summary of Mitigation Measures

Table 8.37 below presents an overall summary of the mitigation measures and how these relate to the likely significant effects of the proposed road development on biodiversity.

Table 8.37: Summary of the Mitigation Measures Required to Address the Likely Significant Effects of the Proposed Road Development on Biodiversity

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance	Mitigation Measures
Designated Areas for Nature Conservation				
Lough Corrib cSAC (including Lough Corrib pNHA)	International (National)	**Construction** Habitat loss Habitat degradation – tunnelling/excavation Habitat degradation – hydrogeology Habitat degradation – hydrology Habitat degradation – air quality Habitat degradation – non-native invasive plant species Mortality risk **Operation** Habitat degradation – hydrogeology Habitat degradation – non-native invasive plant species Mortality risk	Likely significant effect at the international geographic scale	see Section 10 of the NIS
Galway Bay Complex cSAC (including Galway bay Complex pNHA)	International (National)	**Construction** Habitat degradation – hydrology Habitat degradation – non-native invasive plant species Barrier effect Mortality risk	Likely significant effect at the international geographic scale	see Section 10 of the NIS

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance	Mitigation Measures
Lough Corrib SPA (including Lough Corrib pNHA)	International (National)	**Construction** Habitat degradation – hydrogeology Habitat degradation – hydrology Disturbance/displacement **Operation** Habitat degradation – hydrogeology	Likely significant effect at the international geographic scale	see Section 10 of the NIS

Local Biodiversity Areas				
Local biodiversity areas	The value of the biodiversity receptors recorded in the vicinity of the proposed road development, across the local biodiversity areas, range from Local Importance (Lower Value) to Internationally Important	Combinations of all of the potential impacts noted above The specific impacts are related to and dependent upon the potential impacts of the proposed road development on each of the individual ecological receptors that make up the biodiversity resource within a given local biodiversity area	Likely significant effects from local up to the international geographic scale	All of the mitigation measures included within **Section 8.6** The specific mitigation measures are related to and dependent upon the potential impacts of the proposed road development on each of the individual ecological receptors that make up the biodiversity resource within a given local biodiversity area

8.7 Residual Impacts

8.7.1 Designated Areas for Nature Conservation

8.7.1.1 European Sites

The assessment, presented in the NIS, of the potential for the proposed road development to impact upon Lough Corrib cSAC, Lough Corrib SPA, Galway Bay Complex cSAC or Inner Galway Bay SPA concluded that, with the implementation of the mitigation measures proposed, the proposed road development does not pose a risk of adversely affecting (either directly or indirectly) the integrity any European site, either alone or in combination with other plans or projects.

Although the proposed road development will not adversely affect the integrity of any of these European sites, the proposed road development will have some level of residual impact on biodiversity within the boundary of Lough Corrib cSAC. This is not the case of Galway Bay Complex cSAC, Inner Galway Bay SPA and Lough Corrib SPA, which are remote from the proposed development boundary, as the potential impact pathways connecting the proposed road development to these European sites are fully mitigated, as assessed in the NIS (and throughout this chapter).

The residual impacts on non QI habitats and species within Lough Corrib cSAC are as follows:

- At the proposed River Corrib crossing the loss of c.0.15ha of a Dry meadows and grassy verges (GS2), Scrub (WS1), Buildings and artificial surfaces (BL3) and Wet grassland (GS4) mosaic on the west bank and, on the east bank, c.1.25ha of Dry calcareous and neutral grassland (GS1), c.1.45ha of Mixed broadleaved woodland (WD1) and loss of a small area of gravel track
- At the proposed drainage outfall for the N59 Link Road North c.0.03ha of a Treeline (WL2), Scrub (WS1) and Dry meadows and grassy verges (GS2) mosaic
- In the Menlough/Coolagh Lakes area c.0.08ha of Oak-Ash-Hazel Woodland (WN2), c.0.01ha of Wet grassland (GS4), c.0.01ha of Dry calcareous and neutral grassland (GS1), c.0.02ha of Scrub (WS1) along with some local road and gravelled access track
- In the vicinity of the proposed Lackagh Tunnel c.0.21ha of Oak-Ash-Hazel Woodland (WN2) and Scrub (WS1), c.0.09ha of Scrub (WS1), c.0.1ha of Dry calcareous and neutral grassland (GS1), a short section (c.20m) of Treeline (WL2), and c.0.08ha of a mosaic of Treelines (WL2), Scrub (WS1), Dry meadows and grassy verges (GS2) and Spoil and Bare Ground (ED2) habitat
- Impacts of the proposed road development on the local bat populations

None of these residual biodiversity effects compromise the overall biodiversity resource of Lough Corrib cSAC in any way that relates to the integrity of that site and therefore, no likely significant effects are predicted at any geographic scale

Therefore, the proposed road development will not result in a likely significant residual effect on any European site(s).

8.7.1.2 Natural Heritage Areas & proposed Natural Heritage Areas

The residual impacts of the proposed road development on Lough Corrib pNHA and Galway Bay Complex pNHA are as per Lough Corrib cSAC/SPA and Galway Bay Complex cSAC/Inner Galway Bay SPA in **Section 8.7.1.1**. As per the conclusions of that assessment the proposed road development is not likely to have a significant residual effect on either Lough Corrib pNHA or Galway bay Complex pNHA.

Mititgation measures will be implemented to ensure that the peatland habitats for which Moycullen Bogs NHA is designated, and the species they support, will not be affected by the proposed road development during construction or operation.

Therefore, the proposed road development will not affect the integrity of, or result in a likely significant negative residual effect on, any Natural Heritage Areas or proposed Natural Heritage Areas.

8.7.2 Habitats

A mitigation strategy will be implemented during construction and operation to minimise the effects of habitat loss and habitat degradation on biodiversity (**Section 8.6.2**).

Despite these mitigation measures, the proposed road development will result in permanent area loss of a number of Annex I habitat types. None of the areas of Annex I habitat that will be permanently lost are located with any European sites. In the case of the priority Annex I habitats affected, this results in a likely significant negative residual effect at the international geographic scale, as it is adding to an ongoing trend of habitat loss for these habitats of highest conservation concern that are in danger of disappearance at a European level. For non-priority Annex I habitat types, the habitat loss is considered to constitute a likely significant negative residual effect at the national geographic scale, as loss of habitat area affects the conservation status of each of these habitats nationally. The habitat types, and areas affected, are summarised in **Table 8.38** below.

Table 8.38: Summary of *Annex I/Annex I habitat loss

Annex I habitat type	Total Area within the proposed development boundary Potentially Impacted	Area to be Retained	Actual Permanent area of habitat loss	Residual Impact Significance
Turlough [*3180]	c.0.04ha within proposed development boundary (total	All (c.0.04ha)	None	No likely significant residual effect

Annex I habitat type	Total Area within the proposed development boundary Potentially Impacted	Area to be Retained	Actual Permanent area of habitat loss	Residual Impact Significance
	area of Turlough is c.0.1ha)			
Petrifying springs [*7220]	Two Petrifying spring feature at Lackagh Quarry	One feature to be retained	One Petrifying spring feature	Likely significant residual effect at the county geographic scale
Residual alluvial forest [*91E0]	c.0.1ha	None	c.0.1ha	Likely significant residual effect at the international geographic scale
Limestone pavement [*8240]	c.2.18ha	c.1.64ha	c.0.54ha	Likely significant residual effect at the international geographic scale
Limestone pavement/Calcareous grassland [*8240/6210]	c.0.12ha	All (Above Lackagh Tunnel – c.0.12ha)	None	No likely significant residual effect
Wet heath [4010]	c.2.06ha	None	c.2.06ha	Likely significant residual effect at the national geographic scale
Dry heath [4030]	c.1.96ha	c.0.11ha	c.1.85ha	Likely significant residual effect at the national geographic scale
Wet heath/Dry heath/*Molinia* mosaic [4010/4030/6410]	c.1.13ha	c.0.26ha	c.0.87ha	Likely significant residual effect at the national geographic scale

Annex I habitat type	Total Area within the proposed development boundary Potentially Impacted	Area to be Retained	Actual Permanent area of habitat loss	Residual Impact Significance
Calcareous grassland [6210]	c.1.14ha	c.0.44ha	c.0.7ha	Likely significant residual effect at the national geographic scale
Molinia meadow [6410]	c.1.02ha	c.0.74ha	c.0.28ha	Likely significant residual effect at the national geographic scale
Total area	c.9.75ha of Annex I habitats and 2 Petrifying spring features	c.3.35ha of Annex I habitats and 1 Petrifying spring feature	c.6.4ha of Annex I habitats and 1 Petrifying spring feature	

Similarly, despite the mitigation measures the proposed road development will result in likely significant negative residual effects, at the local geographic scale, on the following habitat of a local biodiversity value:

- Calcareous springs (FP1) - fifteen features
- Dry-humid acid grassland (GS3) - c.7.81ha
- Poor fen and flush (PF2) - c.0.13ha
- (Mixed) broadleaved woodland (WD1) - c.2.62ha
- Hedgerows (WL1) - c.7.8km
- Treelines (WL2) - c.4km

8.7.3 Rare and protected plant species

As there are no rare or legally protected plant species present within the ZoI of the proposed road development they will not be affected. Therefore, no mitigation measures are required and no residual impacts are predicted.

8.7.4 Mammals

8.7.4.1 Otter

A mitigation strategy will be implemented (and monitored) to minimise the risk of the proposed road development affecting water quality in receiving watercourses/waterbodies during construction which will ensure that there is not a likely significant negative residual effect on the local Otter population (**Section 8.6.7.1**).

Mitigation measures will be implemented (and monitored) to ensure that, during operation, the proposed road development does not result in a significant negative effect on the local Otter population as a result of severance/barrier effects or mortality risk: the provision of mammal passage facilities in conjunction with mammal resistant fencing (**Section 8.6.7.1.2**).

Therefore the proposed road development will not result in a likely significant negative residual effect on Otter, at any geographic scale.

8.7.4.2 Bats

A mitigation strategy will be implemented (and monitored) prior to and during construction to minimise the risk of direct harm to bats during demolition and tree felling, to provide temporary linear features to reduce the effects of severance of flight paths during construction. Significant residual impacts will still remain as some of the activities are unavoidable and can only be mitigated to a certain level of certainty:

- Demolition of 14 buildings within the proposed development boundary which will affect local populations of Soprano pipistrelle bats, Common pipistrelle bats, Brown long-eared bats and Lesser horseshoe bats
    - One maternity roost is being demolished, a Brown long-eared roost at Aughnacurra (PBR256)
    - One satellite roost for Lesser horseshoe bats will be demolished at Aughnacurra (PBR178) (a satellite roost for the Menlo Castle (PBR06) Lesser horseshoe maternity roost)
- Loss of foraging habitat is regarded to be most significant in the Menlough area where woodland-pasture-hedgerow habitat is being lost and is within the CSZ for the nationally-important population of Lesser horseshoe bats
- Inevitable elevated mortality rates due to vehicle collisions
- Mortality and severance/barrier effects caused by the proposed road development on individual bats. Whilst best practice has been followed in the design of the proposed road development and the inclusion of underpasses/culverts and a wildlife overpass, a small proportion of the local bat population will inevitably fly over the proposed road development and be vulnerable to vehicle collisions. A small proportion of the population will also be adversely affected by the barrier effect posed by the proposed road development across the landscape. The effect of this residual impact on Lesser horseshoe bats is predicted to be significant at a national geographic scale. The impact on other bat species is predicted to be significant at a local geographic scale

These residual impacts have been addressed further by the proposal for specific compensatory measures.

8.7.4.3 Badger

A mitigation strategy will be implemented (and monitored) during construction to ensure that the removal of badger setts and the predicted disturbance to Badger that will occur during construction does not contravene the protection afforded to the breeding and resting places of wild animals (including Badger) under Section 23 (5)(d) of the Wildlife Acts (**Section 8.6.7.3.1**).

Mitigation measures will be implemented (and monitored) to ensure that, during operation, the proposed road development does not result in a significant negative effect on the local Badger population as a result of severance/barrier effects or mortality risk: the provision of mammal passage facilities in conjunction with mammal resistant fencing (**Section 8.6.7.3.2**).

Therefore, the proposed road development will not result in a likely significant negative residual effect on Badger, at any geographic scale.

8.7.4.4 Other Mammal Species

A mitigation strategy will be implemented to minimise the risk of the proposed road development affecting water quality in receiving watercourses/waterbodies during construction which will ensure that there is not a significant negative effect on local aquatic or marine mammal populations (**Section 8.6.7.4.1**).

Mitigation measures will be implemented to ensure that, during operation, the proposed road development does not result in a significant negative effect on local mammal populations (excluding bats) as a result of severance/barrier effects or mortality risk: the provision of mammal passage facilities in conjunction with mammal resistant fencing (**Section 8.6.7.4.2**).

Therefore, the proposed road development will not result in a likely significant negative residual effect on any other mammal species (excluding bats), at any geographic scale.

8.7.5 Invertebrates

8.7.5.1 White-clawed crayfish

As there are no records of White-clawed crayfish from within the ZoI of the proposed road development they will not be affected. Therefore, no mitigation measures are required and no residual impacts are predicted.

8.7.5.2 Freshwater pearl mussel

As there are no records of Freshwater pearl mussel from within the ZoI of the proposed road development they will not be affected. Therefore, no mitigation measures are required and no residual impacts are predicted.

8.7.5.3 Marsh whorl snail

A mitigation strategy will be implemented during construction to minimise the risk of the proposed road development affecting water quality in receiving watercourses/waterbodies and to ensure that the existing groundwater regime is not affected. This will ensure that there is not a significant negative impact on the habitats supporting the Marsh whorl snail during construction (**Section 8.6.8.1.1**).

Mitigation measures will be implemented to ensure that the existing groundwater regime is not affected during operation (**Section 8.6.8.1.2**).

Therefore the proposed road development will not result in a likely significant negative residual effect on the Marsh whorl snail, at any geographic scale.

8.7.5.4 Marsh fritillary

A mitigation strategy will be implemented during construction to avoid any Marsh fritillary mortality during site clearance works (**Section 8.6.8.2.1**). No other likely significant effects on the Marsh fritillary butterfly are predicted during construction.

No likely significant negative effects on Marsh fritillary are predicted during operation and no mitigation measures are required.

Therefore the proposed road development will not result in a likely significant negative residual effect on the Marsh fritillary butterfly, at any geographic scale.

8.7.6 Birds

8.7.6.1 Breeding birds

A mitigation strategy will be implemented during construction to minimise the mortality risk and the effects of habitat loss and disturbance to breeding birds (**Section 8.6.9.1.1**). This includes retaining the ledge used as the Peregrine falcon nest site between 2015 and 2017 within the design and a seasonal restriction on construction works in the vicinity of the nest site.

A mitigation strategy will be implemented (and monitored) to minimise the mortality risk to the local Barn owl population posed by the proposed road development during operation (**Section 8.6.9.1.2**). This includes the provision of additional nesting structures and planting to discourage Barn owl from foraging along the proposed road carriageway.

Therefore, the proposed road development will not result in a likely significant negative residual effect on breeding bird species, at any geographic scale, with the exception of the Peregrine falcon. Due to the likely permanent loss of Lackagh Quarry as a nesting site, the proposed road development is likely to result in a significant negative residual effect on Peregrine falcon, at the county geographic scale.

8.7.6.2 Wintering birds

A seasonal restriction on blasting near Ballindooley Lough will ensure that there are no long-term effects on wintering bird populations from construction works associated with the proposed road development (**Section 8.6.9.2**).

No likely significant negative effects on wintering bird species are predicted during operation, and no mitigation measures are required.

Therefore the proposed road development will not result in a likely significant negative residual effect on wintering bird species, at any geographic scale.

8.7.7 Amphibians

A mitigation strategy will be implemented during site clearance works to minimise the risk of the proposed road development affecting water quality in receiving watercourses/waterbodies, to minimise the mortality risk, and to minimise the effects of habitat loss and disturbance, on the local Common frog and Smooth newt populations. This will ensure that construction of the proposed road development will not have any long-term effects, or affect the conservation status, of these amphibian species. It will also ensure that site clearance works will not contravene the protection afforded to the breeding and resting places of wild animals (including the Common frog and Smooth newt) under Section 23 (5)(d) of the Wildlife Acts (**Section 8.6.10.1**).

The design of the proposed road development, in conjunction with the network of mammal passage facilities, will ensure that there are no long-term severance or barrier effects to the local Common frog and Smooth newt populations associated with the proposed road development (**Section 8.6.10.2**).

Therefore the proposed road development will not result in a likely significant negative residual effect on the Common frog or the Smooth newt, at any geographic scale.

8.7.8 Reptiles

A mitigation strategy will be implemented during site clearance works to minimise the mortality risk, and to minimise the effects of habitat loss and disturbance, on the local Common lizard population. This will ensure that construction of the proposed road development will not have any long-term effects, or affect the conservation status, of the Common lizard. It will also ensure that site clearance works will not contravene the protection afforded to the breeding and resting places of wild animals (including the Common lizard) under Section 23 (5)(d) of the Wildlife Acts (**Section 8.6.11.1**).

The design of the proposed road development, in conjunction with the network of mammal passage facilities, will ensure that there are no long-term severance or barrier effects to the local Common lizard population associated with the proposed road development (**Section 8.6.11.2**).

Therefore the proposed road development will not result in a likely significant negative residual effect on the Common lizard, at any geographic scale.

8.7.9 Fish

In conjunction with the design of the proposed road development, mitigation measures will be implemented to minimise the effects of habitat loss on fish species, and to maintain fish passage along all watercourses crossed by the proposed road development, such that no population level effects are predicted (**Section 8.6.12.1**).

A mitigation strategy will be implemented during construction to minimise the risk of the proposed road development affecting water quality in receiving watercourses/waterbodies and to ensure that the existing groundwater regime is not affected. This will ensure that there is not a likely significant negative effect on fish species during construction (**Section 8.6.4**).

Mitigation measures will also be implemented to minimise the potential for disturbance or mortality of fish species during construction, such that no population level effects are predicted.

No likely significant negative effects on fish species are predicted during operation, and no mitigation measures are required.

Therefore the proposed road development will not result in a likely significant negative residual effect on fish species, at any geographic scale.

8.7.10 Local Biodiversity Areas

All of the local biodiversity areas impacted by the proposed road development will be affected to some degree by the likely significant effects associated with the proposed road development on the KERs that have been identified in each of those areas. These likely significant effects are accounted for, and described, above separately and this section provides some context for these residual impacts with respect to the locations of the local biodiversity area through which the proposed road development passes.

The residual impact of the loss of c.0.01ha of Residual alluvial forest [*91E0] habitat will have a residual impact on the Menlough to Coolough Hill local biodiversity area. The residual impact associated with this habitat loss has been assessed as significant at the international geographic scale.

The residual impact of the loss of c.0.54ha of Limestone pavement [*8240] habitat will have a residual impact on the Menlough to Coolough Hill local biodiversity area and the Doughiska local biodiversity area. The residual impact associated with this habitat loss has been assessed as significant at the international geographic scale.

The residual impact of the loss of c.4.78ha of peatland habitat mosaic (Wet heath [4010], Dry heath [4030] and *Molinia* meadow [6410]) will have a residual impact on the Coast Road (R336) to the N59 Moycullen Road local biodiversity area. The residual impact associated with this habitat loss has been assessed as significant at the national geographic scale.

The residual impact of the loss of c.0.7ha of Calcareous grassland [6210] habitat will have a residual impact on the Menlough to Coolough Hill local biodiversity area and the Doughiska local biodiversity area. The residual impact associated with this habitat loss has been assessed as significant at the national geographic scale.

The residual impact of the loss of c.0.28ha of *Molinia* meadow [6410] habitat will have a residual impact on the Ballindooley – Castlegar local biodiversity area. The residual impact associated with this habitat loss has been assessed as significant at the national geographic scale.

The residual impact of the loss of the calcareous springs (FP1) and the Petrifying springs [*7220] at Lackagh Quarry will have a residual impact on the Menlough to Coolough Hill local biodiversity area. The residual impact associated with this habitat loss has been assessed as significant at the local and county geographic scales, respectively.

The residual impact of the loss of c.7.81ha of dry-humid acid grassland (GS3) and c.0.13ha of Poor fen and flush habitat (PF2) will have a residual impact on the Coast Road (R336) to the N59 Moycullen Road local biodiversity area. The residual impact associated with this habitat loss has been assessed as significant at the local geographic scale.

Hedgerows and treelines will be impacted throughout the local area with the greatest concentrations affected in parts of the Coast Road (R336) to the N59 Moycullen Road local biodiversity area around Ballagh, in the Menlough to Coolough Hill local biodiversity area, and in the Doughiska local biodiversity area. The residual impact associated with this habitat loss has been assessed as significant at the local geographic scale.

The residual impact of the loss of Broadleaved woodland (WD1) and Oak-ash-hazel woodland (WN2) will have a residual impact on the Menlough to Coolough Hill local biodiversity area. The residual impact associated with this habitat loss has been assessed as significant at the local geographic scale.

The residual impact on the local Lesser horseshoe bat population will have a residual impact principally on the Menlough to Coolough Hill local biodiversity area, but is also likely to affect the River Corrib and the Coolagh Lakes local biodiversity area and the Ballindooley – Castlegar local biodiversity area. This residual impact associated has been assessed as potentially significant at the national geographic scale.

The residual impact on all other bat species recorded within the study area will have a residual impact on the Coast Road (R336) to the N59 Moycullen Road local biodiversity area, the River Corrib and the Coolagh Lakes local biodiversity area, the Menlough to Coolough Hill local biodiversity area, the Ballindooley – Castlegar local biodiversity area, and the Doughiska local biodiversity area. This residual impact associated has been assessed as significant at the local geographic scale.

The residual impact on the local Peregrine falcon population will have a residual impact on the Menlough to Coolough Hill local biodiversity area. This residual impact associated has been assessed as significant at the county geographic scale.

The residual impacts of the proposed road road development, as they relate to each of the local biodiversity area, are summarised below:

- Coast Road (R336) to the N59 Moycullen Road local biodiversity area
- Residual impact at the national geographic scale

  Peatland habitat mosaic (Wet heath [4010], Dry heath [4030] and *Molinia* meadow [6410])

- Residual impact at the local geographic scale

  Dry-humid acid grassland (GS3), Poor fen and flush habitat (PF2), Hedgerows and treelines (WL1/WL2), bats other than the Lesser horseshoe bat

River Corrib and the Coolagh Lakes local biodiversity area

- Residual impact at the national geographic scale

  Lesser horseshoe bat

- Residual impact at the local geographic scale

  Bat species other than the Lesser horseshoe bat

Menlough to Coolough Hill local biodiversity area

- Residual impact at the international geographic scale

  Limestone pavement [*8240] and Residual alluvial forest [*91E0]

- Residual impact at the national geographic scale

  Calcareous grassland [6210] and the Lesser horseshoe bat

- Residual impact at the county geographic scale

  Petrifying springs [*7220] and the Peregrine falcon

- Residual impact at the local geographic scale

  Calcareous springs (FP1), Broadleaved woodland (WD1), Hedgerows and treelines (WL1/WL2), Oak-ash-hazel woodland (WN2) and bats other than the Lesser horseshoe bat

Ballindooley – Castlegar local biodiversity area

- Residual impact at the national geographic scale

  Molinia meadow [6410] and the Lesser horseshoe bat

- Residual impact at the local geographic scale

  Bats other than the Lesser horseshoe bat

Doughiska local biodiversity area

- Residual impact at the international geographic scale

  Limestone pavement [*8240]

- Residual impact at the national geographic scale

Calcareous grassland [6210]

- Residual impact at the local geographic scale

  Hedgerows and treelines (WL1/WL2) and bats other than the Lesser horseshoe bat

8.8 Cumulative Impacts

This section of the report presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant effect on biodiversity.

The projects which are either in place, or proposed, which are considered in assessing the potential for cumulative impacts to increase the significance of the impacts predicted for the proposed road development on biodiversity are as follows:

- Galway Transport Strategy (GTS)
- M17 Galway to Tuam Road Project
- N18 Oranmore to Gort Road Project
- N83 Tuam Bypass
- M6 Motorway
- M6 (M17/M18) Motorway Service Area
- N59 Clifden to Maam Cross Road Project (objective in the *Galway County Development Plan 2015-2021*)
- N59 Maam Cross to Oughterard Road Project
- N59 Maigh Cuilinn (Moycullen) Bypass Road Project
- Galway to Dublin Cycleway
- Connemara Greenway (from Galway City to Clifden))
- Galway to Spiddal Greenway (Bearna to Spiddal Cycleway)
- R336 Bearna to Scríb via Ros an Mhíl Upgrade/Improvement (objective in the *Galway County Development Plan 2015-2021*)
- Sáilín to Silverstrand Coastal Protection Scheme
- Salthill Coastal Protection Works (Blackrock to Galway Golf Club)
- Proposed Galway Harbour Port Extension

The potential for other plans or projects to act cumulatively with the proposed road development to adversely affect the integrity of any European sites, is considered in Section 12 of the NIS (termed “in combination effects” in the context of the NIS assessment). The four European sites within the ZoI of the proposed road development are Lough Corrib cSAC, Galway Bay Complex cSAC, Lough Corrib SPA and Inner Galway Bay SPA. There is no potential for any other projects to act in combination with the proposed road development to adversely affect the integrity of any other European sites, as they are beyond the ZoI of the proposed road development.

The in combination assessment identified those plans and projects which have the potential to impact on Lough Corrib cSAC, Galway Bay Complex cSAC, Lough Corrib SPA and Inner Galway Bay SPA and assessed whether they had the potential to adversely affect the integrity of these European sites. Any plan or proposed project that could potentially affect these European sites in combination with the proposed road development must adhere to the overarching policies and objectives of the relevant land use plan(s), as dependent on the location of the specific plan or proposed project. These are the *Galway County Development Plan 2015-2021*, the *Galway City Council Development Plan 2017-2023*, the *Clare County Development Plan 2017-2022* and the *Mayo County Development Plan 2014-2020*[97]. The protective policies and objectives in these land use plans will ensure the protection of European sites across the identified potential impact pathways.

As the proposed road development will not affect the integrity of Lough Corrib cSAC, Galway Bay Complex cSAC, Lough Corrib SPA or Inner Galway Bay SPA, and given the protection afforded to European sites under the overarching land use plans, it was concluded that there is no potential for adverse effects on the integrity of any European sites to arise as a consequence of the proposed road development acting in combination (or cumulatively) with any other plans or projects.

The potential for cumulative impacts to arise are limited to those residual impacts associated with the proposed road development and those effects the proposed road development will have on the receiving environment that are measurable in some way, but themselves will not result in a likely significant residual effect on biodiversity.

The residual impacts associated with the proposed road development relate to the following:

- Habitat loss, including both the permanent loss of Annex I habitats and habitats valued as being of local importance
- The potential loss of a Peregrine falcon nest site due to long-term disturbance/displacement impacts
- Impacts on bats as a result of the construction and operation of the proposed road development

The other impacts associated with the proposed road development that are measurable in some way, but themselves will not result in a likely significant effect on biodiversity and these are also discussed below:

- Impacts on the existing hydrological and hydrogeological regimes

[97] Although the regional and national level Plans sit above the county and local plans in the hierarchy (e.g. Project Ireland 2040 – National Planning Framework and the Regional Planning Guidelines for the West Region 2010-2022), the NPF is given effect at a regional level by the RDP and projects to meet its aims will be implemented locally by the relevant local authority and must comply with the statutory planning requirements, and must be in accordance with the objectives and policies of the relevant land use plans (Development Plans, Local Area Plans etc.).

- Impacts on air quality
- Impacts to species as a result of disturbance or displacement

Impacts from habitat loss

As outlined in **Section 8.5.2**, habitat loss to development and land use change has been an ongoing impact locally which may have already had effects on local biodiversity. Those projects listed above have, or are likely to, result in habitat impacts (including those of a high biodiversity value such as Annex I habitat types) which may also have knock-on effects on fauna species. Therefore, land use change and habitat losses are likely to continue to some degree and the loss and fragmentation of habitat associated with the proposed road development will contribute to this trend locally.

The most notable habitat loss impacts are the losses of areas of internationally or nationally valued habitats: Limestone pavement [*8240], Residual alluvial forest [*91E0], Wet heath [4010], Dry heath [4030], Calcareous grassland [6210], *Molinia* meadow [6410] and a Petrifying spring [*7220]. There are also significant areas of habitat types of a local biodiversity value that will be lost: calcareous springs, reed and large sedge swamps, dry-humid acid grassland, poor fen and flush, broadleaved woodland, hedgerows and treelines. Habitat losses, regardless of their own habitat value, also have the potential to have an effect on the local fauna populations that they support. The most significant impact in that regard are the likely effects of habitat loss on the local bat populations; particularly the Menlo Castle Lesser horseshoe bat population (impacts on bats are discussed separately below).

The losses of areas of Annex I habitat associated with the proposed road development are considered to be at the highest level of geographic significance for the habitats involved. In addition, the proposed road development will be contributing to an existing trend of Annex I habitat loss locally. While the cumulative effect of habitat losses would increase the magnitude of the impact, it does not increase the geographic scale of the impact significance associated with the proposed road development. The protective polices in the *Bearna Local Area Plan 2007-2017*, the *Galway City Council Development Plan 2017-2023* and the *Galway County Development Plan 2015-2021* to protect biodiversity will moderate any future impacts on biodiversity, including those related to Annex I habitat types. Where the losses can be compensated for (see **Section 8.9** below), this offsets the contribution of the proposed road development to existing losses of the habitat type in question whilst ensuring that there is no potential for other developments to result in a significant cumulative impact.

In relation to areas of locally important habitats that will be lost, given the habitat types involved and that at any greater geographic scale they are likely to remain in a favourable conservation condition, any cumulative losses of these habitat types are not likely to increase the impact significance. The protective polices in place in the land use plans will also moderate any future losses of habitats of a biodiversity value. Where habitat losses can be compensated for this would also reduce the impact significance and the potential for any cumulative impacts with any future developments.

Impacts on Peregrine falcon

Due to the potential for long-term disturbance and displacement of the Lackagh Quarry Peregrine falcon pair from the existing nest site, the proposed road development is likely to result in a significant negative residual effect on Peregrine falcon, at the county geographic scale.

The two other Peregrine falcon nest sites that are present locally are likely to continue to support breeding Peregrine falcon. One site is a disused quarry which is zoned for agricultural use and is therefore, not likely to see any increased disturbance from development; the second nest site is a regularly occupied site in an active quarry and the baseline levels of disturbance, to which the resident Peregrine pair are habituated, are likely to remain. Neither of these sites are likely to be affected by any of the projects listed above, given their locations relative to where those strategies/projects will be implemented. Existing pressures at the county level on suitable nest site availability are expected to continue and may act cumulatively at the county geographic scale, but there isn't sufficient data available to quantify this. However, any additional pressures on the Peregrine falcon population will not increase the overall significance of the impact of the proposed road development to a national level impact given that the species is currently considered to be of a low conservation concern for its national population.

Therefore, there are no other projects that are likely to cumulatively act along with the proposed road development to increase the predicted impact significance of the proposed road development on Peregrine falcon from the likely significant negative residual effect, at the county geographic scale.

Impacts on bats

There are predicted residual impacts on bats include loss of roosts, loss of foraging habitat and the barrier/severance effect posed by roads.

Some proportion of existing roost sites in the vicinity of the proposed road development may deteriorate over time and become unsuitable for bats to use (e.g. derelict structures and old trees). Therefore, the roost sites that will be affected by the proposed road development could potentially contribute to such natural declines in other roost sites locally.

Loss of foraging habitat and barriers to bat movements may result from development of zoned land within the northern fringes of Galway City. Lands used by bats which are also zoned for development include light industrial zoning (C2.1) near the N84 Headford Road and Ballindooley, which may affect the proposed artificial roost via increased light spill. The recreation and amenity zoning at NUIG may also interact with the flight paths of bats moving between the Aughnacurra roosts and Menlo Castle and the use of those lands by foraging bats (e.g. where additional lighting may be proposed in the future). However, all of these impacts would be controlled by the assessment of individual planning applications which would consider the effects on protected species such as bats as part of their appraisal by the competent authority, having regard to the protective environmental policies outlines in the *Bearna Local Area Plan 2007-2017*, the *Galway City Council Development Plan 2017-2023*, the *Galway County Development Plan 2015-2021* and the *Ardaun Local Area Plan 2018-2024* to protect biodiversity[98]. Therefore, there are no additional cumulative impacts predicted regarding loss of foraging habitat or from barriers to bat movement.

Impacts on the existing hydrological or hydrogeological regimes

The proposed road development will not have any residual impacts on the existing hydrological regime in those surface water catchments crossed by the proposed road development or the receiving marine environment in Galway Bay, either through affecting existing flow conditions or affecting flooding regimes. The proposed road development will also not have any residual impact on the existing hydrogeological regime.

All of the surface water catchments, the groundwater bodies and the transitional waters of Galway Bay lie within the proposed National River Basin District; what was formerly the Western River Basin District (WRBD)[99]. The *River Basin Management Plan for the Western River Basin District in Ireland (2009-2015)*, and the current draft of the *The River Basin Management Plan for Ireland (2018-2021)*, aims to protect all waters within the district and, where necessary, improve waters and achieve sustainable water use. The purpose of the River Basin Management Plan is to reduce pollution levels, to restore good water quality status and to prevent deterioration in water quality in the river basins and groundwater bodies. There are many land use plans and projects that lie within the WRBD that have the potential to affect surface water and groundwater bodies. However, all of the overarching land use plans have environmental protective policies to protect the existing surface water and groundwater network.

Therefore, there are no other plans or projects that are likely to result in a significant effect on biodiversity, cumulatively with the proposed road development, as a consequence of surface water or groundwater impacts.

Impacts on air quality

There will be some change in air quality in the immediate vicinity of the proposed road development during operation, although it will not in itself result in a likely significant effect on biodiversity. The potential for cumulative impacts to occur through air quality effects is limited to the receiving environment in the immediate vicinity of the proposed road development and any future developments that would introduce air quality pollutants to this local area. There are no current or proposed projects that would be likely to contribute to the air quality baseline in any notable way in the vicinity of the proposed road development. Considering the land use zonings and objectives that relate to this area in the *Bearna Local Area Plan 2007-2017*, the *Galway City Council Development Plan 2017-2023*, the *Galway County Development Plan 2015-2021* and the *Ardaun Local Area Plan 2018-2024*, and the protective policies and objectives in both the *Galway City Council Development*

[98] For example, Policy 4.2 of the *Galway City Council Development Plan 2017-2023* which states "Protect and conserve rare and threatened flora and fauna and their key habitats, (wherever they occur) listed on Annex I and Annex IV of the EU Habitats Directive (92/43EEC) and listed for protection under the Wildlife Acts 1976-2000."

[99] For the next cycle of river basin management plans (2018-2021) the Eastern, South Eastern, South Western, Western and Shannon River Basin Districts will be merged to form one national River Basin District

Plan 2017-2023 and the overarching *Galway County Development Plan 2015-2021* to protect air quality and biodiversity, there are no other plans or projects that are likely to result in a significant effect on biodiversity, cumulatively with the proposed road development, as a consequence of air quality impacts.

Impacts on fauna species (excluding bats) as a result of disturbance or displacement

The proposed road development will not result in a likely significant residual effect on any fauna species (excluding bats) as a result of disturbance or displacement effects during either construction or operation.

Disturbance or displacement impacts during construction are temporary or short-term and are not likely to have long-term population level effects, even cumulatively with any future development projects that might be proposed.

During operation, the predicted ZoI from the proposed road development is limited to the immediate vicinity and will not result in a likely significant residual effect on any fauna species (excluding bats) as a result of disturbance or displacement effects. Considering the land use zonings in the areas through which the proposed road development passes (predominantly rural fringe, recreational amenity, amenity and agri-amenity), and the minimal effect of operational disturbance from road traffic, and the abundance of alternative suitable habitat locally to support those fauna species present, future development is not likely to result in in a significant effect on biodiversity, cumulatively with the proposed road development, as a consequence of disturbance or displacement impacts.

8.8.1 Summary of Residual Impacts

Table 8.39 below presents an overall summary of the likely significant effects of the proposed road development on biodiversity, in consideration of the mitigation measures.

Table 8.39: Summary of Likely Significant Residual Effects of the Proposed Road Development on Biodiversity (including mitigation)

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance	Mitigation Measures	Residual Impact Significance
Designated Areas for Nature Conservation					
Lough Corrib cSAC (including Lough Corrib pNHA)	International (National)	**Construction** Habitat loss Habitat degradation – tunnelling/excavation Habitat degradation – hydrogeology Habitat degradation – hydrology Habitat degradation – air quality Habitat degradation – non-native invasive plant species Mortality risk **Operation** Habitat degradation – hydrogeology Habitat degradation – non-native invasive plant species Mortality risk	Likely significant effect at the international geographic scale	see Section 10 of the NIS	No likely significant residual effect
Galway Bay Complex cSAC (including Galway bay Complex pNHA)	International (National)	**Construction** Habitat degradation – hydrology Habitat degradation – non-native invasive plant species Barrier effect Mortality risk	Likely significant effect at the international geographic scale	see Section 10 of the NIS	No likely significant residual effect

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance	Mitigation Measures	Residual Impact Significance
Lough Corrib SPA (including Lough Corrib pNHA)	International (National)	**Construction** Habitat degradation – hydrogeology Habitat degradation – hydrology Disturbance/displacement **Operation** Habitat degradation – hydrogeology	Likely significant effect at the international geographic scale	see Section 10 of the NIS	No likely significant residual effect
Inner Galway Bay SPA including Galway bay Complex pNHA)	International (National)	**Construction** Habitat degradation – hydrogeology Habitat degradation – hydrology Disturbance/displacement **Operation** Habitat degradation – hydrogeology	Likely significant effect at the international geographic scale	see Section 10 of the NIS	No likely significant residual effect
Moycullen Bogs NHA	National	**Construction** Habitat degradation – air quality Habitat degradation – non-native invasive plant species Habitat degradation – hydrology **Operation** Habitat degradation – non-native invasive plant species	Likely significant effect at the national geographic scale	Air quality during construction – **Section 8.6.3** Non-native invasive plant species during construction and operation – **Section 8.6.6** and **Appendix A.7.5** Water quality during construction – **Section 8.6.4**	No likely significant residual effect

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance	Mitigation Measures	Residual Impact Significance
Habitats (outside of designated areas for nature conservation)					
Limestone pavement [*8240]	International Importance	**Construction** Habitat loss Habitat degradation – air quality Habitat degradation – non-native invasive plant species **Operation** Habitat degradation – non-native invasive plant species	Likely significant effect at the international geographic scale	To reduce the scale of habitat loss – see **Section 8.6.2.1** Air quality during construction – **Section 8.6.3** Non-native invasive plant species during construction and operation – **Section 8.6.6** and **Appendix A.7.5**	Likely significant residual effect at the international geographic scale
Petrifying springs [*7220]	International Importance	**Construction** Habitat loss	Likely significant effect at the county geographic scale (see **Section 8.5.4.3** under petrifying springs)	To reduce the scale of habitat loss – see **Section 8.6.2.1**	Likely significant residual effect at the county geographic scale (see **Section 8.7.2**)
Calcareous grassland [*6210/6210]	International/National Importance	**Construction** Habitat loss Habitat degradation – air quality Habitat degradation – non-native invasive plant species	Likely significant effect at the national geographic scale (No *6210 affected – see **Section 8.5.4.3**	To reduce the scale of habitat loss – see **Section 8.6.2.1**	Likely significant residual effect at the national geographic scale

8.9 Compensation

Where there are significant residual biodiversity impacts as a result of the proposed road development, despite the mitigation measures proposed, compensatory measures are proposed to offset or reduce the predicted impacts[103]. These are not compensatory measures in the context of the requirements of Article 6(4) of the Habitats Directive as they are not compensating for an impact that would adversely affect the integrity of any European site. As concluded in the NIS, the proposed road development will not result in such an impact on any European site.

The likely significant residual effects of the proposed road development relate to habitat loss, the potential permanent loss of a Peregrine falcon nest site, and impacts on the local bat populations. Each of these are discussed below with regard to whether compensatory measures are feasible and likely to succeed in compensating for the potential impacts of the proposed road development.

8.9.1 Habitat loss

Limestone pavement [*8240] has a clint and gryke, or shattered pavement, structure which supports the vegetation characteristic of this habitat type. This underlying rock structure is created over millennia by geological and weathering processes and cannot be artificially recreated and is effectively a non-renewable habitat resource. Therefore, the losses of Limestone pavement habitat associated with the proposed road development cannot be compensated.

Petrifying springs [*7220] are a product of the interaction of groundwater and the underlying geology to create a tufa forming spring that supports the associated species assemblage to correspond to this priority Annex I habitat type. Such features cannot readily be artificially recreated with any degree of certainty and, as per Limestone pavement, are effectively a non-renewable habitat resource. Therefore, the loss of a Petrifying spring associated with the proposed road development cannot be compensated.

Wet heath [4010] is a habitat type that forms on shallow peats with impeded drainage. In the western part of the study area, this is due to the underlying bedrock and undulating topography retaining a water table near to the surface. Wet heath cannot readily be artificially recreated with any degree of certainty. Therefore, the loss of Wet heath associated with the proposed road development cannot be directly compensated.

The areas of Residual alluvial forest [*91E0], Dry heath [4030], Calcareous grassland [6210] and *Molinia* meadow [6410] that will be lost as a result of the proposed road development will be compensated. In each case the area of each habitat type being provided is greater than that being lost. In relation to Dry heath, the area of habitat being provided is greater than the combined losses associated with this habitat type and any Wet heath/*Molinia* meadow mosaics (c.4.78ha). Although this does not reduce the residual impact associated with the loss of Wet heath habitat, it is included in order to provide a biodiversity gain for peatland

[103] "Compensation describes measures taken to make up for residual effects resulting in the loss of, or permanent damage to ecological features despite mitigation" (CIEEM, 2016)

habitats in light of the fact that Wet heath cannot in itself be directly compensated for. This is summarised below in **Table 8.40**.

The full details of the Habitat Compensation Management Plan for each of the Annex I habitat types being compensated for, including monitoring, are presented in **Appendix A.8.26**. The areas where compensatory habitats will be created are shown on **Figures 8.23.1** to **8.23.14**.

In compensating for the losses of these habitat types, the proposed road development is not likely to result in a significant residual effect, at any geographic scale, on Residual alluvial forest [*91E0], Dry heath [4030], Calcareous grassland [6210] or *Molinia* meadow [6410].

Table 8.40: Summary of Residual PriorityAnnex I/Annex I habitat loss after compensation

Annex I habitat type	Permanent Area of Habitat Loss	Area of Compensatory Habitat Created	Residual Habitat Loss	Residual Impact Significance Post-compensation
Petrifying springs [*7220]	One Petrifying spring feature	n/a	One Petrifying spring feature	Likely significant residual effect at the county geographic scale
Residual alluvial forest [*91E0]	c.0.1ha	c.0.18ha	None	No likely significant residual effect
Limestone pavement [*8240]	c.0.54ha	n/a	c.0.54ha	Likely significant residual effect at the international geographic scale
Wet heath [4010]	c.2.06ha	n/a	c.2.06ha	Likely significant residual effect at the national geographic scale
Dry heath [4030]	c.1.85ha	c.7.06ha	None	No likely significant residual effect
Wet heath/Dry heath/*Molinia* mosaic [4010/4030/6410]	c.0.87ha	n/a	c.0.87ha[104]	Likely significant residual effect at the national geographic scale
Calcareous grassland [6210]	c.0.7ha	c.7.14ha	None	No likely significant residual effect

[104] Considered as Wet heath habitat for the purposes of the impact assessment, the loss of which cannot be directly compensated for.

Annex I habitat type	Permanent Area of Habitat Loss	Area of Compensatory Habitat Created	Residual Habitat Loss	Residual Impact Significance Post-compensation
Molinia meadow [6410]	c.0.28ha	c.0.49ha	None	No likely significant residual effect

There are a number of habitat types of a local biodiversity importance that will be permanently lost as a result of the proposed road development, and where significant residual negative effects are likely:

- Calcareous springs (FP1)
- Dry-humid acid grassland (GS3)
- Poor fen and flush (PF2)
- (Mixed) broadleaved woodland (WD1)
- Hedgerows (WL1)
- Treelines (WL2)

Of these, the planting proposed in the landscape design will compensate for the loss of the areas of (mixed) broadleaved woodland (WD1), hedgerows (WL1) and treelines (WL2) by providing a greater area to that being permanently lost to the proposed road development, as follows:

- (Mixed) broadleaved woodland (WD1) - > 2.62ha
- Hedgerows (WL1) - > 7.8km
- Treelines (WL2) - > 4km

In compensating for the losses of these habitat types, the proposed road development is not likely to result in a significant residual effect, at any geographic scale, on (mixed) broadleaved woodland (WD1), hedgerows (WL1) and treelines (WL2).

However, the proposed road development is likely to have a significant residual negative effect, at the local geographic scale, as a result of the permanent loss of fifteen Calcareous spring features (FP1), c.7.81ha of Dry-humid acid grassland (GS3) and c.0.13ha of Poor fen and flush habitat (PF2).

8.9.2 Bats

8.9.2.1 Compensation for loss of bat roosts

Loss of the more “significant” roosts (e.g. maternity roosts or roosts used by Lesser horseshoe bats) will be compensated by the erection of replacement structures (artificial roosts) in locations close to the original roost.

There is a dual purpose to the artificial roosts. Firstly, to ensure that there is no net loss of roosting opportunities for the bats confirmed to be roosting within the proposed development boundary. Secondly, it has been recognised that there will be an inevitable increase in mortality rates due to road collisions as suggested by scientific evidence (see **Section 8.5.6.2.2**). So the second function of the replacement roosts is to create improved conditions for bats to breed and to offset the likely increase in mortality.

Four artificial roost structures are proposed as set out below. The detailed fit-out of these artificial roosts will follow the recommendations of an experienced bat ecologist and further consultation with the Vincent Wildlife Trust will take place to ensure that their experiences in these techniques are taken into account.

Artificial roost structures will be screened from the effects of construction phase disturbance by means of solid hoarding or brushwood screens with an appropriate buffer zone around the roost. The dimensions of the planting will depend on the local topography and surrounding landscape and will be decided on a case-by-case basis by the bat ecologist.

It should be noted that the mitigation strategy, outlined above in **Section 8.6.7.2**, has included ensuring that passage underneath the proposed road development in the vicinity of the roosts has been facilitated by including culverts underneath the proposed road development in locations as close to the roosts as possible.

Proposed Aughnacurra maternity/hibernation roost for Lesser horseshoe bats and Brown long-eared bats

The proposed replacement roost will be located close to the existing Aughnacurra roost (PBR178) structure.

The proposed roost within the proposed development boundary will be screened with brushwood fencing or similar semi-solid screens c.2m high for the construction stage and will also be planted up around it as soon as the roost is constructed to provide long-term screening during the operation of the proposed road development. Non-native ornamental species may be used to provide screening in this case as it is in keeping with the suburban setting.

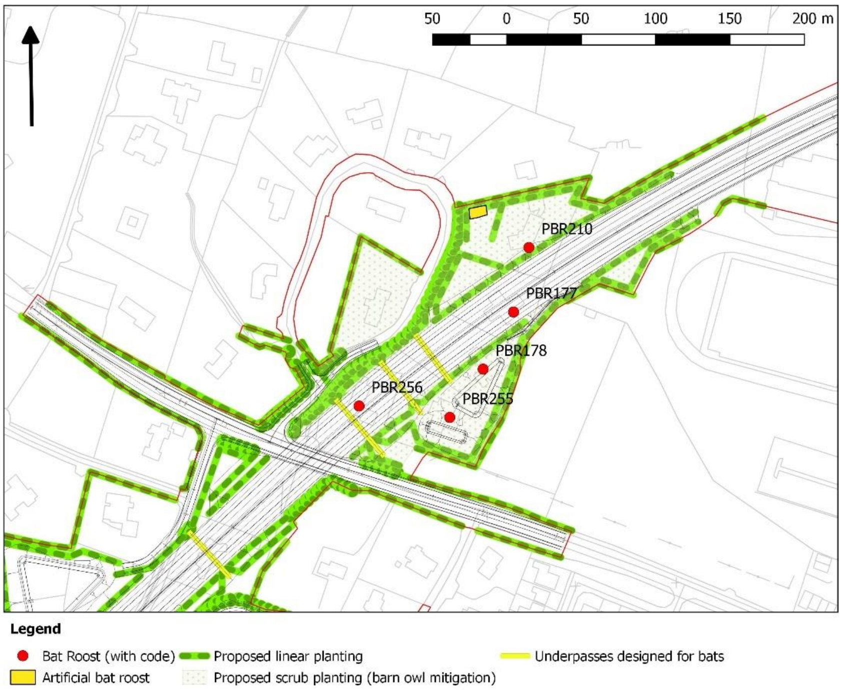
The design of the roost will take account of the Vincent Wildlife Trust (VWT) guidance[105] and will follow the following design parameters:

[105] Vincent Wildlife Trust (2015) *Lesser Horseshoe Bat: Conservation Handbook.*

- The template for the design will be taken from the roost at Garryland, Co. Galway constructed for the N18 Oranmore to Gort road development which has been shown to have worked successfully since its completion in 2011
- Single storey structure with southwest orientation for maximum solar gain on the pitched roof
- Location as set out in **Plate 8.5** below in corner of garden to be acquired
- Rendered block wall structure with natural slate roof. The exterior walls can be clad with rough stone or a material designed to have no adverse visual impact
- The building will have a footprint of c.10m x 8m with a steep pitched slate roof, partitions in the ground floor and roof space and an attic floor laid down with an open hatches for access for bats
- Plywood partitions will be installed within the roof voids to create bat "hotboxes" and separate roosting spaces for different species so that the brown long-eared bat roost can also be accommodated in the same building
- The interior of the roof should be lined with BS747 bituminous felt. All ceilings on the ground floor will be fitted with rough wood
- The entry point for bats shall be on the western side away from the proposed road development and close to the vegetation on the eastern perimeter which will be retained and enhanced. The entry point will be c.500mm x 300mm with bars set 125mm apart and lead flashing to be placed over the window sill under the hatch to prevent predator entry
- The northern corner will include a hibernation room at ground level which will be lined with concrete blocks and insulated to provide suitable conditions for hibernation. Plywood partitions will hang down from the ceiling to provide sheltered pockets at ceiling level. An earth floor will maintain humidity and some of the guttering will be piped inside to create an optional water-filled trough along one wall so that humidity levels can be adjusted if needed
- No water or electricity services are required
- Access for surveyors will be via a door on the southern side. Bats will be allowed to fly around the ground floor via an open hatch in the attic floor near the entry point

The proposed location (within the proposed development boundary) is close to vegetation which is important cover for bats entering and leaving. Additional planting is proposed to link the roost to the perimeter and to connecting features in the wider landscape.

Plate 8.5: Proposed location of Aughnacurra artificial roost structure (not to scale)



Menlo Castle alternative roost - Lesser Horseshoe maternity/hibernation roost

This roost is not replacing any specific loss of roost but is a critical part of the bat compensation measures. It will assist to increase the recruitment in the local Lesser horseshoe bat population so as to offset any increases in mortality as a result of the potential impacts of the proposed road development. The current roost in the chimney of the castle (PBR06) is likely to be unstable, inadequate and vulnerable to being lost if the castle falls into further disrepair. The new Menlo Castle roost would be better in design and aim to increase natural birth rates and thereby neutralise or overturn any negative impacts of the proposed road development. The preferred location is in a field to the east of the castle.

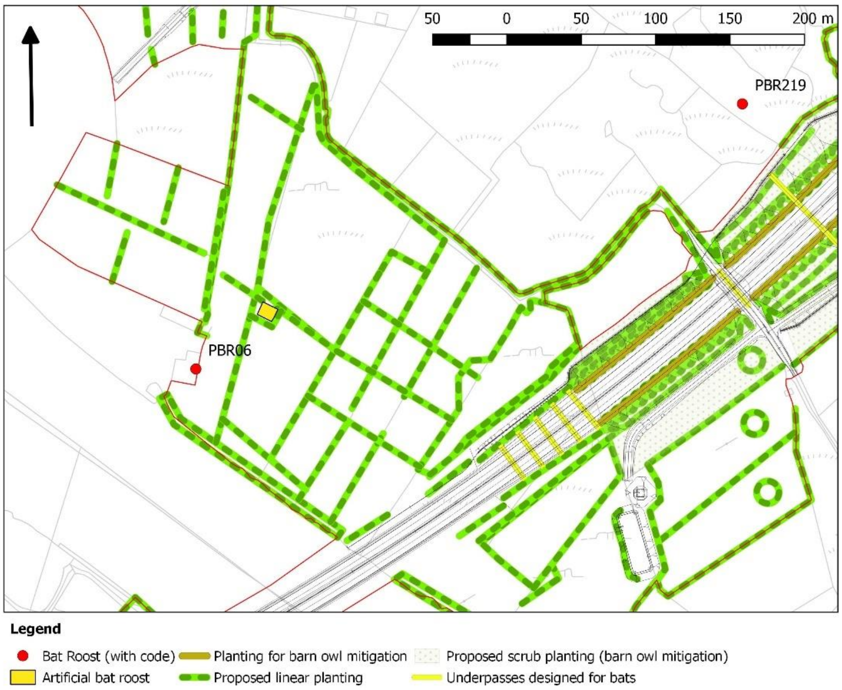
The design of the roost has taken account of the Vincent Wildlife Trust (VWT) guidance and following consultation with Dr Kate McAney and Ruth Hanniffy (VWT) and will follow the following design parameters:

- The template for the design will be taken from the roost at Garryland, Co. Galway constructed for the N18 Oranmore to Gort road development which has been shown to have worked successfully since its completion in 2011.
- Single storey structure with southern orientation for maximum solar gain on the pitched roof.
- Location as set out in **Plate 8.6** below in the northwest corner of the field close to Menlo Castle (PBR06).
- Rendered block wall structure with natural slate roof. The exterior walls can be clad with rough stone or a material designed to have no adverse visual impact.

Additional planting around the perimeter of the building will also screen it from view.

- The building will have a footprint of c.10m x 8m with a steep pitched slate roof, partitions in the ground floor and roof space and an attic floor laid down with an open hatches for access for bats. All ceilings on the ground floor will be fitted with rough wood.
- Plywood partitions will be installed within the roof voids to create bat “hotboxes” and separate roosting spaces for different species so that other bat species roost can also be accommodated in the same building.
- 4 no. wooden Kent bat boxes will be erected on the gable end of the structure to provide roosting opportunities for Daubenton’s and Pipistrelle bat species. See: http://www.bats.org.uk/publications_download.php/938/Kent_Bat_Box_Jul2013_copy.pdf
- The interior of the roof will be lined with BS747 bituminous felt or equivalent bituminous felt
- The entry point for bats shall be on the west gable end sides away from the proposed road development and close to the vegetation on the eastern perimeter which will be retained and enhanced. The entry point will be c.500mm x 300mm with bars set 125mm apart and lead flashing to be placed over the window sill under the hatch to prevent predator entry.
- The northern corner will include a hibernation room at ground level which will be lined with concrete blocks and insulated to provide suitable conditions for hibernation. Plywood partitions will hang down from the ceiling to provide sheltered pockets at ceiling level. An earth floor will maintain humidity and some of the guttering be piped inside to create an optional water-filled trough along one wall so that humidity levels can be adjusted if needed.
- No water or electricity services are required.
- Access for surveyors will be via a door on the southern side. Bats will be allowed to fly around the ground floor via an open hatch in the attic floor near the entry point.
- The proposed location within the proposed development boundary is close to vegetation which is important cover for bats entering and leaving. Additional planting is proposed to link the roost to the perimeter and to connecting features in the wider landscape.

Plate 8.6: Proposed location of Menlo Castle artificial roost structure

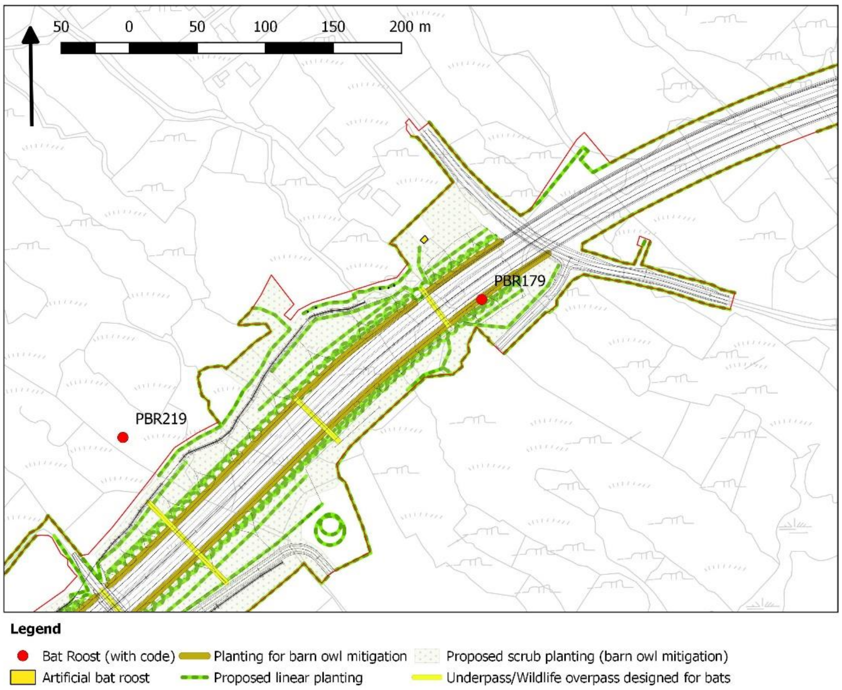


Menlough Woods Replacement Night roost for Lesser horseshoe bats and Soprano pipistrelle and Brown long-eared bats roosts

This is to replace a night roost for Lesser horseshoe bats (PBR219) and also replace roosts for Soprano pipistrelle bats (PBR179) and Brown long-eared bats (PBR179). It will be located near the edge of the proposed development boundary west of An Bóthar Nua and will be a simple wooden shed type structure (1m wide, 2.5m high, 2m deep). The footprint will be much smaller than the area indicated below on **Plate 8.7**. The design parameters include:

- Steep pitched slate roof facing southeast
- Plywood “ceiling” with access open hatch 300mm x 300mm for bats
- Access for bats via gap over access door 500mm x 500mm
- Access for birds prevented by installing plywood baffle 1m behind access gap
- Roof lined with BS747 bituminous felt

Plate 8.7: Proposed location of Menlough Woods artificial night roost structure



Ballindooley Night/Day roost for Brown long-eared and Pipistrelle bat and night/day/hibernation roost for Lesser horseshoe bats

This roost is to replace a Lesser horseshoe day/night roost on the N84 Headford Road (PBR and to replace roosts for Pipistrelle and Brown long-eared bats (PBR204, PBR182, PBR196). The structure will be a small block building (e.g. 6m x 8m footprint) with natural slate roof and some external features e.g. Kent bat boxes for use by other bats species.

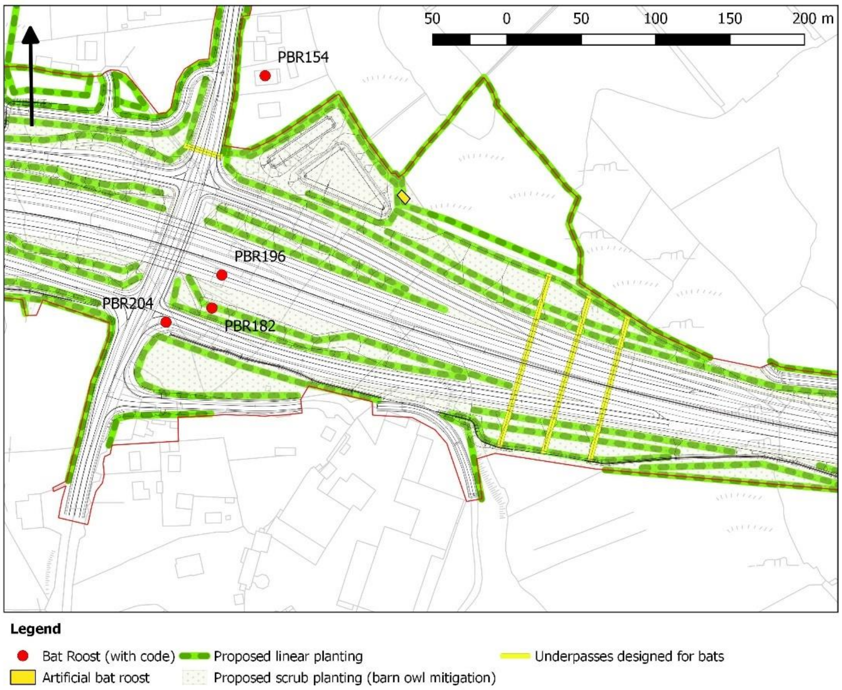
The design parameters include:

- Single storey structure with southwest orientation for maximum solar gain
- Location as set out in **Plate 8.8** below abutting the vegetation for good connections to foraging and shelter
- Rendered block wall structure with natural slate roof and can be clad and designed so as to have no adverse visual impact
- The building would have a footprint in the region of 6m x 8m with a steep pitched slate roof, partition wall in the ground floor and roof space and an attic floor laid down with an open hatch for access for bats[106]
- Plywood partitions may be installed within the roof voids to create bat "hotboxes" and separate roosting spaces for different species
- The interior of the roof should be lined with BS747 bituminous felt

[106] Vincent Wildlife Trust (2015) *Lesser Horseshoe Bat: Conservation Handbook.*

- Entry points for bats shall be on the east facing sides away from the proposed road development and close to the vegetation to the north which will be retained and enhanced
- The northern corner will include a hibernation room at ground level which will be lined with concrete blocks and insulated to provide suitable conditions for hibernation. Plywood partitions will hang down from the ceiling to provide sheltered pockets at ceiling level. An earth floor will maintain humidity and some of the guttering be piped inside to create an optional water-filled trough along one wall so that humidity levels can be adjusted if needed
- No water or electricity services are required
- Access for surveyors will be via a door on the southern side

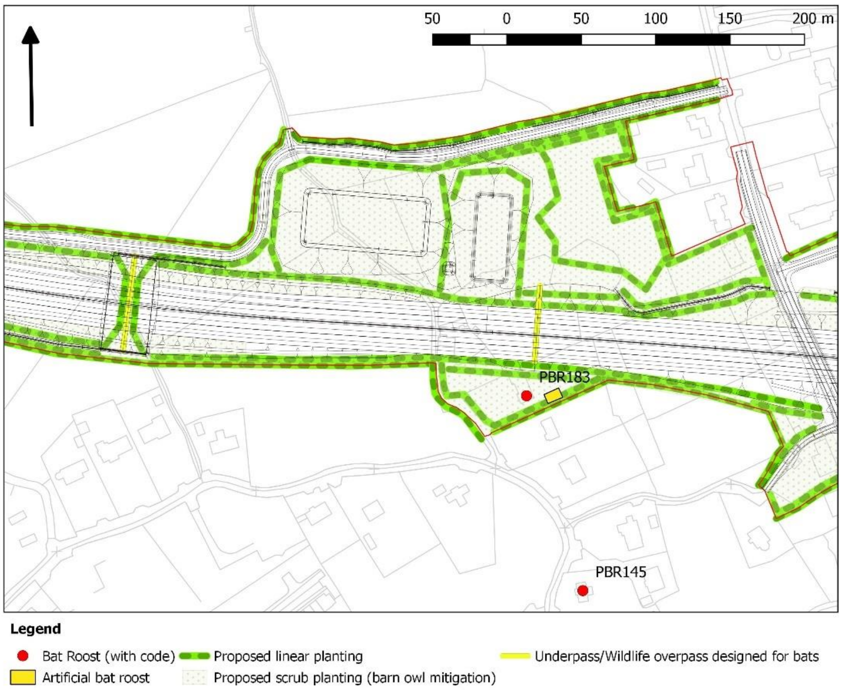
Plate 8.8: Proposed location of Ballindooley artificial night roost structure options



Retrofitting of Existing Structure

At Ch. 12+960 the detached converted garage (next to PBR183) to the south of the proposed road development to be retained and converted for use by several species including Brown long-eared bats and Lesser horseshoe bats. This building is in a strategically-important location as it will connect to the linear planting on the south side of the proposed road development and is just c.250m from the proposed Castlegar Wildlife Overpass in and within a local ecological corridor leading to Cooper's Cave, a proven hibernation and mating site for Lesser horseshoe bats. This structure will undergo minor interior and exterior modifications to create warm areas in the roof space for summer roosting and breeding and also cold conditions for hibernation. **Plate 8.9** shows this location below:

Plate 8.9: Retrofitted roost near PBR183, Castlegar



Bat Boxes

Bat boxes will preferably be located near the roosts to be lost but not immediately adjacent to the proposed road development where risk of collision with vehicles is highest.

Bat boxes will be erected by, or under the supervision of, a bat specialist.

These bat boxes will target Common and Soprano pipistrelle bats and Brown long-eared bats and will consist of Schwegler Type 1FF and 2FN bat boxes (or equivalent) as these have been demonstrated as being successful for these species in Ireland[107]. Mounting boxes on poles close to the edge of tree canopies will also allow the long-term retention of the boxes, as opposed to mounting boxes on small trees which have limited longevity.

A rocket box (as shown in **Appendix A.8.25** - see Drawing GCOB-3000-D-002 in Annex F of the bat derogation licence application) will be installed at Ch. 3+320 near the roost at PBR241, rather than a bat box fixed to the building itself, so as not to detract from its cultural heritage value.

Box locations, as shown on **Figure 8.24.1** to **8.24.15**, will include the following:

- Ch. 3+320: Rocket box to be erected to west of the building PBR241

[107] McAney K. and Hanniffy, R. (2015) *The Vincent Wildlife Trust's Irish Bat Box Schemes* http://www.mammals-in-ireland.ie/wp-content/uploads/2015/11/Ireland-Bat-Box-Project-Report-WEB.pdf

- Ch. 10+050: 5 boxes to be erected along the edge of the tree canopy near the underpass
- Ch. 11+400: 5 boxes to be erected on the entrance road into Lackagh Quarry
- Ch. 15+100: 5 bat boxes to be erected south of Galway Racecourse

In the case of bat boxes provided as replacements for bat tree roosts to be felled, boxes will be Schwegler Type 1F bat boxes (or equivalent) erected on suitable trees or structures retained within the proposed development boundary in the vicinity of the tree to be lost where possible. The type and siting of any bat boxes required will be determined by the bat specialist at that time but preliminary areas for bat boxes have been identified in the areas of woodland around Menlough, Coolough, on retained structures and the quarry walls at Lackagh Quarry and in areas near attenuation and infiltration ponds.

All new roosts, retrofitted structures and bat boxes will be erected in advance of the commencement of site clearance so that replacement roosts are available to bats and that there is reasonable chance that they will have discovered them prior to loss of the existing roost. Boxes can be erected at any time of year and preferably as soon as the necessary consents are in place for the proposed road development.

Protection of proposed artificial roosts during construction works

- Newly-created roosts and bat boxes within the proposed development boundary will be protected from the adverse effects of noise and lighting during the construction phase as it is an essential element of the mitigation strategy that they are accessible and usable by bats during this time
- All existing and proposed artificial roosts retained within the proposed development boundary will be surrounded with wooden panels to a height that allows shading and shelter of key roost access features
- Planting around the existing and proposed artificial roosts retained within the proposed road development will include fast growing shrub species, or fast-growing willow if the ground conditions permit. Planting will aim to guide bats away from the open construction zone toward linear features. Use of non-native species may be appropriate in some locations where it is important to get vegetation established
- All structures will be locked and not used for other purposes such as storage of materials or shelter
- The maintenance of the existing and proposed artificial roosts retained within the proposed development boundary, in a state that they are accessible and usable by bats, will be carried out by the Contractor until the completion of the proposed road development whereby it will be taken in charge by the local authority. Maintenance will include standard building repairs over time and responding to the results of the roost monitoring (e.g. increasing or reducing humidity)

8.9.2.2 Compensation for loss of foraging habitat

Approximately 7ha of woodland-pasture-hedgerow-scrub habitat will be removed from the area between the River Corrib and An Bóthar Nua in Menlough. This habitat is used by the Lesser horseshoe bat population and therefore there is a risk that there may be reduced breeding success if replacement planting is not made available.

An area of land has been identified which is within the known core foraging area of the Menlo Castle roost (PBR06) but is not optimal feeding habitat. It is composed of open fields of varying size used for low density cattle grazing. Hedgerows in this area will be augmented and thickets of hazel, hawthorn, holly and oak will be provided in several of the fields to create pockets of wood and grassland habitat. Grazing will continue on the lands as it has been shown that foraging over grazed land is preferred to ungrazed lands (Downes et al, 2016). Connectivity to foraging areas will also be secured through tying the proposed planting strips to hedgerows and woodland edges.

Planting of new hedgerows in fields between the proposed road development and Menlo Castle will improve the foraging resources of this core foraging area. Such planting will include an additional native hedgerows planted across the existing fields to increase the lengths of hedgerows close to the proposed new roost for Lesser horseshoe bats (refer to **Section 8.6.7.2**). The fields will still be grazed and the hedgerows can be fitted with field gates as required providing gaps are kept to a minimum.

The area of habitat enhancement for the purposes of offsetting the loss of suitable bat habitat due to the proposed road development amounts to approximately 8ha (refer to **Figure 8.24.7**).

8.9.2.3 Proposed Monitoring Programme

The monitoring programme described in **Section 8.6.7.2.3** above also relates to the compensation measures for bats described in this section.

8.9.3 Peregrine falcon

While artificial nest sites for Peregrine falcon can, and have been proven to, be successful, they require suitable cliff face or building of sufficient height at the proposed nest site. However, providing such nest sites does not guarantee that they will be taken up by either the Peregrine pair being displaced or occupied by another breeding pair in the future; particularly when they would likely be remote from the existing site, by at least a few kilometres, due to the topography of the surrounding land and the type and height of building structures nearby. Therefore, the potential loss of a Peregrine falcon nest site associated with the proposed road development cannot be compensated.

8.10 Summary

The proposed road development, despite the implementation of the mitigation and compensation measures proposed, will have the following likely significant residual effects on biodiversity:

- A likely significant residual effect, at the international geographic scale, for the permanent loss of c.0.54ha of the priority Annex I habitat Limestone pavement [*8240]
- A likely significant residual effect, at the national geographic scale, for the permanent loss of c.2.93ha of the Annex I habitat Wet heath [4010][108]
- A likely significant residual effect, at the county geographic scale, for the permanent loss of a Petrifying spring [*7220] feature at Lackagh Quarry
- A likely significant residual effect, at the county geographic scale, for the potential permanent loss of a Peregrine falcon nest site at Lackagh Quarry
- A likely significant residual effect, at the local geographic scale, on all bat species due to the presence of the proposed road development within their foraging areas
- A likely significant residual effect, at the local geographic scale, for the permanent loss of 15 calcareous springs (FP1) at Lackagh Quarry, c.7.81ha of Dry-humid acid grassland (GS3) and c.0.13ha of Poor fen and flush habitat (PF2)

These significant residual impacts will also affect the following local biodiversity areas:

- Coast Road (R336) to the N59 Moycullen Road local biodiversity area

  Residual impact at the national geographic scale for the loss of Wet heath [4010] habitat

  Residual impact at the local geographic scale for the loss of Dry-humid acid grassland (GS3) and Poor fen and flush habitat (PF2) along with impacts on bat species present here

- River Corrib and the Coolagh Lakes local biodiversity area

  Residual impact at the local geographic scale due to impacts on bat species present here

- Menlough to Coolough Hill local biodiversity area

  Residual impact at the international geographic scale for the loss of Limestone pavement [*8240] habitat

  Residual impact at the county geographic scale for the loss of Petrifying springs [*7220] and impact on the Peregrine falcon

[108] As noted in **Table 8.40**, this comprises c.2.13ha of Wet heath dominated habitat and an additional c.0.87ha of habitat mosaic which contains Wet heath.

Residual impact at the local geographic scale from the loss of Calcareous springs (FP1) and along with impacts on bat species present here

- Ballindooley – Castlegar local biodiversity area

  Residual impact at the local geographic scale due to impacts on bat species present here

- Doughiska local biodiversity area

  Residual impact at the international geographic scale for the loss of Limestone pavement [*8240] habitat

  Residual impact at the local geographic scale due to impacts on bat species present here

Although the significant residual effects associated with the losses of Limestone pavement and Wet heath habitat cannot be directly compensated for, areas of related habitats will be created to provide an overall biodiversity gain for both peatland and limestone associated habitats locally. The area of Dry heath habitat being provided is c.7.06ha which is greater than the combined losses of all peatland habitats combined (c.4.78ha). The area of Calcareous grassland habitat being provided is c.7.14ha which is greater than the combined losses of Limestone pavement and Calcareous grassland habitat combined (c.1.24ha).

Table 8.41 presents an overall summary of the ecological receptors, their valuation and potential impacts. It presents the proposed mitigation measures for these potential impacts, the residual impacts, proposed compensation measures where applicable and the overall residual impact significance post-compensation.

Table 8.41: Summary of the Likely Significant Residual Effects of the Proposed Road Development on Biodiversity (post-compensation)

Ecological Receptor	Ecological Valuation (after National Roads Authority, 2009)	Impacts with the Potential to result in Likely Significant Effects	Potential Impact Significance	Mitigation Measures	Residual Impact Significance	Compensation	Residual Impact Significance Post-compensation
Designated Areas for Nature Conservation							
Lough Corrib cSAC (including Lough Corrib pNHA)	International (National)	**Construction** Habitat loss Habitat degradation – tunnelling/excavation Habitat degradation – hydrogeology Habitat degradation – hydrology Habitat degradation – air quality Habitat degradation – non-native invasive plant species Mortality risk **Operation** Habitat degradation – hydrogeology Habitat degradation – non-native invasive plant species Mortality risk	Likely significant effect at the international geographic scale	see Section 10 of the NIS	No likely significant residual effect		
Galway Bay Complex cSAC (including Galway bay Complex pNHA)	International (National)	**Construction** Habitat degradation – hydrology Habitat degradation – non-native invasive plant species Barrier effect Mortality risk	Likely significant effect at the international geographic scale	see Section 10 of the NIS	No likely significant residual effect		
Lough Corrib SPA (including Lough Corrib pNHA)	International (National)	**Construction** Habitat degradation – hydrogeology Habitat degradation – hydrology Disturbance/displacement **Operation** Habitat degradation – hydrogeology	Likely significant effect at the international geographic scale	see Section 10 of the NIS	No likely significant residual effect		
Inner Galway Bay SPA including Galway bay Complex pNHA)	International (National)	**Construction** Habitat degradation – hydrogeology Habitat degradation – hydrology Disturbance/displacement **Operation** Habitat degradation – hydrogeology	Likely significant effect at the international geographic scale	see Section 10 of the NIS	No likely significant residual effect

9 Soils and Geology

9.1 Introduction

This chapter of the EIAR consists of an appraisal of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, under the heading of soils and geology.

This chapter sets out the methodology (**Section 9.2**), describes the receiving environment (**Section 9.3**) and summarises the main characteristics of the proposed road development which are of relevance for soils and geology (**Section 9.4**). The likely significant impacts of the proposed road development on soils and geology are described (**Section 9.5**). Measures are proposed to mitigate likely significant impacts (**Section 9.6**) and residual impacts are described (**Section 9.7)**. The chapter concludes with a summary (**Section 9.8**) and reference section (**Section 9.9**).

This chapter has utilised the information gathered during the previous phases of the proposed road development to inform the soils and geology impact appraisal. **Sections 4.4**, **6.5.2** and **7.6.2** of the **Route Selection Report** considered the soils and geology constraints within the scheme study area and compared the potential soils and geology impacts of the proposed route options respectively. These sections of the Route Selection Report contributed to the design of the proposed road development which this chapter appraises.

9.2 Methodology

9.2.1 Introduction

The following section outlines the legislation and guidelines considered and the adopted methodology for the preparing this chapter.

9.2.2 Guidelines

The main guidelines used in preparing this chapter are:

- Draft EPA Guidelines on the information to be contained in an EIS (EPA, 2015)
- Draft Advice Notes on preparing an EIS (EPA 2015)
- Transport Infrastructure Ireland (TII, the operational name of the National Roads Authority) guidelines on procedures for assessment and treatment of geology, hydrology and hydrogeology for National Road Schemes (TII, 2009), referred to as the TII Guidelines within this chapter
- EPA Guidelines on Information to be contained in EISs (EPA, 2002)
- EPA Advice Notes on current practice in preparation of an EIS (EPA, 2003)
- TII Environmental Impact Assessment of National Road Schemes – A Practical Guide (TII, 2008)

- Institute of Geologists of Ireland (IGI) Guidelines for the Preparation of Soils, Geology and Hydrogeology Chapters of EISs (IGI, 2013)
- Draft Guidelines on the Information to be contained in Environmental Impact Assessment Reports (EPA, 2017)

9.2.3 Study Area

The study area for the proposed road development extends 250m beyond the proposed development boundary. This is in accordance with the TII Guidelines. Where appropriate, the study area has been extended to include nearby geological features which may be impacted as a result of the construction and operation of the proposed road development. The study area is presented on the soils and geology suite of figures, **Figures 9.1.001** to **9.8.012**.

9.2.4 Baseline Data Collection

9.2.4.1 Introduction

In order to identify and quantify the potential impact of the construction and operation of the proposed road development, it is first necessary to undertake a detailed study of the existing (baseline) geological environment along the route of the proposed road development. This requires the collation and evaluation of available regional and local information and more site-specific data obtained from walkover surveys and both historic and commissioned ground investigations.

The information presented in this chapter is based on information obtained from two main data collections:

- Regional and local baseline desk study from:
  - Desk Study Information
  - Historic Ground Investigations
  - Consultations
- Project specific information from:
  - Ground Investigations
  - Field Surveys and Walkovers

9.2.4.2 Regional and local baseline desk study

Desk Study Information

The following sources of information were reviewed[1] in order to evaluate the soils and geological environment in the vicinity of the proposed road development:

- Current and historical Ordnance Survey maps available for the study area (1:2,500 and 1:10,560 scales), 2017

[1] The latest review of all available information sources was conducted in June 2017

- Aerial photography (2012 and 2016) of the study area, supplemented with a sectional drone survey in April 2016
- Aerial imagery from Google (imagery from 2001 to 2015) and Bing accessed in 2017
- Geological maps of the site area produced by the Geological Survey of Ireland (GSI) (www.dccae.gov.ie)
- MacDermot, C.V., McConnell, B. and Pracht, M. (2003) Geology of Galway Bay 1:100,000 scale Bedrock Geology Map Series, Sheet 14, Galway Bay, Geological Survey of Ireland
- Pracht, M., Lees, A., Leake, B., Feely, M., Long, B., Morris, J., McConnell, B. (2004) Geology of Galway Bay: A geological description to accompany the Bedrock Geology 1: 100,000 Scale Map Series, Sheet 14, Galway Bay. Geological Survey of Ireland
- Teagasc and the Environmental Protection Agency Irish Soil Information System (http://gis.teagasc.ie/soils/index.php)
- Flood, P. and Eising, J. (1987). The use of vertical band drains in the construction of the Galway Eastern Approach Road. Proceedings of the 9th European Conference on Soil Mechanics and Foundation Engineering, Dublin, Ireland
- Gannon, M.J. (year unknown) Corrib Quincentenary Bridge, Paper presented to Engineers Ireland
- Lidar elevation data commissioned by OPW
- Results from karst field surveys reported in the June 2016 karst report, Appendix A.9.2
- Constraints reports from the previous N6 Galway City Outer Bypass Scheme (2006 GCOB):
- Galway City Outer Bypass R336 Western Approach Constraints Study Report 2000
- N6 Galway City Outer Bypass Constraints Study Report (2000)
- N6 Galway City Outer Bypass R336 Western Approach Link Route Selection Report (2001)
- N6 Galway City Outer Bypass East Route Selection Report (2001)
- N6 Galway City Outer Bypass Environmental Impact Statement Volume 2 (2006)

Historic Ground Investigations

Ground investigation reports held by the Geological Survey of Ireland for the study area were sourced and details are as follows:

- R1340 Galway County Council Eastern Approach Road Galway (N6) (Ballybane – Doughiska), 1993

- R1365 Thos. Garland and Partners Digital Limited, Galway Industrial Estate, 1983
- R3176 Dermot Rooney and Associates I.D.A Business Park, Dangan, Galway, 1997
- R5906 Irish Linen Proposed Irish Linen Factory, Rahoon, Galway, 2005
- R6136 Galway County Council Residential Development, Headford Road, Galway, 2006
- R6898 Storm Technology Office Block Development, Dangan, Galway, 2006

In addition, ground investigation reports made available within the study area were also sourced and include the following:

- SSE Renewables Ireland, Galway Wind Park 110kV River Corrib Crossing, Menlough, Galway, 2013
- Galway County Council Galway City Outer Bypass Preliminary Ground Investigation, 2006

Consultations

Consultation was carried out with the relevant bodies as detailed below:

- Geological Survey of Ireland (GSI)
- Department of Housing, Planning and Local Government[2]
- Mineral Exploration & Mining Division of the Department of Communications, Climate Action and Environment3
- Teagasc
- Office of Public Works (OPW)
- Galway County Council
- Galway City Council
- Environmental Protection Agency (EPA)
- Landowners

Consultation with these relevant bodies, along with the other specialists on the project team, is ongoing since 2014.

9.2.4.3 Project-Specific Information

Site-specific data was obtained from the following sources:

- Historic Ground investigations (extracts from baseline data collection outlined in **Section 9.2.4.2**)
- Project Specific Ground investigations

[2] Please note that department names have changed during the development of this chapter and consultation may be addressed to a previous superseded name. The names which these departments are referred to currently are provided.

- Field Surveys and Walkovers

The scope of the ground investigations within the study area include:

- Shell and auger boreholes
- Rotary core boreholes
- Trial pits
- Window samples[3]
- Geophysical surveys
- Groundwater level monitoring
- Geotechnical and environmental testing on soil and groundwater samples

Commissioned Ground Investigations

Preliminary ground investigations (GI) were commissioned for the EIAR and details of these are as follows:

- N6 GCTP Phase II Ground Investigation Contract I, November 2015
- N6 GCTP Phase III Ground Investigation Contract I, April 2016
- N6 GCTP Phase III Ground Investigation Contract II, December 2015
- N6 GCTP Phase III Ground Investigation Contract III, December 2016

The ground investigation factual reports for each of these GI is include in **Appendix A.9.1**. A summary of the project specific ground investigation has also been provided in **Table 9.1**. The ground investigation locations are presented on **Figures 9.8.001** to **9.8.012**, **9.9.001** and **9.9.002**.

Table 9.1: Summary of Project Specific Ground Investigations

Project Specific Ground Investigation						
Ground Investigation Activity	**Unit**	**Phase 1 C1**	**Phase 2 C1**	**Phase 3 C1**	**Phase 3 C2**	**Phase 3 C3**
Cable Percussive Boreholes	no.	-	-	29	-	1
Rotary Holes	no.	2	4	40	5	3
Rotary Percussive Holes	no.	-	5	-	-	1
Trial Pits	no.	-	-	38	-	4
Soakaway Testing	no.	-	-	2	-	17
Window Samples	no.	-	-	4	-	
Multi Analysis Surface Wave	m	1726	-	-	-	

[3] A window sample is used to bore shallow boreholes, usually up to 5mbgl depending on the soil type, to obtain soil samples for assessment.

Project Specific Ground Investigation						
Ground Investigation Activity	**Unit**	**Phase 1 C1**	**Phase 2 C1**	**Phase 3 C1**	**Phase 3 C2**	**Phase 3 C3**
Seismic Refraction	m	1726	1285	8496	-	2175
2D Resistivity Survey	m	-	973	6027	-	2175
Electrical Resistivity Tomography	m	-	-	-	1897	
Microgravity	stations	-	-	-	118	

Walkover Surveys

Walkover surveys were conducted while scoping the ground investigation in September and October 2015 and throughout the duration of the ground investigation fieldwork which was conducted between January to May 2016 and December 2016. See also **Chapter 10, Hydrogeology** for a description of karst[4] field surveys.

9.2.4.4 Technical Limitations

The data included in the geological assessment includes existing data from earlier investigations into the region as well as dedicated field surveys and walk overs commissioned for the proposed road development. The data collected provides a comprehensive geological dataset along the route of the propose road development.

The data points provide valuable information on the soils and geology environment at point locations. Between each point the data is assessed by conservative interpretation. While soils and geology can vary the exploratory locations have been selected following the completion of the comprehensive baseline data collection. This review was completed by studying local geological maps, aerial photography, historic ground investigation and completing site walkovers to provide an understanding of the soils and geology. The location and the spacing of the exploratory locations was chosen in order to gain an understanding of the ground conditions. The ground investigation findings for the majority of cases compared favourably with the baseline data collection desk study. In instances where it did not, supplementary ground investigation was undertaken, these locations were:

- Peat areas, additional window samples were undertaken to the establish the peat extent
- Adjacent to the River Corrib, to establish the transition from granite to limestone and the extent of karst

[4] Karst refers to a distinctive terrain that evolves through dissolution of the bedrock and development of efficient underground drainage. The special landforms of karst include sinkholes, dry valleys, pavements, cave systems and associated springs (Waltham *et al.* 2005)

- Coolough, for Lackagh Tunnel to establish rockhead and extent of palaeokarst fill due to an unexpected buried valley feature which was encountered
- Briarhill, to investigate the water table due to unexpected groundwater conditions which were encountered (refer to **Chapter 10, Hydrogeology**)

Based on the comparability of the ground investigation and the baseline data collection the information is deemed sufficient to complete the soils and geology evaluation.

9.2.5 Impact Evaluation Methodology

Having defined the extent and form of the proposed road development, an evaluation is made of its potential likely significant impacts on the soils and geology environments. Mitigation measures are identified to mitigate any significant adverse impacts, where feasible.

This impact evaluation methodology is in accordance with the guidance outlined in Section 5.4 of the TII Guidelines (NRA, 2009) and in accordance with this guidance, all potential impacts of the proposed road development must be identified and assessed as per the conditions provided in **Table 9.2**.

Table 9.2: Identification of Impacts (Section 5.4.2 of TII Guidelines (NRA, 2009))

Condition	Classification	Description
Category of Impact	Direct Impact	Existing geological environment along or in close proximity to the proposed road development is altered, in whole or in part, as a consequence of road construction and/or operation
	Indirect Impact	Geological environment beyond the proposed road development is altered by activities related to road construction and/or operation
	No Predicted Impact	The proposed road development has neither a negative nor a positive impact on the geological environment
Effect of Impact	Positive	The proposed road development enhances a geological exposure
	Neutral	The proposed road development neither has a negative nor a positive impact on the geological environment
	Negative	The proposed road development results in a loss of a geological feature
Likelihood of Impact	Certain	Consideration should be given to such impacts in accordance with TII guidance (NRA, 2009)
	Likely	
	Possible	Consideration not required to such impacts in accordance with TII guidance (NRA, 2009)
	Unlikely	
Duration of Impact	Temporary	Construction related and lasting less than one year
	Short Term	Lasting one to 7 years
	Medium Term	Lasting between 7 to 15 years
	Long Term	Lasting 15 to 60 years

Condition	Classification	Description
	Permanent	Lasting over 60 years
Type / Nature of Impact	**Cumulative**	Combination of many minor impacts create one, larger, more significant impact
	Potential	Impact of the proposed development before mitigation measures are fully established
	Worst – Case	Impact of the proposed development should mitigation measures substantially fail to fulfil their intended function
	Residual	Final or designed impact which results after proposed mitigation measures have been fully established

In accordance with Section 5.4.3 of the TII Guidelines, the rating criteria for assessing the importance of geological features within the study area are outlined in **Table 9.4** and the rating criterion for quantifying the magnitude of impacts is outlined in **Table 9.5**. The rating of potential environmental impacts on the soils and geology environment are based on the matrix presented in **Table 9.6** below which takes account of both the importance of an attribute and the magnitude of the potential environmental impacts of the proposed road development on it.

The magnitude of impacts should be defined in accordance with the criteria provided in the EPA Guidelines. This is outlined in **Table 9.3**.

Table 9.3: Definition of Magnitude of Impact (Table 5.1 (NRA, 2009))

Magnitude of Impact	Description
Imperceptible	An impact capable of measurement but without noticeable consequences
Slight	An impact that alters the character of the environment without affecting its sensitivities
Moderate	An impact that alters the character of the environment in a manner that is consistence with existing or emerging trends
Significant	An impact which by its character, magnitude, duration or intensity alters a sensitive aspect of the environment
Profound	An impact which obliterates all previous sensitive characteristics

These impact ratings are in accordance with impact assessment criteria provided in the aforementioned EPA Guidelines. The criteria apply to potential impacts during both the construction and operational phases.

Table 9.4: Criteria for rating the importance of identified geological features (Table C2 (IGI, 2013) and Box 4.1 (NRA, 2009))

Importance	Criteria	Typical Example
Very High	Attribute has a high quality, significance or value on a regional or national scale. Degree or extent of soil contamination is significant on a national or regional scale. Volume of peat and / or soft organic soil underlying route is significant on a national or regional scale.	Geological feature rare on a regional or national scale (NHA) Large existing quarry or pit Proven economically extractable mineral resource
High	Attribute has a high quality, significance or value on a local scale. Degree or extent of soil contamination is significant on a local scale. Volume of peat and / or soft organic soil underlying route is significant on a local scale.	Contaminated soil on site with previous heavy industrial usage Large recent landfill site for mixed wastes Geological feature of high value on a local scale (County Geological Site) Well drained and / or highly fertility soils
Medium	Attribute has a medium quality, significance or value on a local scale. Degree or extent of soil contamination is moderate on a local scale. Volume of peat and / or soft organic soil underlying route is moderate on a local scale.	Contaminated soil on site with previous light industrial usage Small recent landfill site for mixed wastes Moderately drained and / or moderate fertility soils Small existing quarry or pit
Low	Attribute has a low quality, significance or value on a local scale. Degree or extent of soil contamination is minor on a local scale. Volume of peat and / or soft organic soil underlying route is small on a local scale*.	Large historical and / or recent site for construction and demolition wastes Small historical and / or recent landfill site for construction and demolition wastes Poorly drained and / or low fertility soils. Uneconomically extractable mineral resource

Note: * relative to the total volume of inert soil disposed of and/or recovered

Table 9.5: Criteria for Rating Soil and Geology Impact Significance and Magnitude at EIS Stage (Table C4 (IGI, 2013) and Box 5.1 (NRA, 2009))

Magnitude of Impact	Criteria	Typical Examples
Large Adverse	Results in loss of attribute	Loss of high proportion of future quarry or pit reserves Irreversible loss of high proportion of local high fertility soils Removal of entirety of geological heritage feature Requirement to excavate / remediate entire waste site Requirement to excavate and replace high proportion of peat, organic soils and / or soft mineral soils beneath alignment
Moderate Adverse	Results in impact on integrity of attribute or loss of part of attribute	Loss of moderate proportion of future quarry or pit reserves Removal of part of geological heritage feature Irreversible loss of moderate proportion of local high fertility soils Requirement to excavate / remediate significant proportion of waste site Requirement to excavate and replace moderate proportion of peat, organic soils and / or soft mineral soils beneath alignment
Small Adverse	Results in minor impact on integrity of attribute or loss of small part of attribute	Loss of small proportion of future quarry or pit reserves Removal of small part of geological heritage feature Irreversible loss of small proportion of local high fertility soils and / or high proportion of local low fertility soils Requirement to excavate / remediate small proportion of waste site Requirement to excavate and replace small proportion of peat, organic soils and/or soft mineral soils beneath alignment
Negligible	Results in an impact on attribute but of insufficient magnitude to affect either use or integrity	No measurable changes in attributes
Minor Beneficial	Results in minor improvement of attribute quality	Minor enhancement of geological heritage feature
Moderate Beneficial	Results in moderate improvement of attribute quality	Moderate enhancement of geological heritage feature
Major Beneficial	Results in major improvement of attribute quality	Major enhancement of geological heritage feature

Table 9.6: Rating of Significant Environmental Impacts at EIS Stage (Table C6 (IGI, 2013) and Box 5.4 (NRA, 2009))

		Magnitude of Impact			
		Negligible	Small	Moderate	Large
Importance of Attribute	**Extremely High**	Imperceptible	Significant	Profound	Profound
	Very High	Imperceptible	Significant / Moderate	Profound / Significant	Profound
	High	Imperceptible	Moderate / Slight	Significant / Moderate	Severe / Significant
	Medium	Imperceptible	Slight	Moderate	Significant
	Low	Imperceptible	Imperceptible	Slight	Slight / Moderate

The appraisal of the potential likely significant impacts of the proposed road development on soils and geology will consider the following specific topics in accordance with the TII Guidelines (TII, 2009):

- Soils (range of agricultural uses, fertility and drainage characteristics)
- Requirements for treatment and/or handling of soft, unstable or contaminated soils, subsoils or other geological materials
- Requirements for excavation, disposal and / or recovery of soils, subsoils or other geological materials which may be unsuitable for re-use in construction of earth structures or present a risk to human health and/or the environment
- Environmental impact of engineering works on, in or over karst features (buried open / infilled cavities, slope and pavement stability)
- Impact on Economic Geology (mines, pits and quarries) either currently being extracted or potentially developable in the future
- Geological Heritage
- Requirements for blasting in cuttings which may impact on existing structures or infrastructure nearby (noise and vibration)
- Requirements for transportation and truck movements of excavated material and disposal of waste material (traffic, noise and vibration)
- Requirements for pile driving at bridge structures which may impact on existing structures or infrastructure nearby (noise and vibration)
- Requirements for tunnel construction which may impact on existing structures or infrastructure nearby (noise and vibration, settlement and instability)

An analysis of the potential impacts of the proposed road development on soils and geology during construction and operation is presented in **Section 9.5**.

Through the evolution of the design of the proposed road development measures were included in the design to reduce or avoid specific impacts where possible.

Following the evaluation of potential impacts as a result of the design, specific mitigation measures have been developed to avoid, prevent, reduce and, if possible, remedy any significant adverse impacts on the soils and geology. These are described in **Section 9.6** below. Residual impacts which are the final impacts which result after mitigation measures have been fully established are described in **Section 9.7 Table 9.19** and **Table 9.20**.

9.3 Receiving Environment

9.3.1 Introduction

This section describes the soils and geology within the study area. A regional overview is provided in terms of the geomorphology, topography, soils and solid geology of the local area followed by sub sections identifying the feature importance ranking of the agricultural soils, superficial deposits, bedrock geology, soft and unstable ground, contaminated land, karst solution features, mineral and aggregate resources and geological heritage sites within the study area.

When examining the receiving environment of the study area, the proposed road development has been divided into four sections for ease of presentation and due to the volume of information available. For consistency, these sub-divisions are also applied in **Chapter 10, Hydrogeology**. The four sections are as follows:

- Section 1: Chainage 0+000 to 8+500 (R336 to the N59 Moycullen Road)
- Section 2: Chainage 8+500 to 9+400 (N59 Moycullen Road to the River Corrib)
- Section 3: Chainage 9+400 to 14+000 (River Corrib to the N83 Tuam Road)
- Section 4: Chainage 14+000 to 17+500 (N83 Tuam Road to the existing N6 at Coolagh)

These four sections of the proposed road development are discussed in **Sections 9.3.2** to **9.3.12**.

The description of the regional overview is sub-divided and discussed in terms of the western and eastern areas, which are separated by the River Corrib. Section 1 and 2 of the study area covers the western area and the eastern area covers Sections 3 and 4.

The receiving environment is presented on **Figures 9.1.001** to **9.8.012**.

In **Section 9.2.18** a conceptual site model is presented on **Figures 9.8.001** to **9.8.0012** and summarised in **Table 9.16**. The conceptual model plots the factual ground investigation data within the study area along the existing ground level against the proposed road level, earthworks areas and chainage of the proposed road development. **Table 9.16** presents additional information for each earthworks area.

9.3.2 Regional Overview

The proposed road development traverses from west to east of Galway on the northern side of Galway City. This section will discuss the following aspects of the region surrounding the proposed road development:

- Regional Geomorphology and Topography
- Regional Soils and Bedrock Geology

9.3.2.1 Regional Geomorphology and Topography

The general geomorphology of the western area consists of gently undulating to hummocky[5] topography in areas overlying granite. The ground level is lowest at the shores of Lough Corrib and along the coast (10m OD) and rises to the high points at Gortacleva / Tonabrocky (111m OD), Derry Crih (96m OD) and Corcullen (90m OD). The GSI maps indicate ridge lines exist at Tonabrocky and Derry Crih which run northwest-southeast.

The proposed road development crosses the River Corrib near Menlo Castle on the eastern bank and on the western side it passes through National University of Ireland Galway (NUIG) Sporting Campus at Dangan. On crossing the River Corrib, the topography to the eastern area is less undulating than in the western area. The area around the River Corrib is relatively flat and rises to the east. The highest point is at Coolough (65m OD). This is also directly beside the disused Lackagh Quarry in Coolough. From this point the ground surface gently slopes towards Ballindooley Lough and rises again towards Twomileditch (60m OD). The Geological Survey of Ireland (GSI) have produced Quaternary Geology [6] mapping for Ireland. A presentation of the mapping is provided in **Figures 9.1.001** to **9.1.002** and **Figure 9.1.101** to **9.1.114**.

The Galway Granite Batholith is recorded as an indicator erratic or a known source area, with path direction or known erratic train to the south of Ireland. Glacial erracatics are evident east of the River Corrib.

Striation[7] is rather non-uniform to the west of the River Corrib. However the majority of striae direction and drumlins face in a north to northeast direction. The striae direction, streamlined bedrock and drumlin direction in the east of the River Corrib is provided as a northeast direction.

The Lower Carboniferous Visean Limestone is known to contain karst solution feature including surface features such as springs, turloughs and swallow holes which are present east of the River Corrib. Limestone pavement is also common throughout the study area, east of River Corrib and is located both outside and

[5] Hummocky terrain is defined as uneven or undulating surface which contains subdued and rolling landforms.

[6] The Quaternary mapping consists of unconsolidated sediments, the distribution and outline of the main geomorphological features and ice direction indicators.

[7] This refers to glacial striation or scratches, gouges cut into bedrock by glacial abrasion during movement of the glacier.

within the Lough Corrib cSAC, refer to **Chapter 8, Biodiversity** for the ecological assessment of Limestone pavement.

The proposed road development intercepts several watercourses, predominately to the west of the River Corrib. To the east of the River Corrib, due to the highly karstic nature of the terrain, there is a very sparse network of watercourse features. Lake features include Coolagh Lakes and Ballindooley Lough which are located east of the River Corrib. For further details refer to **Chapter 11, Hydrology**. Blanket peat is widespread on the west of the River Corrib but reduces toward the river. Some isolated areas of cutover peat also exist on the eastern side of the River Corrib.

9.3.2.2 Regional Soils and Bedrock Geology

Generally the western area consists of a mix of peaty podzols, blanket peat, lithosols / regosols and surface water gleys, overlying predominantly granular glacial till over early-middle Devonian granite intrusions known as the Galway Granite Batholith and other igneous intrusive rocks. The lowest ground level is at the shores of Lough Corrib where alluvial deposits and fen peat are encountered. The land in the western area is predominantly used as agricultural land with the lands closer to the River Corrib becoming more urban with many residential, commercial and University areas.

The soils in the east consists predominantly of grey brown podzolics, lithosols peat and renzinas / lithosols, overlying cohesive glacial till derived from the underlying bedrock consisting of overly karstified Carboniferous Visean Limestone. Pracht 2013 refer to these limestone as the Burren Formation. Palaeolandscape features (and likely palaeokarst) were identified which comprise of features of significantly deep infilled buried valleys. The land in the eastern area is predominantly used as agricultural land with the area between Ballybrit and Briarhill as an urban environment. Within this area there is an active and disused limestone quarry located in Twomileditch and Coolough, Menlough respectively.

9.3.3 Agricultural Soils

Soil within the study area was assessed based on agricultural usage, fertility and drainage characteristics. Teagasc developed a national indicative soil map, which classifies the soils of Ireland into simplified categories. The Teagasc Soil Mapping has been reproduced in **Figure 9.2.001** to **Figure 9.2.002** and **Figure 9.2.101** to **9.2.114**. Cognisance was taken of the CORINE (Co-Ordinated Information on the Environment) dataseries, established by the European Community (EC) and nationally coordinated by the EPA, when interpreting the Teagasc Soil maps. This section looks at the agriculture soil only. Potential agriculture impacts are assessed in **Chapter 14, Material Assets Agriculture**.

A summary of the agricultural soils present along the proposed road development and their associated feature importance is provided in **Table 9.7**.

Section 1: Chainage 0+000 to 8+500

The soil from Na Foraí Maola to Aille is typically described as poorly drained shallow deposits with peaty topsoil. From Aille to Dangan, the soil description changes to become a shallow to deep, well drained, non-calcareous deposit. These areas are typically described as agricultural lands with arable land and pastures. Some vegetation typical of peatlands exists in both An Chloch Scoilte and Aille.

Section 2: Chainage 8+500 to 9+400

Soil in the central part of the study area, in the vicinity of the River Corrib, is primarily described as made ground with alluvial deposits indicated along the river catchment. This area has no agricultural soil value as it is part of the urban fabric.

Section 3: Chainage 9+400 to 14+000 and Section 4: Chainage 14+000 to 17+500

To the east of the River Corrib, the majority of the land is described as well drained, with a high percentage of agricultural, fertile land, mixed with small clusters of residential and industrial facilities.

Land is predominantly natural however the potential for contaminated ground is further discussed in **Section 9.3.8**.

Table 9.7: Geological Feature Importance of Soil within Study Area

Soil Type	Description	Location / General Extent	Feature Importance Ranking
Teagasc Soils			
AminSRPT	Shallow, lithosolic or podzolic type soils potentially with peaty topsoil. Predominantly shallow soils derived from non-calcareous (granite) rock or gravels with / without peaty surface horizon	Generally from Na Foraí Maola to An Chloch Scoilte	Low
BktPt	Blanket Peat	An Chloch Scoilte	Low
AminSW	Shallow well drained mineral. Derived from mainly non-calcareous (granite) parent materials	Generally from An Chloch Scoilte to Ballard	High
AminDW	Deep well drained mineral soils derived from mainly non-calcareous (granite) parent materials	Aille to Cappagh and Ballyburke to Dangan	High
AminPD	Deep poorly drained mineral derived from mainly non-calcareous (granite) parent materials	Various locations along the western section of the study area	Low
Made	Made Ground	Dangan to Menlough and Ballybrit	Low
AlluvMIN	Mineral Alluvium	Menlough	Low

Soil Type	Description	Location / General Extent	Feature Importance Ranking
BminSW	Shallow well drained mineral. Derived from mainly calcareous (limestone) parent materials	Generally from Menlough to Ballindooley	High
BminSRPT	Shallow, lithosolic or podzolic type soils potentially with peaty topsoil. Predominantly shallow soils derived from calcareous (limestone) rock or gravels with / without peaty surface horizon	Lackagh and Ballybrit	Low
Cut	Cutover Peat	River Corrib and Ballindooley Lough	Low
BminDW	Deep well drained mineral. Derived from mainly calcareous (limestone) parent minerals	Generally from Ballindooley to Coolagh	High
BminPD	Deep poorly drained mineral. Derived from mainly calcareous parent minerals	Various locations along the eastern section of the study area	Low
BminPDPT	Poorly drained mineral soils with peaty topsoil. Derived from mainly calcareous (limestone) parent materials	Various locations along the eastern section of the study area	Low

9.3.4 Superficial Deposits

Superficial deposits refer to geological deposits associated with the youngest geological deposits formed during the most recent period of geological time, the Quaternary, which extends back about 2.6 million years from the present (http://www.bgs.ac.uk/products/digitalmaps/digmapgb_drift.html).

The Irish Soil Information System [8]project has developed a national association soil map for Ireland, providing information on soil types and properties across Ireland.

Superficial deposits were established based on the Irish National Soil Map 1:250,000, the Teagasc Subsoil Map and relevant ground investigation information along the proposed road development.

A reproduction of the Irish National Soil map 1:250,000, as provided by Teagasc and Cranfield University, has been provided in **Figure 9.3.001** to **Figure 9.3.002** and **Figure 9.3.101** to **Figure 9.3.114**. The Teagasc Subsoil Map, produced by Teagasc, EPA and GSI, was also consulted. This map has also been reproduced in **Figure 9.4.001** to **Figure 9.4.002** and **Figure 9.4.101** to **Figure 9.4.114**.

[8] The Irish Soil Information System project has developed a national association soil map for Ireland at a scale of 1:250,000. The project is co-funded by Teagasc and the Environmental Protection Agency (EPA) Science, Technology and Research & Innovation for the Environment (STRIVE) programme (http://gis.teagasc.ie/isis/about.php)

A summary of the superficial deposits are presented in **Table 9.8**.

Section 1: Chainage 0+000 to 8+500

Generally Section 1 consists of peat over a mixture of granular glacial deposits and highly weathered granite.

Section 2: Chainage 8+500 to 9+400

Section 2 is comprised of shallow granular granite derived till over weathered granite, with some instances of peat. This changes to soft to firm sandy gravelly clay over weathered limestone at the intersection of the rock types.

Section 3: Chainage 9+400 to 14+000 and Section 4: Chainage 14+000 to 17+500

East of the River Corrib, the study area typically consists of glacial till derived from limestone, over weathered limestone. Instances of palaeolandscape infilling were uncovered in various low-lying areas within the study area in Menlough, Coolough, Castlegar and Terryland.

Areas of soft and / or unstable ground are discussed further in **Section 9.3.7**.

Table 9.8: Geological Feature Importance of Superficial Deposits within Study Area

Strata[9]	**General Extent / Location**	**Depth to Top of Strata (m BGL)**	**Thickness Range (m)**	**Notes / Description**
Topsoil	Widespread	0.0	0.0 – 0.7	Occasionally peaty in nature
Made Ground	Widespread	0.0 – 0.3	0.0 – 1.9	Occasional fragments of concrete, red brick, ceramic pipe, timber
Peat	Section 1 and 3	0.0 – 0.8	0.0 – 1.3	Occasionally slightly sandy
Glacial Till derived from Granite	Section 1	0.1 – 2.3	0.0 – 3.5	Cohesive and granular mix
Glacial Till derived from Limestone	Section 2 to 4	0.1 – 1.9	0.0 – 21.6	Cohesive and granular mix
Palaeolandscape Fill	Section 2 and 3	13.7 – 101.5	87m (only confirmed thickness)	Described as silt, organic clay, and a transition zone consisting of cobbles and boulders

[9] Strata indicated may not be present at all locations along the proposed road development.

9.3.5 Bedrock Geology

The underlying bedrock geology was determined based on the Bedrock Geology 1:100,000 online mapping (Geological Survey of Ireland), and relevant ground investigation along the route of the proposed road development and is presented in **Figures 9.5.001** to **Figure 9.5.002** and **Figure 9.5.104** to **Figure 9.5.114**.

Section 1: Chainage 0+000 to 8+500

Section 1 is underlain by the Galway Granite Batholith which consists of a number of distinct granite intrusions and is faulted into three main parts by the Shannawona north northeast trending faults and the Bearna northwest trending faults. The Bearna Fault is indicated by the GSI as running approximately through the center of Section 1 at Aille / Ballard. Faulting in the Galway Granite Batholith was not confirmed in intrusive investigation.

To the west of the inferred Bearna Fault, the underlying granite is described as a black, grey, pink, biotite Megacrystic-Porphyritic Granite. The coarse grained, pink, phenocrystic K-feldspar granite known as the Errisbeg Townland Granite occurs to the east of the fault.

Late stage felsite, quartz porphyry and granite porphyry dykes cross almost all of these intrusions.

The white to grey fine grained aphyric felsic Murvey Granite occurs at or near the margins of the batholith and also at the eastern end of Section 1 in Dangan. The Murvey Granite is considered to be the most fractionated of all the granites in the batholith.

Section 2: Chainage 8+500 to 9+400

West of the River Corrib, the study area is typically underlain by Early to Middle Devonian granite intrusions within the Galway Granite Batholith. The Murvey Granite occurs at the outer periphery of the Errisbeg Townland Granite, adjacent to the Lower Carboniferous Visean Limestone known as the Burren Formation.

The area of limestone between the western shore of the River Corrib and the fault bounding the pre-Carboniferous rocks to the west were originally mapped by C.V. MacDermot in the late 1960's and early 1970's. Based on the results of the project specific ground investigation, the rock type change occurs in the vicinity of the unconformity line. Intrusive investigation and geophysical investigation confirmed the high likelihood that the change in rock type occurs at Ch. 8+880. On the limestone side of the indicative chainage, a zone of low resistivity that is up to 40m wide and greater than 20m deep was encountered. This is likely to be a highly weathered zone at the contact zone. East of this zone, the geology sharply reverts to high resistivity, typical of competent limestone. Therefore, this unconformity line / fault is still considered valid and provided in **Figures 9.5.001** to **Figure 9.5.002** and **Figure 9.5.104** to **Figure 9.5.114**.

The rock is described as thick to thinly bedded, however, the majority of intrusive coring indicates that the limestone rockmass is thinly bedded. Average depth to rock is approximately 5.0m below ground level, however intrusive investigation along the River Corrib indicates that rock can drop to 78m below ground level.

Section 3 and 4: Chainage 9+400 to 17+500

The area to the east of the River Corrib is underlain by the Burren Formation (Visean) of the Lower Carboniferous age. There is limited available information on the depositional sequencing of the Burren Formation west and east of Lough Corrib. The exploratory descriptions for the limestones encountered during the site investigation vary widely and therefore no trend or isolated areas of distinct characteristics have been observed. The bedrock topography associated with the palaeolandscape was encountered at depths deeper than elsewhere within the study area.

Some argillaceous (clayey) material was recorded in the coreholes. The nature of the limestone strongly influences its susceptibility to karstification. Purer limestones (>90% calcite) are more susceptible than impure (shaley / argillaceous) limestones.

The average depth to rock across the Sections 3 and 4 (excluding areas of palaeolandscape features) is approximately 2.4m below ground level. Intrusive coring indicates that the rock is massive to thinly bedded.

Karst within the limestone is discussed in **Section 9.3.6**.

A summary of the bedrock formations and associated descriptions is provided in **Table 9.9**.

Table 9.9: Rock Formations within Study Area

Geological Period	**Bedrock Unit**	**Formation**	**Description**	**General Extent / Location**
Carboniferous	Dinantian Pure Bedded Limestone	Burren Formation (Visean)	Medium to very strong massive to thinly bedded blueish dark grey fine grained slightly weathered	**Section 2, 3** and **4** East of River Corrib, with small section west of river bank
Early-Middle Devonian	Galway Granite Batholith	Porphyritic-Megacrystic Granite	Very strong grey, white, pink, black biotite slightly weathered	**Section 1** Coast Road (R336) to Aille *Principal granite mass west of the Bearna Fault*
		Fine Grained Foliated Granite	Very strong thickly to thinly banded brown pink green medium to coarse grained slightly weathered	**Section 1** Between An Chloch Scoilte and Ballard
		Errisbeg Townland Granite	Very strong thickly to thinly banded brownish purple	**Section 1** and **2** Aille to Dangan

Geological Period	Bedrock Unit	Formation	Description	General Extent / Location
			fine to coarse grained slightly weathered	*Principal granite mass east of Bearna Fault*
		Murvey Granite	Very strong thickly to thinly banded green, white fine coarse grained moderately weathered	**Section 1** and **2** Dangan *Border formation between principal granite and visean limestone*
Ordovician	Other Igneous Intrusive Rocks	Metagrabbo and Orthogneiss Suite (undifferentiated)		**Section 1** and **2** Dangan

9.3.6 Karst Solution Features

From the N59 Moycullen Road at Dangan (Section 1) to the existing N6 at Coolagh, Briarhill (Section 4) the study area is underlain by clean non-argillaceous limestone which is prone to karst. A range of solution features were identified within the study area and presented in **Figure 9.6.001** to **Figure 9.6.002**, **Figure 9.6.101** to **Figure 9.6.114**, **Figure 10.1.001** to **Figure 10.1.002** and **Figure 10.1.101** to **Figure 10.1.114**. These include:

- Limestone pavement
- Epikarst
- Dolines (enclosed depressions)
- Caves
- Estavelles
- Springs
- Superficial Solution Features
- Wells
- Swallow holes
- Turloughs

The solution features have been identified based on the GSI Karst Database and were further assessed in a project specific karst survey, which is available in **Appendix A.9.2**.

Section 1: Chainage 0+000 to 8+500

There is no karst in Section 1 as this area is underlain by granite which is not susceptible to karst.

Section 2, 3 and 4: Chainage 8+500 to 17+500

The Teagasc subsoil mapping indicates that approximately 40% of the landcover over the limestone bedrock is karstified outcrop or subcrop. Site walkovers and ground investigation established that much of Section 3 and 4 is limestone subcrop with a thin / shallow layer of topsoil, glacial till.

Areas of Limestone pavement were uncovered and mapped in Sections 3 and 4. Limestone pavement, which is underlain by limestone bedrock accounts for approximately 10% of the land cover. Limestone pavement occurs within and outside European designated sites. For the purpose of the geological assessment no differentiation has been made between Limestone pavement located within or outside the European designated sites. Refer to **Chapter 8, Biodiversity** for an ecological assessment of Limestone pavement.

Most of the karstification identified along the proposed road development consists of a weak to well-developed zone of epikarst[10], ranging from approximately 0m to 2.7m in thickness[11] (epikarst refers to the zone of partially weathered or weathered limestone which is present between the overburden soils and the underlying unweathered rock).

In a smaller number of areas, more intense karstification has led to deeper weathering (below the epikarst zone) and clay infilling of solutionally enlarged features (typically joints). In some of these, even more intense karstification has occurred, leading to the development of relatively large dissolution features which are typically infilled with sediments. The establishment of the location of these features is achieved through geophysical surveys and intrusive investigation.

Palaeokarst features have been identified with the bedrock formation. These consist of large buried valleys filled with silt and clay.

Various anomalies were encountered in both intrusive investigation and geophysical surveys, which may likely be karst related. These include the following:

- Non intact zones identified in rotary coreholes below bedrock level
- Cavities in rotary coreholes
- Calcite deposits and infilled voids identified in rotary coreholes
- Significant drop in resistivity values recorded during the geophysical survey which do not coincide with typical bedrock resistivity values

[10] Epikarst comprises of highly weathered carbonate bedrock immediately beneath the surface or soil where present.

[11] The values provided are representative of the typical thicknesses observed / recorded. Weathered rock was recorded as 6.4m thick in BH 3/35R conducted during the N6 GCTP Phase 3 Contract 1 Ground Investigation in 2016. However, based on site observations during monitoring of the works and available geophysical data, the material was a mixture of cobbles and boulders with dense granular content. This was an isolated record.

Such anomalies were encountered at various locations across the study area underlain by limestone bedrock. The location of these anomalies are presented in the ground investigation factual data and are not included in

Table 9.10. Refer to **Chapter 10, Hydrogeology** for a full description of both surface karst features and anomalies recorded from the ground investigations.

Table 9.10: Geological Feature Importance of Karst Features within Study Area

ID Code	Karst Feature	Information Source	Location / General Extent	Feature Importance Ranking
Limestone Pavement				
LP	Limestone pavement	Field mapping from Ecologist	Widespread throughout Sections 3 and 4	Very High[12]
Palaeolandscape (Palaeokarst)				
PK	Palaeokarst Valley	Mapping from Hydrogeologist	Menlough, Ballindooley Castlegar	Medium

9.3.7 Soft and/or Unstable Ground

Soft deposits consist of peat, alluvium or very soft cohesive material. These soft compressible deposits, which are located within the study area, are presented in **Figure 9.7.001** to **Figure 9.7.002** and **Figure 9.7.101** to **Figure 9.7.114**. Various sources of information were consulted in establishing these areas along the study area namely:

- Teagasc Subsoil map, produced by Teagasc, EPA and GSI
- GSI database of historical landslides
- EPA subsoil mapping
- Ground Investigation data

The Teagasc Subsoil map outlined locations of soft soil within the study area and the GSI database shows no recorded landslide events within the study area.

Areas containing peat and very soft to soft cohesive material identified within the study area were primarily obtained through assessment of intrusive investigation and consultation of the EPA Subsoil mapping. The ground investigation soil log descriptions (soft, very soft) and in-situ strength testing were used to determine the location of soft deposits. In accordance with EN ISO 14688-2:2004, material with an undrained shear strength of 40 kPa is considered a soft deposit.

According to the Teagasc subsoil mapping for the county, less than 1% of the peatland areas in County Galway fall within the study area. Areas containing peat and soft soil are displayed in **Figure 9.7.001** to **Figure 9.7.002** and **Figure 9.7.101** to **Figure 9.7.114** and the conceptual site model as presented in **Figure 9.8.001** to **Figure 9.8.012**.

Section 1: Chainage 0+000 to 8+500

Intrusive investigation indicates the existence of peaty topsoil and shallow deposits of peat throughout Section 1. The evidence and likelihood of this material reduces at Dangan, where the landcover enters the urban fabric. Typically, the depths observed for the peat were less than 1.0m however a number of locations were identified where the peat extended up to thicknesses of 2.0m or soft deposits up to thicknesses of 3.6m, as presented in **Figure 9.8.001** to **Figure 9.8.012**. The soft deposits are typically non-organic, however organic deposits were encountered in Na Foraí Maola and Aille. These are isolated instances only and are likely due to the overlying peat.

Section 2: Chainage 8+500 to 9+400

Peat is recorded in the upper, northern part of the study area within Section 2. Alluvial deposits and highly organic soft deposits were encountered along the bank of the River Corrib.

Section 3: Chainage 9+400 to 14+000

Peat was observed in the valley area at Coolough, Menlough, west of Lackagh Quarry. This is mixed with highly organic soft ground deposits and alluvial deposits as per the intrusive investigation and GSI subsoil mapping. Geophysical surveying during the commissioned site investigation indicates that the likely deposition of these deposits as is associated with infilling of deep buried valleys or palaeovalleys.

A significant palaeokarst feature was uncovered west of Lackagh quarry with palaeokarst fill encountered to 101.5m below ground level (blg) in one exploratory hole. This is significantly deeper than the shallow bedrock in the immediate vicinity which includes Limestone pavement.

Peat was also encountered at Ballindooley Lough, with historic ground investigation showing peat up to 3.7m in thickness. Soft deposits, mixed with peat are expected both west and east of the N84 Headford Road, as the geophysical survey indicate the potential presence of deep buried valleys either side of the N84 Headford Road.

Section 4: Chainage 14+000 to 17+500

Isolated instances of soft ground were encountered in Section 4. A buried valley was uncovered following a geophysical survey, with intrusive investigation confirming the anomaly. Only two isolated instances of peat were encountered in historic and recent intrusive investigations, along with only one instance of slightly organic material.

In determining the feature importance of soft ground, the soil types have been grouped and are ranked in the **Table 9.11**.

Table 9.11: Geological Feature Importance for Geohazards within Study Area

Feature	Description	Feature Importance Ranking
GEOHZ01	Peat	Low
GEOHZ02	Soft Organic[13]	Low
GEOHZ03	Soft Non-Organic	Low

9.3.8 Contaminated Land

Various sources of information were consulted in assessing the study area for locations of potential contaminated land:

- CORINE land cover mapping
- Teagasc Soil map
- EPA
- Ground Investigation data

No known areas of contaminated ground were identified. Industrial sites may be the source of locally contaminated land due to site activities. Approximately 5% of the study area is comprised of Industrial and Commercial Units in accordance with the CORINE land cover mapping. However, these sites operate within the EPA Industrial Emissions (IE) licence framework and due to the regulated nature of their activities, the risk of contamination is low.

There are no sites within the study area that have been granted a waste water discharge licence.

Made ground has been defined as soil which has been altered in some way by human activity (imported and placed in-situ). Made ground has been observed in the form of inclusions of metal, glass, copper piping, ceramic piping. All locations of made ground are presented in the conceptual site model **Figure 9.8.001** to **Figure 9.8.012**. Based on the Teagasc Soil mapping less than 10% of the study area is comprised as made ground with approximately 30% of the study area comprised of artificial surfaces.

In 1996 the EPA began licensing certain activities in the waste sector which include landfills, transfer stations, hazardous waste disposal and other significant waste disposal and recovery activities. It has been determined from consultation with Galway County Council (29 August 2016) that there are no known historical (or legacy) landfills within the study area.

Section 1: Chainage 0+000 to 8+500

No known areas of contaminated ground were identified.

[13] Palaeolandscape fill is anticipated to be organic in nature, particularly due to the highly organic material encountered along the River Corrib and isolated instance at other locations identified to be overlaying palaeolandscape valleys. No organic testing has been conducted in the palaeolandscape fill in the project specific ground investigation.

CORINE and Teagasc subsoil mapping highlight areas of artificial surfaces due to residential dwellings, commercial properties and industrial usage.

One site was identified which previously had a Certificate of Registration for the importation of Construction and Demolition Waste. The certificate expired on the 28 May 2015.

Section 2: Chainage 8+500 to 9+400

No known areas of contaminated ground were identified.

CORINE and Teagasc subsoil mapping highlight areas of artificial surfaces due to residential dwellings, commercial properties, industrial usage and university buildings.

Section 3: Chainage 9+400 to 14+000

No known areas of contaminated ground were identified.

CORINE and Teagasc subsoil mapping highlight areas of artificial surfaces due to residential dwellings, commercial properties and industrial usage.

Section 4: Chainage 14+000 to 17+500

No known areas of contaminated ground were identified.

CORINE and Teagasc subsoil mapping highlight areas of artificial surfaces due to residential dwellings, commercial properties, sport and leisure facilities and industrial usage.

Three licenced IPPC facilities were identified in Section 4. These are tabulated in **Table 9.12** and are provided in in **Figure 9.7.001** to **Figure 9.7.002** and **Figure 9.7.101** to **Figure 9.7.114**.

Table 9.12: Geological Feature Importance for Contaminated Land within Study Area

Feature	Status / Extent in Percentage	Description	Location / General Extent	Feature Importance Ranking
Licensed IPPC Facilities				
IP01	Licensed	Medtronic Vascular Galway Ltd	Parkmore	Low
IP02	Surrendered	Irish Finishing Technologies Ltd	Ballybrit	Low
IP03	Licensed	Boston Scientific Ireland Ltd	Ballybrit	Low

9.3.9 Mineral / Aggregate Resources

Various datasets were consulted in establishing the economic geology of the study area including:

- GSI: aggregate potential mapping
- GSI: mineral localities
- EPA: active mine sites

These datasets are presented in **Figure 9.6.001** to **Figure 9.6.002** and **Figure 9.6.101** to **Figure 9.6.114**.

A detailed description of how the Aggregate Potential Mapping was developed is available in Issue No. 15 of Geology Matters as part of the Newsletter of the Geological Survey of Ireland or on the GSI website[14].

The existence of high or very high potential aggregate within the study area will result in a loss of available aggregate. However, such potential is beneficial during construction as material can be sourced on site removing the need to import suitable / acceptable material during the construction stage in its place.

No active metallic mines exist today in the study area. Over the past 50 years, parts of the area have been extensively prospected by mineral exploration companies for base metals, but no economically viable deposits have been discovered to date. There is no record of underground mining in the area therefore there would be a low risk of underground structure collapse due to underground excavations, and as such this assessment does not consider this feature any further.

Section 1: Chainage 0+000 to 8+500

The majority of Section 1 consists of very high crushed rock aggregate potential derived from granite with instances of high crushed rock aggregate potential at the beginning of Section 1, Na Foraí Maola, in the middle at An Chloch Scoilte and at the eastern end of Section 1 in Letteragh and Ballagh. Two instances of medium crushed rock aggregate potential were identified in Section 1, at An Chloch Scoilte and Dangan.

An area of low sand and gravel aggregate potential was identified in Rahoon.

All of the metallic mineral localities identified in the study area are located at the beginning of Section 1 in Na Foraí Maola.

One non-metallic locality was identified in An Chloch Scoilte which is described as low lying granite pavement. Four historic pits and one historic quarry were identified in the eastern extent of Section 1, between Keeraun and Dangan.

Section 2: Chainage 8+500 to 9+400

The majority of Section 2 consists of very high crushed rock aggregate potential with smaller instances of both high and moderate crushed rock aggregate potential.

---

[14] The Aggregate Potential Mapping section of the Spring 2014 Newsletter of the Geological Survey of Ireland is available as pdf on the GSI website (https://www.gsi.ie/Newsletters/Aggregate+Potential+Mapping.htm)

The potential crushed rock in the limestone section is predominantly very high potential.

Section 3: Chainage 9+400 to 14+000

Section 3 is ultimately an area of very high crushed limestone rock aggregate potential with some very small, isolated instances of high potential.

One active (Roadstone Quarry at Twomileditch) and one disused quarry (Lackagh Quarry in Coolagh) are located in Section 3.

Section 4: Chainage 14+000 to 17+500

Section 4 is regarded as having very high crushed limestone rock aggregate potential. Two historic quarries and one historical gravel pit are located in Section 4.

Table 9.13: Geological Feature Importance of Mineral / Aggregate Resources within the Study Area

ID	Type	Description	Location / Extent	Feature Importance Ranking

ML24	Non-Metallic	Limestone (in general)	Roadstone Quarry, Twomileditch	Very High

9.3.10 Geological Heritage Areas

The Irish Geological Heritage Programme is a partnership between the GSI and the National Parks and Wildlife Service (NPWS). The programme was developed to identify, document the geological heritage and protect and conserve it. Consultation was conducted with the GSI in order to identify all geological heritage sites within the study area.

The Galway County Development Plan (2015-2021) states that it is a Natural Heritage and Biodiversity policy (NHB 2) to recognise that nature conservation is not just confined to designated sites and acknowledge the need to protect non-designated habitats and landscapes and also (NHB 5) to protect, conserve and enhance important geological and geo-morphological systems in the county and seek to promote access to such sites where possible.

Consideration was given to Table 4.3 Network of Local Biodiversity Areas and Table 4.4 Other Areas/Features of Local Importance in the City from the Galway City Council Development Plan 2017-2023.

Section 1: Chainage 0+000 to 8+500

Igneous intrusions (GHA06) and observable magma mingling are located at the very beginning of Section 1, on the coastal side of the R336.

Section 2: Chainage 8+500 to 9+400

No geological heritage sites have been identified in Section 2.

Section 3: Chainage 9+400 to 14+000

Roadstone Quarry (GHA01) is located at Twomileditch in Section 3.

Section 4: Chainage 14+000 to 17+500

No geological heritage sites have been identified in Section 4.

Table 9.14: Geological Feature Importance of Heritage Areas within Study Area

ID	Site Name	Principle Characteristic	Feature Importance Ranking
GHA01	Roadstone Quarry on Tuam Road	Heritage / large existing quarry. Limestone quarry producing aggregates, agricultural ground limestone and concrete	Very High
GHA06	Igneous Intrusions	Observable magma mingling	Very High

9.3.11 Summary of Geological Feature Importance

A summary of the geological features with an importance of medium or higher found within the study area, are presented below in **Table 9.15**.

Table 9.15: Summary of Geological Features

9.3.12 Conceptual Site Model

A conceptual site model was developed based on the ground investigation data. The model includes the factual data within the study area that was gathered during the ground investigations. The information is presented on **Figure 9.8.001** to **Figure 9.8.012** in plan and profile format with the profile illustrating the existing and proposed ground levels, earthwork sections, local ground investigation logs and geophysical data along the centre-line of the proposed road development. See also **Appendix A.9.1** for all ground investigation data.

The earthworks areas of cut and fill are presented in **Figure 9.8.001** to **Figure 9.8.012** and in **Table 9.16** below. The embankment height (average and maximum, cut height (average and maximum) and the soils and geology at each earthwork areas are presented in **Table 9.16**.

Table 9.16: Earthwork Areas of Cut and Fill

Earthwork Reference	Dominant Earthworks Type	Environment Section	Length (m)	Max Fill (m)	Average Fill (m)	Max Cut (m)	Average Cut (m)	Generalised Overburden and Bedrock Description	Average Depth to Rock (mBGL)
EW01	Cut	Section 1 Na Foraí Maola	460	1.63	0.14	-3.13	-1.06	Peat over granite derived glacial gravels with areas of made ground over granite bedrock	0.50

[15] Depth to rockhead is unavailable over the extent of the River Corrib as no intrusive investigation was conducted.

[16] Some overburden including topsoil exists along the extents of the structure. However, the majority of the area consists of outcropping Limestone pavement. Therefore, the average depth has been provided as 0m to reflect the typically shallow rock.

[17] The change in rockhead, based on intrusive and geophysical ground investigation, is quite significant in this area, with the maximum depth recorded of 109m below ground level. However, this maximum depth is quite isolated with the rockhead typically quite shallow.

[18] While topsoil exists in some of the extent of this earthwork area, the majority consists of outcropping Limestone pavement. This gave rise to the construction of a tunnel through the rock. Therefore, the average depth to rockhead has been indicated as 0m in order to reflect this environment.

[19] This earthworks area extends along the floor of the disused Lackagh Quarry. Therefore, the depth to rockhead has been provided as zero.

9.4 Characteristics of the Proposed Road Development

A detailed description of the proposed road development and construction activities are provided in **Chapter 5, Description of Proposed Road Development** and **Chapter 7, Construction Activities**.

This section of the report outlines the key design features and the construction and operational characteristics and activities of the proposed road development of relevance to soils and geology. The potential impacts related to such construction activities are provided in **Section 9.5**.

9.4.1 Key Design Features

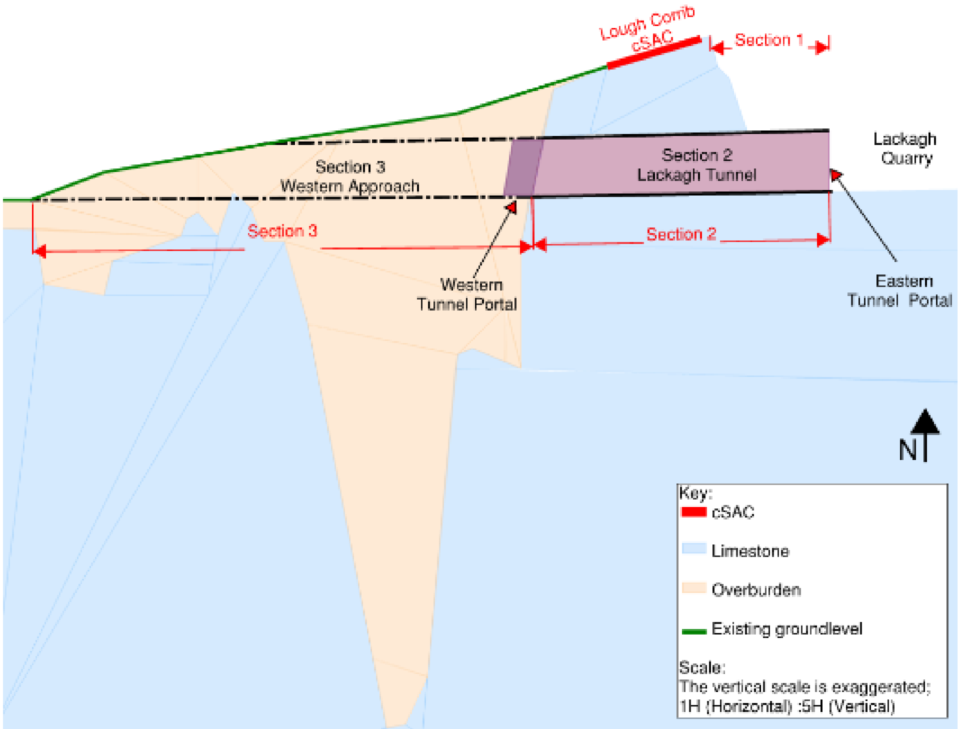
The key design measures of relevance to avoid or reduce impact to soils and geology features, in particular Limestone pavement, are:

- Lackagh Tunnel and the Western Approach
- Menlough Viaduct and Culvert
- Reinforced / retained slopes

9.4.1.1 Lackagh Tunnel and the Western Approach

Lackagh Tunnel comprises of three sections between Ch. 10+775 to Ch. 11+420 of the proposed road development namely Section 1 Lackagh Quarry Face, Section 2 Lackagh Tunnel and Section 3 Western Approach, refer to **Plate 9.1**.

Plate 9.1: Schematic cross section of Sections 1-3 at Lackagh Tunnel



Lough Corrib cSAC which includes Limestone pavement is located immediately west of Section 1. Section 2, Lackagh Tunnel (ST11/01) is a drill and blast mined twin bored tunnel approximately 270m long, from Ch. 11+150 to Ch. 11+420. Section 2 tunnels beneath Lough Corrib cSAC, including Limestone pavement, between approximately Ch. 11+240 and Ch. 11+350. Section 3 lies partially within the Lough Corrib cSAC and traverses between areas of Limestone pavement which is located north and south of the proposed road development.

Given the presence of Limestone pavement, the potential geological impacts of Lackagh Tunnel and its immediate approaches on limestone pavement include:

- Rock mass instability and slope instability in Sections 1 and 3 resulting in potential encroachment onto Limestone pavement within Lough Corrib cSAC, due to its proximity to the proposed road development
- Blasting activities required for the construction of Sections 2 and 3 resulting in potential impact on the structural integrity of the Limestone pavement
- Collapse of the tunnel and ground settlement from the tunnel bore in Section 2 resulting in potential impact on the Limestone pavement within Lough Corrib cSAC

To avoid these geological impacts the following measures are included in the design of Lackagh Tunnel and its approaches (Sections 1, 2 and 3) along with a conservative design approach:

- In Section 1, stabilisation of Lackagh Quarry face will be carried out around the eastern tunnel portal in order to prevent rock mass instability and slope instability. The conservative design approach requires that stabilisation of the Lackagh Quarry face (western face of the quarry) around the eastern tunnel portal will be completed in advance of tunnelling works for Section 2 (Lackagh Tunnel). These stabilisation works include a composite support system of rock bolts, rock dowels, steel mesh and sprayed concrete

- Section 2 is a mined twin bore tunnel in rock constructed using a drill and blast methodology. This method of construction is commonly used for tunnels of this length through hard rock. The conservative design approach of Section 2 requires the following the tunnel design elements to ensure that collapse of the tunnel and ground settlement does not arise:
  - At least 8.0m of clear bedrock is required above the crown of the tunnel bore to the top of the Limestone pavement ground surface in order to maintain the bore stability. This design requirement is achieved in the Lackagh Tunnel design with the proposed alignment providing bedrock cover ranging from ~10m to 14.5m above the crown of the tunnel to the Limestone pavement ground surface
  - A 7m wide separation pillar is required between the two bores in order to maintain the twin bore stability. This design requirement has also been achieved in the Lackagh Tunnel design with the proposed alignment allowing for a rock pillar of 7.3m between the two bores
- In Sections 2 and 3, to prevent rock mass instability, rock mapping assessments will be completed by a geotechnical expert following each tunnel blast in Section 2, rock blast in Section 3 and during the excavation of the Section 3. The outcome of these assessments will govern which rock stability design solution and tunnel design support measure to be employed
- In Section 3, retaining systems will be implemented at pinch points along the Western Approach to support the cut face between existing ground level and the proposed road level preventing slope instability and encroachment onto Limestone pavement. The conservative design approach includes the following retaining systems:
  1. Rock bolts, rock dowels, steel mesh, and sprayed concrete in areas of rock only
  2. Piled retaining walls, supported with ground anchors in areas of overburden only and in areas with a combination of overburden and rock that will be monitored during construction and compared with the design
- In all sections blast design limitations, these include a maximum vibration limit of 25mm/sec, a construction target vibration limit of 20mm/sec which is less than the maximum vibration limit and a monitored trial blast undertaken in the same bedrock formation by the blasting contractor in a controlled location that will pose no risk to sensitive receptors. The trial blast will not exceed the vibration limitations of the local sensitive receptors. The information obtained from the trial blast will calibrate and refine the blast design to a site specific design.

The tunnel construction activity is outlined in **Section 9.4.2.5**, potential construction and operational impacts are outlined in **Section 9.5.3.4** and **9.5.4** with mitigation measures presented in **Section 9.6**. Refer to **Chapter 8, Biodiversity** for the ecological assessment and **Chapter 10, Hydrogeology** for the hydrogeology assessment.

Further details on Lackagh Tunnel can be found in **Appendix A.7.1**.

9.4.1.2 Menlough Viaduct and Culvert

The design includes a viaduct structure, Menlough Viaduct (ST10/01) from Ch. 10+100 to Ch. 10+420. The total length of the viaduct is governed by the area of Limestone pavement and a Turlough (karst feature ID code K31), which are both located outside of the Lough Corrib cSAC. The viaduct has a total length of approximately 320m, and the proposed road development is on embankment on both approaches to it. The viaduct contains eight spans of a similar 40m span length. The span lengths have been adjusted to minimise the substructure and foundation footprint on the Limestone pavement and avoid the extent of the Turlough.

There is a culvert in Menlough that is also included in the design from approximately Ch. 10+025 to Ch. 10+050. This structure spans Limestone pavement surface (outside of the Lough Corrib cSAC) avoiding the removal of the feature at this location.

9.4.1.3 Reinforced Slopes

The retaining wall in the Menlough area (between Ch. 9+850 and Ch. 10+050) is located adjacent to the Lough Corrib cSAC. This structure will be constructed to retain the embankment of the proposed road development from encroachment on the Annex I habitat of the Lough Corrib cSAC including Limestone pavement. The construction of the retaining wall will be undertaken within the proposed development boundary and outside the areas of Annex I habitat.

9.4.2 Construction activities

As discussed in **Chapter 7, Construction Activities**, it is envisaged that an east to west build will be adopted for the construction of the proposed road development and it may be completed in two concurrent phases or a single overall contract. The two phases are:

- Phase 1 – N6 Coolagh to N59 Letteragh Junction – 9.9km (Including the N59 Link Road North and South)
- Phase 2 – N59 Letteragh Junction – R336 West of Bearna 7.5km

The construction activities involved in the proposed road development relevant to soils and geology are listed below and further discussed in the following sub-sections, **Sections 9.4.2.1** to **9.4.2.10**. The construction activities relevant to soils and geology include:

- Embankment construction
- Excavation of cuts
- Soil and rock slopes

- Reuse and processing of site material
- Importation, exportation and disposal of materials
- Tunnelling
- Construction of foundations for structures
- Contaminated ground
- Soft Soil
- Karst features
- Dewatering

A Construction Environmental Management Plan (CEMP) is provided in **Appendix A.7.5**.

9.4.2.1 Embankment construction

As outlined in the conceptual site model in **Figures 9.8.001** to **9.8.012** and **Table 9.16**, certain areas along the proposed road development will require the placement of fill material to achieve the proposed alignment level. These embankment sections will be formed using imported fill or site won[20] material. The imported fill will be transported on site access roads using trucks and on routes outlined in **Chapter 7, Construction Activities**.

For embankments less than 3.0m in height, topsoil will require removal from beneath the embankment footprint. For areas identified as medium and high karst risk, topsoil will require removal in order to proof roll the underlying material. Topsoil will be excavated, transported and stored at a designated stockpile on site and reused for landscaping across the proposed road development.

Material evaluated to be soft beneath the footprint of the embankment will be removed in order to provide a more suitable founding strata. Bituminous or hard standing material will also be removed.

The potential impact from this construction activity are discussed in **Section 9.5.3.1.**

9.4.2.2 Excavation of cuts

Where the proposed road level is below the existing ground level, existing material will require excavation and removal. As outlined in **Table 9.16**, these cut areas along the proposed road development will require the removal of overburden (fertile soil, soft soils, made ground, superficial deposits) and bedrock (granite and limestone).

Based on the factual ground investigation information available, for cuts in rock, hard ripping using a hydraulic hammer or blasting of the bedrock will be required.

[20] Material which has been recovered as part of the construction excavation activities. If purposed for use in embankment construction, the material must comply with material properties and constituents outlined in the TII Series 600 Earthworks Specification.

See **Appendix A.9.1** for ground investigation data. All other excavation, and removal of broken or blast rock, will be completed using an excavator and transported to other areas of the site or to a designated disposal site. Topsoil will be excavated, transported, stored at a designated stockpile on site and reused for landscaping across the proposed road development. See details in relation to waste in **Chapter 7, Construction Activities**.

As part of the blast design assessment monitored trial blasts in the same bedrock formation as the proposed blast locations at locations of proposed blasting will be conducted. These trial blasts will calibrate the blast design to site specific designs and will refine and validate the blast design properties. Trial blasts will not exceed the limitations of the local sensitive receptors.

Excavations are typically undertaken in a ‘dry’ environment, therefore cuts that intercept the groundwater table may require temporary dewatering, if permitted. These locations are outlined and assessed in **Chapter 10, Hydrogeology**.

The potential impacts related to this activity are further discussed in **Section 9.5.3.1**.

9.4.2.3 Reuse and processing of site material

Site won material, obtained from cuttings, will where possible be reused as fill for the construction of embankments and other elements along the proposed road development. Crushing and processing of suitable material obtained on site during the earthworks for re-use will be employed insofar as is possible.

The potential impacts related to this activity are discussed in **Section 9.5.3.2**.

9.4.2.4 Importation, exportation and disposal of materials

Earthworks quantities along the proposed road development are subdivided into a number of earthworks sections based upon natural physical boundaries such as rivers and existing roads. The estimated quantities of imported and exported fill within these areas are outlined in **Chapter 7, Construction Activities**.

The construction of Phase 1 will result in a surplus of material however in the unlikely event that the construction of Phase 2 is first this will result in a deficit of acceptable material.

The deficit of aggregate will require the importation of suitable material. Material shall be sourced from quarries which are listed on the register maintained by the local authority. Designated haulage routes and access routes have been identified and are further discussed in **Chapter 7, Construction Activities**.

In line with the principles of sustainable development, the proposed road development will minimise the amount of materials brought into the construction site. This will be achieved by re-using as much of the materials generated during construction as possible subject to further testing to determine if materials meet the specific engineering standards for their proposed end-use.

Where the excavation contains a combination of acceptable and non-acceptable material for reuse, the excavation will be conducted so that acceptable material is excavated separately without contamination by the unacceptable material.

Any hazardous material, as evaluated from appropriate environmental testing, will result in the necessity for off-site disposal to designated disposal sites in accordance with all relevant legislation. This is further discussed in **Chapter 7, Construction Activities**.

The potential impacts related to this activity are further discussed in **Section 9.5.3.3**.

9.4.2.5 Tunnelling

Two tunnels are proposed along the proposed road development as follows:

- Mined Tunnel at Coolough, Menlough (Lackagh Tunnel– Approximately 270m tunnel through limestone bedrock and overburden)
- Cut and Cover at Ballybrit (Galway Racecourse Tunnel – Approximately 230m tunnel in limestone bedrock)

Mined Tunnel

The proposed mined tunnel, Lackagh Tunnel, comprises two bores for the eastbound and westbound carriageways of the proposed road development. Each bore comprises an approximately 15m wide span tunnel with water tight concrete arch lining with the internal elements (road, walkways, lighting, ventilation etc.) placed within this shell. The proposed alignment for Lackagh Tunnel provides bedrock cover ranging from approximately 10m to 14.5m above the tunnel crown below the Limestone pavement surface.

The tunnel excavation, in Menlough, will be a mined tunnel (drill and blast), which is commonly used for tunnels through hard rock. The tunnel commences in Lackagh Quarry at the tunnel portals using drill and blast methods. Excavation progresses for the tunnel in a cyclic manner with drilling, blasting, rock face mapping, mucking out, installation of support measures and then preparing for the next advance of the tunnel.

Further details on Lackagh Tunnel can be found in **Appendix A.7.3**.

Cut and Cover Tunnel

The cut and cover tunnel, Galway Racecourse Tunnel, will consist of 230m twin box construction, with a maximum depth of approximately 11m below ground level, with all elements constructed using cast in-situ reinforced concrete or precast concrete box units, which are assembled longitudinally and transversely from discrete precast elements.

The tunnel excavation will be undertaken from ground level. The overburden will be excavated, followed by blasting of the bedrock in order to break it prior to excavation. Rock excavation will progress in a cyclic manner with drilling blast holes, blasting, rock face mapping and mucking out.

The potential impacts related to tunnelling are further discussed in **Section 9.5.3.4**.

9.4.2.6 Construction of Structures

The proposed road development requires the construction of a number of structures. The proposed structures are discussed in **Chapter 5, Description of Proposed Development**.

In general, foundations are likely to require shallow solutions which require a limited, shallow excavation at the footing locations. However, depending on the structure and the ground conditions encountered, some areas will require a more robust solution, which may include:

- Pile foundation in areas of poor, soft ground or in areas of high karst risk
- Earth retaining structures in areas where soil must be restrained at unnatural slopes
- Excavate and replace at footing locations due to karst risk, to expose rock surface in areas underlain by limestone

From existing ground information, the structures identified in **Table 9.17** will likely require deep or a specialised foundation solution due to ground conditions or karst risk.

The potential impacts related to this activity are further discussed in **Section 9.5.3.5**.

Table 9.17: Structures requiring specialised foundation solutions

9.4.2.7 Contaminated ground

Ground investigation information along with the current and historical site activities indicated the potential locations of contamination. These included areas adjacent to existing road networks, infrastructure networks, man-made drainage systems and general built construction.

No areas of contamination were identified during the investigations. See conceptual site model in **Figure 9.8.001** to **Figure 9.8.012**. While areas of contamination are unlikely, out of an abundance of caution, all potential locations will be further investigated during construction and the makeup of the ground evaluated. Any shallow made ground deposits will be excavated and replaced.

Hazardous material removed as part of the excavation may require specialist disposal to designated disposal sites. This is further discussed in **Chapter 7, Construction Activities**.

The potential impacts related to this activity are further discussed in **Section 9.5.3.6**.

9.4.2.8 Soft soil

Soft soil, which includes both peat and soft organic clay / silt, exist across the study area. Typically, peat is present in the western section, underlain by granite, while the limestone area has soft organic and alluvial material. Soft ground areas have been identified and are indicated in **Figure 9.7.001** to **Figure 9.7.002** and **Figure 9.7.101** to **Figure 9.7.114**.

Areas of shallow deposits will likely be excavated and removed. Deeper soft soil deposits may require excavation or in-situ ground improvement.

The potential impacts related to this activity are further discussed in **Section 9.5.3.7**.

9.4.2.9 Karst Features

In Sections 2, 3 and 4, from the N59 Moycullen Road at Dangan to the existing N6 at Coolagh, Briarhill the proposed road development overlies Visean Limestone which is prone to karst. The proposed road development subsequently crosses numerous karst features. Identified surface karst features are presented in **Table 9.10**.

Certain anomalies were encountered during the ground investigation in the area underlain by karstified limestone, refer to **Appendix A.9.1** for all ground investigation data and **Figures 9.8.001** to **9.8.012**.

The hydrogeology of karst features is dealt with in **Chapter 10, Hydrogeology**.

9.4.2.10 Dewatering

The ground investigation data suggests that groundwater will be encountered in some areas of cut and for a number of foundation excavations, refer to **Chapter 7, Construction Activities**. Dewatering is required where significant ingress of water will occur during construction.

The potential impacts of this dewatering and dewatering limitations are assessed and presented in **Chapter 10, Hydrogeology**.

9.4.3 Operational activities

The proposed road development will require periodic maintenance of the development, embankment slopes, cut slopes, tunnels and drainage channels.

9.5 Evaluation of Impacts

9.5.1 Introduction

An appraisal of the potential impacts to geological features and of construction activities was undertaken in accordance with the TII Guidelines (NRA, 2009) considerations as presented in **Section 9.2.5** of this chapter. The evaluation and corresponding impact significance for geological features are presented and summarised in **Table 9.19** for the Construction Phase and **Table 9.20** for the Operational Phase. **Section 9.5.3** and **9.5.4** describes the potential construction and operational activity impacts respectively on soils and geology pre-mitigation.

9.5.2 Do-Nothing Scenario

In the case where the proposed road development was not to be developed there would be no resulting impacts on the soils or geology along the route of the proposed road development. The impact would therefore be *neutral*.

9.5.3 Construction Phase Impacts

The potential soils and geology impacts during the construction phase for each construction activity described in **Section 9.4** are presented in this section, along with their impact significance. These potential impacts also relate to and interact with other environmental factors which are described within the EIAR. Specific interactions are outlined below, with further detail provided in the relevant chapters.

9.5.3.1 Earthworks construction

The soils and geology at each earthworks area are identified in **Table 9.16**. This section relates to potential impacts associated with embankment construction and cutting excavation as discussed in **Section 9.4.2.1** and **Section 9.4.2.2** respectively.

The potential impacts of earthworks construction are listed and described below:

- Compression of Substrata
- Loss of Agricultural Land
- Loss of Solid Geology
- Loss of Future Quarry Reserves
- Introduction of Material derived from a different Lithology
- Flood Barrier
- Earthworks Haulage
- Washout of Fines / Sediment Runoff
- Effect on Surrounding Ground

Compression of Substrata

This impact applies to embankments only.

The construction of an embankment over in-situ virgin ground will cause compression of the sub-strata thus affecting the current characteristics of the ground. The magnitude of such an impact, as per **Table 9.5**, however is deemed to be insignificant due to the small footprint of the embankment areas relative to the local environment.

The significance, as per **Table 9.6** of the potential impact is imperceptible.

Loss of Agricultural Land

The construction of embankments or the excavation of cuts in areas of arable or agricultural land will result in the loss of said resource. The area lost or removed would encapsulate the width of the embankment or cut plus the footprint required for such a construction.

Refer also to **Chapter 14, Material Assets – Agricultural**.

The significance of the potential impact is moderate / slight.

Loss of Solid Geology

This impact applies to cuttings in rock only.

In accordance with the aggregate potential mapping undertaken as part of the National Development Plan 2007-2013, the study area is predominately classified as a very high aggregate potential. The construction of the proposed road development would result in the loss of the aggregate resource.

The type of bedrock that will be excavated is widely available, and as per the TII Guidelines, the portion to be removed will be small adverse in comparison to the volumes retained.

The significance of the potential impact is significant / moderate.

Loss of Future Quarry Reserves

This impact applies to Lackagh Quarry (disused quarry) and Roadstone Quarry (active quarry).

Lackagh Quarry (disused) intersects the proposed road development, impacting future quarry reserves at this location. With appropriate planning permission, the potential for future quarry reserves at Lackagh Quarry, are located beneath the disused quarry footprint and along the east and southern boundaries. Given the presence of a European designated site along the north and western boundaries of Lackagh Quarry expansion in these directions is highly unlikely. The magnitude of impact for loss of a moderate proportion of future reserves is moderate adverse.

The significance of the potential impact is moderate.

The proposed road development is located south of the active Roadstone Quarry in Twomileditch and does not directly impact the quarry. The magnitude of the impact is considered negligible, as the impact to the active quarry is of insufficient magnitude to affect the use or future quarry reserves.

The significance of the potential impact is imperceptible.

Introduction of Material derived from a different Lithology

This impact applies in granite bedrock areas.

The overburden across the study area consists of glacial till derived from the underlying bedrock. The bedrock changes in Section 2 at the N59 Moycullen Road, from a granite to a limestone bedrock which have different chemical compositions.

If limestone derived material is placed over granite bedrock, surface water run-off or groundwater movements through the material have the potential to impact local areas of peatland habitats by changing the pH of the groundwater.

This is further discussed in **Chapter 8, Biodiversity**, **Chapter 10, Hydrogeology** and **Chapter 11, Hydrology**.

The significance of the potential impact is significant / moderate.

Refer also **Chapter 7, Construction Activities**.

Flood Barrier

This impact applies to embankments only.

There are no significant encroachment of any significant floodplains. Embankment constructed in areas prone to flooding have the potential to erode, resulting in a change in the local environment and potential ground movement at the base of the embankment slope. Potential for flooding is discussed further in **Chapter 11, Hydrology**.

The significance of the potential impact is significant / moderate.

Earthworks Haulage

During earthworks construction, heavily loaded large earthmoving vehicles will travel through the site, causing ground vibrations, unwanted compaction and disturbance of natural ground of unfinished road surfaces.

See also **Chapter 7, Construction Activities**, **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration**.

The significance of the potential impact is slight.

Washout of Fines / Sediment Runoff

During or following heavy rainfall events, surface water run-off from embankments comprising of fine material (silt and clay) or exposed cuttings could have a high percentage of suspended solids and result in accumulation of unwanted material in adjacent lands.

See also **Chapter 10, Hydrogeology** and **Chapter 11, Hydrology**.

The significance of the potential impact is slight.

Effect on Surrounding Ground

Soil and rock excavation has the potential to induce movement and settlement of surrounding ground. The breaking or blasting of the bedrock could result in ground vibrations and destabilisation of existing slopes, existing rock slopes, with affects felt in the immediate vicinity of the works.

See also **Chapter 7, Construction Activities**, **Chapter 8, Biodiversity**, **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration**.

The significance of the potential impact is moderate / slight.

9.5.3.2 Re-use and processing of site material

The impacts associated with the introduction of material derived from a different lithology and earthworks haulage are applicable for the re-use and processing of site material. As mentioned in **Section 9.5.3.1** the potential impacts include:

- in the granite bedrock area, where limestone derived material is placed over granite bedrock there is potential to impact the local areas of peatland habitats by changing the pH of the groundwater. The significance of this potential impact is significant / moderate.
- ground vibrations, unwanted compaction and disturbance of natural ground of unfinished road surfaces as a result of haulage during the earthworks construction where heavily loaded large earthmoving vehicles will travel through the site. The significance of this potential impact is slight.

See also **Chapter 7, Construction Activities**, **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration**.

9.5.3.3 Importation, exportation and disposal of materials

The impacts associated with the introduction of material derived from a different lithology and earthworks haulage are applicable for the importation, exportation and disposal of materials, the impacts are mentioned above in **Section 9.5.3.2**.

See also **Chapter 7, Construction Activities**, **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration**.

9.5.3.4 Tunnelling

This section outlines the associated impacts for the construction of the mined tunnel at Coolough, Menlough (Lackagh Tunnel) and the cut and cover tunnel at Ballybrit (Galway Racecourse Tunnel).

A summary of the potential impacts for the proposed tunnel construction at each of the tunnel locations are provided below:

Potential Impact on Limestone Pavement

This potential geological impact applies to Lackagh Tunnel only.

Potential geological impacts on the integrity of the geological attribute (Limestone pavement), due to the mined tunnel, include such impacts as ground settlement, and rock mass instability. The potential geological impacts from the mining activities could include blast damage due to ground vibration and air blast vibrations. See also **Chapter 8, Biodiversity** and **Chapter 10, Hydrogeology**.

Considering the key design features presented in **Section 9.4.1** and the conservative design approach the magnitude of the potential geological impact is considered to be negligible, as the potential geological impact would result in impact on attribute but of insufficient magnitude to affect either use or integrity, as per **Table 9.5**. Further details on the proposed Lackagh Tunnel are provided in **Appendix A.7.3**.

The significance, as per **Table 9.6**, of the potential geological impact is imperceptible.

Other potential geological impacts to Limestone pavement are discussed in **Section 9.5.3.5** where Limestone pavement occurs under structures and in **Section 9.5.3.8** where it occurs within the study area.

Loss of Feature

The tunnel bores are to advance through Visean limestone, resulting in the loss of the intact rock. The cut and cover tunnel in Ballybrit will require the excavation of Visean limestone, which will also result in the loss of intact rock.

The impacts associated with the loss of solid geology are applicable for loss of feature. As mentioned in **Section 9.5.3.1** the potential impact which applies to cuttings in rock only will result in the loss of the aggregate resource. The significance of this potential impact is significant / moderate.

Ground Settlement

The impacts associated with the effects to surrounding ground are applicable for ground settlement. As mentioned in **Section 9.5.3.1** soils and rock excavations, including the breaking or blasting of the bedrock, could result in ground vibrations and destabilisation of existing slopes, existing rock slopes and has the potential to impact the surrounding ground by inducing movement. The significance of this potential impact is moderate / slight.

Potential Impact due to Blasting

The impacts associated with the effects to surrounding ground are also applicable for potential impact due to blasting and are outlined above.

Other potential construction impacts from Lackagh Tunnel and Galway Racecourse Tunnel are discussed in **Chapter 7, Construction Activities**, **Chapter 8, Biodiversity**, **Chapter 10, Hydrogeology**, **Chapter 11, Hydrology**, **Chapter 16, Air Quality and Climate**, **Chapter 17, Noise and Vibration** where the potential impacts of construction traffic, dewatering, dust and noise and vibration from blasting bedrock are described in detail.

9.5.3.5 Construction of Structures

The construction activities for structures presented in **Chapter 5, Description of Proposed Development** may impose some of the following impacts, dependant on the geology encountered at the location of the structure footings:

- Ground Settlement
- Noise and vibration
- Material disposal i.e. bored pile installation

See also **Chapter 7, Construction Activities**, **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration**.

The significance of the potential impact is slight.

Potential Impact on Limestone Pavement

Two structures along the proposed road development traverse Limestone pavement in Menlough. It should be noted, at both of these locations the Limestone pavement is outside the Lough Corrib cSAC, refer to **Chapter 8, Biodiversity** for the ecological assessment.

The proposed road development includes the construction viaduct in Menlough. The proposed Menlough Viaduct will result in the minor loss (circa 500m^2) of a small part of the attribute (Limestone pavement).

The magnitude of the potential geological impact, as per **Table 9.5** is considered small adverse, as the potential geological impact would result in loss of small part of the attribute[21].

The significance of the potential geological impact, as per **Table 9.6**, is significant / moderate.

A culvert is located in an area of Limestone pavement in Menlough. The magnitude of the potential geological impact is negligible, as the structural integrity of the Limestone pavement is maintained. The significance of the potential geological impact is imperceptible.

Other potential geological impacts to Limestone pavement are discussed in **Section 9.5.3.4** for Lackagh Tunnel and in **Section 9.5.3.8** where Limestone pavement occurs within the study area.

9.5.3.6 Contaminated Ground

No known areas of contaminated ground were located within the study area. Exposure of locations of contamination and excavation of contaminated soil may potentially lead to a risk to the surrounding environment or underlying soil if not dealt with in an appropriate manner in accordance with the Environmental Protection Agency guidance on Land Contamination.

The underlying soil could be impacted from the exposure of previous buried hazardous material, in an unlicensed dumping site for example, or from the discharge of wash water from concrete operations.

The potential impacts could also include the potential for leakage or spillage of construction related materials, contaminating the subsoils present.

For example, raw or uncured concrete and grouts, washed down water from exposed aggregate surfaces, cast-in-place concrete from concrete trucks, fuels, lubricants and hydraulic fluids for equipment used on the development site, bitumen and sealants used for waterproofing concrete surfaces can all potentially impact on soils and groundwater during construction stage.

The significance of the potential impact is moderate / slight.

9.5.3.7 Soft soil

The potential impacts associated with soft ground removal are discussed under Effects of Surrounding Ground in **Section 9.5.3.1**.

As mentioned in **Section 9.5.3.1** soil excavations could result in destabilisation of existing slopes and has the potential to impact the surrounding ground by inducing movement.

The significance of this potential impact is moderate / slight

[21] Box 5.1: Criteria for rating impact significance at EIA stage. A magnitude of impact of small adverse is one where there is a "minor impact on integrity of attribute or loss of small part of attribute" (NRA, 2009)

The potential impact associated with the presence of soft ground at structure locations is ground settlement as discussed **Section 9.5.3.5**.

9.5.3.8 Karst features

The study area contains the following karst features (which have a geological feature importance of medium or higher):

- Limestone pavement
- Turlough
- Springs

See also **Chapter 10, Hydrogeology**.

Potential Impact on Limestone Pavement

The proposed road development traverses six locations of limestone pavement in Sections 3 and 4. These locations include:

- One location at Lackagh Tunnel, which passes under an area of Limestone pavement, within Lough Corrib cSAC, refer to **Section 9.5.3.4**. The significance of this potential geological impact is imperceptible
- Two locations of Limestone pavement are under structures in Menlough, located outside Lough Corrib cSAC, refer to **Section 9.5.3.5**. The significance of this potential geological impact at these locations is considered significant / moderate and imperceptible
- Three other locations, all outside the Lough Corrib cSAC, are under the proposed road development and discussed below.

At these three locations the Limestone pavement is encapsulated under the proposed road development. Two of these locations are in Menlough and one location is in Coolagh, at these locations the proposed road development results in loss of small part of the Limestone pavement.

The significance of the potential geological impact for areas of Limestone pavement lost under the proposed road development is significant / moderate.

All other Limestone pavement areas within the study area are not directly impacted by the proposed road development.

The significance of the potential geological impact for areas of Limestone pavement within the study area but outside of the proposed road development is imperceptible.

Refer to **Chapter 8, Biodiversity** for the potential ecological impacts to Limestone pavement.

Surface Karst Solution Features

The proposed road development will result in the loss of part of the enclosed depression (K12), the enclosed depression (K97) and the spring (K193).

The significance of the potential impact for these attributes is moderate.

Additional individual karst features have been identified in the study area, as presented in
Table 9.10, however these additional ones, excluding K12, K97 and K193, will not be directly affected by the proposed road development as they exist outside the fence line.

In such situations, the significance of the potential impact is imperceptible.

9.5.4 Operational Phase

The significance rating on the soils and geology from the operational phase of the proposed road development will generally be Imperceptible according to the TII Guidelines criteria (TII, 2009). Overall there is neutral long term impact on the soils and geology along the route of the proposed road development. The potential geological impacts on the environment have been provided below for the operational phase:

Contamination

Maintenance works could lead to occasional accidental leakage of oil, petrol or diesel, allowing contamination of the surrounding environment. However, the magnitude of the impact is negligible as spills will be contained and materials will be disposed of appropriately using a fully licensed waste contractor with the appropriate permits. The significance of the potential impact is imperceptible.

Ground Movement

The mined tunnel in Coolough, Menlough, Lackagh Tunnel, may experience minimal long term ground movement (settlement) of the local environment. With the support measures as outlined in the design phase, **Section 9.4.1.1**, and monitoring during the construction phase the magnitude of the potential impact is negligible.

The significance of the potential impact is imperceptible.

9.6 Mitigation Measures

9.6.1 Introduction

This section describes the mitigation measures to reduce or avoid potential impacts where possible, for both the construction (**Section 9.5.2**) and operational phases (**Section 9.5.3**) of the proposed road development.

The mitigation measures for potential impacts to geological features are presented and summarised in **Table 9.19** for the Construction Phase and **Table 9.20** for the Operational Phase.

9.6.2 Construction Phase

The mitigation measures for the potential construction impacts are provided below.

9.6.2.1 Earthworks construction

Construction techniques that comply with the requirements of statutory bodies in terms of noise, vibration, soil and groundwater contamination and disposal of contaminated material for both soil and rock cuttings will be adopted.

Loss of Agricultural Land and Solid Geology

All excavated material, excluding a small potential volume of hazardous material, will be re-used as construction fill and material deposition areas minimising the loss of the feature. The Contractor will ensure acceptability of the material for re-use within the proposed road development with appropriate handling, processing and segregation of the material.

Introduction of Material derived from a different Lithology

A construction earthworks programme will be implemented as part of the CEMP, which is finalised by the contractor, for the proposed road development which categorises the source of material for each fill section. During the finalisation of this programme, the fill limitations outlined below will be incorporated.

To prevent impact to the local peatland habitats, described in **Chapter 8, Biodiversity**, the following fill limitations will be incorporated at the locations identified **Table 9.18**.

- Only pavement and capping layers protected from surface water runoff and groundwater movements are permitted to be derived from non-native material
- All other acceptable fill material will be derived from native material or other pH compatible material

Table 9.18: Fill Limitation Areas

Location	Annex I Habitat / Fossitt (2000) ID Codes*	Fill Limitation Chainage area	
		From	To
1	4030 mosaic	0+620	0+775
2	4010	1+300	1+450
3	4010	1+830	2+065
4	4010	2+875	3+090
5	4010	3+440	3+550
6	4030/4010 and 4010	3+595	3+890
7	4030 mosaic and 4010	4+800	5+150
8	PF2	7+850	7+900

*Refer to **Chapter 8, Biodiversity** for details

Flood Barrier

A drainage layer or starter layer, in accordance with the TII publication CC-SCD-00606, will be implemented for the construction of embankments in areas prone to flooding. The introduction of a drainage layer will ensure hydraulic conductivity exists across the flood plain and removes the risk of the embankment acting as a flood barrier.

Earthworks Haulage

Earthworks haulage will be along predetermined routes within and outside the proposed development boundary as shown on **Figures 7.101** to **7.123**.

The identified haulage routes are along existing national, regional and local routes or within the proposed development boundary.

Where compaction occurs due to truck movements and other construction activities on unfinished surfaces, remediation works will be undertaken to reinstate the ground to its original condition. Where practicable, compaction of any soil or subsoil which is to remain in-situ along the proposed road development will be avoided.

Washout of Fines / Sediment Runoff

The use of granular fill material in embankment construction will remove the likelihood of the washout of fines. However, in the event the embankment will be constructed of local material, the introduction of a drainage layer or starter layer (as discussed in Flood Barrier section above) will reduce the likelihood of run-off of fine material.

Alternatively, the introduction of a geotextile separator will reduce the potential impact in areas. A composite system, combining a drainage layer and a geotextile separator will be implemented in embankments constructed with cohesive fill material.

Sediment control methods are outlined in the CEMP in **Appendix A.7.5** and in **Chapters 10, Hydrology** and **11, Hydrogeology**.

Effect on Surrounding Ground

Ground settlement, horizontal movement and vibration monitoring will be implemented during construction activities to ensure that the construction does not exceed the design limitations.

In situations where the site specific blast design has determined that blasting is not feasible in a particular location due to excessive ground vibrations, alternative extraction methods such as hydraulic breaking, hydraulic splitting, chemical splitting and electrical disintegration may be implemented and monitored. Monitoring will be implemented during blasting, during excavation of cuts, for overburden slopes steeper than 1V:2H (V= vertical slope, H = horizontal slope) and rock slopes steeper than 1V:1.5H.

A geotechnical expert will be appointed by the contractor and will be present to monitor the surrounding ground vibrations near sensitive receptors during blasting works. In the unlikely event that the blast vibration limit at the surface is exceeded, blasting works will cease on site until it is understood the basis for the increased vibration. The blast design will then be recalibrated and blasting works will proceed with continued monitoring.

Allowable distances for the various construction methods are outlined in **Chapter 17, Noise and Vibration**.

9.6.2.2 Reuse and processing of site material

A construction earthworks programme will be implemented for the proposed road development which categorises the source of material for each fill section. During the finalisation of this programme the fill limitations outlined in **Section 9.6.2.1** will be incorporated at the locations presented in **Table 9.18**.

9.6.2.3 Importation, exportation and disposal of materials

Importation of materials from outside the site will be minimised by ensuring that materials arising within the site area are used to the greatest extent possible. Any surplus material remaining which cannot be incorporated into the construction fill activities shall be placed in material deposition areas within the proposed road development. This will significantly reduce the deposition of material off-site.

Hazardous material will be transported off site for disposal or recovery at appropriately licence or permitted sites as outline in **Chapter 7, Construction Activities**.

9.6.2.4 Tunnelling

The adopted construction techniques will comply with the requirements of statutory bodies in terms of noise, vibration, soil and groundwater contamination and disposal of contaminated material.

During the construction of Lackagh Tunnel the supported rock face of Lackagh Quarry Face and retaining walls for the Western approach will be monitored for movement. A geotechnical expert will be appointed, by the contractor and will be present to monitor the rock mass stability during their construction period. In the unlikely event that instability within the rock mass is observed, additional support measures will be installed to ensure that there is no impact to the surface above. The additional rock support measures comprise ground anchors, rock bolts, rock dowels, rock mesh, shotcrete or a combination of these measures, designed to the relevant design standards and best practice guidance documents. However, based on the conservative design approach it is considered that the risk of instability will be avoided and additional support measures will not be required.

A geotechnical expert will be appointed by the contractor and will be present to monitor the vibrations at the surface, including the areas of Limestone pavement, during blasting works for the construction of Lackagh Tunnel and the Western Approach. The blast target vibration limit is defined as 20% more conservative than the conservative design approach vibration limit of 25mm/sec at the ground surface which includes areas of Limestone pavement, which provides an added factor of safety to the construction works to ensure that blasting will not impact the structural integrity of the Limestone pavement. In the unlikely event that the blast target vibration limit at the surface is exceeded, blasting works will cease on site until it is understood the basis for the increased vibration. The blast design will then be recalibrated and blasting works will proceed with continued monitoring.

For further information on Lackagh Tunnel is presented in **Appendix A.7.3**.

9.6.2.5 Construction of Structures

Construction of structures will be completed in accordance with the Construction Environmental Management Plan (CEMP) in **Appendix A.7.5** and as described in the following:

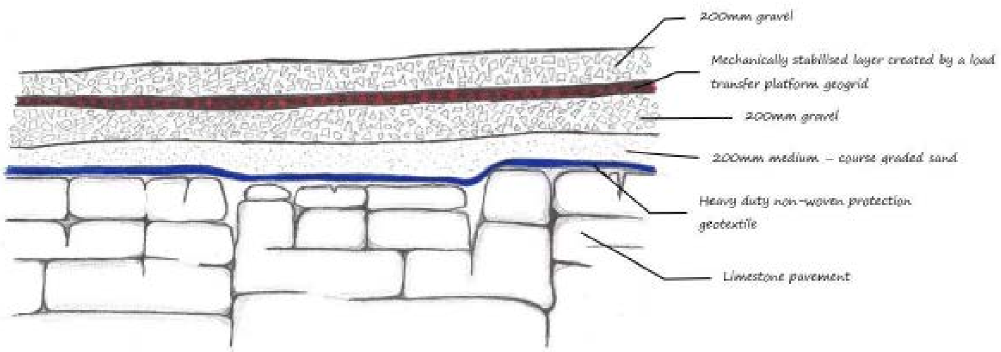
- River Corrib Bridge Constructability Examination **Appendix A.7.1**
- Menlough Viaduct Constructability Examination **Appendix A.7.2**
- Lackagh Tunnel Geotechnical and Hydrogeological Appraisal **Appendix A.7.3**
- Galway Racecourse Tunnel Constructability Report **Appendix A.7.4**

Ground settlements will be controlled through selection of the foundation type and method of construction which are suitable for the particular ground conditions.

To minimise soil movements due to pile operations in the vicinity of sensitive receptors, each pile shall be constructed sequentially in a direction away from the sensitive receptor. Previously installed piles act as a shield as soil movements are greater in a direction away from the stiffer zone i.e. away from the piles and sensitive receptors.

During construction, the Limestone pavement at Menlough Viaduct will be protected and will not be impacted by implementing a protection system comprising of geogrid, protection geotextile and layers of material, as per **Plate 9.2**. This will be removed once construction is complete. Refer to Menlough Viaduct Constructability Report in **Appendix A.7.2** for further details.

Plate 9.2: Limestone pavement protection system



9.6.2.6 Contaminated ground

No known areas of contaminated ground were located within the study area. Samples of ground suspected of contamination will be tested for contamination during the detailed investigation and ground excavated from these areas will be disposed of to a suitably licence or permitted sites in accordance with the current Irish Waste Management legislation.

Good housekeeping (daily site clean-ups, use of disposal bins, etc.) on the site, and the proper use, storage and disposal of these substances and their containers will prevent soil contamination.

For all activities involving the use of potential pollutants or hazardous materials, material such as concrete, fuels, lubricants and hydraulic fluids will be carefully handled and stored to avoid spillages. Potential pollutants shall also be adequately secured against vandalism and will be provided with proper containment according to codes of practice. Any spillages will be immediately contained and contaminated soil removed from the site and disposed of to an appropriately permitted or licenced site according to the current Irish Waste Management Legislation by the contractor.

The contractor is required to make provision for removal of any concrete wash water. Concrete trucks will be directed back to their batching plant for washout. The arrangement for concrete deliveries to the site will be discussed with suppliers before commencement of work, outlining the agreed assessed routes, prohibiting on site washout and discussing emergency procedures.

9.6.2.7 Karst features

As a minimum, the carriageway drainage network will be sealed in areas where the proposed road development crosses rock particularly prone to karstification. Through the use of engineered solutions, including an impermeable barrier, cement slurry or grout, direct run-off from the paved surface of the proposed road development will be prevented from entering into the rock along the proposed alignment, as this could cause further deterioration and instability of the rock mass. Individual mitigation measures will be assessed on a case by case basis, determined by the extent of karst and make up of the proposed road development as outlined in the karst protocol which is part of the CEMP (**Appendix A.7.5**). Inspections of karst features will be undertaken by a hydrogeologist and/or geotechnical expert in order to determine the appropriate remediation measure. These remedial measures include but are not limited to the removal of all loose, soft, weak or voided soil material, backfilling voids with an agreed combination of boulders cobbles / chunk rock / cement slurry and installation of a high strength geosynthetic to form a competent, safe foundation platform.

Mitigation measures for the protection of karst features are further outlined in **Chapter 10, Hydrogeology** and included in the Construction Environmental Management Plan (CEMP) as part of the karst protocol.

9.6.3 Operational Phase

During the operational phase, monitoring of the rock mass stability will continue. The rock and overburden retaining systems in Lackagh Quarry and Western Approach will continue to be monitored as part of the TII (Transport Infrastructure Ireland) maintenance schedule. In the extremely unlikely event that instability within the rock mass is observed additional support measures outlined above in **Sections 9.4.1.1** and **9.6.2.4**, for the construction phase will be installed to ensure that there is no impact to the structural integrity of the Limestone pavement. However, based on the conservative design approach, (the installed composite support system and monitoring during construction) it is considered that the risk of instability will be avoided and additional support measures will not be required.

Operation mitigations measures for Lackagh Tunnel are further discussed in **Appendix A.7.3**.

The implementation of the design, construction methodology control measures and mitigations measures results in no other operational phase mitigation measures for avoiding potential direct and indirect impact to the soils and geology environment for the proposed road development.

9.7 Residual Impacts

9.7.1 Construction and Operation Residual Impacts

Implementing the outlined mitigation measures will result in a number of significant residual negative impacts on the soil and geological at the construction phase. These impacts occur where the construction of the proposed road development will result in a small loss of Limestone pavement (all outside European designated sites).

Implementation of the outlined mitigation measures will result in imperceptible residual negative impacts on the soil and geological at the operation phase.

The residual impacts are shown in **Table 9.19**: Predicted Residual Impacts for Geological Features and Activities during Construction Phase and **Table 9.20**: Predicted Residual Impacts for Geological Features and Activities during Operational Phase.

Table 9.19: Predicted Residual Impacts for Geological Features and Activities during Construction Phase

Feature / Construction Activity				**Impact Assessment**				
Name	**Importance**	**Assessment Section**	**Location**	**Magnitude of Impact**	**Criteria for Impact Assessment**	**Significance of Impact**	**Mitigation Measure**	**Residual Impact**
Limestone pavement [22]– Menlough Viaduct (outside European designated sites)	Very High	3	Menlough	Small Adverse	Results in loss of small part of attribute	Significant / Moderate	The magnitude of the loss of the attribute was minimised during the design stage where the number of piers and size of the pier footings was kept to a minimum. During construction of the viaduct, the Limestone pavement will be protected using a protection system, comprising of geogrid, protection geotextile and layers of material. This will be removed once construction is complete.	Significant / Moderate

[22] This table presents the geological assessment of Limestone pavement, refer to **Chapter 8, Biodiversity** for an ecological assessment.

Feature / Construction Activity				Impact Assessment				
Name	**Importance**	**Assessment Section**	**Location**	**Magnitude of Impact**	**Criteria for Impact Assessment**	**Significance of Impact**	**Mitigation Measure**	**Residual Impact**
Limestone pavement – Covered by the proposed road development (outside European designated sites)	Very High	3 and 4	Menlough and Coolagh	Small Adverse	Results in loss of small part of attribute	Significant / Moderate	No mitigation available	Significant / Moderate
Limestone pavement – Lackagh Tunnel (within European designated sites)	Very High	3	Coolagh	Negligible	Results in an impact on attribute but of insufficient magnitude to affect integrity	Imperceptible	The engineered design solutions to reduce the impact of the integrity of the geological feature will be monitored on site during construction. These solutions include sufficient rock above the tunnel bores, a suitable pillar between the bores to protect the tunnel from collapse and suitable blasting sequences. The site control measures include probing ahead of the tunnel and	Imperceptible

9.7.2 Cumulative Impacts

The cumulative residual construction and operational impacts of the proposed road development and the following projects and plans have been assessed:

- The N59 Oughterard to Maam Cross
- M17 / N18 Gort to Tuam PPP Scheme
- Galway Harbour Port Extension
- Galway Transport Strategy (GTS), which includes the following:
  - Investigate prospective sites to the east of the city for Park and Ride
  - Bearna Greenway
  - Tuam Road Bus Corridor Scheme
  - Expansion of Public Bike Hire Scheme
- Galway City Development Plan 2017–2023
- Galway County Development Plan 2015–2021

Cumulative soils and geology impacts can occur when other projects in the locality have similar soils and geology potential impacts as the proposed road development. Cumulative impacts are assessed based on the residual impact[23] of these impacts on the proposed projects.

The following feature / construction activity impacts are identified in the projects and plans, listed above, and are also present in the proposed road development:

- Peat Removal / Disposal
- Impact to Geological Heritage Sites
- Contaminated Ground
- Loss of agricultural land and solid geology
- Haulage of material

As part of the environmental evaluation of the proposed road development the residual impact from peat removal/disposal, of geological heritage sites and contaminated ground is imperceptible. Due to the mitigation measures considered in the other project, the residual impact of those projects is also considered imperceptible. Therefore, the cumulative impact of these impacts is imperceptible.

The cumulative impact for:

- peat removal /disposal is considered to be imperceptible as peat is intended to remain within the proposed development boundary for each respective project
- geological heritage sites is considered to be imperceptible as none of the projects indicate that a geological heritage sites or county geological sites will

[23] This infers that mitigation measures have been implemented and the cumulative impact is assessed against the residual risk.

be impacted. The Galway Transport Strategy specifically outlines that it will seek to protect such sites from any inappropriate measures

- contaminated ground is considered to be imperceptible as the Galway City Development Plan (2017-23) waste management policy contains policy to ensure that proposals on contaminated lands include appropriate remediation measures

Loss of agricultural land and solid geology and haulage of material, whether imported or sourced from site, are activities that are also considered on other projects. Mitigation measures for other projects include the reduction and minimisation of removal or disposal of material off-site and the reuse of such material whether in construction fill or in designated material deposition areas. Consideration has been given to the extent of material which will be imported, exported or disposed and their combined impact. The cumulative impact is considered to remain unchanged as the combination of the impact will not increase the magnitude of the impact from small adverse.

The significance of the impact of the proposed road development operational activities is imperceptible and is considered not to change in combination with the other projects.

Therefore, there are no other plans or projects that are likely to result in a significant effect on soils and geology cumulatively with the proposed road development.

9.7.3 Residual Impacts Summary

The construction and operational residual impacts for the proposed road development are presented in **Table 9.19** and **9.20** respectively. After consideration of the other projects in the locality, the cumulative residual impact for the construction and operational stage is as per **Table 9.19** and **9.20** for the proposed road development and there are no cumulative soils and geology impacts.

9.8 Summary

The soils and geology environment will be impacted by the proposed road development.

Certain geological features will be impacted in all earthwork sections and these are highlighted in **Section 9.8.1**, loss of attributes.

Potential impacts due to construction or operational activities have the potential to occur, but the significance of the impact will be reduced, where possible, with implementation of mitigation measures. The potential residual impacts are presented in **Section 9.8.2** and **Section 9.8.3** respectively.

A summary review of the four sections of the proposed road development is presented in **Section 9.8.4** to **Section 9.8.7**.

Construction will be completed in accordance with the Construction Environmental Management Plan in **Appendix A.7.5**.

9.8.1 Loss of Attributes

A proportion of well drained fertile soil and crushed rock aggregate potential will be lost within the footprint of the proposed road development. The significance of such a loss is considered a moderate / slight impact in the case of agricultural soil and significant / moderate in the case of the crushed rock aggregate potential. While no mitigation measure can be implemented to reduce the impact on the agricultural soil, all excavated material will be used as construction fill or placed in deposition areas, thus contributing to the construction material requirements for the proposed road development. The re-use of the crushed rock aggregate potential is considered to be a reduction in impact to future quarry reserves, thus reducing the impact to a residual impact of moderate / slight.

The loss of part of three karst features will result from the proposed road development, enclosed depression (K12), enclosed depression (K97) and spring (K193). The significance of the potential impact for these attributes is moderate.

The proposed road development traverses locations of Limestone pavement in Sections 3 and 4 that is located both within and outside European designated sites. The geological assessment (importance and impact) has not differentiated between Limestone pavement located within or outside the European designated sites. Refer to **Chapter 8, Biodiversity** for an ecological assessment of Limestone pavement.

Lackagh Tunnel passes under an area of Limestone pavement that is within a European designated site resulting in minimal to no impact on the feature from a geological perspective. Menlough Viaduct and a culvert in Menlough pass over Limestone pavement (both outside European designated sites), resulting in a loss of a small part of the attribute under the viaduct piers and no impact on the feature under the culvert. There are three locations where the proposed road development traverses and covers Limestone pavement (all outside European designated sites): two locations in Menlough and one location in Coolagh. At these locations it will result in loss of a small part of the Limestone pavement, it should be noted that both of these locations are outside of the European designated sites.

The geological significance of loss of Limestone pavement was assessed at each location with the results ranging from imperceptible where there is no impact to significant/ moderate where loss of small part of the attribute occurs.

The proposed road development will result in the loss of part of the palaeolandscape in the east of the city. These features are known to be located in Menlough, Ballindooley and Castlegar. The significance of the loss of these features is slight.

The proposed road development will also result in the moderate loss of future reserves, with appropriate planning, at Lackagh Quarry (disused quarry). The significance of the loss of future reserves is considered moderate.

9.8.2 Residual Impacts due to Construction

Introduction of material derived from a different lithology, washout of fines, spread of contamination, construction induced flooding or unwanted disturbance of environment are all potential construction impacts on the receiving environment. Development and implementation of mitigation measures reduce such impacts to a moderate / slight or imperceptible residual impact on the soils and geology environment.

9.8.3 Residual Impacts due to Operation

All operational activities of the proposed road development are deemed to produce imperceptible impacts to the surrounding geological environment.

9.8.4 Section 1: Chainage 0+000 to 8+500 (R336 to the N59 Moycullen Road)

Section 1 contains the least number of potential impacts out of all four sections. All unique impacts applicable to Section 1 are presented in this section.

Settlement or movement of the surrounding environment can be induced adjacent to large cuttings, such as in Ballard or Letteragh. A clear understanding of the soil /rock behaviour, following detailed ground investigation, will contribute to the development of the detailed design and construction methodology in order to reduce or completely remove construction induced movement.

Blasting will be required for deep cuttings in rock, such as the characteristics anticipated for the cut sections in Ballard and Letteragh. Data obtained from trial blasts will calibrate the blast design to site specific designs and will refine the blast design properties. Where blasting is not viable, rock breaking will be conducted by hydraulic breaking/splitting or other industry methods.

In this granite region to prevent impact to the local peatland habitats**,** the following fill limitations will be incorporated at the locations identified **Table 9.18** of this chapter.

- Only pavement and capping layers protected from surface water runoff and groundwater movements are permitted to be derived from non-native material
- All other acceptable fill material will be derived from native material or other pH compatible material

This will be included in the construction earthworks programme which categorises the source of material for each fill section.

9.8.5 Section 2: Chainage 8+500 to 9+400 (N59 Moycullen Road to the River Corrib)

Section 2 is completely in fill and contains the second least number of potential impacts of all sections. The section is also the shortest length at only 900m. All unique impacts applicable to Section 2 are presented in this section.

The bedrock changes from granite to limestone in Section 2 at the N59 Moycullen Road, with the overlying materials having different chemical compositions. As such at the locations identified in **Table 9.18** in the granite region the following fill limitations will be incorporated:

- Only pavement and capping layers protected from surface water runoff and groundwater movements are permitted to be derived from non-native material
- All other acceptable fill material will be derived from native material or other pH compatible material

River Corrib Bridge will require a specialised foundation solution due to the soft ground anticipated and karst risk in the area. The foundation solution will require the installation of piles which could induce ground settlement in the surrounding environment and cause noise and vibrations from the installation works.

9.8.6 Section 3: Chainage 9+400 to 14+000 (River Corrib to the N83 Tuam Road)

Section 3 contains the largest number of impacts out of all four sections. All unique impacts applicable to Section 3 are presented in this section.

Sixteen structures located in Section 3 will potentially require specialised foundation solutions. The location and name of these structures are presented in **Table 9.17**. Two of the structures are located on the boundary between Section 3 and 4.

The proposed road development traverses locations of Limestone pavement located within and outside European designated sites in Sections 3. These locations are:

- Menlough Viaduct and a culvert structure traverse over areas of Limestone pavement both outside European designated sites resulting in loss of a small part of Limestone pavement at the viaduct
- There are two other locations in Menlough which will result in loss of part of the Limestone pavement that is located outside European designated sites through encapsulation
- Lackagh Tunnel traverses beneath Limestone pavement that is located within European designated sites and will emerge into Lackagh Quarry. A conservative design approach has been adopted for Lackagh Tunnel including ground anchors, rock bolts, rock dowels, steel mesh and shotcrete controlling rock stability and tunnel design features. As an additional control measure, a geotechnical expert will be appointed to monitor the rock mass stability at construction and operation stages. In the extremely unlikely event, due to the adopted conservative design approach, that instability within the rock mass is observed additional support measures such as ground anchors, rock bolts, rock dowels will be installed to ensure that there is no impact to the Limestone pavement. Based on the conservative design approach, it is considered that the risk of instability will be avoided and additional support measures will not be required. The residual risk is considered imperceptible to the Limestone pavement. Further details in relation to this can be found in **Appendix A.7.3**.

The remaining structures in **Table 9.17** are likely to require a robust foundation solution due to soft ground or karst which is present throughout section 3. The foundation solutions will require either the installation of piles or an excavation and replace of soft ground, which could induce ground settlement in the surrounding environment and cause noise and vibrations from the works.

Settlement or movement of the surrounding environment can be induced adjacent to large cuttings. The implemented design and selected construction methodology, will reduce or completely remove construction induced movement.

Blasting will be required for the tunnel construction and for deep cuttings in rock. Blasting may not be viable at all locations as a result of the local receptors limitations. Where blasting is not viable, alternative rock breaking methods will be implemented such as hydraulic breaking/splitting or other industry methods. As part of the blast design assessment monitored trial blasts in the same bedrock formation as the proposed blast locations at locations of proposed blasting will be conducted. These trial blasts will calibrate the blast design to site specific designs and will refine the blast design properties. Trial blasts will not exceed the limitations of the local sensitive receptors.

The proposed road development intersects a disused Lackagh Quarry and is located south of an active Roadstone Quarry in Twomileditch. Considering the proposed road development, the quarry location, proximity and status the potential impact of future reserves was assessed. The proposed road development will result in the loss of moderate proportion of future quarry reserves at Lackagh Quarry. The magnitude of such an impact is considered moderate adverse. No mitigation measure can be implemented to reduce this impact. The significance of the impact is moderate for the disused Lackagh Quarry. At Roadstone Quarry the proposed road development does not directly impact the quarry. The magnitude of the impact is considered negligible, as the impact to the active quarry is of insufficient magnitude to affect the use or future quarry reserves. The significance of the potential impact is imperceptible for the active Roadstone Quarry.

9.8.7 Section 4: Chainage 14+000 to 17+500 (N83 Tuam Road to the existing N6 at Ardaun, Coolagh)

All unique impacts applicable to Section 4 are presented in this section.

Two structures in Section 4 will potentially require specialised foundation solutions. The location and name of these structures are presented in **Table 9.17**. The foundation solution may require the installation of piles, which could induce ground settlement in the surrounding environment and cause noise and vibrations from the piling works.

Settlement or movement of the surrounding environment can be induced adjacent to large cuttings. The implemented design and selected construction methodology, will reduce or completely remove construction induced movement. Tolerances will be set for cuttings adjacent to properties.

The proposed road development traverses one location of Limestone pavement, which is located outside the European designated sites, in Sections 4 in Coolagh resulting in the loss of small part of the Limestone pavement.

Blasting will be required for the construction of the Galway Racecourse cut and cover tunnel. As part of the blast design data obtained from trial blasts will calibrate the blast design to site specific designs and will refine and validate the blast design properties. Where blasting is not viable, rock breaking will be conducted by hydraulic breaking/splitting or other industry methods.

10 Hydrogeology

10.1 Introduction

This chapter of the EIAR consists of an appraisal of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, under the heading of hydrogeology.

This chapter initially sets out the methodology followed (**Section 10.2**), describes the receiving environment (**Section 10.3**) and summarises the main characteristics of the proposed road development which are of relevance for hydrogeology (**Section 10.4**). The evaluation of impacts of the proposed road development on hydrogeology are described (**Section 10.5**) and measures are proposed to mitigate these impacts (**Section 10.6**). The residual impacts are also described (**Section 10.7**). The chapter concludes with a summary (**Section 10.8**) and reference section (**Section 10.9**).

This chapter has utilised the information gathered during the constraints and route selection phases of the proposed road development to inform the hydrogeology impact appraisal. **Sections 4.5**, **6.5.3** and **7.6.3** of the **Route Selection Report** considered the hydrogeology constraints within the proposed road development study area and compared the potential hydrogeology impacts of the proposed route options respectively. These sections of the **Route Selection Report** contributed to the design of the proposed road development which this chapter appraises.

10.2 Methodology

10.2.1 Introduction

This section outlines the methodology used to prepare this chapter of the EIAR and is founded on current legislation and guidelines.

10.2.2 Legislation and Guidelines

This chapter is prepared having regard to the requirements of Section 50 Sub-section (2 and 3) of the Road Act 1993 as amended, and with the following guidance:

- Environmental Protection Agency (EPA) Guidelines on Information to be contained in Environmental Impact Statements (EPA, 2002)
- Environmental Protection Agency (EPA) Advice Notes on Current Practice in the Preparation of Environmental Impact Statements (EPA, 2003)
- Transport Infrastructure Ireland (TII) Environmental Impact Assessment of National Road Schemes – A Practical Guide (NRA, 2008)

- Transport Infrastructure Ireland (TII) Guidelines on Procedures for Assessment and Treatment of Geology, Hydrology and Hydrogeology for National Road Schemes (NRA, 2009)
- Institute of Geologists of Ireland (IGI) Guidelines for the Preparation of Soils, Geology and Hydrogeology Chapters of Environmental Impact Statements (IGI, 2013)
- Environmental Protection Agency (EPA) Draft Revised Guidelines on Information to be contained in Environmental Impact Statements (EPA, 2015)
- Environmental Protection Agency (EPA) Draft Advice Notes for Preparing Environmental Impact Statements (EPA, 2015)
- Transport Infrastructure Ireland (2015) Design Manual for Roads and Bridges
- Guidelines on the Information to be contained in Environmental Impact Assessment Reports (Environmental Protection Agency, Draft May 2017)

The main guidelines used in preparing this chapter are the EPA Guidelines on the Information to be contained in Environmental Impact Assessment Reports (EPA, 2002, 2015 and 2017) and the most recent publication by the TII which outlines the assessment methodology for Soils, Geology and Hydrogeology for National Road Schemes (NRA, 2009). The latter guidelines are referred to as TII Guidelines within this chapter.

Water resource management in Ireland is dealt with in the following key pieces of legislation:

- Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy
- Directive 2006/118/EC of the European Parliament and of the Council of 12 December 2006 on the protection of groundwater against pollution and deterioration
- European Communities (Water Policy) Regulations 2014 (S.I. No 350 of 2014)
- European Communities (Water Policy) Regulations 2014 (S.I. No. 350 of 2014)
- European Communities Environmental Objectives (Groundwater) Regulations 2010 (S.I. No. 9 of 2010), as amended
- European Communities Environmental Objectives (Surface Waters) Regulations 2009 (S.I. No. 272 of 2009) as amended
- European Union (Drinking Water) Regulations 2014 (S.I. No. 122/2014)
- European Communities (Quality of Salmonid Waters) Regulations, 1988 (S.I. No. 293/1988)
- Water Services Acts 2007 to 2014

10.2.3 Consultations

Consultation was carried out with relevant bodies to identify any hydrogeological features which may be impacted by the proposed road development. Consultation was undertaken by the design team with additional consultation undertaken by the project hydrogeologists with hydrogeology specialists in the Geological Survey of Ireland, Environmental Protection Agency and the National Federation of Groundwater Schemes.

Those consultations relevant to the hydrogeology impact assessment are:

- Geological Survey of Ireland (GSI) (Department of Communications, Climate Action and Environment (DoCCAE)) Groundwater Division
- Local Area engineers in Galway County Council and Galway City Council. The Water Services Section confirmed the location of the nearest public supply schemes
- National Parks and Wildlife Services (NPWS) part of the Department of Culture, Heritage and the Gaeltacht (DCHG)
- Landowners within the study area potentially affected by the proposed road development
- Environmental Protection Agency (EPA) – EPA was consulted to determine the location of any waste licence or groundwater monitoring locations within the study area. There are no EPA monitoring sites within the proposed development boundary of the proposed road development. There are a number of EPA monitoring sites on the River Corrib as outlined in **Chapter 11, Hydrology**
- Teagasc
- Office of Public Works (OPW)
- National Federation of Group Water Schemes (NFGWS)

Consultation was also undertaken with other environmental experts on the project team in order to assess the potential impact of the interaction with other environmental factors. This included discussions on the following:

- Biodiversity – Consultation on the potential impact on groundwater dependant habitats
- Soils and Geology – Consultation on geotechnical and contaminated land issues
- Hydrology – Consultation on the potential impact on surface water systems
- Drainage – Consultation on design of runoff and groundwater management
- Material Assets – Consultation on the impact on private wells

10.2.4 Study Area

In accordance with the TII Guidelines, the area of hydrogeological study should include all features which may be impacted from the proposed road development. The study area extent is dependent on the hydrogeological characteristics of the bedrock aquifer that the proposed road development traverses e.g. the potential study area for a poor aquifer will be significantly smaller than the study area for a regionally important karst aquifer.

Based upon the screening undertaken at route selection stage the extent of the study area was conservatively taken as being 250m from the proposed development boundary for the western section of the proposed road development (west of the N59 Moycullen Road), where the aquifer is classified as being poorly productive.

The eastern section of the proposed road development (east of the N59 Moycullen Road) includes regionally important karstified aquifers and the extent of the study area was taken as the extent of the groundwater catchments, or sub-catchments as appropriate, that the proposed road development traverses.

Groundwater catchments, referred to as groundwater bodies (GWB) have been mapped by the Geological Survey of Ireland (GSI). The boundaries for these groundwater divides have been refined as part of this assessment to provide a full assessment of all receptors that have the potential to be impacted by the proposed road development.

For some GWB, the project data demonstrates that parts of the GWB are hydrogeologically separate from the rest of the GWB and this has allowed sub-catchments for some of the GSI GWB to be defined. The refined GWB and identification of sub-catchments are presented in the conceptual model in **Section 10.3.3** and the implications for the impact assessment are discussed in **Section 10.3.4** and **Section 10.4**.

10.2.5 Data Sources and Baseline Data Collection

The existing baseline ground conditions within the study area of the proposed road development have been interpreted from desk studies, field studies and commissioned ground investigations. The data sources for each of these are described below.

10.2.5.1 Desk Study

The following sources of information were reviewed in order to evaluate the hydrogeology of the proposed road development:

- Current and historical Ordnance Survey maps available for the study area (1:2,500 and 1:10,560 scales)
- Aerial photography (2012) of the study area
- Aerial imagery from Google (imagery from 2003 to 2017) and Bing accessed in 2017
- Geological and hydrogeological maps of the site area produced by the Geological Survey of Ireland (GSI) (www.dcenr.gov.ie, accessed 2017)
- MacDermot, C.V., McConnell, B. and Pracht, M. (2003) *Geology of Galway Bay 1:100,000 scale Bedrock Geology Map Series*, Sheet 14, Galway Bay, Geological Survey of Ireland

- Pracht, M. and Somerville I.D., 2015. A Revised Mississippian lithostratigraphy of County Galway (western Ireland) with analyses of Carbonate lithofacies, biostratigraphy, depositional environments and paleogeography reconstructions utilising new borehole data. Journal of paleogeography. Volume 4, Issue 1, January 2015, Pages 1-26
- Teagasc and the Environmental Protection Agency Irish Soil Information System (http://gis.teagasc.ie/soils/index.php, accessed 2017

10.2.5.2 Field Studies

As part of the environmental studies a number of surveys and walkovers were undertaken to assess the hydrogeological environment. These can be summarised as follows and additional information is provided below:

- Geophysical surveys (Appendix A.9.1)
- Well Condition Survey (Appendix A.10.1)
- Karst Survey (Appendix A.10.2)

Geophysical surveys were commissioned across the route of the proposed road development to provide additional detail on the subsurface ground conditions. These, along with the ground investigations discussed in **Section 10.2.5.3** were used to develop the hydrogeological conceptual model for the study area. The data for the geophysics surveys are presented in **Appendix A.9.1**.

A well condition survey was undertaken in 2014 to determine the condition of existing monitoring wells which were installed as part of the 2006 Galway City Outer Bypass (2006 GCOB) studies. This survey allowed historic wells, some of which required remediation, to be incorporated into the monitoring network for the proposed road development. The report on the condition of these wells is detailed in **Appendix A.10.1**.

Detailed karst surveys were completed for the constraints and route selection studies for the proposed road development in 2014. The karst survey was updated in July 2016 following completion of site walkovers and ground investigations (this updated report supersedes the karst Survey report included in the N6 Galway City Transport Project Route Selection Report, Arup 2016). The karst survey is presented in **Appendix A.10.2**.

10.2.5.3 Commissioned Ground Investigations

Five ground investigations were commissioned for the project. These ground investigations included boreholes, trial pits and window sampling, which are fully described **Chapter 9, Soils and Geology**. The ground investigations also included groundwater monitoring and groundwater testing. The full list of investigation is detailed in the following appendices:

- Groundwater Level Monitoring Report (June 2017) (Appendix A.10.3)
- Water Quality Monitoring Report (June 2017) (Appendix A.10.4)
- Aquifer Testing Report (June 2017) (Appendix A.10.5)
- N6 GCTP Phase I Ground Investigation Contract I, November 2014. Factual Report (Appendix A.9.1.2)
- N6 GCTP Phase II Ground Investigation Contract I, November 2015. Factual Report (Appendix A.9.1.3)
- N6 GCTP Phase III Ground Investigation Contract I, June 2017. Factual Report (Appendix A.9.1.4)

- N6 GCTP Phase III Ground Investigation Contract II, May 2016. Factual Report (Appendix A.9.1.5)
- N6 GCTP Phase III Ground Investigation Contract III, April 2017. Factual Report (Appendix A.9.1.5)

In summary, the hydrogeological investigations for the proposed road development comprised of the following project specific groundwater installations and testing:

- 34 No. groundwater monitoring wells
- 16 No. groundwater level monitoring rounds [1]
- 12 No. groundwater quality monitoring rounds
- 15 No. infiltration test
- 16 No. small scale pumping test and variable head permeability tests
- 3 No. Packer tests
- 1 No. step pumping test

All investigation locations were sited based on the design of the proposed road development. Groundwater level, groundwater quality and aquifer testing in particular was focused on locations of cuttings, structures and receptors.

10.2.6 Technical Limitations

The data included in the hydrogeology assessment includes existing information from earlier investigations in the region as well as dedicated field surveys, walkovers and ground investigations commissioned for the proposed road development. The data collected provides a comprehensive hydrogeological dataset along the route of the proposed road development. As is standard for hydrogeological studies the dataset comprises of point data (boreholes), linear data (geophysics) and surface data (topography, water courses and karst) to develop a conceptual model of the study area.

Where groundwater dependent receptors were identified, the locations were investigated to determine the hydrogeological regime. Due to the ecologically sensitive nature of sites the investigation methodologies selected were those that would not impact on the hydrogeology of a European site. In the absence of site specific data in these sensitive locations, a conservative approach was taken in appraising any potential impacts.

Based on the comparability of the ground investigation and the baseline data collection the information is deemed sufficient to complete the hydrogeology evaluation.

---

[1] Groundwater monitoring was undertaken between February 2015 and April 2017. This included a total of 16 groundwater monitoring rounds. Measurements on individual wells were also taken during commissioning, well testing and spot checks. In total 54 individual wells were regularly measured, which comprised of 34 project specific wells, 16 (2006 GCOB wells and 4 private wells. Contractors also undertook a period of monitoring following the well installation for this project and their data is presented in the Ground Investigation Reports in **Appendix A.9.1**.

10.2.7 Impact Assessment Methodology

The TII Guidelines have been used to provide the criteria for the impact assessment during construction and operation of the proposed road development.

The rating of potential impacts from the proposed road development on the hydrogeological environment has been assessed by:

1. Classifying the importance of the relevant attributes (**Table 10.1**)
2. Quantifying the likely magnitude of any impact on these attributes (**Table 10.2**)
3. Determining the resultant significance (**Table 10.3**)

Table 10.1: Criteria for Rating Site Attributes - Estimation of Importance of Hydrogeology Attributes (TII, 2009)

Importance	Criteria	Typical Example
Extremely High	Attribute has a high quality or value on an international scale	Groundwater supports river, wetland or surface water body ecosystem protected by EU legislation e.g. cSAC or SPA status
Very High	Attribute has a high quality or value on a regional or national scale	Regionally important aquifer with multiple well fields. Groundwater supports river, wetland or surface water body ecosystem protected by national legislation – NHA status Regionally important potable water source supplying >2500 homes Inner source protection area for regionally important water source
High	Attribute has a high quality or value on a local scale	Regionally Important Aquifer Groundwater provides large proportion of baseflow to local rivers Locally important potable water source supplying >1000 homes Outer source protection area for regionally important water source Inner source protection area for locally important water source
Medium	Attribute has a medium quality or value on a local scale	Locally Important Aquifer Potable water source supplying >50 homes Outer source protection area for locally important water source
Low	Attribute has a low quality or value on a local scale	Poor Bedrock Aquifer Potable water source supplying <50 homes

Table 10.2: Criteria for rating impact significance at EIA stage – Estimation of magnitude of impact on hydrogeology attributes (TII, 2009)

Magnitude of Impact	Criteria	Typical Examples[1]
Large Adverse	Results in loss of attribute and/or quality and integrity of attribute	Removal of large proportion of aquifer Changes to aquifer or unsaturated zone resulting in extensive change to existing water supply springs and wells, river baseflow or ecosystems Potential high risk of pollution to groundwater from routine run-off[2] Calculated risk of serious pollution incident during operation >2% annually[3]
Moderate Adverse	Results in impact on integrity of attribute or loss of part of attribute	Removal of moderate proportion of aquifer Changes to aquifer or unsaturated zone resulting in moderate change to existing water supply springs and wells, river baseflow or ecosystems Potential medium risk of pollution to groundwater from routine run-off[2] Calculated risk of serious pollution incident during operation >1% annually[3]
Small Adverse	Results in minor impact on integrity of attribute or loss of small part of attribute	Removal of small proportion of aquifer Changes to aquifer or unsaturated zone resulting in minor change to water supply springs and wells, river baseflow or ecosystems Potential low risk of pollution to groundwater from routine run-off[2] Calculated risk of serious pollution incident during operation >0.5% annually[3]
Negligible	Results in an impact on attribute but of insufficient magnitude to affect either use or integrity	Calculated risk of serious pollution incident during operation <0.5% annually[3]

1 Additional Examples are provided in the TII Guidance Document

2 refer to Method C, Annex 1, Annex 1 of HA"16/06

3 refer to Method D, Appendix B3/Annex 1of HA216/06

Table 10.3: Rating of Significant Environmental Impacts (NRA, 2009)

		Magnitude of Impact			
		Negligible	**Small**	**Moderate**	**Large**
Importance of Attribute	**Extremely High**	Imperceptible	Significant	Profound	Profound
	Very High	Imperceptible	Significant / Moderate	Profound / Significant	Profound
	High	Imperceptible	Moderate / Slight	Significant / Moderate	Profound / Significant
	Medium	Imperceptible	Slight	Moderate	Significant
	Low	Imperceptible	Imperceptible	Slight	Slight / Moderate

The 2009 NRA significance ratings were designed to be in accordance with impact assessment criteria provided in the EPA publication Guidelines on the Information to be contained in Environmental Impact Assessment Reports (Environmental Protection Agency 2002 guidelines). However, it should be noted that the 2017 EPA guidelines include two additional 'Significance' rankings over previous EPA and the current TII guidance. The two additional rankings 'Not Significant' and 'Very Significant' ratings have not yet been incorporated by TII into the Significance ranking matrix (refer to **Table 10.3**) and as such the rating of significance used in this EIAR follows TII 2009 significance nomenclature and does not include 'Not Significant' nor 'Very Significant'. Where 'Not Significant' would apply based on EPA (2017) then Imperceptible is used for NRA (2009) and where 'Very Significant' would apply based on EPA (2017) then Profound is used for TII (2009).

The rating of significant environmental impacts is also assessed in terms of duration and frequency. With each impact described as being momentary, brief, temporary, short-term, medium-term, long-term or permanent. The frequency of effects is also described either in terms of reoccurrence (one, rarely, occasionally, frequently, constantly) or timing (hourly, daily weekly, monthly, seasonally or annually). If an effect is reversible, for example through remediation or restoration, then this is also described. Description of the durations are listed below:

- Momentary effects last from seconds to minutes
- Brief effects last less than one day
- Temporary effects last less than one year
- Short-term effects last one to seven years
- Medium-term effects last seven to fifteen years
- Long-term effects last fifteen to sixty years
- Permanent effects last over sixty years

In line with guidelines, following the assessment of potential impacts, specific mitigation measures are presented to avoid, reduce and remedy any negative impacts on the hydrogeological environment. These are described in **Section 10.6** below. Residual impacts which are the potential impacts which result after mitigation measures have been fully established and are described in **Section 10.7** below. The length of time it takes for each mitigation measure to take effect varies but they are designed to ensure that predicted impacts are minimal.

10.3 Receiving Environment Baseline

This section provides a characterisation of the hydrogeological receiving environment of the proposed road development. The hydrogeological environment is presented firstly in the regional context using publically available information and then secondly in detail for the study area based on information obtained specifically for the project.

Both the regional and site specific assessments document the hydrogeological characteristics of aquifer classification, groundwater vulnerability, recharge and groundwater receptors, such as aquifers, groundwater abstractions and groundwater dependant terrestrial ecosystems (GWDTE) (refer to the glossary of technical terms provided with this EIAR.

10.3.1 Regional Hydrogeology

The hydrogeological study area is divided into two main regions on the basis of the contrasting aquifer properties for the two main geological rock types in the region. As described in **Chapter 9, Soils and Geology**, the bedrock geology may be divided into:

- The Galway Granite Batholith (comprising of granite and orthogranite) underlies the western section of the proposed road development from the R336 west of Bearna Village to the N59 Moycullen Road
- The Visean Undifferentiated Limestone, which underlies the eastern section of the proposed road development from the N59 Moycullen Road to existing N6 at Coolagh

10.3.1.1 Western Section

The GSI bedrock aquifer map for the western section is presented in **Figure 10.1.001**. The GSI classification of the granite and orthogranite (including multiple dolerite dykes) of the Galway Granite Batholith are all classified to be Poor Aquifers that are only productive in local zones (Pl). Poor Aquifers generally provide little groundwater for water supply or for baseflow to surface water bodies. However, they are sometimes used for local supplies to individual houses/farms. The GSI assessment of the Galway Granite Batholith being a Pl aquifer is based on the low occurrence of high yielding groundwater wells and the abundance of surface water features as well as man-made drainage ditches.

Under the Water Framework Directive, the GSI have delineated a number of groundwater bodies (GWB) in Ireland. In the area of the Galway Granite Batholith there are two groundwater bodies, with their boundaries determined based on topography and surface watersheds (refer to **Figure 10.2.001**). The two groundwater bodies are:

1. Spiddal GWB
2. Maam-Clonbur GWB

The GSI describe both groundwater bodies as being overlain by blanket peat except in urban areas where the bedrock is overlain by man-made fill. Where the blanket peat is present then the overburden thickness is generally less than 3m.

The vulnerability of the groundwater body is the term used to describe the ease with which the groundwater in the area can be contaminated by human activities. The vulnerability is determined by many factors including the travel time, the quantity of contaminants and the capacity of the deposits overlying the bedrock to attenuate contaminants. These factors in turn are based on the thickness and permeability of the overburden e.g. groundwater in bedrock which is exposed at the surface. The criteria for determining groundwater vulnerability, as described by the GSI, is shown in **Table 10.4** below.

Table 10.4: GSI Groundwater Vulnerability Mapping Guidelines (DoELG 1999)

Vulnerability Rating	**Hydrogeological Conditions**				
	Subsoil Permeability (Type) and Thickness			**Unsaturated Zone**	**Karst Feature**
	High permeability (sand/gravel)	**Moderate permeability (e.g. Sandy subsoil)**	**Low permeability (e.g. Clayey subsoil, clay, peat)**	**(Sand/gravel aquifers only)**	**(<30m radius)**
Extreme (E)	0 - 3.0m	0 - 3.0m	0 - 3.0m	0 - 3.0m	-
High (H)	>3.0m	3.0 - 10.0m	3.0 - 5.0m	>3.0m	N/A
Moderate (M)	N/A	>10.0m	5.0 - 10.0m	N/A	N/A
Low (L)	N/A	N/A	>10.0m	N/A	N/A

Notes: (1) N/A = not applicable.

(2) Precise permeability values cannot be given at present.

(3) Release point of contaminants is assumed to be 1-2m below ground surface.

The GSI data on groundwater vulnerability shown in **Figure 10.3.001**, shows that bedrock is often at or near surface (X or E category) for circa 25% of the western section of the proposed road development. Where cover is present on the granite bedrock it is generally thin (<3m), with rock outcropping on higher ground, and thick subsoil deposits (up to 6m) on lower ground. Peat bogs occur in a number of locations across the granite landscape, generally in low lying areas or hollows where surface water ponding is present. Where peat is present it will generally allow very limited recharge and promote horizontal flow to drains, ditches and water courses.

The combination of poor aquifer and Blanket bog cover, where rock is not exposed, limits the quantity of recharge that can infiltrate to ground. The recharge quantities are estimated by the GSI and are shown on **Figure 10.4.001**.

Met Éireann reports an annual average of 1,250mm of rainfall for the area and with losses by evapotranspiration accounted for (450mm/yr) then the available effective rainfall is 800mm (**Table 10.5** below). Given a recharge cap of 100m/yr for the Galway Granite Batholith only 12.5% of effective rainfall is available as recharge, with the remaining balance of 700mm/yr flowing to streams as either overland flow or shallow flow through the subsoil. The Galway Granite Batholith is a poor aquifer (Pl) with low recharge acceptance, with groundwater bodies that will match surface water drainage divides.

Table 10.5: Recharge assessment for the Galway Granite Batholith (Pl) (av mm/yr Met Éireann)

Vulnerability	Rainfall (mm/yr)	PE (mm/yr)	Effective Rainfall (mm/yr)	Recharge (mm/yr)	Runoff (mm/yr)
Granite and Orthogranite (irrespective of vulnerability)	1250	450	800	100	700

On the basis of the poor aquifer properties and the low likelihood of local productive zones, then actual recharge quantities for Galway Granite Batholith will not vary significantly from **Table 10.5**.

The GSI overburden thickness for the area shows that rock outcrops on topographic highs but in low lying areas the soils and subsoils are thicker, generally up to 5m thick. Generally, the aquifer properties (hydraulic conductivity and storage) will be low for the Galway Granite Batholith, especially on higher ground, where the rock is most competent. In low lying areas the aquifer properties remain poor but hydraulic conductivity may be locally productive due to weathering along fault lines.

Effective rainfall will generally run off to surface water by means of drains and ditches. In elevated areas the effective rainfall will rapidly run off the steeper gradient. In low lying areas the slight topographic gradients and thicker overburden is likely to cause impoundment of effective rainfall causing perching above the rock head with local ponding to surface.

The GSI descriptions of the Spiddal GWB and Maam - Clonbur GWB (GSI 2004a and 2004b) state that the water table is shallow in the Galway Granite Batholith and yields from wells are low. Groundwater flow paths are only in fractured and weathered zones, typically in the vicinity of faults. These pathways will be short and flow directions will follow topography towards watercourses. The GSI report flow paths in the Spiddal GWB to be up to 100m long whilst the Maam-Clonbur GWB to be 30-300m. Groundwater will discharge to streams and rivers but the baseflow contribution will be relatively low.

10.3.1.2 Eastern Section

The GSI bedrock aquifer map for the eastern section is presented in **Figure 10.1.002**. The GSI classify the Visean Undifferentiated Limestone as being a regionally important karstified aquifer, which is dominated by conduit flow (Rkc).

Regionally important aquifers are important groundwater resources. A regionally important bedrock aquifer is capable of supplying regionally important abstractions (e.g. large public water supplies), or 'excellent' yields (>400 m^3/d). The assessment by the GSI is based upon the occurrence of high yielding groundwater wells, the presence of karst landforms and features but also the relatively low abundance of surface water features and man-made drainage.

Under the Water Framework Directive, the GSI have delineated groundwater bodies (GWB) for Ireland. Those in the Visean Undifferentiated Limestone of the study area (refer to **Figure 10.2.002**) include:

1. GWDTE Lough Corrib Fen 1 (Menlough)
2. GWDTE Lough Corrib Fen 2
3. GWDTE Lough Corrib Fen 3 & 4
4. Clarinbridge
5. Clare-Corrib
6. Ross Lake

The Geological Survey of Ireland (GSI) national dataset for groundwater vulnerability (Refer to **Figures 10.3.001** and **10.3.002**) shows that the subsoil cover has a variable thickness across the Visean Undifferentiated Limestone. Generally, on higher ground the limestone either outcrops or is near surface but there are areas where significantly deeper overburden is identified, such as Coolagh Lakes, Ballindooley Lough, Terryland River and Lough Atalia. During the ground investigation for the 2006 Galway City Outer Bypass (GCOB, 2006) a number of areas with thick overburden were investigated by geophysics and drilling, these included areas near the River Corrib at Menlough as well as the north edge of Ballindooley Lough (**Appendix A.9.1** and **A.9.2**).

Adjacent to Ballindooley Lough, geophysics undertaken for the 2006 GCOB identified that whilst bedrock was near surface in the fields to the northwest and southeast of Ballindooley, in the valley floor itself the overburden was greater than 18m deep. Similar features of bedrock being near surface at one location but then a short distance away being significantly deeply buried were also encountered near the River Corrib at Menlough where drilling proved the overburden to be up to 70m thick. In these areas at Ballindooley and Menlough the morphology of the bedrock topography and burial by overburden can be described as being a buried valley, which is often referred to in academic texts as a palaeolandscape.

Related to the vulnerability mapping is the GSI recharge mapping. **Figure 10.4.002** shows the GSI quantification of recharge for the eastern section. Based on the GSI mapping the limestone aquifer has a significantly high infiltration capacity. Areas of outcrop are attributed a recharge rate of 85% (greater if karst present), with areas of thin overburden attributed 60% if the subsoil is of a moderate or high permeability. Those areas where the overburden is thicker and of low permeability, such as Coolagh Lakes, Ballindooley Lough, Terryland River and Lough Atalia then the recharge coefficient is estimated by the GSI as 15% or less. Due to the generally high recharge acceptance of the Rkc aquifer the GSI do not apply a recharge cap to the annual quantity of recharge. **Table 10.6** below presents regional estimates on recharge and run-off for the eastern section.

Table 10.6: Recharge assessment for the Visean Undifferentiated Limestone (Rkc) (av mm/yr Met Éireann)

Vulnerability	Recharge coefficient	Rainfall (mm/yr)	PE (mm/yr)	Effective Rainfall (mm/yr)	Recharge (mm/yr)	Runoff (mm/yr)
Limestone at (X) or near (E) surface	60-100%	1250	450	800	480-800	0-320
Moderate (M) or high (H) vulnerability	15-60%	1250	450	800	120-800	320-680
Low (L) vulnerability	<15%	1250	450	800	120	680

Limestone bedrock designated as regionally important karst with conduit (Rkc), has triple permeability characteristics, namely that hydraulic connectivity occurs via matrix, fracture and karst pathways (Waltham, 2005). Flow by the matrix of the rock is of a significantly low permeability and often lower than $1x10^{-7}$m/s. Flow by fractures can be variable but typically will range between $1x10^{-4}$m/s to $1x10^{-6}$m/s. Karst flow can be significant if conduits are present and generally flow in conduits is $1x10^{-3}$m/s or lower (Waltham, 2005).

On the basis of the Rkc classification by the GSI the bulk permeability of the aquifer is likely to be high but local areas of low or moderate permeability will exist where the aquifer has not developed karst enhancement Karst features are also discussed in **Chapter 9, Soils and Geology**.

It should be noted that some additional karst features are identified in this chapter which have not been included in **Chapter 9, Soils and Geology** due to the larger study area in the east for the hydrogeological assessment.

The hydrogeological assessment assesses those karst features which are either supporting the hydraulic regime of the area or specific receptors e.g. ecological features and these have been identified and discussed in S**ection 10.3.4**.

As well as supporting specific receptors, karst features such as enclosed depressions support the hydrogeology of an area by providing enhanced recharge (point input) at those locations.

As outlined in **Section 10.2.5.2**, a detailed karst survey of the scheme study area was undertaken as part of the constraints and route selection studies for the proposed road development and was updated for this assessment. The karst survey report is presented in **Appendix A.10.2**.

10.3.2 Local Hydrogeology within the Study Area

As highlighted in **Section 10.3.1** the footprint of the proposed road development is divided into two main geological units, which have contrasting aquifer, vulnerability and recharge characteristics. The western section of the proposed road development is underlain by the poorly productive (Pl), low recharge aquifer of the Galway Granite Batholith and the eastern section is underlain by the regionally important karstified (Rkc), high recharge aquifer of the Visean Undifferentiated Limestone.

When examining the receiving environment of the study area, the proposed road development has been divided into four sections to allow for ease of presentation and description of the underlying ground conditions due to the volume of information available. To allow for consistency, these sub-divisions were also applied in **Chapter 9, Soils and Geology**. The four sections are as follows:

- Section 1: R336 to the N59 Moycullen Road
- Section 2: N59 Moycullen Road to the River Corrib
- Section 3: River Corrib to the N83 Tuam Road[2]
- Section 4: N83 Tuam Road to the existing N6 at Ardaun, Coolagh

The ground investigations undertaken in each of the four sections were tailored to provide data that will allow hydrogeological assessment specific for the proposed road development in that section. For example, aquifer testing and groundwater monitoring wells were sited where cuttings would be required by the proposed road development whereas geophysics was used to determine the depth to bedrock or as an indicator for karst.

The information presented in this section forms the basis for **Section 10.3.3**, which develops a conceptual site model for the study area.

10.3.2.1 Section 1 – R336 to N59 Moycullen Road (Ch. 0+000 – 7+600)

Section 1 of the proposed road development is situated on the Galway Granite Batholith. The topography of Section 1 is undulating with the highest point of 100mOD forming part of a northwest to southeast ridge at Letteragh. This ridge also marks the watershed for surface water and groundwater sub catchments. West of the ridge all the surface water drainage and the Spiddal GWB drain southwards to Galway Bay, whilst east of the ridge all surface water all the Maam-Clonbur GWB drain eastwards to the River Corrib (**Figure 10.2.001**).

Bedrock Aquifer

As identified in the section on regional hydrogeology, the Galway Granite Batholith is a poor aquifer (Pl) that is locally productive in local zones such as faults (**Figure 10.1.001**). Where faults are present then these tend to form areas of deeper subsoil in low lying ground.

[2] Formally known as the N17 Tuam Road

The geophysics undertaken included electrical resistivity tomography (ERT) and seismic surveying, this data is presented in **Appendix A.9.1**. As presented in the **Chapter 9, Soils and Geology**, the ERT survey shows that the bedrock is generally shallow and of high resistivity, indicating competent rock. There are shallow zones where lower resistivity is measured. These may indicate areas of increased weathering along vertical features such as faults where there is a localised linear feature that may have increased storage of groundwater.

Shallow features (<10m) can be observed on the mainline of the proposed road development at Ch. 5+500 and Ch. 7+750, as well as a deeper feature (c.20m) on the N59 Link Road North (LNR) at Ch. 0+250 LNR. These features are likely to be zones locally productive with groundwater. The unconformity contact between the Galway Granite Batholith and the Visean Undifferentiated Limestone is marked by a sharp change in slope at Ch. 8+890, which also conforms to a deep vertical feature in the ERT profile at Ch. 8+920. This feature is developed in the limestone side of the contact with the granite and as such is described in **Section 10.3.3.2**.

The seismic survey is used to identify the top of competent bedrock and as such is a good indicator for the thickness of the combined overburden and weathered layer. The seismic data shows that competent bedrock is generally 2-3m in depth, being slightly deeper (up to 5m) in low lying areas.

Aquifer Properties

Aquifer testing was undertaken in five monitoring boreholes in the Galway Granite Batholith. These tests were small scale pumping tests so that observation could be made on the drawdown in the well as well as monitoring of the recovery as a rising head test. The data from the test as well as analysis of the rising head test are presented in **Appendix A.10.5**. This data shows that the water level in the wells was drawn down fairly rapidly at a low abstraction rate, which is indicative of low hydraulic conductivity. Measurement of the recovery of the wells indicates a range of hydraulic conductivity in the Galway Granite Batholith between 9.7×10^{-7} and 4.6×10^{-6}m/s.

Groundwater Vulnerability

Comparison of GSI vulnerability and information from GI and walkover surveys identifies that at topographic highs rock is generally at or very near surface. Borehole records confirm that the depth to bedrock increases away from topographic highs. The ground investigation and walkover surveys generally confirm with the vulnerability mapping by the GSI for the Galway Granite Batholith (**Figure 10.3.001**). Approximately 40% of the route of the proposed road development in Section 1 has rock at or near surface based upon GSI vulnerability mapping.

As presented in the regional hydrogeology, recharge quantities are low for the available effective rainfall. This is due to the peaty blanket bog which is of low permeability and will promote runoff, but also due to the relatively thin weathered zone and low aquifer properties of the aquifer. The GSI recharge cap of 100mm/yr is considered appropriate based on site observation and the aquifer tests undertaken (**Figure 10.4.001**).

Groundwater Levels

Groundwater level monitoring was initiated in February 2015 for existing wells. New monitoring wells, installed as part of the studies for the proposed road development, were monitored from November 2015. The monitoring continued on all wells to January 2017. Due to the shallow or non-existent nature of the overburden in this area, the monitoring wells all have their response zones in the Galway Granite Batholith.

A review of pre-existing wells was undertaken early in 2014 and the commissioning report from this survey is presented in **Appendix A.10.1**. A report of all groundwater level data used in the assessment is presented in **Appendix A.10.3**. The groundwater level data from **Appendix A.10.3** is presented on the cross-sections as groundwater contours in **Figure 10.6.001** to **10.6.006** for the mainline of the proposed road development and **Figure 10.6.012** for the N59 Link Road (North and South). These profile cross sections confirm that the groundwater along the proposed road development is generally near the surface. A summary table of minimum and maximum groundwater levels monitored in Section 1 is presented in **Table 10.7** below.

In higher ground the water table is within 2m of ground level and on lower lying ground the water table is at ground level. Areas of low lying ground typically include saturated peat with ponding at surface caused by naturally poor drainage. Due to the low aquifer properties of the granite, interaction between groundwater and surface water is minimal. A summary table of minimum and maximum groundwater levels monitored in Section 1 is presented in **Table 10.7** below.

Table 10.7: Groundwater levels measured in the Galway Granite Batholith (Section 1)

Monitoring Borehole	Source	East (ITM)	North (ITM)	Ground Elevation (mOD)	Groundwater Level		
					Min (mOD)	Max (mOD)	Range (m)
RC422	N6 GCOB	524196	724742	21.20	19.45	20.75	1.30
