Includes groundwater level data from project specific monitoring wells

Groundwater levels are measured on site to the nearest centimetre below top of casing. All effort has been made to ensure the accuracy of the data.

Seasonal fluctuation is generally within 1.5m for higher ground but minimal in lower ground where the water table generally remains at surface throughout the year. Exception to this generalisation is borehole BH-3-11 near the Rahoon Road, which shows up to 4m of seasonal fluctuation. The higher seasonal fluctuation at BH-3-11 is considered to be natural and a factor of the narrow ridge within which the borehole is located.

Groundwater elevations confirm that groundwater flow follows the general topography and surface water drainage. In the Spiddal GWB the groundwater contours conform to the surface water drains and flow towards Galway Bay by seeping into the surface water courses that drain the area. In the Maam-Clonbur GWB the groundwater contours also conform to surface topography and surface water drainage and flow eastwards to the River Corrib.

In the steep eastern granite slopes draining towards the River Corrib there are a number of seepages, which emerge where the topography steepens and intersects the groundwater table. The largest of these is spring at W1000-01 (**Figure 10.5.001**), which is used as a private water supply (see **Section 10.3.4)**. Other smaller seepages occur in both groundwater bodies and these drain to surface water streams and ditches.

Seepages in the Galway Granite Batholith are generally associated with weathering and/or fault zones (refer to **Chapter 9, Soils and Geology**) and generally the seepages dry out in the summer. As per GSI descriptions (2004a and 2004b) these locally productive pathways are considered to be relatively short and to have limited lateral extent. On this basis, they are likely to have limited storage and rely on recharge, which would suggest they will respond to storm events and reduce in flow during the summer (GSI 2004a and 2004b).

Based on GSI descriptions of groundwater bodies in granite the length of the flow paths is considered to have a general maximum of 100m but in extreme cases where significant faulting is present then they may extend up to 300m.

Water Quality

Water sampling from monitoring wells in the Galway Granite Batholith indicates that the groundwater is generally of good quality with moderate levels of calcium and magnesium. There are local detections of bacteria such as faecal coliform, which is most likely agricultural or from poorly operating domestic wastewater treatment plants. Water quality data is presented in **Appendix A.10.4**.

10.3.2.2 Section 2 - N59 Moycullen Road to River Corrib (Ch. 7+600 – 9+300)

Between the N59 Moycullen Road and the River Corrib there is a narrow section of limestone (**Figure 10.1.001**). This strip of limestone bedrock comprises the Ross Lake GWB (**Figure 10.2.001**), which extends 3km northwest to Kentfield.

Input to the aquifer comprises of recharge to the limestone area (1.5km^2), and also runoff from the granite slopes of the Maam-Clonbur GWB (3km^2), which flows down slope and onto the limestone. There is a significant amount of urban development in this area and it is likely that some streams are culverted below developments to the River Corrib, others may infiltrate into the limestone.

Bedrock Aquifer

The contact between the Galway Granite Batholith and the Visean Undifferentiated Limestone is an unconformity (GSI Geology Memoir). The ERT geophysics data for the contact is shown in geophysics profile 3/5 (GP3/5) confirms the contact between granite and limestone at Ch. 8+890 to be vertical and sharp. The geophysics profile matches a distinct change in the topography and indicates that the contact slopes steeply eastwards.

The depth to rock in the limestone is significantly more variable than the granite bedrock. The vertical nature of the low resistivity feature and general vertical steps in the rock topography indicates that the limestone may be locally faulted and / or fractured.

Groundwater flow is likely to be dominated by fracture flow but the low resistivity feature in the limestone near the contact between granite and limestone indicates likely karstification and possible conduit flow. There are a number of small scale karst landforms located between the N59 Moycullen Road and the River Corrib, which include small enclosed depressions (K10, K11 and K12) and small springs (K2, K7 and K9).

No site specific groundwater level or aquifer properties data were collected in Section 2. As outlined in **Section 10.2.5.3** groundwater level, aquifer properties and groundwater quality monitoring was focused on areas of cutting or dewatering of the bedrock aquifer. This section of the proposed road development is entirely on embankment and geophysics was the primary investigative tool used, with boreholes (BH3/23 and BH3/24) installed to calibrate the geophysical data.

Groundwater Vulnerability

The criteria for determining groundwater vulnerability, as described by the GSI, is shown in **Table 10.4**. Groundwater vulnerability as mapped by the GSI is presented in **Figure 10.3.001**. Comparison of GSI vulnerability and information from GI and walkover surveys indicate that the data sets are consistent in this area.

Key inferences from the vulnerability mapping are: the confirmation that the depth of rock head increases towards the River Corrib and that recharge is higher where the bedrock is shallower (this infers that effective rainfall increasingly runs off to surface water closer to the river) (**Figure 10.4.001**).

10.3.2.3 Section 3 - River Corrib to N83 Tuam Road (Ch. 9+300 – 14+000)

Section 3 of the proposed road development comprises the area between the River Corrib and the N83 Tuam Road. This area encompasses of the GWDTE Lough Corrib Fen 1 Groundwater Body (GWB), GWDTE Lough Corrib Fen 2 GWB, GWDTE Lough Corrib Fens 3 and 4 GWB and the Clare Corrib GWB (**Figure 10.2.001**). The use of GWDTE in naming for these groundwater bodies by the GSI does not signify that the GWB is a GWDTE but rather because GWDTE do receive groundwater from these GWB.

The topography of Section 3 is undulating with the highest point being 40m OD immediately west of Lackagh Quarry. There are also extensive lowland areas at Coolagh Lakes, Ballindooley Lough and Terryland River.

Bedrock Aquifer

As identified by the regional hydrogeology the eastern section of the proposed road development is underlain entirely by the Visean Undifferentiated Limestone, which is a regionally important karst aquifer (Rkc) (**Figure 10.1.002**).

The GSI karst database includes a national record of all karst landforms, which identifies that turloughs, dolines, stream sinks and one cave have been recorded in the area. The karst survey (**Appendix A.10.2**) referred to previously characterises the type of landforms.

Aquifer Properties

The Visean Undifferentiated Limestone aquifer is a regionally important aquifer that is associated with a high permeability and very productive groundwater abstraction wells. Abstraction rates of wells identified in the study area are particularly high confirming the characteristics of the aquifer.

The GSI have characterised the aquifer as having a high recharge coefficient (85%) with high infiltration rates and no recharge cap. The Rkc characterisation by the GSI is due to the presence of karst. Although karst is present (refer to **Appendix 10.2** Karst survey report) observations from quarries and bedrock exposure indicate a moderate to high frequency of fracturing in the bedrock. Based on the relatively high fracture frequency then fracture flow, as opposed to conduit flow, is considered to be the most common pathway in the limestone aquifer.

Aquifer testing was undertaken in six monitoring boreholes in Section 3. These tests were small scale pumping tests so that observation could be made on the drawdown in the well as well as monitoring the recovery as a rising head test. The data from the drawdown test as well as analysis of the rising head test, are presented in the aquifer testing data. This data is variable showing a wide range of response to the drawdown and recovery.

Measurement of the recovery of the wells indicates a non-karst range of hydraulic conductivity in the Visean Undifferentiated Limestone between 3.1×10^{-5} and 5×10^{-9}m/s. The higher permeability is likely to be testing fracture flow or small scale conduit flow in the aquifer, whilst the lower permeability values indicate the borehole mainly represents matrix flow.

Section 3 includes surface karst features, such as enclosed depressions (dolines), estavelles, turloughs, limestone pavement, springs, and one cave. Karst features are presented in **Figure 10.1.002** and detailed in the Karst Survey Report (**Appendix A.10.2**). The karst features located in Section 3 can be divided into those between Menlough and Ballindooley as well as those associated with the Terryland River.

There are a number of karst features between Menlough and Ballindooley including springs, turloughs and enclosed depressions. There are two karst springs (K17 and K25). Of these K17 is a small spring with a discharge too slight to gauge that discharges to Lough Corrib, whilst K25 (referred to as Western Coolagh Spring) is a more significant spring and is the main groundwater supply to the Upper Coolagh Lake.

During the site workover, a pond with a ditch outfalling to the Upper Coolagh Lake was identified as being a potential spring and this is referred to as the Eastern Coolagh Spring (K45). However, this spring is not a karst spring because it sits on clay subsoil as evidenced by GI. Monitoring of the water level between 2014 and 2018 at the Eastern Coolagh Spring showed the water level is static and failed to identify a correlation with groundwater levels in bedrock. The Eastern Coolagh Spring (K45) is instead supplied by a combination of seepage via the subsoil and surface water runoff. There is no bedrock exposed at the Eastern Coolagh Spring and due to the thick cover of clayey subsoil it is unlikely there is any direct discharge from the limestone aquifer to the Eastern Coolagh Spring.

There are three turloughs between Menlough and Ballindooley, two near Menlough (K20 and K31) and one (K72) near Ballindooley. There are a number of enclosed depressions across the area, which are sometimes associated with limestone pavement (for locations of limestone pavement refer to **Chapter 8, Biodiversity**). Other karst features in the area include a small estavelle adjacent to Ballindooley Lough (K86) and a dug karst feature (K92) that like K86 has a free water surface that fluctuates seasonally.

The Terryland River bifurcates from the River Corrib near Quincentenary Bridge and drains eastwards along the low lying ground through Terryland towards Ballybrit. Under normal conditions the Terryland River sinks at two stream sinks, named Pollavurleen West and East (K87 and K96) near Glenanail (Refer to karst study in **Appendix A.10.2**).

Section 3 also includes areas of thick subsoil, including those from the 2006 GCOB investigation at Menlough and Ballindooley Lough that are interpreted as being buried landscapes. Based on geophysics and drilling from the project specific ground investigation, buried landscapes have been identified in the townland of Coolagh (Menlough), Coolagh Lakes, Ballindooley Lough, Castlegar and the N83 Tuam Road (refer to **Chapter 9, Soils and Geology**). Some of these buried landscapes are palaeokarst features, i.e. karst that had developed in the bedrock but subsequently was buried by thick accumulations of sediment.

Groundwater Vulnerability

The GSI vulnerability mapping for Galway is presented in **Figure 10.3.002**. Buried features are identified on these maps as where present they will modify the vulnerability locally to low. A number of areas where buried features have been identified, for example the buried features at Menlough and N83 Tuam Road, the GSI vulnerability had been mapped as high or extreme. In light of the buried features, their vulnerability is considered to be low. These areas also have significantly reduced recharge and a corresponding increase in run-off (**Figure 10.4.002**).

Groundwater Levels

Groundwater monitoring has been undertaken in the Menlough and Ballindooley area since February 2015 for existing wells and since November 2015 for new monitoring wells installed as part of the environmental studies for the proposed road development. A review of the condition of existing monitoring wells is presented in **Appendix A.10.1** and the groundwater level data for Section 3 is presented in **Appendix A.10.3**. This data is plotted in **Figures 10.6.007** to **10.6.010** Summary groundwater levels for Section 3 of the proposed road development are presented below in **Table 10.8**.

Table 10.8: Groundwater levels measured in the Visean Undifferentiated Limestone (Section 3)

Notes:
Includes groundwater level data from project specific monitoring wells
Groundwater levels in LQMW4 are the same as LQMW1, 2, 3 and 4.
It was not possible for IGSL to access to BH-2-32R during May, August, September and November 2016. Water levels for April, June and July are reported. As the groundwater levels recorded during these months are representative of low groundwater levels only 'not representative'(NR) is reported for the maximum groundwater level.
Monitoring wells LQMW5 and BH05 both straddle a thin black argillaceous limestone that overlies a clay wayboard in the geology sequence, which perches recharge above the main groundwater body. The groundwater levels recorded in LQMW5 and BH05 represent

interaction between the main groundwater body and recharge. The water levels in LQMW5 and BH05 are not representative of groundwater levels in the main groundwater body.

Groundwater levels are measured on site to the nearest centimetre below top of casing. All effort has been made to ensure the accuracy of the data.

Figures 10.6.007 to **10.6.110** show the groundwater level between River Corrib and the N83 Tuam Road to form an undulating groundwater table with low points at the River Corrib, Coolagh Lake and RP-2-03 at Castlegar. These low points in the groundwater table form areas where groundwater flows towards. Between these groundwater low points are groundwater highs. The main groundwater high in Section 3 is plotted between Menlough and Lackagh Quarry. At this location the water table forms a divide between westward groundwater flow towards Coolagh Western Spring, which feeds Coolagh Lakes, and eastward flow to the groundwater low at monitoring well RP-2-03. A second lesser groundwater high occurs between Coolagh Lakes and the River Corrib. This local water table high forms a groundwater divide between Coolagh Western Spring and the River Corrib.

The range in groundwater levels shown in **Table 10.8** shows differing seasonal variability in the Visean Undifferentiated Limestone across Section 3. Discounting those monitoring wells where the recorded range was not representative (refer to notes in **Table 10.8**) (BH-3-29R, BH3-31R LQMW5, BH05 and BH-3-32R), then the minimum and maximum ranges recorded are 7.54m (BH04) and 0.51m (BH-3-27R). BH04 is located close to the groundwater dive between Menlough and Lackagh Quarry, whilst BH-3-27R is located close to Western Coolagh Spring. Based on the data presented, those monitoring locations close to discharge points (rivers and springs) show the least seasonal fluctuation, whilst those near groundwater divides have the greatest seasonal fluctuation.

The data collected for the project and the identification of groundwater divides presented in **Figure 10.6.007** to **Figure 10.6.010** provides significant new data for the extent and boundaries of the groundwater bodies as defined by the GSI. **Section 10.3.3** of this chapter provides reinterpretation for the extents of the GWDTE Lough Corrib Fen 1 (Menlough) GWB, GWDTE Lough Corrib Fen 2 GWB, GWDTE Lough Corrib Fen 3 & 4 GWB and the Clare-Corrib GWB.

Water Quality

Water sampling from monitoring wells in the Menlough and Ballindooley area indicates that the groundwater is generally of good quality with high levels of calcium and magnesium. There are local detections of bacteria such as faecal coliform, which is most likely agricultural or from poorly operating domestic wastewater treatment plants. Water quality data is presented in **Appendix A.10.4**.

10.3.2.4 Section 4 – N83 Tuam Road to existing N6, Coolagh (Ch. 14+400 – 17+500)

Section 4 of the proposed road development extends between the N83 Tuam Road and the existing N6 at Coolagh, Briarhill (**Figures 10.2.002**). This section of the proposed road development traverses the GSI GWDTE Lough Corrib Fens 3 & 4 GWB and the Clarinbridge GWB. There is a significant amount of urban development in this area, which includes the Galway Racecourse. There are no surface water features apart from seasonal pluvial flooding on the existing N83 Tuam Road during winter.

The ground investigation identified that the subsoil at the N83 Tuam Road overbridge has a thickness in excess of 30m which is confirmed by boreholes (RC-3-62 & BH-3-35) and geophysics (GP-3-13 and GP-3-14) (**Appendix 9.2**). There is significant thickness of subsoil in the valley floor (below the fields) but bedrock is shallow along the School Road in Castlegar (BH3/33 and BH3/34) and Galway Racecourse (BH3/36, BH3/47). This indicates that a significant buried landscape is located along the existing N83 Tuam Road. The pluvial flooding that occurs seasonally along the N83 Tuam Road occurs where the areas of thick subsoil are present. Trial pits and soakaway tests into the valley floor of the N83 Tuam Road (SW3/02, SW3/15, SW3/16, SW3/17, SW3/18) confirm that the subsoil is of clay and as such of low permeability.

The buried landscape identified at the N83 Tuam Road is the only feature observed in Section 4. East of the feature the bedrock rises steeply and forms high ground that forms the Galway Racecourse and business parks in Ballybrit and Parkmore.

Bedrock Aquifer

Section 4, like sections 2 and 3 is classified by the GSI as being a regionally important karst aquifer with conduit (Rkc) (**Figure 10.1.002**). Ground investigations (GI) include geophysics, drilling and trial pitting Groundwater monitoring wells have been installed into boreholes and included as part of the groundwater monitoring network. Section 4 is generally absent of karst, with only a number of small scale features, which are shown in **Figure 10.1.002**. The recorded karst features include:

- Two small enclosed depressions east and north of the Galway Racecourse (K104 and K131)
- Three shallow enclosed depressions north of the existing N6 Coolagh Roundabout ((K172, K175 and K179)
- Small seepages and small enclosed depressions west of the existing N6 Coolagh Roundabout (K126, K129, K130, K132, K134 and K135)
- Further south and downgradient of the existing N6 Coolagh Roundabout an old quarry has some small scale inflows (K160 and K173), there are some shallow enclosed depressions (K112, K140, K142, K145, K151, K152, K154, K159, K163) and there is one spring (K182)

- Further east and downgradient of the existing N6 Coolagh Roundabout there are a number of small scale karst features, including enclosed depressions (K198, K201, K202, K203, K213, K211, K222 and K215) and one spring K215

Aquifer Properties

The Visean Undifferentiated Limestone aquifer is a regionally important aquifer that is associated with high permeability and highly productive groundwater abstraction wells.

Aquifer testing was undertaken in four monitoring boreholes located in Section 4. These tests consisted of three small scale pumping tests and one 72-hour pumping test. The data from and analysis of the tests is presented in the aquifer testing report **Appendix A.10.5**. It is noted that the 72-hour test undertaken in December 2016 failed to last the intended duration as the well became dry after a short period and did not recharge. A summary of the aquifer properties is presented below in **Table 10.10** and **Plate 10.1**.

This aquifer data shows a range in hydraulic conductivity in the Visean Undifferentiated Limestone of Section 4 between $1.7x10^{-6}$m/s and $4.2x10^{-7}$m/s. The higher permeability values are likely to be testing fracture flow, whilst the lower permeability values indicate mainly matrix flow with only small scale fractures intersected.

Groundwater Vulnerability

The criteria for determining groundwater vulnerability, as described by the GSI, is shown in **Table 10.4**. Groundwater vulnerability as mapped by the GSI is presented in **Figure 10.3.002**.

GSI vulnerability shows the rock within three meters of surface at the N83 Tuam Road to the Galway Racecourse and then mainly at or near surface from Briarhill to the existing N6. Information from ground investigations and walkover surveys indicates that the bedrock is significantly deeper than this at N83 Tuam Road where the deep buried valley is present and slightly deeper on the higher ground where thicknesses range from at surface to within 8m below ground level.

The GSI show that recharge estimates indicate a recharge coefficient of 30% for the limestone with thicker subsoil and 85% for the limestone at or near surface, with no recharge cap applied. Recharge acceptance of the Briarhill area is considered to have high recharge acceptance of 172-649mm/yr.

Groundwater Levels

Groundwater monitoring wells are located along the route of the proposed road development from N83 Tuam Road to the existing N6. The location of these wells and the water level data is presented in **Appendix A.10.3** and groundwater levels are presented **Figure 10.6.010** and **Figure 10.6.011**. The groundwater level for Section 4 of the proposed road development has a higher elevation than elsewhere on the limestone section of the proposed road development. A summary of the groundwater levels is presented below in **Table 10.9**.

Table 10.9: Groundwater levels measured in the Visean Undifferentiated Limestone (Section 4)

Monitoring Borehole	Source	East ITM	North ITM	Ground Elevation (mOD)	Groundwater Level		
					Min mOD	Max mOD	Range m
BH-3-36R	N6 GCRR	533125	728205	24.43	42.55	43.83	1.28

BH-3-41R	N6 GCRR	534580	727065	54.92	42.55	43.83	1.28
BH-3-42R	N6 GCRR	534756	726840	45.17	39.30	39.89	0.59

Notes

Includes groundwater level data from project specific monitoring wells

Groundwater levels are measured on site to the nearest centimetre below top of casing. All effort has been made to ensure the accuracy of the data.

The water level data collected for the project and the identification of groundwater divides presented in **Figure 10.6.010** and **Figure 10.6.011**, provides significant new data for the extent and boundaries of the groundwater bodies as defined by the GSI. **Section 10.3.3** of this chapter provides reinterpretation for the extents of the Lough Corrib Fen 3 & 4 GWB, the Clare-Corrib GWB and the Clarinbridge GWB.

Water Quality

Water sampling from monitoring wells in Section 4 indicates that the groundwater is generally of good quality with high levels of calcium and magnesium. There are local detections of bacteria such as faecal coliform, which is most likely agricultural or from poorly operating domestic wastewater treatment plants. Water quality data is presented in **Appendix A.10.4**.

10.3.3 Conceptual Site Model

This section considers all desk study data together with the project specific surveys and ground investigations to develop a conceptual model for the hydrogeology of the study area. The conceptual model includes a refinement of the existing GSI groundwater bodies map based on interpretation of the project data. The updated map showing revised extents of groundwater bodies is used in the individual assessments for groundwater receptors, which follows this section.

The Galway Granite Batholith and Visean Undifferentiated Limestone contrast strongly in terms of aquifer classification, recharge and flow pathways and as such are considered as two distinct aquifer units.

The Galway Granite Batholith is classified as a poor aquifer (Pl) by the GSI and the investigation undertaken as part of this project confirms this. Aquifer testing has shown that the rock type generally has a low permeability but can locally have zones where permeability is higher.

The Visean Undifferentiated Limestone is classified by the GSI as a regionally important karst aquifer (Rkc) that includes conduits. The ground investigation has shown that the Visean Undifferentiated Limestone has a wide permeability range and whilst there are zones of karst there are also areas where no karst features exist.

An overview of the Galway Granite Batholith and Visean Undifferentiated Limestone aquifer is presented below, which is based on the regional and local data presented in **Section 10.3.1** and **Section 10.3.2**. The hydrogeology for the Galway Granite Batholith and the Visean Undifferentiated Limestone are then discussed in detail individually below.

Groundwater flows can be more complex in limestone than granite due to karst pathways and the ground investigation data includes aquifer testing of both rock types to calculate their range of hydraulic conductivity. The aquifer testing is presented in **Plate 10.1** below for granite and limestone. This data shows that whilst the granite has a relatively narrow range of values, the limestone spans a significantly wider range. For the limestone areas, this data (as well as the spatial distribution of karst features) is used to identify those areas where karst flow paths through the aquifer are likely but also areas where such pathways are not present. These assessments are based on a combination of trial pits, window samples, drilling, surface geophysical surveys, pumping test and groundwater monitoring and interpretation.

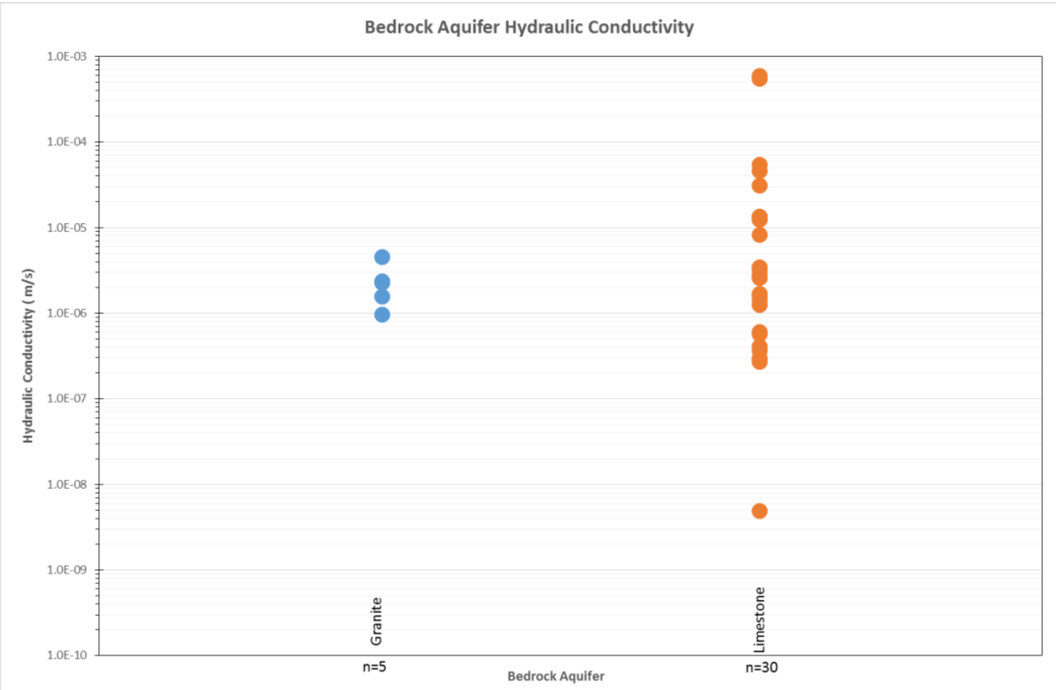
The karst survey (**Figure 10.1.002**) undertaken is used as an indicator that karst pathways are present within groundwater bodies. The observation of conduit flow at Western Coolagh Spring (K25) data and presence of karst features in the area are indicative that karst pathways are likely within GWDTE Lough Corrib Fen 1 (Menlough) GWB. Similarly, the karst survey identifies karst landforms across the Clare-Corrib GWB, which is also likely to have conduit pathways in the GWB. However, the survey identified only small scale karst features in the Clarinbridge GWB, which comprised of small or shallow enclosed depressions and seepages rather than springs.

Aquifer testing was undertaken for both the Galway Granite Batholith and Visean Undifferentiated Limestone across the proposed road development. The data from one pumping test, 15 small scale pumping tests with recovery, three packer tests and 15 soakaway tests are presented in **Appendix 10.5**. **Plate 10.1** below shows the distribution of hydraulic conductivity and **Table 10.10** shows the distribution for both granite and limestone. This data shows that those groundwater bodies that do not have karst, the Galway Granite Batholith and the Visean Undifferentiated Limestone within the footprint of the proposed road development within the Clarinbridge GWB have a relatively narrow range of hydraulic conductivity. In contrast the Visean Undifferentiated Limestone aquifer has significant karst in the GWDTE Lough Corrib Fen 1 (Menlough) GWB, the GWDTE Lough Corrib Fen 2 GWB and the Clare-Corrib GWB. In these areas where karst is present then the range of hydraulic conductivity is wider. Notably the maximum hydraulic conductivity is an order of magnitude higher. The highest recorded values for hydraulic conductivity are those measured in karst (5.3×10^{-4}m/s).

Table 10.10: Distribution of calculated hydraulic conductivity

Geological Unit	GWB	Min hydraulic conductivity m/s	Max hydraulic conductivity m/s
Galway Granite Batholith	Spiddal Maam - Clonbur	9.7 x10-7	4.6 x10-6
Visean Limestone Undifferentiated	Lough Corrib Fen 1 (Menlough) Clare-Corrib	5.0 x10-9	3.1 x10-5
Visean Limestone Undifferentiated	Clarinbridge	4.2 x10-7	1.7 x10-6

Plate 10.1: Distribution of calculated hydraulic conductivity



10.3.3.1 The Galway Granite Batholith Aquifer

The GSI descriptions for groundwater bodies in the Galway Granite Batholith such as the Spiddal GWB (GSI 2004a) and the Maam-Clonbur GWB (2004b), describes the aquifer as being a poor aquifer with low storage and short groundwater pathways.

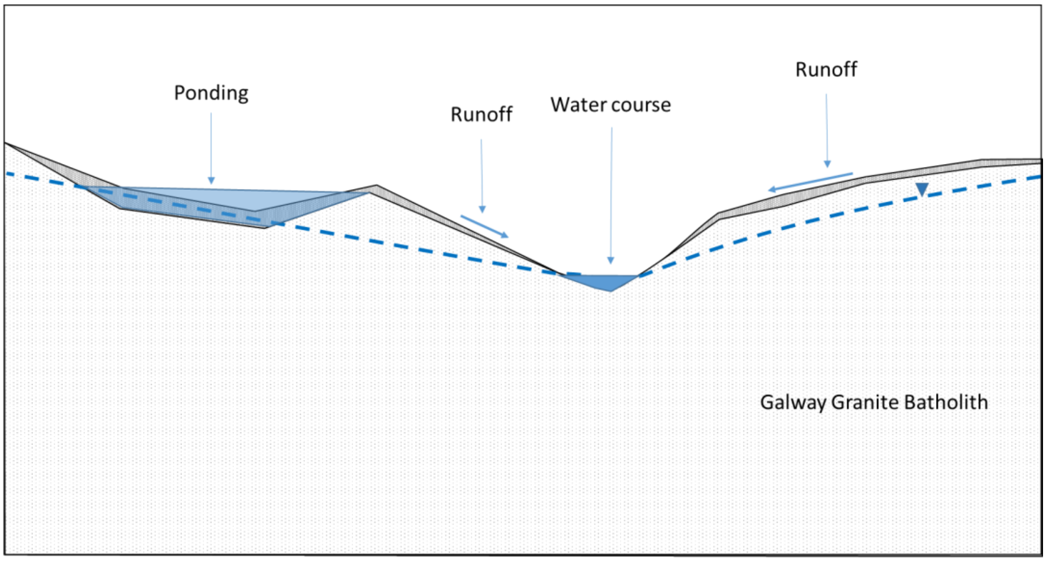
The water level data presented in **Section 10.3.2**, identifies that the groundwater table remains close to the surface and generally follows topography. On this basis groundwater levels will lower towards the coast and the River Corrib. The groundwater divide between the GSI Spiddal GWB and Maam-Clonbur GWB matches the watershed between Galway Bay and the River Corrib, which extends along the high ground at Letteragh and west of Dangan.

The GSI vulnerability data and ground investigation data for the project confirm that subsoil overlying the granite thins on higher ground and is up to 3m thick in low lying ground. The soil and subsoil comprises of glacial tills with high fines content, which is confirmed by particle size distribution (PSD) data that is presented in **Appendix A.9.1**. This data indicates that the permeability or the subsoils is in the low to moderate range (DELG, 1999).

The groundwater level data collected for this project agrees with the GSI division of groundwater bodies and on this basis the extent and naming of these remains unchanged. Based on GSI (2004a and 2004b), groundwater flow in the Galway Granite Batholith is isolated to weathered zones and fracture zones. None of the groundwater level data presented is indicative of high permeability zones.

The Galway Granite Batholith includes areas where there is poor drainage and water ponding at the surface, these areas include the Moycullen Bogs (NHA) and a number of other wetland areas (refer to **Chapter 8 Biodiversity**). The Moycullen Bogs comprise of a main area in the west near Lough Inch and two isolated areas at Tonabrocky and Letteragh (ref **Figure 10.5.002**). Where the surface water ponding occurs there is often little or no seasonal variation in the water level, with most areas remaining ponded throughout the summer.

Plate 10.2: Hydrogeological conceptualisation of runoff and surface water ponding on the Galway Granite Batholith



The undulating topography of the Galway Granite Batholith includes areas of topographic highs where bedrock is near surface and topographic lows where the subsoils are thicker (up to 3m). On the topographic highs rainfall runs off as overland flow whilst it is the lying ground where surface ponding as discussed above tends to occur.

The GSI vulnerability data and the project ground investigation data together with the Ordnance Survey topographic data show that the granite has an undulating rock topography (**Plate 10.2**). As the granite is of low permeability it will perch surface water and where drainage is poor, surface water can be impounded and ponded.

Connectivity between groundwater and the ponded surface water will be slight. As such, the water ponding on the surface at the Moycullen Bogs is not groundwater from the bedrock but water ponded on the top of the bedrock that has saturated the subsoil, has no natural discharge point, so breaches the ground surface.

10.3.3.2 The Visean Undifferentiated Limestone Aquifer

The GSI subdivided the aquifer of the Visean Undifferentiated Limestone into the following groundwater bodies.

- GWDTE Lough Corrib Fen 1 (Menlough)
- GWDTE Lough Corrib Fen 2
- GWDTE Lough Corrib Fen 3 & 4
- Clarinbridge
- Clare-Corrib
- Ross Lake

Each of the groundwater bodies are characterised below and discussed in terms of their interaction with surface water. In all cases the extent of the GWB is reviewed based on the project groundwater monitoring data. In most cases there has been refinement to the extent of groundwater bodies. The GWB retain the names provided by the GSI, however, the prefix of GWDTE is removed from those GWB named so by the GSI.

Ross Lake Groundwater Body

The Ross Lake GWB encompasses the limestone on the western side of the River Corrib. The Ross Lake GWB as mapped by the GSI is presented in **Figure 10.2.002**. The extent of the Ross Lake GWB was revised based upon the ground investigation for the proposed road development and the revised extent is presented in **Figure 10.5.002**.

The GWB receives recharge from rainfall but also runoff from the adjacent granite. There are several drains and ditches that cross from the granite and onto the Ross Lake GWB. As such, the surface catchment for the Ross Lake GWB includes runoff within the local catchment for the River Corrib. As the GWB boundary conditions are physical (i.e. bedrock contact and river) they do not fluctuate seasonally.

GWDTE Lough Corrib Fen 1 (Menlough) Groundwater Body

The GWDTE Lough Corrib Fen 1 (Menlough) GWB extends east from the River Corrib to the townland of Coolough. The eastern extent of the GSI GWDTE Lough Corrib Fen 1 (Menlough) GWB (**Figure 10.5.002**) has been revised westwards to the townland of Coolough to accommodate the groundwater divide identified between it and the Clare-Corrib GWB, which has been refined based on groundwater monitoring for this project.

This GWB has been divided into two areas, namely Lough Corrib Fen 1 Menlough and Lough Corrib Fen 1 Lackagh (note that in the revised mapping of the GWB the term GWDTE has not been used in the GWB title), on the basis of the thick silt and clay subsoils (up to 106m deep) that occur in the townland of Coolough. These thick subsoils deposits, which underlie Coolagh Lakes and form a deep valley fill/palaeokarst feature west of Lackagh Quarry, compartmentalise the GWB so that Lough Corrib Fen 1 (Menlough) lies north of Coolagh Lakes and Lough Corrib Fen 1 (Lackagh) forms a small GWB (<0.04km^2) between Coolagh Lake and Lackagh Quarry. It is noted that Lackagh Quarry lies within the revised Clare-Corrib GWB and not the revised Lough Corrib Fen 1 (Menlough) GWB or Lough Corrib Fen 1 (Lackagh) (**Figure 10.5.002**).

Groundwater flows westwards within the Lough Corrib Fen 1 (Menlough) from the groundwater divide with the Clare-Corrib GWB to the Coolagh Lakes and the River Corrib. Lough Corrib Fen 1 (Menlough) GWB supplies groundwater to Coolagh Lakes via the Western Coolagh Spring (K25). Due to the compartmentalisation of the aquifer by buried valleys/palaeokarst, the groundwater in Lough Corrib Fen 1 (Lackagh) GWB is largely contained. Due to the thick clay subsoil there are no observed discharges from the limestone bedrock to the Eastern Coolagh Spring and the compartmentalisation prevents discharge to Western Coolagh Spring. Instead, groundwater flow from Lough Corrib Fen 1 (Lackagh) is likely to flow eastwards to Lackagh Quarry during peak groundwater levels. There is a potential for seepage from the limestone aquifer through the clayey subsoil to the Eastern Coolagh Spring but due to the low permeability and thickness of the clayey subsoil, these potential seepages are of a very low flow rate. If present, seepages from the subsoil to the Eastern Coolagh Spring would represent a very small fraction of the groundwater contribution to Coolagh Lakes compared to the karst inflow at Western Coolagh Spring (K25), which provides the main groundwater contribution flow to Coolagh Lakes. As described in **Section 10.3.2.3** the Eastern Coolagh Spring (K45) is not a karst spring because it sits on thick clay subsoil as evidenced by ground investigations (GI).

Coolagh Lakes lie in a low-lying area that are shown by GSI data as well as records from 2006 GCOB GI and observations from the site walkover to be underlain by thickness of low permeability overburden and that the overburden adjacent to Upper Coolagh Lake comprises of silt and clay. On this basis, groundwater inflows through the base of the lakes are unlikely and the only significant groundwater input is the karst inflow via the Western Coolagh Spring (K25). Groundwater contribution to Coolagh Lakes from the Eastern Coolagh Spring and any other potential seepages (such as underwater springs from the margin of the Clare-Corrib GWB) are very limited due to the thick clay subsoil that fills the buried valley and forms a very low permeability barrier to the limestone aquifer.

Plates 10.3 and **10.4** below show the interactions between the Coolagh Lakes and Western Coolagh Spring at high and low groundwater levels. During periods of high groundwater levels groundwater contributes flow to the lakes (**Plate 10.3**), while during the summer the groundwater level lowers to just above the lake level and the springs have minimal flow. **Plate 10.4** below, shows the relationship between groundwater levels and surface water levels in the springs that feed Coolagh Upper Lake.

Plate 10.3: Schematic north south cross-section through Coolagh Lakes (groundwater high)

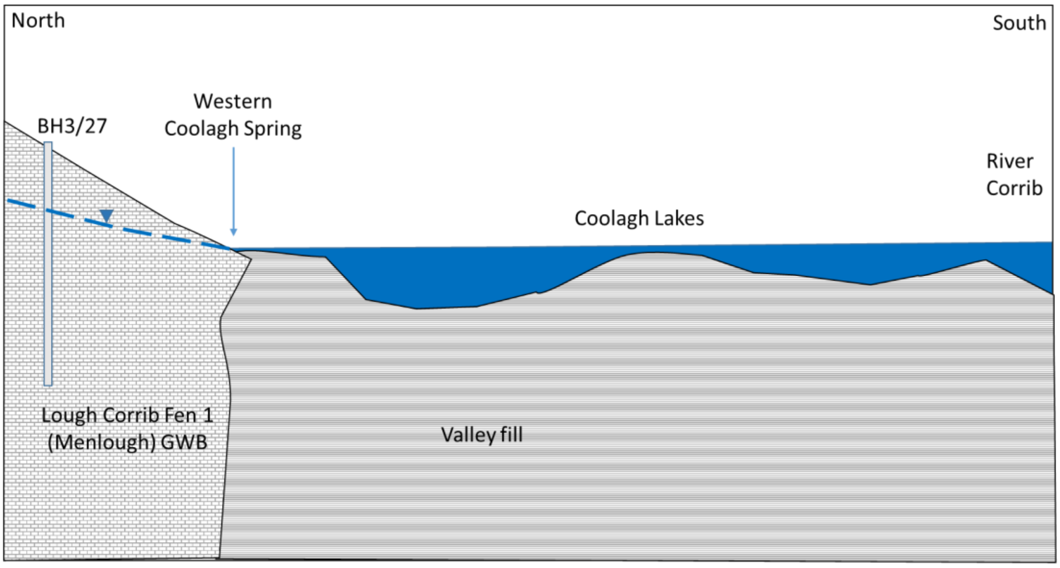


Plate 10.4: Schematic north south cross-section through Coolagh Lakes (groundwater low)

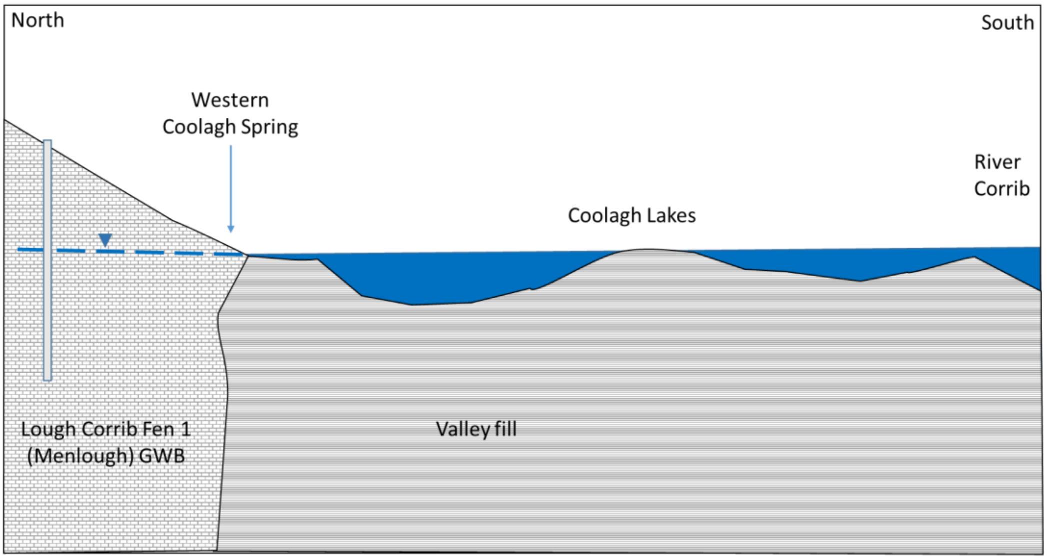
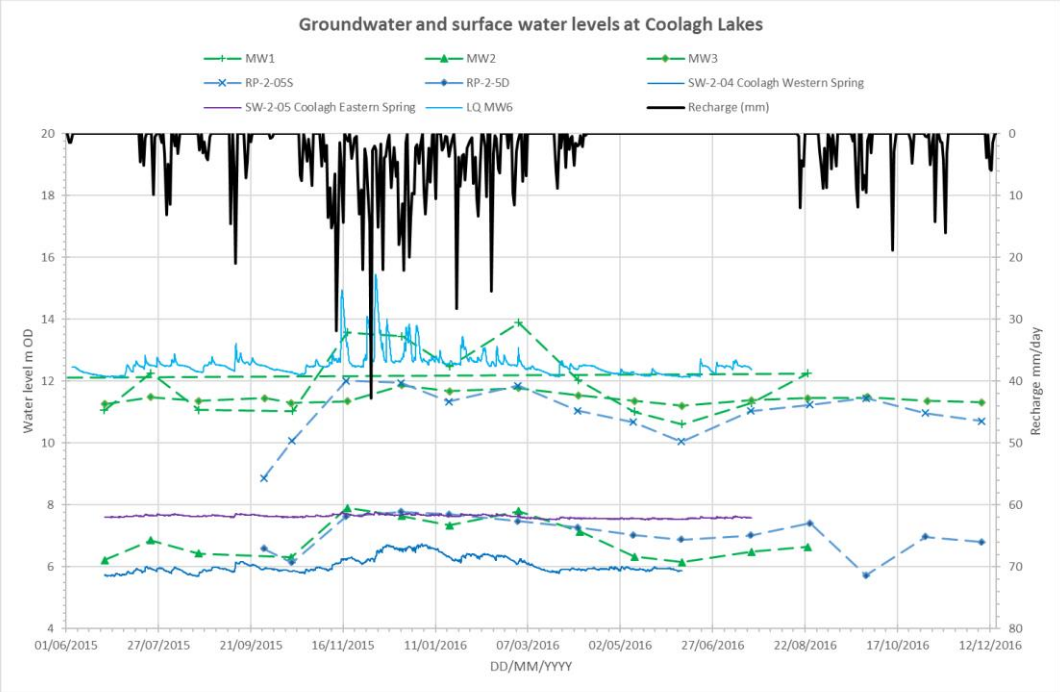


Groundwater hydrographs for the GWB are presented below (**Plate 10.5**), and show the groundwater responses in the aquifer locally as well as levels at the Western Coolagh Spring and Eastern Coolagh Spring.

Plate 10.5: Groundwater and surface water levels at Coolagh Lakes



Western Coolagh Spring is the main water inflow to Coolagh Lakes and has a seasonal variance in water level of 0.7m. Western Coolagh Spring is a karst resurgence in the eastern side of a shallow valley at the head of Upper Coolagh Lake. At this location groundwater flow rises from conduit in limestone bedrock. Flow is turbulent, with flow velocity up to 0.3m/sec (flow of 35l/s) estimated during the winter of 2016. During the summer time the flow at the spring is low (<1l/min). There are a number of seepages associated with Western Coolagh Spring in the western side of the shallow valley. Western Coolagh Spring is the collective of the main spring and the smaller seepages.

Eastern Coolagh Spring is separate from Western Coolagh Spring, being located 850m away in a north eastward direction and 3m higher in elevation. It has a very slight seasonal variable of 0.1m and with no measureable flow. Due to the geological setting of the Eastern Coolagh Spring with clayey subsoil, this feature is not considered is not considered to be a karst feature. As discussed there is potential for seepage from the clayey subsoil inputs to Coolagh Lakes at Eastern Coolagh Spring as well as seepage from elsewhere around the periphery of the lake shore. However, even if seepages are present, the potential seepages rates will be very low when compared to Western Coolagh Spring, even when considering the total seepage flow for the full extent of the lake periphery. This hydrogeological assessment however is based on the precautionary principle and assumes that these seepages occur even though they were not observed.

The extent of the Lough Corrib Fen 1 (Menlough) GWB is shown in **Figure 10.5.002**. The GWB is bound to the west by the River Corrib, to the east by a groundwater divide with the Clare-Corrib GWB, north by a divide with the Lough Corrib Fen 2 GWB and south by thick clayey subsoil deposits on which the Coolagh Lakes have formed.

The Lough Corrib Fen 1 (Lackagh) GWB is relatively small in size ($0.7km^2$) and is also internally subdivided by features such as the thick clayey subsoil deposits that infill the palaeokarst west of Lackagh Quarry. The boundaries, as well as thick subsoil deposits within the GWB, isolate the potential surface catchments for both the Western Coolagh Spring and Eastern Coolagh Spring, and on this basis their catchments can be defined.

The sub catchment for Western Coolagh Spring is defined as the surface area of the Lough Corrib Fen 1 (Menlough) GWB from the eastern GWB boundary (BH4) to the topographic high at MW3. At MW3 there is a small groundwater ridge that allows a divide between groundwater that flows to Western Coolagh Spring and groundwater that flows the River Corrib. As MW3 lies 200m east of the River Corrib the extent of the groundwater sub catchment that drains to the River Corrib is limited to the 200m wide strip adjacent to the river (less than $0.1km^2$).

The pond at Eastern Coolagh Spring has the potential to receive seepage from the subsoil surrounding the feature. The extent of the catchment is restricted to the area in the valley floor. Any groundwater flow from the limestone aquifer to the Eastern Coolagh Spring would have to seep through the clayey subsoil and hence be of a very low quantity.

The groundwater levels in the GWB (**Plate 10.5**) show that as well as having the largest sub-catchment in the Lough Corrib Fen 1 GWB, the Western Coolagh Spring is also the lowest measured point of the groundwater table. On this basis the Western Coolagh Spring (as well as Coolagh Lakes and River Corrib) is the main receiving water. Based on the descriptions presented, the Western Coolagh Spring is considered to be the sole significant groundwater contributor to Coolagh Lakes.

The western boundary of the Lough Corrib Fen 1 (Menlough) GWB is physically bound by a river. The seasonal variance is very slight due to the level of the river. However, the eastern boundary of the Lough Corrib Fen 1 (Menlough) GWB is a groundwater divide and the seasonal fluctuation in groundwater levels has the potential to cause the divide to shift laterally.

Due to the compartmentalisation of the Lough Corrib Fen 1 (Lackagh) GWB, flow is prevented from draining to Western Coolagh Spring and only small scale seepage via the clayey subsoil is possible at the Eastern Coolagh Spring. The compartmentalisation of the aquifer means that during peak levels the groundwater in the Lough Corrib Fen 1 (Lackagh) may flow eastwards towards Lackagh Quarry.

Based on the maximum and minimum groundwater levels data presented in **Table 10.8** and **Figure 10.6.107** to **Figure 10.6.110** the groundwater divide occurs at near BH4 during the winter. During the summer the groundwater table gradient flattens and the divide migrates north westwards by an estimated 250m (based on the seasonal groundwater level data for BH4 and LQMW4, refer to **Appendix 10.3**).

On the basis of the above descriptions, the Lough Corrib Fen 1 (Menlough) GWB is the sole significant groundwater contributor (via Western Coolagh Spring (K25)) to Coolagh Lakes. The Coolagh Lakes discharge to the River Corrib, both of which are part of the Lough Corrib cSAC and therefore the Lough Corrib Fen 1 (Menlough GWB contributes to this cSAC. As the River Corrib discharges into Galway Bay this GWB also contributes (indirectly) to Galway Bay Complex cSAC and Inner Galway Bay SPA.

GWDTE Lough Corrib Fen 2 Groundwater Body

The GSI mapping of the extents of GWDTE Lough Corrib Fen 2 is shown in **Figure 10.2.002**. Based on the groundwater level data collected for the proposed road development the southern boundary of the GWB as per GSI is set 0.3km too far south. Based on the water level data for the proposed road development the GWB extent has been updated and is shown in **Figure 10.5.002**. Note that in the revised mapping of the GWB the term GWDTE has not been used in the title.

Although the proposed road development does not extend into this GWB (**Figure 10.5.002**) the divide between the GWB and the adjacent GWDTE Lough Corrib Fen 1 GWB lies in close proximity to it. On this basis this GWB is considered as one of the GWB traversed by the proposed road development.

The seasonal fluctuation in the GWB as 2.5m, as recorded in monitoring well RC133, which is located close to the groundwater divide (**Table 10.8**). Based upon slight seasonal variation and relatively low hydraulic gradients in the area the groundwater divide is considered to be stable and not fluctuate laterally.

Lough Corrib Fen 2 GWB contributes to Lough Corrib. The only surface water recorded in the GWB is Turlough K20 and spring K17.

GWDTE Lough Corrib Fen 3 and 4 Groundwater Body

Based on groundwater level data collected for the proposed road development, the southern extent of the GSI Lough Corrib Fen 3 and 4 GWB has been reduced and been moved north by over 2km. The revised groundwater bodies are presented in **Figure 10.5.002**, although it is noted that based on the revised extent, this GWB no longer extends onto the figure. Note that in the revised mapping of the GWB the term GWDTE has not been used in the title.

Clare-Corrib Groundwater Body

The GSI mapping of the GWB is shown in **Figure 10.2.002**. Based on the groundwater level data collected for the proposed road development, the extent of the Clare-Corrib GWB has been revised with the GWB extended further west, as far as the townland of Coolough, near Menlough, and further east to the N83 Tuam Road (**Figure 10.5.002**).

There are a number of features in the GWB that have ponded water and these have the potential to interact with groundwater. These pond features include Ballindooley Lough (which comprises of the main Ballindooley Lough and a number of smaller surface water bodies immediately to the south), a small surface water body at Ballinfoyle, an enclosed depression referred to as K97 in the karst survey (refer to **Appendix 10.2**), and the Terryland River, including adjacent ecology have been identified in the **Chapter 8, Biodiversity** as being potential water dependant habitats. The hydrogeological aspects of these features are presented below.

Ballindooley Lough

Geophysics undertaken south of Ballindooley Lough for this project and north of the Ballindooley Lough for 2006 GCOB indicate that thick subsoils underlie the extents of Ballindooley Lough. From this data it is inferred that a feature, such as a buried valley, underlies the length of the lake. The subsoils below the lake explain the permanent perching of the surface water level when groundwater levels are low.

The groundwater data shows that Ballindooley Lough lies up gradient of the proposed road development. The data also shows the lough to be perched during the summer when groundwater levels (RP-2-01 & RC1104) drop below the lake water level (**Plate 10.6** and **10.7**). On this basis, during low groundwater levels the perched water in Ballindooley Lough and the groundwater in the limestone aquifer form separate and distinct water bodies.

Plate 10.6: Schematic east west cross-section through Ballindooley Lough showing the interaction of groundwater with the lake during high groundwater levels

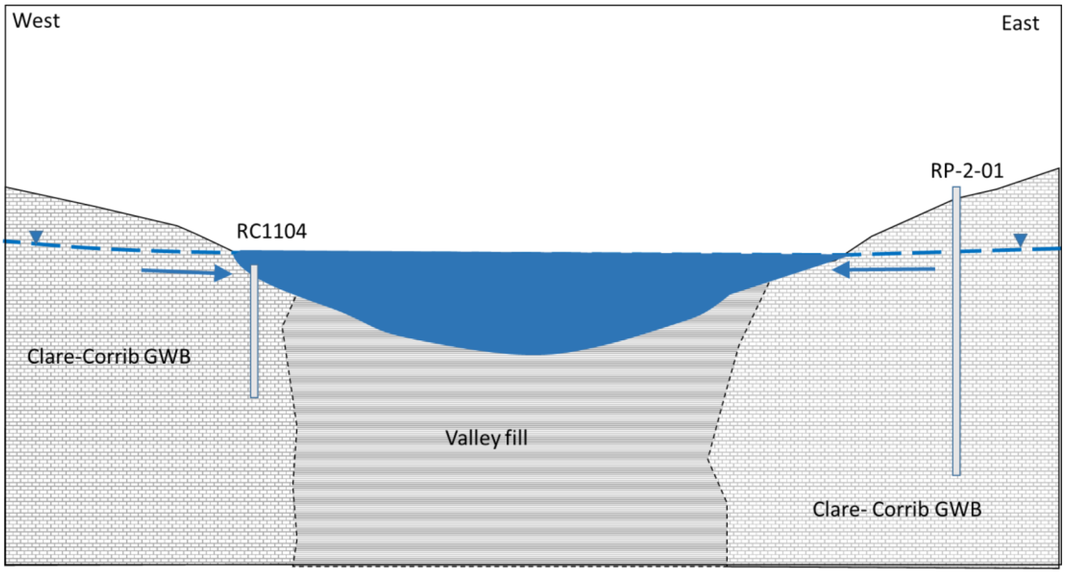


Plate 10.7: Schematic east west cross-section through Ballindooley Lough showing the interaction of groundwater with the lake during low groundwater levels

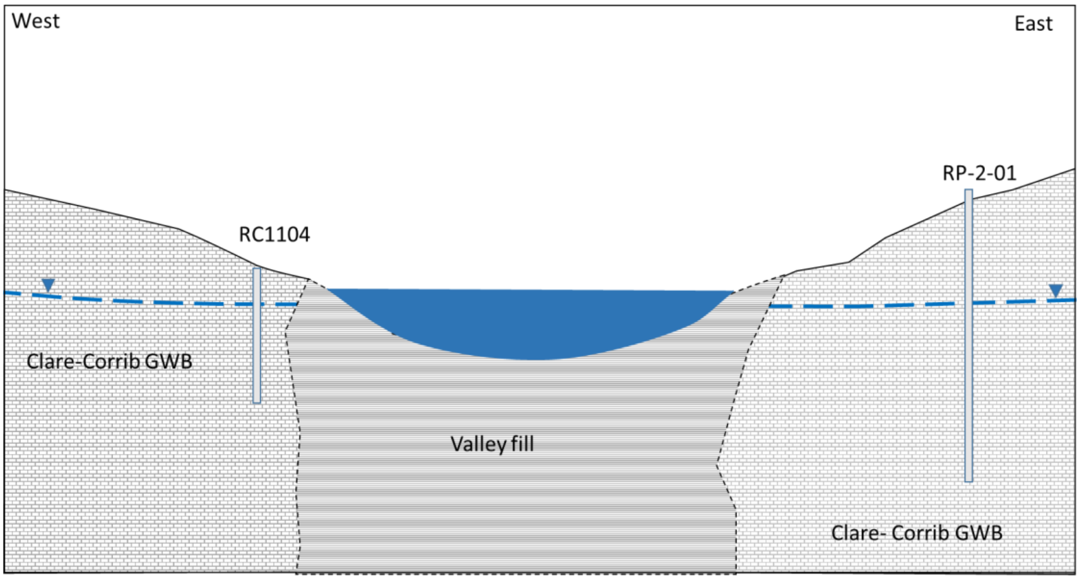


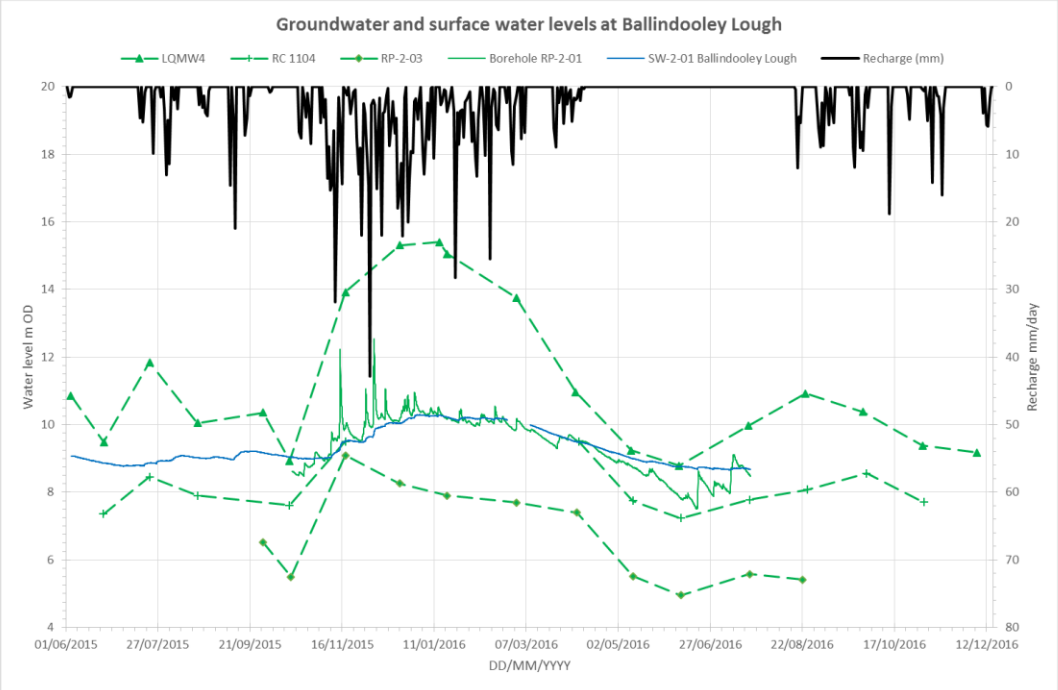
During the winter, the lake level in Ballindooley Lough and the groundwater level in the limestone aquifer are in continuity. On this basis, Ballindooley Lough only receives groundwater during high groundwater levels.

Bathymetry of Ballindooley Lough shows that the lake has a max depth of 10m (-2.5m OD). Based on the geophysics data and the analyses that the summer lake water level is distinct from groundwater, then the base of summer water level in Ballindooley Lough lies on low permeability subsoil and not limestone.

The hydrographs for the GWB below in **Plate 10.8** show that the groundwater level in wells surrounding Ballindooley Lough are continuous with the level of Ballindooley Lough during the winter. However, in the summer the groundwater level lowers below the permanent water level of the lough perching it.

Also notable are the groundwater levels in monitoring well RP-2-03 located 300m south of Ballindooley Lough (**Figure 10.6.009**) are significantly lower than other groundwater levels in the area and the surface water level at Ballindooley Lough. The lower water table in RP-2-03 indicates the direction of flow southwards within the groundwater body.

Plate 10.8: Groundwater and surface water levels at Ballindooley Lough



Enclosed depression (Doline) K97

Doline K97 was identified by the karst survey. It is a c.40m circular enclosed depression, with soft clay in the base, that is located near Castlegar (**Figure 10.1.002**). This doline is included in this assessment as it was originally highlighted as potentially being a turlough, however as outlined below and in **Chapter 8, Biodiversity** it has since been confirmed as not meeting either the ecological or hydrogeological criteria for a turlough.

Based on the above groundwater levels it is clear that there is a distinct difference in groundwater level to the west (Monitoring well BH3/34) and to the east (monitoring well RC-2-01 & RC-2-03) (Refer to **Plate 10.9** and **Plate 10.10**).

The ground investigation data shows that the feature K97 is located within thick subsoil. BH3/32 shows silt and clay subsoil to 23m below ground level (bgl) and geophysics GP3/32 (ERT) (**Appendix 9.1**) shows low resistivity material to a depth of greater than 20m. However, to the east of the site BH3/33 (no piezometer) and geophysics GP3/13 show bedrock to be with 3m of the surface.

Plate 10.9: Schematic east west cross-section through enclosed depression K97 showing the interaction of groundwater with the feature during high groundwater levels

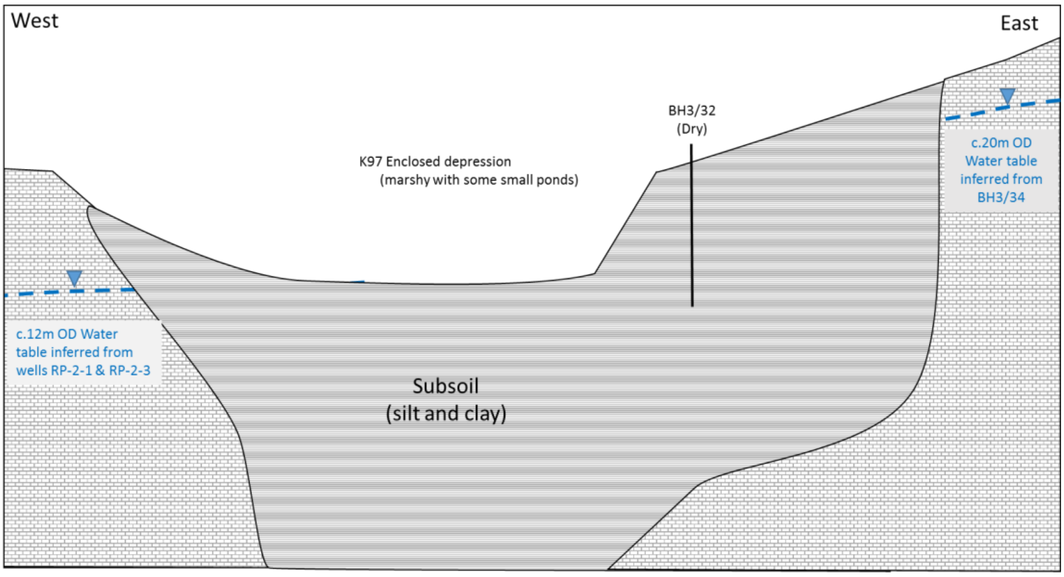


Plate 10.10: Schematic east west cross-section through enclosed depression K97 showing the interaction of groundwater with the feature during low groundwater levels

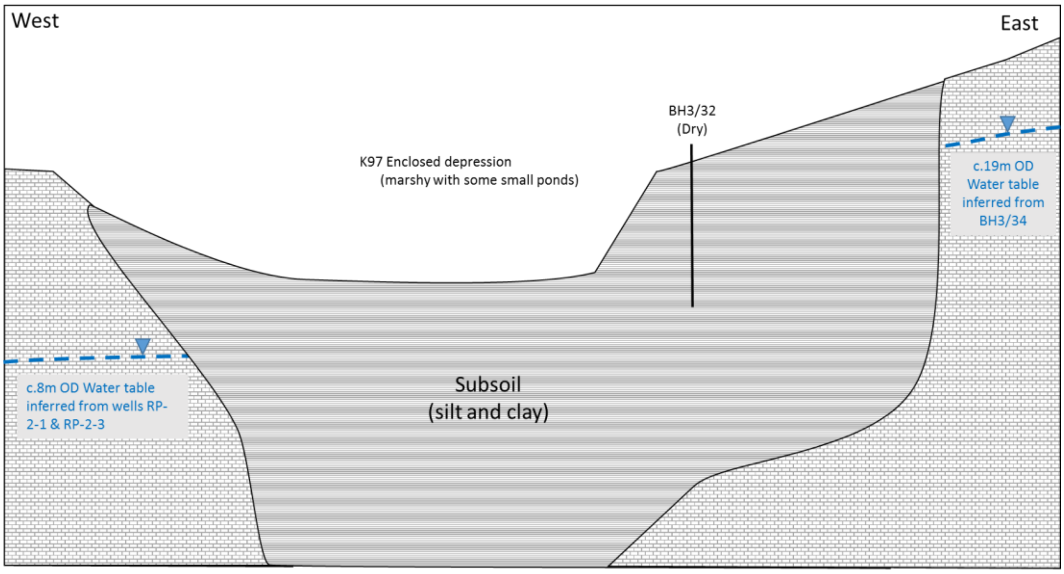

Due to the low permeability nature of the subsoils it is very unlikely that there is a groundwater contribution to the base of the depression. Water ponding in the base is likely to be entirely due to incident rainfall, captured by the depression. The hydrogeological descriptions provided strongly indicate that the feature does not receive groundwater.

<u>Surface water at Ballinfoyle</u>

The surface water feature at Ballinfoyle (N97) lies in the valley floor approximately 600m southwest of Ballindooley Lough, adjacent to and immediately east of the N84 Headford Road at Ballinfoyle (**Figure 10.1.002**). The feature is square in shape measures with 80m long sides and is located within silt/clay subsoils.

It is a seasonal lake that fills during the autumn and drains during spring. Groundwater levels on the north-western side (monitoring wells LQMW1-4) rise above the feature's floor and cause it to flood during the winter. Notably the groundwater level on the south-eastern side remains below the feature's floor at all times (monitoring well RP-2-03). The disparity in groundwater levels across the feature (refer to **Plate 10.11** and **Plate 10.12**) indicates a barrier to groundwater flow and based on the location along the trend of the valley at Ballindooley it is likely that this feature is located on thick clay subsoil.

Based on the groundwater level data, this feature receives groundwater from the bedrock aquifer to the northwest during the winter. The ponding occurs in the feature due to the subsoil deposits that underlie the feature. As the feature is not located on limestone the feature does not have the hydrogeological characteristics of a turlough and is surface water ponding.

Plate 10.11: Schematic east west cross-section through Feature (N97) showing the interaction of groundwater with the feature during high groundwater levels

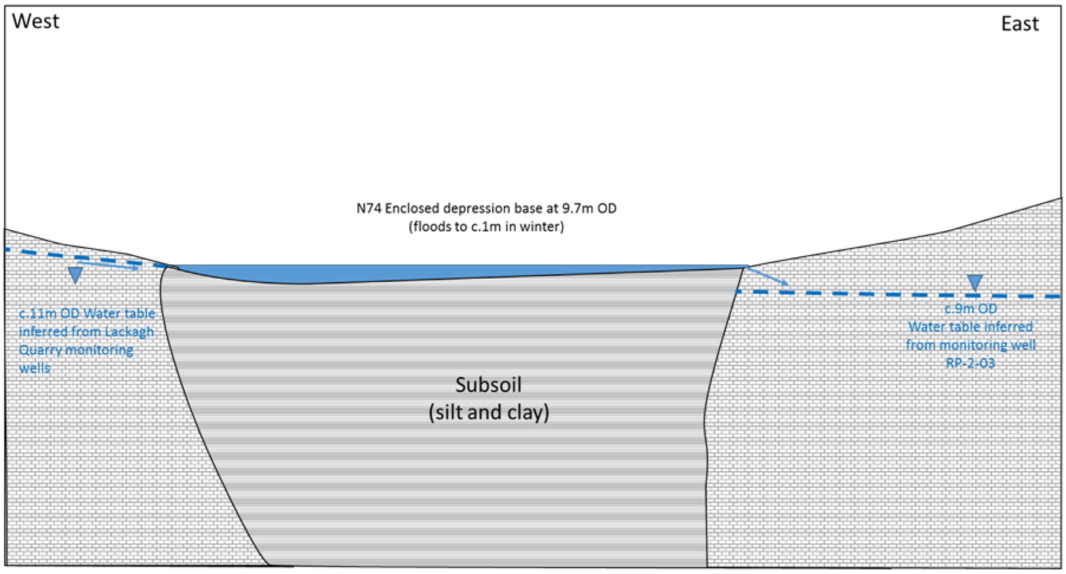

Plate 10.12: Schematic east west cross-section through Feature (N97) showing the interaction of groundwater with the feature during low groundwater levels

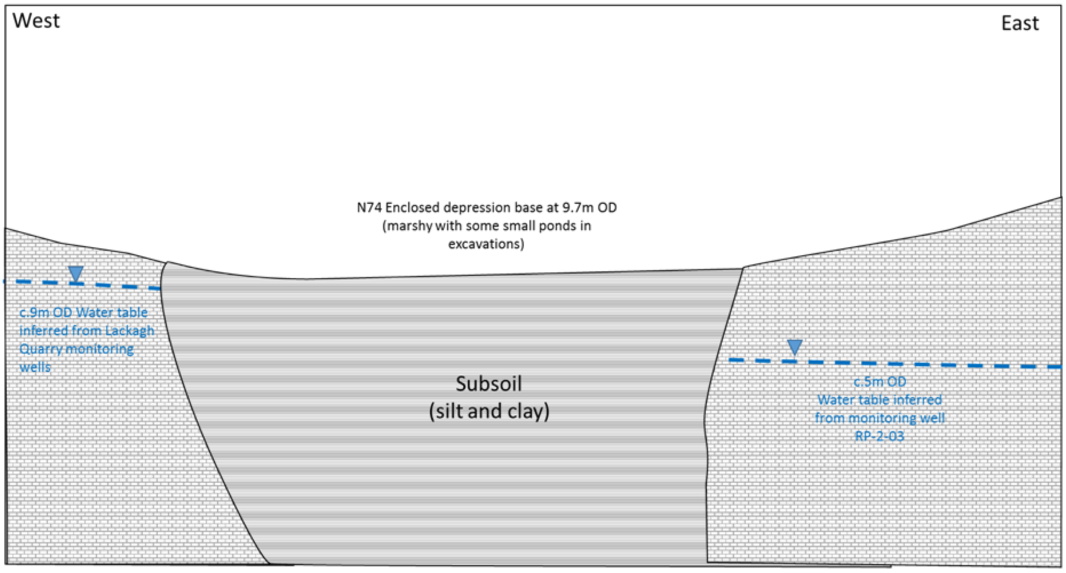

Terryland River

Under normal conditions the Terryland River sinks at two stream sinks, named Pollavurleen West and East (K87 and K96) near Glenanail (Refer to karst study in **Appendix A.10.2**) (**Plate 10.13**). However, during high groundwater levels, the Terryland sinks become resurgences and discharge groundwater to the Terryland River that flows back and joins the River Corrib (**Plate 10.14**).

The switching between sink to resurgence makes these estavelles. Whilst the sinks are located near limestone outcrop, the Terryland River flows for its length along a low-lying area that has thick overburden. The low permeability of the subsoil here carries the surface water across the valley until the limestone is met at the southern side of the valley.

Plate 10.13: Schematic north south cross-section through Terryland River showing the operation of the estavelles at Pollavurleen West and East during high groundwater levels

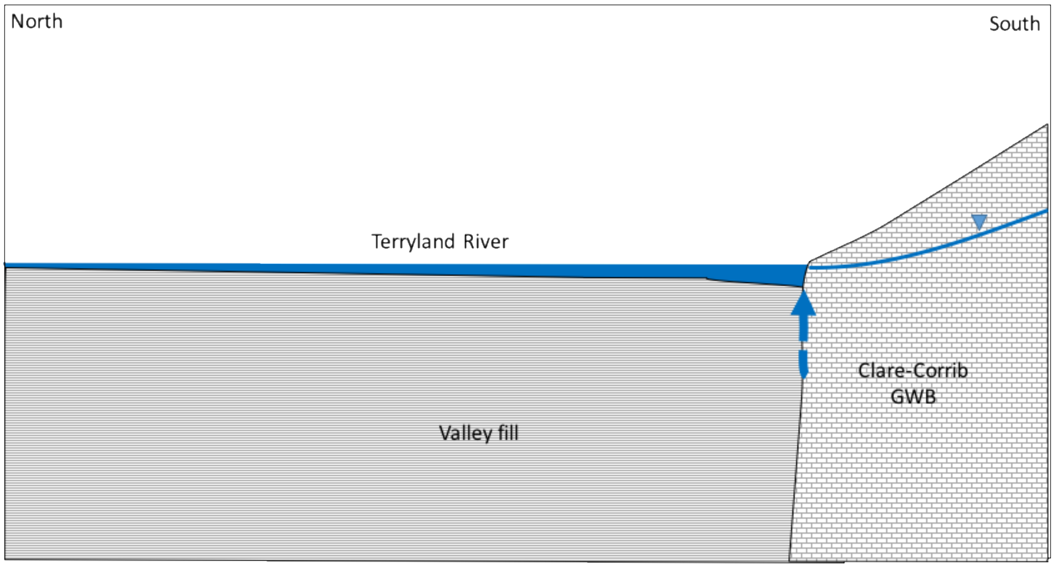

Plate 10.14: Schematic north south cross-section through Terryland River showing the operation of the estavelles at Pollavurleen West and East during low groundwater levels

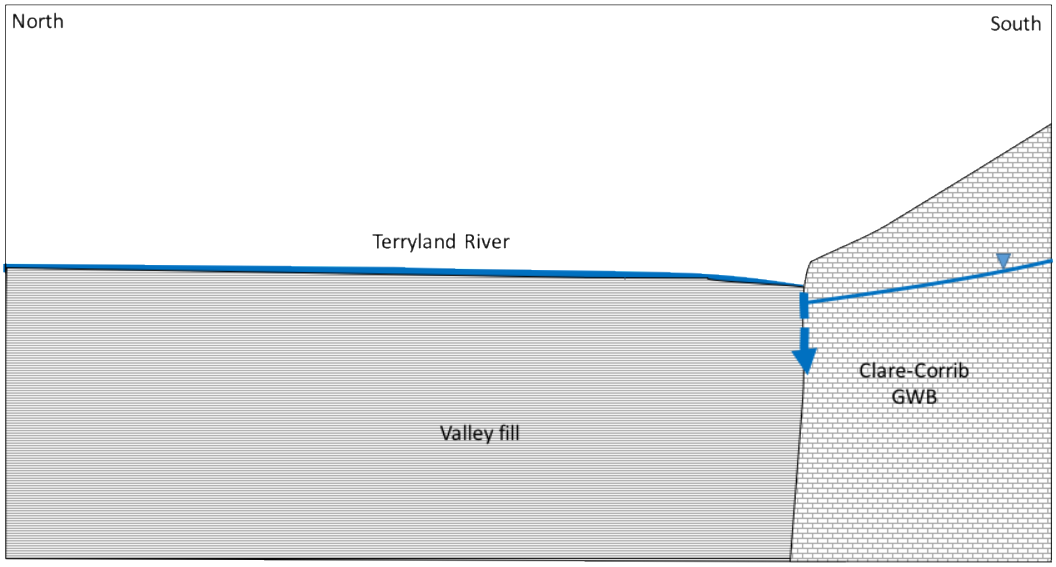

There are a number of Annex 1 habit that occur in the valley of the Terryland River on the thick subsoil deposits. As these features are not located on bedrock but on the thick subsoil, these features are dependent on pluvial flooding and are not groundwater dependent.

Clarinbridge Groundwater Body

The Clarinbridge GWB as delineated by the GSI is a large groundwater body that extends from Galway City eastwards past Galway Airport to Athenry and then south from Athenry to Clarinbridge and as far south as Ardrahan. As the Clarinbridge GWB extends over a number of rivers and streams it can be subdivided into several smaller groundwater bodies that are distinct and isolated from each other. One of these smaller sub-catchments of the Clarinbridge GWB is the area of the higher ground between Galway Airport and Ballybrit.

The divide between the Clarinbridge GWB and the Clare-Corrib GWB is marked by the thick overburden deposits along the line of the N83 Tuam Road. These thick low permeability superficial deposits have been proven to a minimum depth of 30m. Conceptually these thick low permeability deposits form a hydraulic barrier between the Clare-Corrib and Clarinbridge groundwater bodies.

The groundwater level monitoring data collected in the Clarinbridge GWB for the proposed road development has a shallow water table relative to the rest of the study area. The shallow groundwater table is generally within 4m of the surface and follows topography, lowering gradually southwards towards Galway Bay. The seasonal fluctuation in the aquifer is of the order of 2m. The characteristics of the Visean Limestone Undifferentiated in the GWB indicate lower aquifer properties, with fracture flow and only small scale surface karst landforms present.

10.3.4 Groundwater Receptors

There are a number of receptors within the study area which are connected to or dependent upon groundwater to maintain their hydrogeology. The types of receptors that could be affected by the proposed road development are:

- Groundwater resources and abstractions
- Groundwater dependent habitats
- Groundwater dependent surface water features

The individual receptors identified under these headings are described below and an outline of the receiving environment for each is provided. Based on the conceptual model outlined in **Section 10.3.3**, a number of these will not be affected by the proposed road development and a full impact assessment will not be required. These are clearly identified and those which do require an impact assessment are assessed in full in **Section 10.5**.

The importance of these groundwater receptors is ranked according to TII Guidelines on the attribute classification criteria presented in **Table 10.1**. Potential hydrogeological impacts are defined as any negative changes to the baseline groundwater quantity and / or groundwater quality.

10.3.4.1 Groundwater Resources

As outlined in **Section 10.3.1** and presented on **Figure 10.1.001**, the west of the study area, the aquifer is classified as a Pl aquifer and in the east of the study area, the aquifer is classified as a Rkc aquifer. These aquifers have an importance ranking of Low and Extremely High respectively in line with TII importance ranking criteria presented in **Table 10.1**.

10.3.4.2 Groundwater Supplies

Water Supplies refer to any large springs, groundwater abstractions for local authorities, commercial / industrial, holy wells, Group Water Schemes or private well supplies.

Source Protection Plans have been published by the GSI or EPA to define the groundwater catchment for some large public water supplies and state appropriate land use practices within the catchment. The Source Protection Areas include Inner and Outer Protection areas. There are no Source Protection Areas within the study area for the proposed road development.

Figures 10.5.002 shows the locations of all wells recorded by the GSI. However, as it is not a requirement for wells to be registered with the GSI the GSI list of wells is not necessarily complete. Local authority and National Federation of Group Water Schemes (NFGWS) records were also consulted to determine the locations of groundwater abstractions.

During consultations with landowners they were asked if they had a private well supply and this information has been incorporated into this assessment (refer to **Section 10.2.5**). Where no information is available on the construction or abstraction details of these private well supplies, a conservative approach has been undertaken (i.e. the assumption has been made that they are shallow wells so more vulnerable to pollution).

The GSI database identifies one major groundwater abstraction in the Galway Granite Batholith at Knocknacarra (W50-01) which is a group water scheme that supplies approximately 50 houses. The GSI database also lists one private supply well (W50-09) and one spring supply (W1000-01). The site walkover and consultations with landowners has not identified any additional wells in the Galway Granite Batholith.

Based on TII importance ranking criteria, the importance ranking for the major abstraction at Knocknacarra (WS50-01) is ranked as Medium and the well (W50-09) and spring (W1000-01) are ranked as Low. All of the groundwater supplies identified in the Galway Granite Batholith are within 1km beyond the study area extent and are identified as part of the desk study. These groundwater abstractions are included in the assessment as a conservative measure to ensure that the catchments for each well is appropriately assessed.

The Visean Undifferentiated Limestone has four large groundwater abstractions within the study area, these comprising of one commercial groundwater abstraction (W50-12) on the N84 Headford Road and three groundwater abstractions for Galway Racecourse (W50-13, 14 and 15).

W50-12 is an industrial supply well for a commercial water bottling facility and has an abstraction rate of approximately 250m^3/day. TII criteria only applies to domestic wells, however for this assessment commercial supplies are considered equal to domestic supplies with the average metered (residence) water consumption ranging between 274 to 383 litres per day (Central Statistics Office, 2015[3]). On this basis, W50-12 has an equivalent supply of up to 1,000 houses and is ranked as having an importance ranking of 'High'.

Galway Racecourse wells W50-13 and W50-14 provide a cumulative 2,000m^3/day of groundwater that is primarily for use for watering of the track but is also used to supply drinking water for the horses and water to wash down the yard. The cumulative abstraction of W50-13 and W50-14 has a combined equivalent of >2,500 houses and a 'Very High' importance.

Galway Racecourse well W50-15 abstracts 380m^3/day for potable use. Based on TII criteria for domestic wells W50-15 has an equivalent of 1,400 houses and is ranked as having a 'High' importance.

The Visean Undifferentiated Limestone is tapped into for 20 private domestic wells. These comprise of W50-02, 03, 04, 05, 06, 07, 08, 10 and 11, W100-01,02,03, 04, 05 and 06, W500-1 and W1000-02, 03 and 04.

One geothermal well has been identified (G50-01), which located on Ballybrit Crescent. The geothermal well is of a closed loop design developed within the Visean Undifferentiated. Consultation with the landowner identified that the well relies on an open borehole design, which uses the thermal conductance of the groundwater from the bedrock to heat the closed loop piping.

Based on TII importance ranking criteria, domestic abstraction wells have an importance ranking of 'Low'. Domestic closed loop geothermal wells are assessed as being comparable to domestic abstraction wells and also have an importance ranking of 'Low'.

10.3.4.3 Groundwater dependant Habitats

A full review of ecological features and designated ecological sites in the study area are detailed in **Chapter 8, Biodiversity**. The habitats listed in this section are those identified in **Chapter 8, Biodiversity** as being water dependant. Those habitats dependent on hydrogeological characteristics include groundwater dependant terrestrial ecosystems (GWTDE) receptors that are dependent on emergent groundwater but also features such as limestone pavement and associated ecosystems, which are dependent on well drained karst bedrock.

European sites comprise of (candidate) Special Areas of Conservation ((c)SAC) and Special Protection Areas (SPA), whilst National sites comprise of National Heritage Areas (NHA) and potential Heritage Areas (pNHA). As detailed in TII Guidelines, those sites that are designated as European sites status are ranked of

[3] Central Statistics Office. Statistical Release 25 April 2017. Domestic Metered Public Water Consumption.

international importance whilst those designated as National sites are ranked of national importance.

Habitats outside of European and National sites are ranked dependent on hydrogeological characteristics. Annex 1 habitats are attributed as ‘Very High’ owing to their national importance.

European sites

This section identifies those European sites that have the potential to be impacted from a hydrological perspective. All European sites within 30km of the proposed road development have been considered using the precautionary principle. The European sites beyond 15km do not have a groundwater connection from the proposed road development and are not considered further.

The screening of all European sites within 15km of the proposed road development is presented below in **Table 10.11**. Those European sites that are located in separate and distinct groundwater bodies or sub catchments are not considered further as there is no groundwater connection from the proposed road development.

Table 10.11: Screening of European sites by proximity to the proposed road development

Site Name	Proximity to Proposed Road Development	Screening	Result
Black Head-Poulsallagh Complex cSAC	11km	Site lies in separate groundwater body	Not considered further
Moneen Mountain cSAC	13km	Site lies in separate groundwater body	Not considered further
Castletaylor Complex cSAC	14km	Site lies in separate groundwater body	Not considered further
Galway Bay Complex cSAC	0.2km	Site lies adjacent to groundwater body that the proposed road development traverses	Impact assessment required
Lough Corrib cSAC	0km	Site lies adjacent to groundwater body that the proposed road development traverse	Impact assessment required
Rahasane Turlough cSAC	13km	Site lies in separate groundwater body sub catchment	Not considered further
Lough Fingall Complex cSAC	11km	Site lies in separate groundwater body sub catchment	Not considered further
Gortnandarragh Limestone Pavement cSAC	14km	Site lies in separate groundwater body sub catchment	Not considered further

Site Name	Proximity to Proposed Road Development	Screening	Result
Kiltiernan Turlough cSAC	14km	Site lies in separate groundwater body sub catchment	Not considered further
Ross Lake and Woods cSAC	10km	Site lies in separate groundwater body sub catchment	Not considered further
East Burren Complex cSAC	13km	Site lies in separate groundwater body	Not considered further
Connemara Bog Complex cSAC	6km	Site lies in separate groundwater body	Not considered further
Ardrahan Grassland cSAC	15km	Site lies in separate groundwater body sub catchment	Not considered further
Inner Galway Bay SPA	1km	Site lies adjacent to groundwater body that the proposed road development traverses	Impact assessment required
Lough Corrib SPA	0.1km	Site lies adjacent to groundwater body that the proposed road development traverses	Impact assessment required
Rahasane Turlough SPA	13km	Site lies in separate groundwater body sub catchment	Not considered further
Cregganna Marsh SPA	4km	Site lies in separate groundwater body sub catchment	Not considered further
Connemara Bog Complex SPA	9km	Site lies in separate groundwater body	Not considered further

Based on the above regional screening there are four European sites that are either located within or receiving groundwater from catchments that the proposed road development traverses (**Figure 10.5.002**). These are:

- Lough Corrib cSAC
- Lough Corrib SPA
- Galway Bay Complex cSAC
- Inner Galway Bay SPA

Ballindooley Lough is identified in **Chapter 8, Biodiversity** as supporting the wintering birds of the Lough Corrib SPA and Inner Galway Bay SPA. On this basis Ballindooley Lough is included in the assessment under the heading of European sites.

Lough Corrib cSAC, Lough Corrib SPA, Galway Bay Complex cSAC and Inner Galway Bay SPA receive groundwater from the Galway Granite Batholith and the Visean Undifferentiated Limestone that the proposed road development traverse. The supporting site, Ballindooley Lough, only receives groundwater from the Visean Undifferentiated Limestone. A breakdown of the contributions from groundwater bodies traversed by the proposed road development to these European sites (including supporting sites) are summarised below in **Table 10.12**.

Table 10.12: Groundwater bodies traversed by the proposed road development and the European sites they potentially contribute to

Groundwater Body	Lough Corrib cSAC	Lough Corrib SPA	Galway Bay Complex cSAC	Inner Galway Bay SPA	Ballindooley Lough
Spiddal GWB	-	-	Contributes	Contributes	-
Maam Clonbur GWB	Contributes	Contributes	Contributes	Contributes	-
Ross Lake GWB	Contributes	Contributes	Contributes	Contributes	-
Lough Corrib Fen 1 (Menlough) GWB and Lough Corrib Fen 1 (Lackagh) GWB	Contributes	-	Contributes	Contributes	-
GWDTE Lough Corrib Fen 2	Contributes	Contributes	Contributes	Contributes	-
Clare-Corrib	Contributes	Contributes	Contributes	Contributes	Contributes
Clarinbridge	-	-	Contributes	Contributes	-

Based on the hydrogeological characterisation (**Section 10.3.3**) the Visean Undifferentiated Limestone contributes a greater component of groundwater to the River Corrib than the Galway Granite Batholith.

The Visean Undifferentiated Limestone includes a number of karst point discharges to the Lough Corrib cSAC, which include the Western Coolagh Spring and Terryland River (during high groundwater flow). These karst point discharges provide significant contribution to habitat in the Lough Corrib cSAC.

Each of these European sites has a ranking of ‘Extremely High’ importance in line with TII Guidelines. Potential impacts to these European sites from the characteristics of the proposed road development are evaluated in **Section 10.5**.

National Heritage Area (NHA)

This section identifies those National sites (both National Heritage Areas and proposed National Heritage Areas) that have the potential to be impacted from a hydrological perspective. All National sites within 30km of the proposed road development have been considered using the precautionary principle. The National sites beyond 15km do not have a groundwater connection from the proposed road development and are not considered further.

The screening of all National sites within 15km of the proposed road development is presented below in **Table 10.13**. Those National sites that are located in separate and distinct groundwater bodies or sub catchments are not considered further as there is no groundwater connection from the proposed road development.

Table 10.13: Screening of National Heritage Areas (NHA) and proposed National Heritage Areas (pNHA) by proximity to the proposed road development

Site Name	Proximity to the proposed road development	Screening	Result
Ross Lake and Woods pNHA	11km	Site lies in separate groundwater body sub catchment	Not considered further
Moycullen Bogs NHA (Lough Inch / Na Foraí Maola Thair, Tonabrocky and Letteragh)	0km	Lough Inch / Na Foraí Maola Thair lies within 250m Tonabrocky lies at 250m Letteragh lies adjacent	Impact assessment required for all three locations
Furbogh Woods pNHA	2km	Site lies beyond 250m but within groundwater body traversed by proposed road development	Impact assessment required
Gortnandarragh Limestone Pavement pNHA	14km	Site lies in separate groundwater body	Not considered further
Drimcong Wood pNHA	8km	Site lie in separate groundwater body	Not considered further
Killarainy Lodge, Moycullen pNHA	8km	Site lies in separate groundwater body	Not considered further
Ballycuirke Lough pNHA	5km	Site lies in separate groundwater body	Not considered further
Lough Corrib pNHA	0km	Site lies adjacent at the Corrib crossing	Impact assessment required
Kiltullagh Turlough pNHA	2km	Site lies within same groundwater body sub catchment	Impact assessment required
Cregganna Marsh NHA	4km	Site lies in separate groundwater body sub catchment	Not considered further

Site Name	Proximity to the proposed road development	Screening	Result
Galway Bay Complex NHA	0.2km	Site lies adjacent to groundwater body traversed by proposed road development	Impact assessment required
East Burren Complex pNHA	14km	Site lies in separate groundwater body	Not considered further
Rahasane Turlough pNHA	14km	Site lies in separate groundwater body sub catchment	Not considered further
Lough Fingal Complex pNHA	11km	Site lies in separate groundwater body	Not considered further
Castletaylor Complex pNHA	14km	Site lies in separate groundwater body sub catchment	Not considered further
Kiltiernan Turlough pNHA	14km	Site lies in separate groundwater body sub catchment	Not considered further
Ballyvaughn Turlough pNHA	15km	Site lies in separate groundwater body	Not considered further
Blackhead Poulsallagh Complex pNHA	11km	Site lies in separate groundwater body	Not considered further

Based on the above regional screening there is one NHA site and four pNHA sites that have the potential to be impacted by the proposed road development. These are:

- Moycullen Bogs NHA
- Furbogh Woods pNHA
- Kiltullagh Turlough pNHA
- Galway Bay Complex pNHA
- Lough Corrib pNHA

The Moycullen Bogs NHA, which are located on the Galway Granite Batholith, occur as one main site encompassing west of Lough Inch and two isolated sites one at Letteragh and one at Tonabrocky. The southern corner of the main site lies within 250m of the proposed road development, whilst the site at Letteragh lies adjacent to the proposed road development. The site at Tonabrocky lies 250m away from the footprint of proposed road development.

The Moycullen Bogs include areas of surface water ponding, which is present at all sites. Based on the conceptual site model for the Galway Granite Batholith (**Section 10.3.3**) the surface water ponding is caused by the low aquifer properties of the underlying granite, which causes water infiltrating through the subsoil to perch above the undulating rock head.

These surface ponds are not dependant on groundwater per se but they are dependent on the site specific hydrogeology, specifically the low aquifer properties, the undulating nature of the rock head and also rainfall. The Moycullen Bogs are ranked as having a 'Very High' importance based on the TII guidance and are assessed in the evaluation of impacts (**Section 10.5**).

Furbogh Woods pNHA area located at the coast within the Spiddal GWB approximately 2km west of the proposed road development. Groundwater flow within the Spiddal GWB follows surface water patterns and may be divided into sub catchments on the basis of surface water streams. On this basis the Furbogh Woods pNHA lies in a separate sub catchment to the proposed road development, and is not considered further in this assessment.

Kiltullagh Turlough pNHA lies near Galway Airport, 2.5km east of the proposed road development. The turlough lies within the Clarinbridge GWB at an elevation of approximately 10m OD. Based on the groundwater levels recorded for the environmental studies for the proposed road development (refer to **Section 10.3.2**) the groundwater flow direction is southwards towards Galway Bay. On this basis, although Kiltullagh Turlough NHA is topographically low, it is located 2.5km upgradient of the proposed road development and is not considered further.

Lough Corrib NHA and Galway Bay Complex NHA receive groundwater from the Galway Granite Batholith and the Visean Undifferentiated Limestone that the proposed road development traverse. Both the Lough Corrib NHA and Galway Bay Complex NHA has a ranking of 'Very High' importance in line with TII Guidelines.

In summary, the following National sites are considered receptors for the proposed road development:

- Moycullen Bogs NHA (Lough Inch/Na Foraí Maola Thair, Tonabrocky and Letteragh)
- Galway Bay Complex pNHA
- Lough Corrib pNHA

A breakdown of the groundwater bodies that contribute to those NHA identified above to be included in the evaluation of impacts are summarised below in **Table 10.14**.

Table 10.14: Summary of groundwater bodies traversed by the proposed road development that contribute to National Heritage Areas (NHA) and proposed National Heritage Areas (pNHA)

Groundwater Body	Lough Corrib pNHA	Galway Bay Complex pNHA	Moycullen Bogs NHA	Moycullen Bogs at Tonabrocky NHA	Moycullen Bogs at Letteragh NHA
Spiddal GWB	-	Contributes	Contributes	Contributes	Contributes
Maam Clonbur GWB	Contributes	Contributes			Contributes
Ross Lake GWB	Contributes	Contributes	-	-	-
Lough Corrib Fen 1 (Menlough) GWB and Lough Corrib Fen 1 (Lackagh) GWB	Contributes	Contributes	-	-	-
GWDTE Lough Corrib Fen 2 GWB	Contributes	Contributes	-	-	-
GWDTE Lough Corrib Fen 3 & 4 GWB	Contributes	Contributes			
Clare-Corrib GWB	Contributes	Contributes	-	-	-
Clarinbridge GWB	-	Contributes	-	-	-

Annex I habitats

In addition to the European sites, **Chapter 8, Biodiversity** details Annex I water dependant habitat that are outside of the European site boundaries. These habitat names are listed in **Table 10.15** below (refer to **Chapter 8, Biodiversity** for further details on the habitat). The locations of Annex I habitat are presented on **Figure 10.5.002**.

Table 10.15: Annex I water dependant habitat

Annex I habitat code	Habitat name
4010	Wet heath
6410	Molinia meadows
6430	Hydrophilous tall herb
*7130/7130	Blanket bog (active*)
7140	Transition mires
7150	Rhynchosporion depressions
*7210	Cladium fen*
*7220	Petrifying Springs*
7230	Alkaline fens
*8240	Limestone pavement*
*91E0	Residual alluvial forests*
*3180	Turloughs*

Notes: Denotes a priority habitat*

On the Galway Granite Batholith, the Annex I habitats outside of European and National sites include wet heath, blanket bog and Molinia Meadows. On the Visean Undifferentiated Limestone the Annex I habitats outside of European and National sites include Turloughs, Limestone pavement, Petrifying springs. Annex I habitats are ranked as having a 'Very High' importance, and unless shown to be beyond the potential zone of contribution, are considered in the evaluation of impacts assessment.

Like the Moycullen Bogs, as described in the section on NHA, the surface water ponding within wetland sites on the Galway Granite Batholith are not derived from groundwater, rather that they are caused by ponding above rock head where the rainfall and runoff is perched and trapped by basins in the bedrock topography. These include the following wetlands:

- Wetland habitats in townlands of Na Foraí Maola Thiar (Ch. 0+650 to Ch. 0+750), Na Foraí Maola Thoir (Ch. 1+250 to Ch. 1+500), Troscaigh Thiar (Ch. 1+850 to Ch. 2+400), Bearna (Ch. 2+600 to Ch. 3+100), Aille (Ch. 3+300 to Ch. 3+900) and Ballyburke (Ch. 4+800 to Ch. 5+900)
- Wetland habitats at National University Galway (Ch. 8+800 to Ch. 8+950 and Ch. 9+150 to Ch. 9+250)

Karst features are considered in this section of the assessment based on the water dependent ecology that they support. Three Turloughs (referenced as K20, K31 K72 in the karst database) were identified during the field surveys and their locations are presented in **Figure 10.5.002**. The Turloughs are all located in different groundwater bodies as follows:

- K31 is located in the Lough Corrib Fen 1 (Menlough) GWB

- K20 is located in the Lough Corrib Fen 2 GWB
- K72 is located in the Clare-Corrib GWB

Turlough K31 is crossed to the proposed road development and in this regard is included as a receptor in the evaluation of impacts.

Turlough K20 is located 425m north of the proposed road development in an adjacent GWB. Although in a separate GWB, the feature lies within 250m of the groundwater divide between Lough Corrib Fen 1 (Menlough) and Lough Corrib Fen 2, and as such is included as a receptor in the evaluation of impacts.

Turlough K72 is located in the same groundwater body as the proposed road development albeit 500m up-gradient of it. Turlough K72 is included as a receptor in the evaluation of impacts.

Limestone pavement is also considered in this section as it is present in the region between Lackagh Quarry and Menlough (**Chapter 8, Biodiversity**). Whilst Limestone pavement habitat is not dependent on groundwater it does require the development of a free draining upper zone in the limestone (referred to as epikarst) that rapidly drains rainfall into the aquifer so as not to cause ponding.

Limestone pavement is considered as a hydrogeological receptor as it is susceptible to groundwater level rise and could be impacted if groundwater were to flood the habitat. Limestone pavement is also described as a receptor in both **Chapter 8, Biodiversity** and **Chapter 9, Soils and Geology**. Limestone pavement ecosystems are included as potential hydrogeological receptors.

Lackagh Quarry includes 27 (No.) seepages points, which are mainly located on the northern quarry faces. **Chapter 8, Biodiversity**, classifies six of these seepages as petrifying springs, which have tufa (calcium carbonate) deposition. Hydrogeological observation of all the seepages concludes that all are seasonal and are generally only active between September and May, but they can also activate following prolonged or heavy summer rainfall. All the seepages including the six identified as petrifying springs occur higher than the regional water table. All the seepages occur where karst flow paths through the unsaturated limestone bedrock have been intercepted by the quarry void.

As the petrifying springs are Annex 1 habitats dependant on recharge along karst pathways they ranked as ‘Very High’ in terms hydrogeology.

Non Annex I habitat

A number of locally important ecological habitat, which are dependent on water or hydrogeological characteristics, have been identified and these are included in the **Chapter 8, Biodiversity**. These include a wetland site on the Galway Granite Batholith and calcareous springs in Lackagh Quarry. These features are described in **Chapter 8, Biodiversity**.

The wetland site at Ch. 7+850 is similar in hydrogeological character to the Moycullen Bogs discussed earlier in this section on NHA. The site is located in a topographic hollow in the Galway Granite Batholith where surface water ponds. Often the Galway Granite Batholith forms basins in the rock topography and surface water ponds in these hollows and is slow to drain away. The wetland at Ch.

7+850 is where a fen is located in a hollow on the highest point in the granite topography.

Of the 27 (No.) seepages identifies in Lackagh Quarry a total of 21 (No.) are classified in **Chapter 8, Biodiversity** as being calcareous springs, which is a non-annex 1 habitat. These seepages are seasonal and typically flow between September and may or following prolonged or heavy summer rainfall.

10.3.4.4 Groundwater Dependent Surface Water Features

As presented in the conceptual site model, the study area includes surface water features that are dependent on groundwater. These include the River Corrib, Ballindooley Lough, Coolagh Lakes, Turlough K20, Turlough K31, Turlough K72 and Terryland River. It is noted that whilst the Eastern Coolagh Spring has the potential for groundwater contribution, Coolagh Lakes is not dependent on this spring. Coolagh Lakes is however dependent on the Western Coolagh Spring.

Of these the River Corrib, Ballindooley Lough, Coolagh Lakes, Turlough K20, Turlough K31 and Turlough K72 are part of a European sites or Annex I habitat outside of European sites and have been described in previous sections.

Groundwater can contribute to the Terryland River and also the River Corrib via the Terryland River but only during times of a high water table. In this regard groundwater can provide a significant baseflow to the Terryland River but, unusually, only during winter. On the basis that groundwater contributes to the River Corrib which is part of the Lough Corrib cSAC is considered to have an ‘extremely high’ importance rating but only when flow in the Terryland River has reversed its normal flow.

10.3.4.5 Summary

This section has identified all hydrogeological receptors within the study area that have the potential of being impacted by the proposed road development. Hydrogeological receptors are divided in three sub categories, ecosystems, surface water and resources. Those sites and features from each of these three subcategories within the study area are summarised below in **Table 10.16**.

Table 10.16: Ranking of Importance of all hydrogeological features within the project study area

Feature	Location relative to proposed road development	Importance Ranking	Justification
Groundwater Resources			
Poor Bedrock Aquifer (Pl)	Section 1 of proposed road development	Low	Poor Bedrock Aquifer
Regionally Important Aquifer (Rkc)	Sections 2, 3 and 4 of the proposed road development	Very High	Regionally Important Aquifer (Rkc)
Groundwater supplies (Wells and springs)			

Feature	Location relative to proposed road development	Importance Ranking	Justification
Knocknacarra GWS (W50-01)	1km	Medium	Group water scheme supplying up to 50 houses
W50-02	2km	Low	Agricultural / Domestic supply
W50-03 04, 05, 06 and 07	2km	Low	Agricultural / Domestic supply
W50-08	1.4km	Low	Agricultural / Domestic supply
W50-09	0.5km	Low	Agricultural / Domestic supply
W50-10	0km	Low	Agricultural / Domestic supply
W50-11	0.5km	Low	Agricultural / Domestic supply
W50-12	0km	High	Commercial supply 250m^3/d
W50-13 and W50-14	0km	Very High	Commercial supply 2,000m^3/d
W50-15	0km	High	Commercial supply 380m^3/d
W100-01 & 02	0.6km	Low	Agricultural / Domestic supply
W100-03, 04, 05 and 06	0.3km	Low	Agricultural / Domestic supply
W500-01	0.8km	Low	Agricultural / Domestic supply
W1000-01	0.5km	Low	Agricultural / Domestic supply
W1000-02	0.2km	Low	Agricultural / Domestic supply
W1000-03	1.1km	Low	Agricultural / Domestic supply
W1000-04	0.5km	Low	Agricultural / Domestic supply
G50-01	0.1km	Low	Geothermal well
Surface Water Features			
Terryland River	0.6km	Extremely High	Contributes to River Corrib during peak groundwater levels
Ecosystems			
Galway Bay Complex cSAC	0.8km	Extremely High	European site

Feature	Location relative to proposed road development	Importance Ranking	Justification
Inner Galway Bay SPA	1km	Extremely High	European site
Lough Corrib SPA	0km	Extremely High	European site
Lough Corrib cSAC	0km	Extremely High	European site
Ballindooley Lough	0.1km	Extremely High	Supporting feature for Lough Corrib SPA
Moycullen Bogs	0.2km	Very High	National site
Moycullen Bogs (Tonabrocky)	0.3km	Very High	National site
Moycullen Bogs (Letteragh)	0km	Very High	National site
Lough Corrib NHA	0km	Very High	National site
Galway Bay NHA	0.2km	Very High	National site
Turlough K20	0.4km	Very High	Annex 1 habitat
Turlough K31	0km	Very High	Annex 1 habitat
Turlough K72	0.5km	Very High	Annex 1 habitat
Petrifying springs (Lackagh Quarry)	0km	Very High	Annex 1 habitat
Calcareous springs (Lackagh Quarry)	0km	Low	Locally important habitat
Fen Ch. 7+850	0km	Low	Locally important habitat

10.4 Characteristics of the Proposed Road Development

A detailed description of the proposed road development and construction work is provided in **Chapter 5, Description of Proposed Road Development** and **Chapter 7, Construction Activities**. This section outlines the characteristics and activities of the proposed road development which will interact with hydrogeology and hydrogeological receptors.

The elements of the proposed road development that will interact with the hydrogeological environment are those activities that have the capacity to change the groundwater regime in terms of recharge groundwater levels and water quality. These activities could be:

- **Construction:** dewatering of the bedrock aquifer for cuts or structures, accidental spillages of potentially polluting materials etc.
- **Operation:** discharge of road drainage; road cuts intercepting groundwater or structures (tunnels, sealed cuttings) acting as a barrier to flow

The profile of the proposed road development presented in **Figure 10.6.101** to **Figure 10.6.112** shows the locations where the proposed road development is in cutting, fill and at grade as well as showing the location of minimum and maximum groundwater levels for comparison.

Lowering of groundwater levels is referred to as water table ‘draw down’. **Table 10.17** summarises the excavations along each section of the proposed road development and identifies those sections of the proposed road development that will incur drawdown. Based on properties for the aquifers (**Table 10.10**) the maximum drawdown from the cutting is calculated, which is included in **Table 10.17** as a measurement from the footprint of the proposed road development.

With respect to the aquifer types discussed in **Section 10.3.3** the location and extent of excavations can be summarised as:

- Galway Granite Batholith: there are seven road cuttings (**Table 10.17**) namely, EW01, EW02 (three cuttings), EW04, EW07 and EW11. There are bridge structures at Troscaigh (S01/01), Aille (S03/01), Rahoon (S06/01), Letteragh (S07/01), N59 Link Road North and South (S07/02) and the N59 Moycullen Road (S08/02).
- Visean Undifferentiated Limestone: includes EW22, EW25, EW27, EW28 and EW34-35 (combined) (five cuttings) (**Table 10.17**). There are two tunnels, Lackagh Tunnel (S11/01) and Galway Racecourse Tunnel (S14/02) both of which have approaches. Bridge structures comprise of one crossing of the River Corrib (S08/04), one viaduct at Menlough (S10/01) to cross limestone pavement and road bridges for Menlo Castle Boithrin (S09/01), Coolagh Road (S10/02), the N84 Headford Road (S12/01), Wildlife Overpass Castlegar (S12/02), School Road (S13/01), N83 Tuam Road (S13/02), Park Road Link (S14/01), Monivea Road (S15/01) and Coolagh Junction (S16/01 and S16/02).

The maximum depth of the proposed finished road level below ground level for each cut section is presented in **Table 10.17**. The excavation depths for foundations and drainage have a maximum cut depth elevation of 3m below the finished road elevation, which is applied to the full length of the proposed road development. This is an over estimation on the maximum potential cut depth for drainage and foundations.

As outlined **Section 10.4**, the construction schedules for Lackagh Tunnel and the Menlough Viaduct shall accommodate the seasonal groundwater fluctuation so that construction works always occurs above the water table and dewatering in the bedrock aquifer is not required. For this reason, there will be no lowering in groundwater levels at these locations and accordingly the drawdown is represented as ‘0m’ in **Table 10.17**.

Table 10.17: Summary of earthwork (EW) locations for the proposed road development

Feature type	Earth works Ref no.	Approx. Chainage	Length (m)	Max depth of finished road level (m BGL)	Max depth of construction excavation (m BGL)	Depth to peak winter groundwater level (m BGL)	Max groundwater drawdown (m)	Max Zone of influence radius (m) from footprint of the proposed road development

Western Approach to Galway Racecourse Tunnel	EW30	14+450 – 14+950	500	11.4	14.4	18.5[*5]	2	14
Galway Racecourse Tunnel (S14/02)	EW31	14+950 – 15+190	240	9.2	12.2	8.9	4	35
Eastern Approach to Galway Racecourse Tunnel	EW32	15+190 – 15+500	310	8.7	11.7	7.8	4	35

Feature type	Earth works Ref no.	Approx. Chainage	Length (m)	Max depth of finished road level (m BGL)	Max depth of construction excavation (m BGL)	Depth to peak winter groundwater level (m BGL)	Max groundwater drawdown (m)	Max Zone of influence radius (m) from footprint of the proposed road development
Road Cutting	EW34-35	16+200 – 17+500	740	6.8	9.8	11.9*6	2	12

Notes:

Structure depths are presented to 10cm. Predicted drawdown and radius are rounded up to nearest 1m.
The maximum depth of proposed road level refers to the finished road level.
Max drawdown depth = Max baseline groundwater level - (max finished road level - 3m over excavation for drains)
*Maximum groundwater level uses maximum groundwater levels measured during the project monitoring period 2015 - 2017 (**Section 10.3.2**) for the chainage with the maximum excavation depth*
Winter water table at eastern end of cutting (Ch. 14+950) has seasonal peak 1.6m higher than max excavation depth
Winter water table at western end of cutting (Ch. 16+200) has seasonal peak 1.3m higher than max excavation depth

The drainage design of the proposed road development is presented in **Chapter 5, Description of the Proposed Road Development**, and is summarised below for the four hydrogeological sections:

- Section 1 – R336 to N59 Moycullen Road: Ch. 0+000 to Ch. 8+850
  - Permeable drains where possible on mainline, side roads and service roads
  - Treated road runoff discharged to surface watercourse (refer to **Chapter 11, Hydrology**) or public sewers
  - Permeable sub-surface groundwater interception drains in road cuttings
- Section 2 - N59 Moycullen Road to River Corrib Ch. 8+850 to Ch. 9+400
  - Sealed drains on mainline, side roads and service roads
  - Discharge of road runoff to River Corrib (refer to **Chapter 11, Hydrology**)
- Section 3 - River Corrib to N83 Tuam Road Ch. 9+400 to Ch. 14+000
  - Sealed drains on mainline, side roads and service roads
  - Discharge of treated road runoff to ground via infiltration basins in the absence of surface water (refer to **Chapter 11, Hydrology**) or public sewers
  - Permeable sub-surface groundwater drains in all cuttings
- Section 4 – N83 Tuam Road to existing N6
  - Sealed drains on mainline, side roads and service roads
  - Discharge of treated road runoff to ground via infiltration basins in the absence of surface water features or public sewers
  - Permeable sub-surface drains in all cuttings

The assessment of the potential impacts that these design elements may have on the hydrogeological environment is presented in **Section 10.5**.

10.5 Evaluation of Impacts

10.5.1 Introduction

The potential impacts on hydrogeology receptors from the proposed road development are presented in this section. An assessment of potential impacts for the construction phase is presented in **Section 10.5.3** and during the operation phase in **Section 10.5.4**.

Hydrogeological receptors within the study area are listed and ranked for importance in **Section 10.3.3** for each of the four hydrogeological sections. A summary of these rankings is presented in **Table 10.16**.

This section ranks the Magnitude and Significance of any potential hydrogeological impacts in line with TII Guidelines. Where hydrogeological impacts are predicted then these are also assessed for interaction with other aspects of the environment, most notably Biodiversity, Soils and Geology, Hydrology and Material Assets.

10.5.2 Do-Nothing Scenario

In the absence of the proposed road development then the baseline hydrogeological environment will remain as presented in **Section 10.3**.

10.5.3 Construction Phase

Construction activities can interact with hydrogeological receptors by changing the groundwater regime that a receptor is dependent upon. The potential impacts outlined in this section are pre-mitigation. Mitigation measures are described in **Section 10.6** and residual impacts post mitigation are outlined in **Section 10.7**.

There are a number of ways the hydrogeological environment may potentially be impacted during the construction phase and these include:

- the removal of the aquifer during excavations
- changes in recharge characteristics
- changes in groundwater levels
- changes in water quality

These potential changes to the groundwater regime are considered here and the interaction of these changes on receptors are considered below for groundwater resources (**Section 10.5.1**), groundwater supplies (**Section 10.5.2**), groundwater dependant habitats (**Section 10.5.3**) and groundwater contributions to surface water (**Section 10.5.4**).

Removal of part of the aquifer occurs in cut sections where saturated rock is removed. Those cuttings that intercept groundwater will lead to a reduction in groundwater level, the aquifer saturated thickness and the aquifer unsaturated thickness for the cutting footprint. If groundwater is not intercepted, then there will only be a reduction in the unsaturated thickness.

The concept of recharge is explained in **Section 10.3**. During construction where vegetation is removed then there will be an increase in the quantity of effective rainfall available to recharge to ground or runoff as surface water. Where vegetation is removed then there typically is an increase in the quantity of runoff. Any potential impacts of this on the identified receptors are discussed further below where relevant.

Groundwater levels will be lowered by dewatering of the bedrock aquifer during the construction phase of the proposed development for those elements of the road being constructed below the water table. These include road cuttings and construction phase excavations for drainage (attenuation ponds, infiltration ponds, stream realignment) as well as excavations for structures including bridges, viaducts, tunnels and underpasses. This section of the report outlines how the groundwater levels will change during the construction phase. The potential impacts on specific receptors are discussed below, which also includes potential impact on groundwater levels from the interception of karst pathways during construction.

The drawdown extents are presented in **Figure 10.7.101** to **Figure 10.7.114** for the construction phase for the full dataset (road cuttings and drainage excavations combined). A summary extract of the drawdown extents at individual road cuttings (road cuttings and drainage excavations combined) are presented below in **Table 10.17**. The Zone of Influence (ZoI) of the cutting / dewatering location is the area within which groundwater levels are affected by dewatering of the bedrock aquifer – outside of this area groundwater levels will remain at their natural level. The ZoI is presented as a radius on either side of the proposed road development, which is calculated using the upper range of aquifer properties and the hydraulic gradient of the water table. The detailed calculations are presented in **Appendix A.10.6** and summarised in **Table 10.17**. The assessment of drawdown is conservative as it assumes that drainage excavation extends across the full width of the footprint of the proposed road development, when in reality the excavations only extend part of the way.

In summary, **Table 10.17** identifies that groundwater levels will be lowered during the construction phases at the following sections:

- Section 1 (Galway Granite Batholith): EW01, 02 (three cuttings), 04, 07 and 09. EW11 includes the N59 Link Road North and South
- Sections 2 - 4 (Visean Undifferentiated limestone): EW27 and Galway Racecourse Tunnel and its approaches. The dewatering of the bedrock aquifer in EW27 will only be required seasonally

The quality of groundwater is potentially at risk during construction and activities on site are managed in accordance with guidelines to ensure that this potential risk managed appropriately. Risk to groundwater quality derives from the following main sources:

- storm runoff, which can have high turbidity
- occurrence of karst, which can lead to point recharge input to the aquifer
- Accidental spillages of polluting materials on site
- Vandalism

The above risks are assessed for receptors in the below **Section 10.5.3.1** to **Section 10.5.3.4**. Management of the above risks are dealt with by mitigation measures, which are detailed in **Section 10.6**.

10.5.3.1 Potential Impact to Groundwater Resources

The potential impact assessment on the groundwater resources during the construction phase considers the impact that the changes in the groundwater regime and groundwater quality have on the characteristics of the two aquifers. The potential impacts on each of these aquifers is assessed below.

10.5.3.1.1 Galway Granite Batholith (Section 1)

In line with TII guidance, the magnitude of the impact on the aquifers within the study is based on the portion of the aquifer that will be removed. The Pl Galway

Granite Batholith is 2,378km^2 (2,378,000,000m^2) in size (GSI Groundwater data viewer) and 1,000m thick (Pracht, 2015), giving an aquifer volume of 2,824,800,000,000m^3.

As outlined in **Chapter 9, Soils and Geology**, 905,345m^3 of granite will be excavated for the construction of the proposed road development. This volume is a very small percentage of the aquifer volume and for this reason, in line with TII rating, the Magnitude of the impact on the aquifer is Negligible and the Significance of the impact is Imperceptible.

Section 10.5.3 highlights that changing the recharge characteristics has the potential to impact the aquifer. GSI data indicates that the recharge rate to the Galway Granite Batholith is 100mm/yr (**Table 10.5**) and this will not change during construction. In line with TII rating, the Magnitude of the impact on the aquifer from changing recharge is Negligible and the Significance of the impact is Imperceptible.

Changing groundwater levels during construction activities may affect the aquifer characteristics. Eight locations have been highlighted in **Section 10.5.3** where groundwater levels will be lowered locally during construction.

Table 10.17 presents the Zone of Influence (ZoI) for each of these, which is the area away from the proposed road development within with groundwater levels will be lowered during construction. The largest drawdown ZoI occurs at the N59 Letteragh Junction (EW11). Based upon the assessment undertaken (**Appendix A.10.6**) the drawdown at this junction will extend for up to 54m from the edge of the footprint of the proposed road development.

Owing to the low aquifer properties of the Galway Granite Batholith the expected inflows from the construction are expected to be low. During construction the quantities of water intersected will initially be higher as the groundwater storage in the bedrock is tapped into, when the storage has been drained then the quantities that are intercepted will relate to recharge within the ZoI. Groundwater intercepted during construction will remain within the surface water catchment that they would naturally have been received by.

This, along with the minimal influence of the construction activities on the proposed road level indicates that, in line with TII rating, the Magnitude of the impact on the aquifer from changing groundwater levels is Negligible and the Significance of the impact is Imperceptible.

As outlined in **Section 10.5.3** suspended solids in site runoff is the prime concern with pollution from accidental spillages or vandalism also being a risk. Based on the recharge cap of 100mm more than 90% of the effective rainfall during construction will remain overland flow and will not recharge to ground. Spillages, accidental or by vandalism, the low infiltration rate will promote runoff rather than infiltration.

Pollutants that do infiltrate to ground will have limited mobility and will be limited to the construction footprint. On this basis the risk to the groundwater in the Galway Granite Batholith is limited to the construction footprint and not beyond it. In the unlikely event of significant flow paths (fault or fracture zones) being encountered during construction, then these shall be mitigated against using the same methodology as the Karst Protocol (refer to **Section 10.6**). The ZoI for construction phase pollution risk is presented for the Galway Granite Batholith in **Figure 10.7.101** to **Figure 10.7.105**.

The balance of rock excavated in cuttings and used for embankments and fill calculates a surplus of granite but a deficit of limestone. Due to the chemically inert nature of granite, if it is transported and used on embankments in limestone areas then there is no water quality concerns in terms of hydrogeology.

If any of these unplanned activities which have the potential to impact water quality occur, these have the potential to contaminate groundwater. In line with TII guidance, the magnitude of this potential impact on the aquifer is Moderate Adverse and the significance Significant / Moderate.

10.5.3.1.2 Visean Undifferentiated Limestone (Sections 2, 3 & 4)

In line with TII guidance, the magnitude of the impact on the aquifers within the study is based on the portion of the aquifer that will be removed. The Rkc Visean Undifferentiated Limestone aquifer is 7,062km^2 (7,062,000,000m^2) in size (GSI Groundwater data viewer) and 400m thick (Pracht, 2015), giving an aquifer volume of 2,824,800,000,000m^3.

As outlined in **Chapter 9, Soils and Geology**, 2,096,175m^3 of limestone will be excavated for the construction of the proposed road development. This volume is a very small percentage of the aquifer volume and for this reason, in line with TII rating, the Magnitude of the impact on the aquifer is Negligible and the Significance of the impact is Imperceptible.

Section 10.5.3 highlights that changing the recharge characteristics has the potential to impact the aquifer. The effect of an increased recharge in areas where vegetation has been removed may cause a groundwater rise below the footprint of the proposed road development due to an increase in recharge. Based on the baseline recharge quantities listed in **Table 10.5**, and the increase in recharge/runoff being equal then recharge is estimated to rise to 705- 803mm/yr and runoff to 447-545 mm/yr. Using these estimations there will be a temporary increase in winter groundwater levels of up to 0.1m during the construction period (**Appendix A.10.6**).

Where infiltration basins are used to discharge runoff during the construction period then there will be modest temporary rises in groundwater level at these locations, of up to approximately 0.4m. Calculations for the estimated groundwater level rise are presented in **Appendix A.10.6**).

In conclusion, the removal of vegetation will increase effective rainfall and lead to increases in recharge and runoff in the Visean Undifferentiated Limestone. It is estimated that there will be a temporary rise of up to 0.1m in peak groundwater levels below the construction site.

If karst is intercepted in any of these earthworks or infiltration basin excavations, then there is a risk of point recharge from construction site runoff directly to the aquifer. If karst is encountered during construction then the Karst Protocol will be implemented, which is a project specific procedure that is detailed in the Construction Environmental Management Plan (CEMP) (refer to **Appendix A.7.5**) and also presented in **Section 10.6 Mitigation Measures**.

For those sections of the aquifer which will not be subject to the influence of dewatering, in line with TII rating, the Magnitude of the impact on the aquifer from changing recharge rates is Negligible and the Significance of the impact is Imperceptible as the increases will not lead to groundwater flooding.

Changing groundwater levels during construction activities may affect the aquifer characteristics. Three locations have been highlighted in **Section 10.5.3** where groundwater levels will be lowered locally during construction.

Table 10.17 presents the ZoI for each of these, and this is the area away from the proposed road development within with groundwater levels will be lowered during construction. However, it should be noted that due to the design of the proposed road development, where dewatering of the bedrock aquifer will not be undertaken in the most sensitive areas, the drawdown and zones of influence associated with the construction impacts are relatively small.

For example, the largest ZoI in the Visean Undifferentiated Limestone will be observed in EW27 which lies west of the N83 Tuam Road. The groundwater levels recorded in this part of the Clare-Corrib GWB show a seasonal variation of 9m (ref BH3/34) and based on the design elevations for the cutting (refer to **Figure 10.6.108**) then groundwater has the potential to enter the cutting only during peak winter water levels. The impact from the dewatering of the bedrock aquifer is localised around the cutting and calculated to have a maximum lateral extent of 70m (**Table 10.17**), which is calculated using the upper range of permeabilities measured from testing. In line with TII rating, the Magnitude of the impact on the aquifer from changing groundwater levels is Negligible and the Significance of the impact is Imperceptible.

For a number of the structure excavations concrete is required as part of the foundation construction, which may need to be poured into excavations. There is a risk that poured concrete may enter the aquifer if karst is present in the foundation excavations. If karst is present then the concrete could migrate into the aquifer and potentially block pathways, modifying flow paths to receptors. Of the GWB with karst there are three structures that have a risk to groundwater quality, namely the Corrib Bridge, Menlough Viaduct and Lackagh Tunnel. This risk requires mitigation which is presented in **Section 10.6**. In line with TII rating, the Magnitude of the impact on the aquifer from blocking conduits is High and the Significance of the impact is moderate adverse.

The overburden across the study area consists of glacial till derived from the underlying bedrock. The bedrock changes in Section 2 at the N59 Moycullen Road, from a granite to a limestone bedrock which have different chemical compositions.

If limestone derived material is placed over granite bedrock, surface water run-off or groundwater movements through the material have the potential to impact local areas of peatland habitats by changing the pH of the local groundwater. In line with TII rating, the Magnitude of the impact on the aquifer from placing non-native rock is small and the impact imperceptible. Due to the chemically inert nature of granite, if it is transported and used on embankments on limestone then there are no water quality concerns in terms of hydrogeology.

As outlined in **Section 10.5.3** unplanned discharges such as site runoff with a high proportion of fines / sediment or accidental spillages of fuel, lubricants have the potential to cause groundwater quality to deteriorate.

Unlike the low aquifer properties encountered in the granite, the limestone has a wide range of aquifer properties with zones where conduit flow can occur. Similarly, the Visean Undifferentiated Limestone has a high recharge coefficient when karst is present and in these areas runoff generally recharges to ground rather than becoming overland flow.

These features mean that if potential pollutants enter karst pathways then they can travel significant distances relatively quickly. The groundwater bodies (GWB) that have karst are Ross Lake GWB, Lough Corrib Fen 1 (Menlough) GWB, Lough Corrib Fen 1 (Lackagh) GWB, Lough Corrib Fen 2 GWB and Clare-Corrib GWB.

In the Clarinbridge GWB there are no recorded significant karst features and surface water ponding as well as overland flow occurs during storm events, which is due to the lower recharge rates that are present in this area. Infiltration to ground will diffuse and provide slow pathways to the groundwater table that will naturally promote settlement of fines. In the groundwater there will be significant dilution and some attenuation of any fines.

Earthworks along the proposed road development include areas where the subsoil is removed leaving a reduced thickness of subsoil or exposing the underlying limestone. The removal of subsoil will reduce the natural protection for groundwater and increases the groundwater vulnerability (**Table 10.4**). During construction the excavation of subsoil will increase the risk to groundwater from accidental pollution. The area’s most susceptible to pollution are those where the subsoil is already thin, which are the high and extreme areas presented in **Figure 10.7.106** to **Figure 10.7.114**.

Conversely, in the natural environment, recharge to limestone where there is no karst relies in part on storage in the overlying subsoil which provides superficial storage to the fracture flow network in the underlying limestone. In the situation where the subsoil is removed there is an increase in overland flow with recharge significantly reduced. As such, where the limestone bedrock is exposed there will be an increase in runoff except for in zones of weathered limestone or karst (in those GWB with karst). The potential impacts associated with this are discussed in **Chapter 11, Hydrology**.

For the Ross Lake GWB, Lough Corrib Fen 1 (Menlough) GWB, Lough Corrib Fen 1 (Lackagh) GWB, Lough Corrib Fen 2 GWB and the Clare-Corrib GWB where there is a potential for karst and point input of runoff the areas at higher risk of pollution is extended over the full extent downstream of the proposed road development. For the Clarinbridge GWB where aquifer properties are relatively low, this area encompass the full extent of the construction footprint.

Infiltration from construction runoff on the Visean Undifferentiated Limestone will occur both on the construction footprint and from infiltration basins. The infiltration basins will be excavated at the construction stage to allow their use during construction. These may act as a source of point contamination to the karst. In line with TII rating, the Magnitude of the potential impact on the water quality of the aquifer is high and the Significance of the impact is moderate adverse.

Hydrogeological mitigation measures are required to control runoff to limit the potential impacts of accidental discharges to groundwater quality during construction. These are outlined in **Section 10.6**.

10.5.3.2 Potential Impacts to Groundwater supplies

A number of groundwater abstractions which may be impacted by the proposed road development were identified in **Section 10.3.4.3**. If groundwater levels at supply wells were lowered due to construction dewatering of the bedrock aquifer, or the groundwater quality at these wells was impacted, it could render the wells unusable. For the case of geothermal wells, a reduction in groundwater level can reduce the heat supply if the well relies on groundwater for thermal conductance.

The potential impact of construction dewatering of the bedrock aquifer on the wells can be assessed by comparing the well locations to the drawdown zone of influence. If the wells are located within the zone of influence, then by the precautionary principle it is assumed that they will be impacted by dewatering of the bedrock aquifer.

The first consideration for water supply wells is to assess whether the water quality at a well will be impacted by construction activities, which depends on whether a well is up- or down-gradient of the proposed road development. If a well is up-gradient of the proposed road development, it cannot be impacted by any potentially polluting materials at the proposed road development.

If a well is down-gradient, then the travel time of any contamination to that well should be considered. The GSI determine the inner Source Protection Area as the area within which human activities may have an immediate effect on the source and it is defined by the 100-day time of travel (TOT) from any point below the water table to the source.

The 100-day TOT has been calculated for each well down-gradient of the proposed road development to determine if it may potentially be impacted.

There is one well in the granite down-gradient of the proposed road development. Based on maximum locally measured permeability of $4.6x10^{-7}$m/s [4], the distance which defines the 100-day TOT for this well is 80m.

There are 10wells in the limestone down-gradient of the proposed road development. Based on maximum locally measured permeability of $3.1x10^{-5}$m/s[4] for the Menlough and Ballindooley area and maximum locally measured permeability of $1.7x10^{-6}$m/s[4] for the Ballybrit to Briarhill area, then the distance

[4] This has been calculated based on the hydraulic conductivity rather than the average linear velocity. Using hydraulic conductivity to determine 100-TOT is considered to be more conservative.

which defines the 100-day TOT for these is 1,500m and 500m respectively (rounded up).

It should be noted that this is a highly conservative assessment as the 100-day TOT was derived based on the likelihood of microbial contamination. These contaminants are more mobile than those associated with road runoff, however, the resultant distance indicates the maximum travel distance in 100 days and allows an informed decision on whether there is any potential for the well to be impacted.

The assessment of the potential impacts on each individual well has been summarised in **Table 10.18**.

Table 10.18: Impact assessment of wells within the study area (pre-mitigation)

Feature	Location relative to radius of influence	Position relative to proposed road development	Within 100-day TOT of the well?	Potential impact	Magnitude of impact	Significance of impact
Knocknacarra GWS (W50-01)	Outside the zone of influence	Down-gradient	No	None	No Impact	N/A
W50-02	Outside the zone of influence	Down gradient	No	None	No Impact	N/A
W50-03 04, 05, 06 and 07	Outside the zone of influence	Down gradient	No	None	No Impact	N/A
W50-08	Outside the zone of influence	Down gradient	No	None	No Impact	N/A
W50-09	Outside the zone of influence	Up gradient	N/A	None	No Impact	N/A
W50-10	Inside the zone of influence	Below footprint of proposed road development	Yes	Well will be lost	Large adverse	Slight / moderate
W50-11	Outside the zone of influence	Down gradient	No	None	No Impact	N/A
W50-12	Inside the zone of influence	Below footprint of proposed road development	Yes	Well will be lost	Large adverse	Profound / Significant

Feature	Location relative to radius of influence	Position relative to proposed road development	Within 100-day TOT of the well?	Potential impact	Magnitude of impact	Significance of impact
W50-13 & W50-14	Inside the zone of influence	Below footprint of proposed road development	Yes	Both wells will be lost	Large adverse	Profound
W50-15	Inside the zone of influence	Below footprint of proposed road development	Yes	Well will be lost	Large adverse	Profound / Significant
W100-01 & 02	Outside the zone of influence	Down gradient	No	None	No Impact	N/A
W100-03, 04, 05 and 06	Outside the zone of influence	Up gradient	N/A	None	No Impact	N/A
W500-01	Outside the zone of influence	Down gradient	No	None	No Impact	N/A
W1000-01	Outside the zone of influence	Up gradient	N/A	None	No Impact	N/A
W1000-02	Outside the zone of influence	Down gradient	Yes	Potential water quality deteriorati on	Moderate adverse	Slight
W1000-03	Outside the radius of influence	Down gradient	No	None	No Impact	N/A
W1000-04	Outside the radius of influence	Down gradient	No	None	No Impact	N/A
G50-01 (Geothermal well)	Outside the radius of influence	Up gradient	N/A	None	No impact	N/A

This assessment highlights that five wells (W50-10, W50-12, W50-13, W50-14 and W50-15) will be permanently impacted. Accordingly, these will be removed as part of the proposed road development and decommissioned based on IGI (2007) and EPA (2013) guidelines.

One well (W1000-02) has a potential risk for water quality deterioration as it lies down gradient and within the 100-day TOT from the proposed road development.

10.5.3.3 Potential Impacts to Groundwater Dependent Terrestrial Ecosystems (GWDTE)

This section assesses potential impact to groundwater dependent habitats and limestone pavement habitat from the construction phase of the proposed road development. Ecosystems may be potentially impacted through accidental contamination of the groundwater which supports them, the alteration of groundwater levels and/or the reduction in the groundwater contribution to the ecosystem. The characteristics which determine the potential impact are:

- The proximity to the feature
- The level of hydraulic connection between the feature and the section of aquifer at the proposed road development i.e. is the feature in the same aquifer unit as the proposed road development, or is there a hydraulic divide between the feature and the proposed road development
- The groundwater flow direction in the vicinity
- The level of cut of the proposed road development, which may determine the degree of variation in the groundwater level and also the extent of dewatering which may occur
- The water quality of the feature and the groundwater from which it receives its baseflow

Those receptors which need an impact assessment have been identified in **Section 10.3.4.2**. Ecosystem receptors comprise of European sites (cSAC and SPA), National sites (NHAs and pNHAs) and Annex I habitats.

It should be noted that this chapter identifies the potential impacts to the hydrogeology that supports these ecological features and does not assess the Magnitude and Impact Significance of the habitats themselves, which is presented in **Chapter 8, Biodiversity** based on the information provided here.

European Sites

Four European sites have been identified as receiving groundwater from groundwater bodies that are traversed by the proposed road development. These include:

- Lough Corrib cSAC
- Lough Corrib SPA
- Galway Bay Complex cSAC
- Inner Galway Bay SPA

Ballindooley Lough is also included in this assessment as it supports the wintering birds of the Lough Corrib SPA and Galway Bay SPA but also includes Annex 1 habitat on the fringe of the lough. The receiving environment of Ballindooley Lough has been discussed in detail in **Section 10.3.3.2**.

The discussion of the characteristics of the Galway Granite Batholith in **Section 10.5.3.1.1** outlines the zones of influence for dewatering of the bedrock aquifer and the areas vulnerable to contamination. Based on these there will be no impact either from drawdown or water quality impacts from the proposed road development to European sites.

The discussion of the characteristics of the Visean Undifferentiated Limestone in **Section 10.5.3.1.2** outlines the zones of influence for dewatering of the bedrock aquifer and interception of karst pathways as well as the areas vulnerable to contamination.

For the Visean Undifferentiated Limestone, the drawdown zones of influence do not impact on any European sites or Ballindooley Lough. However, this section of the report provides additional detail on the construction in order to relate the conceptual model to any potential impacts that may arise during construction.

The Western Approach to Lackagh Tunnel (EW19) and Lackagh Tunnel (EW20) are discussed in the Lackagh Tunnel Appraisal Report, which is included in **Chapter 7, Construction Activities**. The hydrogeological setting of the Western Approach to Lackagh Tunnel (EW19) and Lackagh Tunnel (EW20) are located at the groundwater divide between Lough Corrib Fen 1 (Menlough) and Clare-Corrib GWBs.

Due to the dependency of Coolagh Lake (part of the Lough Corrib cSAC) on Western Coolagh Spring the design excludes dewatering of the bedrock aquifer within this spring’s catchment. Based on the mapping of groundwater levels (refer to **Figure 10.6.008**) this catchment encompasses the area Ch. 9+700 and Ch. 11+500.

Dewatering of the bedrock aquifer will not be permitted during construction so there is no reduction in groundwater flow transmitted by these pathways through the aquifer to the Western Coolagh Spring. By not dewatering, the boundary between Clare-Corrib GWB and Lough Corrib Fen 1 (Menlough) will not be impacted. All construction works will remain above the groundwater table for the duration of the works to ensure the groundwater table is not intercepted and dewatering of the bedrock aquifer is not required.

On this basis there will be no drawdown in the Western Approach to Lackagh Tunnel (EW19) and Lackagh Tunnel (EW20) and therefore no impact to the groundwater divide between the Lough Corrib Fen 1 (Menlough) GWB and the Clare-Corrib GWB or to the Lough Corrib cSAC.

In addition, as detailed in the Karst Protocol (refer to CEMP **Appendix A.7.5**), if karst conduits are encountered during the excavation of structure foundations, concrete poured in these may block the conduits. This may affect the hydrogeological regime of the groundwater body feeding the ecological receptors. Mitigation measures for this are presented in **Section 10.6**.

The bridge over the River Corrib (EW15) requires excavations on the east and west shore to install piers. These excavations will extend below the groundwater table and will require dewatering to enable dry working conditions. As the eastern excavations occur on the margins of the Lough Corrib Fen 1 (Menlough) GWB with the River Corrib, there is no potential for impact to Western Coolagh Spring, which is up-gradient of the location.

There are European sites that receive groundwater from GWB with karst pathways that the proposed road development traverses. These GWB and the European sites they contribute to are listed below:

- Lough Corrib Fen 1 (Menlough) GWB, from groundwater flowing westwards to Western Coolagh Spring and the River Corrib (Lough Corrib cSAC). Water emergent from Western Coolagh Spring is the main contribution to Coolagh Lakes.
- Clare Corrib GWB, from groundwater flowing southwards to Galway Bay. This also includes emergent groundwater to the Terryland River during times of high groundwater levels, which flows to the River Corrib (Lough Corrib cSAC). Groundwater contribution from Clare-Corrib GWB provides a minor component of flow to Galway Bay or River Corrib.

The extent of the area where contamination may extend to is caused by the potential presence of karst which could allow pathways to carry pollutants from the construction site or infiltration basins to receptors. Mitigation has been developed to accommodate potential karst and these are detailed in **Section 10.6**.

Ballindooley Lough is up gradient of the proposed road development and as such not considered to be at risk from pollution.

National Heritage Areas

Three National Heritage Areas have been identified as receiving groundwater from groundwater bodies that are traversed by the proposed road development. These include:

- Moycullen Bogs NHA (including Tonabrocky and Letteragh)
- Galway Bay Complex pNHA
- Lough Corrib pNHA

The hydrogeological assessment undertaken in **Section 10.5.3** identified a zone of influence for drawdown and an area more prone to potential pollution.

Based on the zones of influence extent for the Galway Granite Batholith, there will be no impact either from drawdown or water quality impacts from the proposed road development to NHA receptors. The Moycullen Bog at Letteragh is close to the proposed road development however, the calculated drawdown does not extend as far as the habitat. Moycullen Bog at Letteragh lies upgradient of the proposed road development and as such there is no risk of pollution.

For the Visean Undifferentiated Limestone the drawdown zones of influence do not impact on any NHA receptors. The zone of influence for water quality at the Clarinbridge GWB shows no impact to NHA receptors. However, the areas which may be prone to potential pollution shows a potential groundwater impact for:

- Lough Corrib Fen 1 (Menlough) westwards to Western Coolagh Spring and the River Corrib (Lough Corrib NHA)
- Clare Corrib GWB southwards to Terryland River, which flows to the River Corrib (Lough Corrib NHA) during times of high groundwater levels

The extent of the area where contamination may extend to is caused by the potential presence of karst which could allow pathways to carry pollutants from the construction site to receptors. Mitigation has been developed to accommodate potential karst and these are detailed in **Section 10.6**.

Annex I habitats

A number of Annex I habitats have been identified as water dependant and are located on groundwater bodies that are traversed by the proposed road development and are listed below:

- Wetland habitats in townlands of Na Foraí Maola Thiar (Ch. 0+650 to Ch. 0+750), Na Foraí Maola Thoir (Ch. 1+250 to Ch. 1+500), Troscaigh Thiar (Ch. 1+850 to Ch. 2+400), Bearna (Ch. 2+600 to Ch. 3+100), Aille (Ch. 3+300 to Ch. 3+900) and Ballyburke (Ch. 4+800 to Ch. 5+900)
- Wetland habitats at National University Galway (Ch. 8+800 to Ch. 8+950 and Ch. 9+150 to Ch. 9+250)
- Turlough K31 is located in the Lough Corrib Fen 1 (Menlough) GWB
- Turlough K20 is located in the Lough Corrib Fen 2 GWB
- Turlough K72 is located in the Clare-Corrib GWB
- Petrifying springs, located on the northern face of Lackagh Quarry
- Wetland habitats at Terryland River

The zone of influence for drawdown shows that impacts from groundwater lowering will occur to the Annex I habitats within the townlands of Na Foraí Maola Thiar (Ch. 0+650 to Ch. 0+750), Na Foraí Maola Thoir (Ch. 1+250 to Ch. 1+500), Troscaigh Thiar (Ch. 1+850 to Ch. 2+400), Bearna (Ch. 2+600 to Ch. 3+100), Aille (Ch. 3+300 to Ch. 3+900) and Ballyburke (Ch. 4+800 to Ch. 5+900).

Wetland habitats at NUIG Sporting Campus lie downgradient and upgradient of the proposed road development. Neither habitat at NUIG Sporting Campus lies within the drawdown ZOI, however, the habitat to the south, which lies downgradient, has the potential to be impacted from pollution.

Turlough K31 also lies within the footprint of the proposed road development but as it is traversed as part of the Menlough Viaduct. As the viaduct can be constructed without dewatering of the bedrock aquifer there will be no impact from groundwater lowering at turlough K31.

The extent of the area identified as being prone to potential pollution shows that Turlough K31 lies within this area but that Turloughs K20 and K72 lie beyond it. The potential impacts to Turlough K31 derive from the potential of karst being encountered during construction and as such pollution from the site draining to ground, and the turlough.

Petrifying springs have been included in **Chapter 8, Biodiversity** as occurring on the western face of the inactive Lackagh Quarry. The Petrifying springs occur as seepages that are located above the regional groundwater table, which occur from small pathways in the limestone bedrock that are fed by recharge. The source area for the seepages is the limestone pavement immediately north and west of Lackagh Quarry. These seepages have developed from the excavation of the quarry. Rock bolting is proposed to stabilise the quarry face at the eastern portal of Lackagh Tunnel in Lackagh Quarry. Rock bolting will have an insignificant impact on recharge pathways through the unsaturated zone. Concreting will not be part of the face stabilisation works.

Wetland habitats associated with the Terryland River are located on thick low permeability subsoils. The water dependence of these habitats is derived from water ponding on the surface rather and are therefore not groundwater dependant.

Local Ecosystems

A number of local ecosystems are identified in the **Chapter 8, Biodiversity** that are water dependant and these include a wetland site on the Galway Granite Batholith at Ch. 8+850 and quarry wall seepages in the Visean Undifferentiated Limestone in Lackagh Quarry that have calcareous springs.

Based on the zone of influence for draw down, the wetland site at Ch. 8+850 will be impacted by the drawdown and its southern margin where the groundwater level will lower during construction.

The calcareous spring locations identified in Lackagh Quarry are all located above the groundwater table and mainly in the western quarry face. All seepages occur above the water table and occur from recharge within the unsaturated zone. The proposed road development will not impact on water quality.

Summary

The hydrogeology of ecological receptors with dependence on groundwater have been assessed (in the absence of mitigation measures) for the construction phase of the proposed road development. The assessment takes into account receptors within the study area for both the drawdown zone of influence and areas which are potentially vulnerable to pollution. **Table 10.19** below provides a summary of the ecological receptors and identifies those that lie within the drawdown zone of influence and those areas that lie down gradient of the proposed road development and are at risk from pollution.

The magnitude and significance of hydrogeological impacts refer to potential changes in groundwater quantity and/or quality at the European or National site or groundwater dependent Annex I habitat. The assessment in accordance with TII Guidelines. For assessment on ecological impacts as a consequence of these potential hydrogeological impacts, please refer to **Chapter 8, Biodiversity**.

Table 10.19: Summary of potential hydrogeological impacts at GWDTE during construction phase (pre-mitigation)

Feature	Potential Impact to Groundwater Level	Potential Impact to Groundwater Quality	Magnitude of Hydrogeology Impact	Significance of Hydrogeology Impact
European Union sites				
Galway Bay Complex cSAC	Potential temporary quantity deterioration of groundwater in karst pathways to Galway Bay. 	groundwater contribution from GWB is of insufficient magnitude to affect integrity	GWB is of insufficient magnitude to affect integrity		
Annex I habitats (outside of European sites)				
Na Foraí Maola Thiar Ch. 0+650 to Ch. 0+750	Within drawdown zone of influence	Within area liable to contamination	Large Adverse	Profound
Na Foraí Maola Thoir Ch. 1+250 to Ch. 1+500	Within drawdown zone of influence	Within area liable to contamination	Large Adverse	Profound
Troscaigh Thiar (Ch. 1+850 to Ch. 2+400)	Within drawdown zone of influence	Within area liable to contamination	Large Adverse	Profound
Bearna (Ch. 2+600 to Ch. 3+100)	Within drawdown zone of influence	Within area liable to contamination	Large Adverse	Profound
Aille (Ch. 3+300 to Ch. 3+900)	Within drawdown zone of influence	Within area liable to contamination	Large Adverse	Profound
Ballyburke (Ch. 4+800 to Ch. 5+900)	Within drawdown zone of influence	Within area liable to contamination	Large Adverse	Profound
NUI Galway (Ch. 8+800 to Ch. 8+950	No (upgradient of the proposed road development)	No (upgradient of the proposed road development)	N/A	N/A
NUI Galway (Ch. 9+150 to Ch. 9+250	No Outside of drawdown zone of influence	Within area liable to contamination	Moderate Adverse	Profound / Significant
Turlough K20 (Menlough North East)	No Outside of drawdown zone of influence	No (upgradient of proposed road)	N/A	N/A
Turlough K31 (Menlough East)	No Outside of drawdown zone of influence	Within area liable to contamination	Large Adverse	Profound

Feature	Potential Impact to Groundwater Level	Potential Impact to Groundwater Quality	Magnitude of Hydrogeology Impact	Significance of Hydrogeology Impact
Turlough K72 (Coolagh North)	No Outside of drawdown zone of influence	No (upgradient of proposed road)	N/A	N/A
Petrifying Springs (Lackagh Quarry)	Rock bolts may intersect recharge pathways	No Located above the groundwater table	Negligible	Insignificant
Local habitats				
Fen Ch. 7+850	Within drawdown zone of influence	Within area liable to contamination	Large Adverse	Slight / Moderate
Calcareous springs (Lackagh Quarry)	Rock bolts may intersect recharge pathways	No Located above the groundwater table	Negligible	Insignificant

On the basis of the above assessment impacts to groundwater dependant habitat are assessed based on the importance of the hydrogeology attribute and the magnitude of impact. Those features that lie beyond the zone of influence to hydrogeological impacts and away from the area vulnerable to contamination are assessed to have no impact.

10.5.3.4 Hydrogeological Impacts to Groundwater Dependent Surface Water Features

Groundwater contributes to surface water in the study area. In the area of the Galway Granite Batholith, the groundwater contribution is minimal, as evidenced by low baseflow. However, groundwater provides more significant contribution to baseflow in the area of the Visean Undifferentiated Limestone (refer to **Chapter 11, Hydrology**). Whilst, the River Corrib receives most of its contribution from upstream of the study area, surface water features such as Ballindooley Lough, Coolagh Lakes, turlough K20, Turlough K31, Turlough K72 and the Terryland River (during high groundwater levels), are dependent on groundwater. It is noted that whilst the Eastern Coolagh Spring has the potential for groundwater contribution, Coolagh Lakes is not dependent on this spring. Coolagh Lakes is however dependent on the Western Coolagh Spring.

Based on the ZoI for drawdown there will be no reduction in groundwater flow from the Galway Granite Batholith or the Visean Undifferentiated Limestone. Furthermore, for the Galway Granite Batholith those areas highlighted as being vulnerable to potential pollution do not extend to surface water features.

For the Visean Undifferentiated Limestone the areas which have been described as having karst or being highlighted as potentially vulnerable to pollution include surface water features dependant on groundwater. Of these features listed above Ballindooley Lough, Turlough K20, Turlough K72 have been described in **Section**

10.5.3.3 (Potential Impacts to GWDTE). As such, only the Terryland River is described under the heading of hydrogeological impacts to surface water.

The hydrogeology of the Terryland River is described in **Section 10.3.3**, which explains the importance of two estavelles at the eastern end of the river. Although the Terryland River sinks at the estavelles for most of the year, these reverse during peak groundwater levels and become resurgences. On these occasions groundwater from the Clare-Corrib GWB contributes to the River Corrib and the Lough Corrib cSAC. On this basis the Clare-Corrib GWB contributes Galway Bay during normal conditions but Galway Bay and the River Corrib during high groundwater levels.

The potential impact magnitude to the Terryland River during high groundwater is quantified as ‘Small Adverse’. As during these times the Terryland River is entirely groundwater fed, then the rating significance is ‘Significant’. The hydrological impacts are described in **Chapter 11, Hydrology**.

The magnitude and significance of hydrogeological impacts refer to potential changes in groundwater quantity and/or quality at receiving surface water from the proposed road development. The assessment is made in accordance with TII Guidelines. For assessment on surface water impacts as a consequence of these potential hydrogeological impacts, please refer to **Chapter 11, Hydrology**.

10.5.3.5 Summary

This section has provided a detailed assessment of the potential impacts to receptors for the proposed road development prior to implementation of mitigation measures. Based on the conceptual site model (**Section 10.3.3**) a zone of impact has been delineated for groundwater level drawdown. Areas that lie downgradient of the proposed road development have also been identified as being at risk from pollution, with the extent downgradient being dependant on the aquifer properties.

The design of the proposed road development is cognisant of the hydrogeological existing environment and specifically groundwater receptors. Below is a summary of the design measures incorporated into the design of the proposed road development for the construction phase:

- The design of the construction minimises areas of land stripping so as to reduce the increase in runoff from where vegetation (and evapotranspiration) is removed
- In the area of the Galway Granite Batholith the aquifer properties are poor and recharge is very low. In these areas runoff is managed on site and discharged to surface water (refer to **Chapter 11, Hydrology**). There is no reliance on groundwater infiltration where the road traverses the Galway Granite Batholith
- Groundwater inflows will occur in road cuttings due to the high water table in the Galway Granite Batholith. Where groundwater inflows occur these are likely to be minimal owing to the low aquifer properties. In the case of local zones of higher inflow, for example at a fault zone, then mitigation measures will be employed to control the inflow and isolate the pathway from the construction site

- The assessment has identified a risk specific to the Visean Undifferentiated Limestone where karst is present within the groundwater bodies that the proposed road development traverses. Karst has been identified in Lough Corrib Fen 1 (Menlough) GWB and Lough Corrib Fen 1 (Lackagh) GWB, GWDTE Lough Corrib Fen 2 GWB and the Clare-Corrib GWB. If karst was encountered in these groundwater bodies then there is a risk that runoff and accidental spills could impact on groundwater quantity and quality. These potential impacts require mitigation using the karst protocol, which is detailed in **Section 10.6** mitigation measures
- During construction of the proposed tunnel at Lackagh Quarry there is a risk of groundwater impacts if dewatering of the bedrock aquifer occurs, which could have hydrogeological impacts at Western Coolagh Spring which in turn could impact Coolagh Lakes which are part of Lough Corrib cSAC. Detail of the assessment of Lackagh Tunnel and its approaches are presented in **Appendix A.7.3**. For the tunnel section the eastern section of the western portal and approach the construction works will be restricted to above the groundwater table at all times
- At the eastern approach to Lackagh Tunnel support system of rock bolts will be used to stabilise the quarry face rather than concrete. Rock bolts will prevent impact to the petrifying springs and calcareous identified in the faces of Lackagh Quarry
- To facilitate groundwater flow around the completed tunnel the construction design includes a drainage blanket up to the winter groundwater level (+16.7mOD). It is envisaged that this will take the form of a drainage layer, drainage pipes or similar placed outside the permanent cast in-situ reinforced concrete tunnel lining and waterproof membrane
- The proposed finished level of the proposed road development at Lackagh Quarry will lie above the groundwater table, however, the embankment starter layer at the eastern approach would, in part, be submerged during peak winter groundwater high. In this regard the starter layer will be constructed so as not to dam groundwater in parts of the quarry floor. Similarly, the drainage network will not be installed during the seasonal groundwater high so as to avoid the need for dewatering of the bedrock aquifer and groundwater lowering
- A watertight seal will be installed on the road base of Lackagh Tunnel and its western approach and the cutting sides to protect against groundwater inflow. This area will be sealed during construction (and permanently) to +17.7mOD; which is derived from the groundwater high (+15.7mOD) plus 2m free board. Slope or retaining structures will be utilised from +17.7mOD to existing ground level where required

Based on the design measures above each of the receptors have been assessed. **Table 10.20** below provides a summary of impact magnitude and impact significance for those hydrogeological receptors considered at risk during the construction phase. The assessment of ecological and surface water receptors refers only to the hydrogeology of each location (refer to **Chapter 8, Biodiversity** and **Chapter 11, Hydrology**).

Table 10.20: Summary of impact magnitude and significance for hydrogeological aspects of receptors at risk during the construction phase of the proposed road development

Feature	Importance of Hydrogeology Attribute	Hydrogeology Impact Summary	Hydrogeology Impact Magnitude	Hydrogeology Impact Significance
Groundwater Resources				
Galway Granite Batholith (Pl)	Low	Permanent groundwater quality and quantity impacts	Negligible	Imperceptible
Visean Undifferentiated Limestone (Rkc)	Very High	Permanent groundwater quality and quantity impacts	Negligible	Imperceptible
Groundwater Supplies				
W50-10	Low	Well will be lost	Large adverse	Slight / moderate
W50-12	High	Well will be lost	Large adverse	Profound / significant
W50-13 & W50-14	Very High	Well will be lost	Large adverse	Profound
W50-15	High	Well will be lost	Large adverse	Profound / significant
W1000-02	Low	Potential risk to water quality	Moderate adverse	Slight
Ecological Receptors				
Lough Corrib cSAC	Extremely High	Potential temporary quantity and quality deterioration of groundwater in karst pathways within contributing GWB would lead to impacts at Western Coolagh Spring, which is the main water contribution for Coolagh Lakes	Large Adverse	Profound
		The groundwater contribution from GWB to River Corrib is of insufficient	Negligible	Insignificant

Feature	Importance of Hydrogeology Attribute	Hydrogeology Impact Summary	Hydrogeology Impact Magnitude	Hydrogeology Impact Significance
		magnitude to affect integrity		
Galway Bay Complex cSAC	Extremely High	Potential temporary quantity and quality deterioration of groundwater in karst pathways to Galway Bay. The groundwater contribution from GWB is of insufficient magnitude to affect integrity	Negligible	Insignificant
Inner Galway Bay SPA	Extremely High	Potential temporary quantity and quality deterioration of groundwater in karst pathways to Galway Bay. The groundwater contribution from GWB is of insufficient magnitude to affect integrity	Negligible	Insignificant
Lough Corrib pNHA	Very High	Potential temporary quantity and quality deterioration of groundwater in karst pathways within contributing GWB would lead to impacts at Western Coolagh Spring, which is the main water contribution for Coolagh Lakes	Large Adverse	Profound

Feature	Importance of Hydrogeology Attribute	Hydrogeology Impact Summary	Hydrogeology Impact Magnitude	Hydrogeology Impact Significance
		levels below the habitat		
NUI Galway (Annex I) (Ch. 9+150 to Ch. 9+250)	Very High	Potential contamination impact	Moderate Adverse	Profound
Turlough K31 (Annex I) Menlough East	Very High	Proposed road development traverses the habitat Potential temporary groundwater contamination impact	Large Adverse	Profound
Petrifying springs	Very High	Rock bolting to stabilise eastern portal of Lackagh Tunnel	Negligible	Insignificant
Unnamed Fen (Locally important) Ch. 7+850	Low	Within calculated drawdown zone of influence Drawdown will permanently lower groundwater levels below the habitat	Large Adverse	Slight / moderate
Calcareous springs	Low	Rock bolting to stabilise eastern portal of Lackagh Tunnel	Negligible	Insignificant
Surface water				
Terryland River	Extremely High	Potential temporary water quantity and quality impact to Terryland estavelles (K87 & K96) during high groundwater levels when these outflows contribute to the River Corrib	Small Adverse	Significant

10.5.4 Operational Phase Impacts

There are a number of operation phase activities or features of the proposed road development that have the potential to cause hydrogeological impacts. The potential impacts of these on the hydrogeological receptors identified in **Section 10.3.4** are discussed in this section of the chapter. The potential impact outlined in this section are pre-mitigation. Residual impacts are outlined in **Section 10.7**.

As with construction activities, the main impacts to groundwater from operation arises from the potential to impact on groundwater level and groundwater quality. Operation can alter the groundwater regime by:

- Lowering of groundwater level from operational dewatering
- Raising groundwater levels by impeding or impounding groundwater
- Discharge of road runoff to ground

The quantification of these potential operational impacts are presented in this section of the chapter, while the impacts on receptors identified in **Section 10.3.4** are presented in **Section 10.5.4.4**. Many of these impacts are similar to the impacts quantified in the construction phase of this assessment e.g. the operation of road cuttings in the Galway Granite Batholith, and should be cross referenced to **Section 10.5.3** where necessary.

There will be no active dewatering of the bedrock aquifer required during the operation phase but passive dewatering will occur at a number of cutting locations and the drainage associated with the proposed road development will cause the groundwater levels to adjust locally.

The drawdown and ZoI for road cuttings was presented in **Table 10.17** of the construction impacts and should also be referred to when considering the impacts from the operation phase. It should be noted that all tunnels and associated approaches will be sealed as part of their construction where below the winter water table and so, for example, the Galway Racecourse Tunnel and approaches will require dewatering of the bedrock aquifer during construction but they will not require dewatering during operation. Dewatering of the bedrock aquifer either during construction or operation at Lackagh tunnel and its approaches is not permitted.

The potential impacts from interception of karst conduits was highlighted during the construction phase as having a potential impact on the hydrogeological regime by either modifying pathways (reactivating sediment filled karst or blocking active karst) or from point input recharge for contaminants. Mitigation measures to prevent these impacts from occurring are presented in **Section 10.6**. If implemented during the construction phase, these impacts will not occur during the operation phase.

During operation, potential groundwater quality impacts occur from the discharge of road runoff or from accidental spillages. Potential impacts of the discharge of routine road runoff is assessed in line with HD45/15 ‘Road Drainage and the water Environment’ Method C, while the assessment of accidental spillages is undertaken in **Chapter 10, Hydrology** line with HD45/15 'Road Drainage and the water Environment' Method D.

Within HD45/15, a Groundwater Protection Response (GPR) is presented which is a risk assessment methodology based on the vulnerability and aquifer classification of the aquifer where the discharge will occur. A matrix of these elements, presented below in **Table 10.21**, is used to determine the potential risk and sets out a series of 'Responses' that the drainage design of the proposed road development should comply with to minimise the risk to the groundwater environment. The assessment is considered a screening tool which can be superseded by a site specific hydrogeological risk assessment.

Table 10.21: Groundwater response matrix for the use of permeable drains in road schemes (TII, HD45/15, 2015)

Vulnerability rating	**Source protection area**	**Resource protection area (Aquifer category)**							
		Regionally Important Aquifer			**Locally Important Aquifer**			**Poor aquifer**	
		Rk*	**Rf**	**Rg**	**Lg**	**Lm**	**LI**	**PI**	**Pu**
Extreme: Rock near Surface or karst (X)	R4	R4	R4	R3(2)	R3(2)	R3(1)	R3(1)	R3(1)	R3(1)
Extreme €	R4	R2(3)	R2(2)	R3(2)	R3(2)	R2(2)	R2(2)	R2(1)	R2(1)
High (H)	R3(2)	R2(2)	R2(2)	R2(2)	R2(2)	R2(2)	R2(2)	R2(1)	R2(1)
Moderate (M)	R3(1)	R2(1)	R2(1)			R2(1)	R2(1)	R1	R1
Low (L)	R3(1)	R1	R1			R1	R1	R1	R1

*A small proportion of the country (~0.6%) is underlain by locally important karstic aquifers (Lk); in these areas, the groundwater protection responses for the Rk groundwater protection zone shall apply.

The Geological Survey of Ireland (GSI) provides mapped classifications of the aquifer and vulnerability criteria across the country, however it is recommended that the vulnerability criteria is updated based on site specific information.

Groundwater vulnerability assesses the geological and hydrogeological characteristics of the subsoil overlying the aquifer and provides a rating response using the TII HD45/15 GPR (**Table 10.21**). The GSI make a distinction between extreme vulnerability with bedrock at surface (X) and extreme vulnerability with subsoil being 0-3m thick (E). Where extreme (X) vulnerability refers to rock outcrop at surface or the location of a karst feature.

The groundwater protection response for the proposed road development is presented in **Appendix A.10.7** and concludes the following:

- Significant areas of the Galway Granite Batholith are identified by the GSI as being rock at or near surface. However, as most of the proposed road development is on embankment the groundwater vulnerability is mainly extreme (E). Those areas where groundwater vulnerability is extreme (X) are areas where the proposed road development is in cutting. In these areas the drainage design includes verges and swales that maintain a 1m constructed subsoil above bedrock. As the granite is of a low permeability infiltration to the bedrock is very low

- Drainage design for the Visean Undifferentiated Limestone is sealed up to the point of discharge, where to surface water or infiltration basin. Where discharge is proposed by infiltration basins then all locations have a GPR response of R2(3)
- Permeable drainage is acceptable for both R2(1) and R2(3) responses subject to subject to minimum Design Manual for Roads and Bridges (DMRB) standards and GPR Notes
- Permeable drainage is acceptable for the proposed road development where it traverses the Galway Granite Batholith subject to minimum DMRB conditions and GPR requirements 1,2 and 3. The design takes into account those ground receptors identified in **Section 10.3.4**. In the event of a vertical fault crosscutting the proposed road development then the drainage design will locally be sealed to prevent communication between flow zone and runoff
- Permeable drainage is acceptable for the proposed road development where it traverses the Visean Undifferentiated Limestone subject to minimum DMRB conditions and GPR requirements 1, 2, 3, 4, 5, 6 and 7. The drainage design takes into account karst primarily by avoidance but also by incorporating pre-treatment prior to discharge. Drainage design for the Visean Undifferentiated Limestone employs a sealed design with discharge either to surface water courses or infiltration basins. Where runoff discharges to surface water then there is no discharge to groundwater and a detailed hydrogeological assessment is not required. For those networks with discharge by infiltration basin then a hydrogeological assessment has been undertaken for each networks to assess the potential risks to groundwater. The individual assessments are included into **Appendix A.10.7**

On the basis of this hydrogeological assessment the design and measures of the infiltration basins assessed meet the criteria for HD45/15 for permeable drainage.

The potential impacts from accidental spillages have been assessed in line with TII Guidelines HD45/15 Method D. The potential risk of a serious pollution incident occurring has been calculated >1% and the calculations to confirm this are presented in **Chapter 10, Hydrology**.

The potential zone of influence for operation drawdown and water pollution impacts are presented in **Figure 10.8.101** to **Figure 10.8.114**.

10.5.4.1 Potential Impacts to groundwater resources

The potential impact assessment on the groundwater resources during the operation phase considers the impact that the changes in the groundwater regime and groundwater quality have on the aquifer.

In line with TII guidance, the magnitude of the impact on the aquifers within the study area is based on the portion of the aquifer that will be removed. This has been presented for the construction phase in **Section 10.5.3**, however it also applies here.

In summary, the volume of the aquifer is a very small percentage of the aquifer volume and for this reason, in line with TII rating, the Magnitude of the impact on the aquifers is 'Negligible' and the Significance of the impact is 'Imperceptible'.

The presence of the proposed road development itself can affect the aquifer by changing the recharge pattern to it. Details of the drainage design for the proposed road development are provided in **Chapter 5, Description of the Proposed Road Development**, which includes the surface areas of the proposed road development where recharge to the aquifer will not occur. Using this data, the surface area of the proposed road development is negligible when compared to the surface area of the land providing recharge to the aquifer. The Magnitude of the impact on the aquifer is 'Negligible' and the Significance of the impact is 'Imperceptible'.

Other impacts that have the potential to impact groundwater resources changing groundwater levels and changing water quality. The magnitude and significance of other impacts on the two aquifer types along the proposed road development is outlined in **Sections 10.5.4.1.1** and **10.5.4.1.2**.

10.5.4.1.1 Galway Granite Batholith (Section 1)

Based on the results presented in **Table 10.17** there are seven cuttings in the Galway Granite Batholith which have the potential to intersect the groundwater table locally. These road cuttings are EW01, EW02 (three cuttings), EW04, EW07 and EW11. As outlined in **Section 10.4**, EW11 has the largest ZoI with drawdown extending up to 54m from the edge of the footprint of the proposed road development.

The installation of drainage both for the proposed road development runoff and for pre-earthworks drainage will locally intercept drainage and for this reason, the conservative assumption is that the operational ZoI will mimic the construction ZoI for these excavations.

Other excavations which are included in the construction ZoI such as excavation for structures and attenuation ponds are relevant for construction only and hence the ZoI for operation will locally be reduced from the ZoI for construction.

Using the reported aquifer properties, the operation ZoI within the Galway Granite aquifer will yield relatively small volumes of groundwater, which will be managed on site and discharged to those nearby watercourses that the groundwater would contribute too indicating that there will be no net change to the volume of water in the aquifer. On this basis, in line with TII rating, the Magnitude of the impact of lowering the groundwater level on the aquifer is Negligible and the Significance of the impact is 'Imperceptible'.

Potential impacts to groundwater quality during operation occur from infiltration to ground from the proposed road runoff. The assessment of the infiltration of proposed road runoff for the Galway Granite Batholith is detailed in **Appendix A.10.7** and a summary is provided below.

The assessment of the operational discharges to ground is based on the TII HD45/15 GPR assessment which is based on the groundwater vulnerability and the aquifer type. For the Galway Granite Batholith, the GSI Groundwater vulnerability varies between extreme (X) and high (H) and the aquifer characterisation is poor (Pl). Based upon the design of the proposed road development with the mainline of the proposed road development on embankment or where in cutting verges and swales for over the edge drainage are proposed, the GPR returns a R2(1) response and meets TII HD45/15 guidelines. Due to the low hydraulic conductivity of the granite bedrock the potential impact to groundwater quality is local to the proposed road development. In line with TII guidance, the Magnitude of this potential impact on the aquifer is Moderate Adverse and the Significance of this impact is Significant / Moderate respectively. The duration of the impact is permanent.

If accidental spillages occur during the operation of the proposed road development, they have the potential to impact water quality. In line with TII guidance, the Magnitude of this potential impact is 'Moderate Adverse' and the Significance of this impact 'Significant / Moderate' respectively. The duration of such impacts will be brief, lasting less than one day.

10.5.4.1.2 Visean Undifferentiated Limestone (Section 2, 3 & 4)

During the operation phase of the proposed road development, there are thirteen sections in the Visean Undifferentiated Limestone Aquifer that remain in an open cutting or tunnel (see **Table 10.17**). This is two less than during construction as the River Corrib Bridge and Menlough Viaduct do not have excavations during operation.

The potential for impact is assessed on the basis of the depth of the cutting, including drainage, and the maximum groundwater levels monitored during the project specific ground investigation (2015-2017). Of these thirteen cuttings, six remain above the water table at all times and will not impact on groundwater levels. Seven cuttings do have the potential to intersect and impact on the water table locally during operation.

The seven cuttings/tunnel that have the potential to intersect the water table include three cuttings (EW27, EW34 and EW35), three tunnel approaches (EW19, EW30 and EW32) and two tunnels (EW20 Lackagh Tunnel and EW31 Galway Racecourse Tunnel). Both the Lackagh Tunnel and its western approach and the Galway Racecourse with its eastern approach will be sealed.

Based on the water level data collected for the proposed road development and the sealed design of the tunnels and their approaches the only excavations that have the potential to require operational dewatering of the bedrock aquifer are EW27, (Clare-Corrib GWB) EW34 and EW35 (Clarinbridge GWB).

The installation of drainage both for proposed road runoff and for pre-earthworks drainage will locally intercept drainage and for this reason, the conservative assumption is that the operational ZoI will mimic the construction ZoI for these three excavations. Based on the different aquifer properties for the various groundwater bodies outlined in the **Section 10.3.2**, the ZoI for drainage will be larger for the cuttings in the Clare-Corrib GWB than in the Clarinbridge GWB.

EW27 lies immediately west of the N83 Tuam Road and is a cutting where the proposed finished road level lies 10m above the summer groundwater level and 0.5m above the peak recorded winter groundwater level. As part of the design permanent drains will be installed to control the groundwater level 2m below the finished road level.

All groundwater intercepted by drains during the peak groundwater rise will be carried eastwards by unlined 150mm perforated pipes either side of the proposed road development with discharge along the pipe length and overflow to an infiltration basin. All groundwater intercepted by these drains will be discharged back into the groundwater body further east where groundwater levels are <5m below the proposed road level.

Within the Clarinbridge GWB the aquifer properties are relatively low and on this basis the volumes of groundwater to be generated during excavations are relatively small. Any groundwater lowering required will be kept within the same GWB so that groundwater volumes are maintained.

In the area of the Visean Undifferentiated Limestone there are few surface water features present. Where there is no option for discharge via surface water or storm water sewers the proposed road development will discharge to ground. As outlined in **Section 10.5.4** a hydrogeological assessment, in line with TII HD45/15 guidelines, was undertaken for the drainage design for discharges to ground. The full assessment is presented in **Appendix A.10.7** and is summarised below.

The design of the infiltration basin includes a 2m over excavation from the invert to place a 2m thick subsoil that will meet the TII definition of being an appropriate material (TII HD45/15). All of the infiltration basins are more than 15m from surface karst mapped during the karst survey (refer to **Figure 10.1.002**) and will be sealed up to the point of discharge. Additionally, all infiltration basins are designed to include the following features as standard design:

- A containment area
- A hydrocarbon interceptor
- A wetland

There is also a containment area in each drainage network that can manually be activated to contain spillage on the proposed carriageway.

Groundwater levels have been monitored along the route of the proposed road development between February 2015 and January 2017 in order to determine the seasonal variation in the groundwater level. On the basis of these measurements the minimum thicknesses of the saturated zone have been calculated for the infiltration basins and are presented in **Table 10.22**.

Table 10.22: Summary the unsaturated thicknesses below invert level for all infiltration basins

Network Ref	S19A	S19B	S20	S21A	S21B	S22A	S22B	S22C2	S22E	S40
Minimum unsaturated zone (m)	1.4	0.3	0	2.6	9.1	2.0	3.9	15.2	9.9	1.0

The groundwater level data shows significant seasonal variation locally and whilst all infiltration basins meet the requirement of 2m unsaturated zone during the groundwater low, infiltration basins S19a, S19b, S20 and S40 have less than 2m unsaturated zone during winter peaks. On this basis, infiltration basins at networks S21A, S21B, S22A, S22B, S22C2 and S22E meet and exceed the TII HD45/15 GPR criteria for R2(3) due to the pre-treatment.

Networks S19a, S19b, S20 and S40, however, do not meet the R2(3) criteria during the winter period when groundwater levels are elevated and there is less than 2m unsaturated zone (**Table 10.22**). However, as the standard design for infiltration basins for the proposed road development includes containment, a hydrocarbon interceptor and a wetland, then each infiltration basin includes significant pre-treatment of runoff prior to infiltration.

HD45/15 provides data on the event mean concentrations (EMC) of significant contaminants in routine runoff. The potential contaminants and their EMC are reproduced below in **Table 10.23**. The EMC data presented in TII HD45/15 is indicative of runoff water pre- treatment.

Table 10.23: Significant pollutants and their EMC

Determinand	Routine runoff Mean EMC µg/l
Total Copper	91.22
Dissolved Copper	31.31
Total Zinc	352.63
Dissolved Zinc	111.09
Total Cadmium	0.63
Total Fluoranthene	1.02
Total Pyrene	1.03
Total PAHs	7.52

As the pre-treatment aspect exceeds the requirements of HD45/15 for all infiltration basins then the treated run-off at infiltration basins S19a, S19b, S20 and S40 is of a higher quality than that listed in **Table 10.23**.

In addition to this, as noted in **Section 10.3.3** the maximum water levels were recorded during a period of unusually elevated groundwater levels following sustained rainfall events in the winter 2015/2016. Outside of these events, the minimum thickness requirement for the unsaturated zone will be present.

On this basis, the use of infiltration basins is assessed as being appropriate if no karst is encountered during construction of the excavation. Mitigation measures will be employed if karst is encountered during construction (refer to **Section 10.6**).

The presence of karst has been accommodated in the placement of the infiltration basins and no known active surface karst is present within 15m of any infiltration basin. However, there is a potential for karst to be encountered during the construction of infiltration basins and this is dealt with in the evaluation of construction impacts in **Section 10.5.3**.

The potential impact of karst is recognised as a significant aspect of the infiltration basins and is included in the mitigation measures of **Section 10.6**, which includes inspections to ensure that the infiltration basins remain in good working order for the operational life of the proposed road development.

Based on the TII HD45/15 Method C for groundwater protection response for routine runoff and site specific hydrogeological assessments the drainage design for operation of the proposed road development is considered to have an impact of negligible magnitude and imperceptible significance for all networks.

The potential accidental spillages to occur during the operation of the proposed road development, has the potential to impact on groundwater quality and has been assessed in line with TII HD45/15 Method C risk assessment. Based on the spillage risk assessment (refer to **Chapter 11, Hydrology**) the risk of a serious spillage occurring has an annual probability of less than 0.5% and is considered as acceptable based on TII guidelines.

In line with TII guidance, the Magnitude of this potential impact on the aquifer is negligible. The Significance of this impact on the Regionally Important is insignificant.

10.5.4.2 Potential Impacts to Groundwater supplies

An impact assessment on abstraction wells was completed for the construction phase and is presented in **Section 10.5.3.1**. The same assessment is valid for the operation phase. It highlights that five wells (W50-10, W50-11, W50-12, W50-13 and W12-14) will be removed by the proposed road development at the construction phase. One well (W1000-02) has been identified as lying downgradient and within the 100-day TOT from the proposed road development.

Mitigation measures for wells impacted outside of the proposed development boundary are proposed in **Section 10.6** and the residual impacts are summarised in **Section 10.7**.

10.5.4.3 Potential Impacts to Groundwater Dependent Terrestrial Ecosystems (GWDTE)

Potential impacts to GWDTE during operation derive from the interception of groundwater in cuttings and the deterioration of water quality from discharges and accidental spillages. A description of the specific locations where groundwater will be intercepted and where discharges will occur during operation of the proposed road development are detailed in **Section 10.5.4.1** for both the Galway Granite Batholith and the Visean Undifferentiated Limestone.

Based on the characteristics of the proposed road development **Section 10.4**. the zone of influence has been calculated for the operational passive dewatering of the bedrock aquifer. The zone of influence has been considered for those GWDTE listed in **Section 10.3.4.3** and the proximity for the operation ZoI to these GWDTE are presented in **Table 10.24**.

The water quality assessment of discharges from the proposed road development has been undertaken as part of TII HD45/15 groundwater protection response and individual hydrogeological assessments. The HD45/15 assessments conclude that the magnitude of the impact is 'Negligible' and the significance 'Imperceptible' for groundwater receptors (refer to **Section 10.5.4.1**). It should be noted that operational impacts are assessed on the basis of construction with guidance of the project karst protocol. In this regard, if karst was encountered during the construction of infiltration basins then these features would have been mitigated against at the construction phase.

Table 10.24: Summary of potential hydrogeological impacts at GWDTE during operation phase (pre-mitigation)

Feature	Impact to Groundwater Quantity	Impact to Groundwater Quality	Magnitude of Hydrogeology Impact	Significance of Hydrogeology Impact
European sites

Operation specific mitigation measures are presented in **Section 10.6**.

10.5.4.4 Potential Impacts to Groundwater Dependent Surface Water Features

Groundwater contributes to surface water at River Corrib, Ballindooley Lough, Coolagh Lakes, Turlough K20, Turlough K31, Turlough K72, Ballinfoyle Lough and Terryland River. It is noted that whilst the Eastern Coolagh Spring has the potential for groundwater contribution, Coolagh Lakes is not dependent on this spring. Coolagh Lakes is however dependent on the Western Coolagh Spring.

A zone of influence for drawdown has been calculated for both the Galway Granite Batholith and the Visean Undifferentiated Limestone. The design of the cutting carries any groundwater intercepted in cuttings and infiltrates back to ground within the same GWB. On this basis there is no net reduction to groundwater flow in each GWB. There are no operational groundwater impacts to surface water contribution.

10.5.4.5 Summary

The design of the proposed road development is cognisant of the hydrogeological existing environment and specifically groundwater receptors. Below is a summary of the design measures incorporated in the operation phase:

- Passive operational dewatering of the bedrock aquifer will be required within cuttings in the Galway Granite Batholith. Any intercepted groundwater will remain within its natural receiving catchment
- The drainage design in the Galway Granite Batholith is not sealed. Discharge of treated runoff will be to surface water. There will be small (<10%) losses of runoff (treated and untreated) to ground and these have no impact on groundwater quality beyond the footprint of the proposed road development
- Dewatering of the bedrock aquifer will not be undertaken in the catchment for Coolagh Lakes. This area of the proposed road development includes Menlough Viaduct and Lackagh Tunnel (including its approaches)
- Passive operational dewatering of the bedrock aquifer will be required in cutting EW27 but will only be operational during the seasonal groundwater peak. Any intercepted groundwater will remain within the GWB by being carried down gradient and recharged back to ground in an infiltration basin
- The design of the Galway Racecourse Tunnel and its eastern approach includes waterproofing to seal from groundwater ingress. The western approach includes groundwater interception (during peak winter only) which will drain westwards down gradient to an infiltration basin
- The drainage design of the proposed road development in the Undifferentiated Visean Limestone includes a sealed system and uses infiltration basins (operational phase) to discharge of treated runoff

Based on the design measures above each of the receptors have been assessed.

Table 10.25 below provides a summary of impact magnitude and impact significance for those hydrogeological receptors considered at risk during the operation phase. The assessment of ecological and surface water receptors refers only to the hydrogeology of each location (refer to **Chapter 8, Biodiversity** and **Chapter 11, Hydrology**).

Table 10.25: Summary of impact magnitude and significance for hydrogeological aspects of receptors at risk during the operation phase of the proposed road development

Feature	Importance of Hydrogeology Attribute	Hydrogeology Impact Summary	Hydrogeology Impact Magnitude	Hydrogeology Impact Significance
Groundwater resources				
Galway Granite Batholith (Pl)	Low	Permanent groundwater quality and quantity impacts	Negligible	Imperceptible

10.6 Mitigation Measures

10.6.1 Introduction

This section describes the measures to mitigate the potential impacts for both the construction (**Section 10.6.2**) and operational phases (**Section 10.6.3**) of the proposed road development.

In order to protect receptors identified in **Section 10.3.4**, both in terms of groundwater resources and water quality, mitigation measures will be put in place during the construction and operational phases of the proposed road development.

Through the evolution of the design of the proposed road development measures were included in the design to reduce or avoid specific impacts where possible. Following the evaluation of potential impacts as a result of the design, specific mitigation measures have been developed to avoid, prevent, reduce and, if possible, remedy any significant adverse impacts on hydrogeology. These are described below.

10.6.2 Construction Phase

The measures listed below will be adopted during the construction phase of the proposed road development.

The following measures were incorporated into the design (refer to **Section 10.5**) of the proposed road development:

- No dewatering of the bedrock aquifer will occur during construction at Menlough Viaduct or Lackagh Tunnel (or its approaches). Furthermore, the construction sequence will take into account the seasonal groundwater fluctuation. During the winter groundwater high it may be necessary to limit the depth of works so that dewatering of the bedrock aquifer is not required
- Galway Granite Batholith EW01, 02 (three cuttings), 04, 07 and 09: Groundwater intercepted will be collected and piped to the surface water receptor it would naturally have drained to
- Limestone: Construction dewatering of the bedrock aquifer may seasonally be required in EW27 during peak groundwater levels. Any dewatering will be discharged to the same GWB.
- Construction of the Galway Racecourse Tunnel and its approaches will require dewatering of the bedrock aquifer. All groundwater intercepted will be managed and discharged within the same GWB
- EW27: Groundwater will be controlled within the excavation by collection in drains or sumps. If groundwater is intercepted, it will be piped and discharged at an infiltration basin within the same GWB. Intercepted groundwater is controlled and infiltrates back to the same groundwater body
- Where infiltration basins are used for discharge of site runoff during construction the runoff will be managed on site, collected and treated as per the

Sediment Erosion and Pollution Control Plan (Refer to Section 8 of the CEMP in **Appendix A.7.5**).

The design of the proposed road development includes dewatering of the bedrock aquifer in cuttings in the Galway Granite Batholith and in cuttings in the Visean Undifferentiated Limestone. The drawdown from these cuttings has been assessed. Drawdown impacts are limited in extent and do not impact on European sites or National Heritage Areas. No hydrogeological mitigation is proposed with regard to the design of construction dewatering.

For the Visean Undifferentiated Limestone due to the risk of karst features being intercepted in excavations for earthworks (including viaducts, bridges and tunnels) and infiltration basins, mitigation measures have been developed to preserve the hydraulic connectivity of the feature and then seal it from the excavation. The Karst Protocol mitigation measure will ensure that there is no impact on groundwater flow paths to water dependant receptors. The Karst mitigation plan is detailed in the Construction Environmental Management Plan (CEMP) (**Appendix A.7.5**) and is summarised below in **Section 10.6.2.2.1** Aquifer Specific Mitigation Measures.

Those infiltration basins in the Lough Corrib Fen 1 (Menlough) GWB (S19a and S19b) shall have additional measures incorporated into their construction to provide further protection to the groundwater body. Infiltration basin S19a and S19b include lining the sides of the excavation to ensure vertical groundwater infiltration so that all discharges drain through the placed subsoil for the full thickness of the unsaturated zone.

10.6.2.1 Standard Mitigation Measures

Mitigation of potential construction impacts will be achieved through the stringent implementation of good construction practice procedures and environmental controls so as minimise the opportunity for contaminated releases of construction runoff as set out in the CEMP (**Appendix A.7.5**). Such practices will include adequate bunding for oil containers, wheel washers and dust suppression on site roads, and regular plant maintenance.

The following measures included in the CEMP will be implemented to control the potential for pollution from accidental spillages on site:

- Stockpiling of contaminated material is not permitted
- Good housekeeping (daily site clean-ups, use of disposal bins, etc.) on the site during construction, and the proper use, storage and disposal of these substances and their containers will prevent groundwater contamination
- For all activities involving the use of potential pollutants or hazardous materials, under the CEMP, the contractor will be required to ensure that material such as concrete, fuels, lubricants and hydraulic fluids will be carefully handled and stored to avoid spillages. Potential pollutants shall also be adequately secured against vandalism and will be provided with proper containment according to codes of practice. Any spillages will be immediately contained and contaminated soil removed from the site and properly disposed of

- The contractor will finalise the Incident Response Plan in the CEMP in **Appendix A.7.5** prior to work commencing and regularly update it for pollution emergencies which will be developed by the appointed contractor. The plan identified the actions to be taken in the event of a pollution incident. As recommended in the CIRIA document, the contingency plan for pollution emergencies includes the following:
    - Containment measures
    - Emergency discharge routes
    - List of appropriate equipment and clean-up materials
    - Maintenance schedule for equipment
    - Details of trained staff, location and provision for 24-hour cover
    - Details of staff responsibilities
    - Notification procedures to inform the Environmental Protection Agency (EPA) or environmental department of the Galway County Council
    - Audit and review schedule
    - Telephone numbers of statutory water consultees
    - List of specialist pollution clean-up companies and their telephone numbers
    - No direct untreated point discharge of construction runoff to groundwater will be permitted
    - Where a pollution incident is detected, construction works will be stopped until the source of the construction pollution has been identified and remedied
    - Pollution control facilities and procedures set out in the Sediment, Erosion and Pollution Control Construction Management Plan included in the CEMP will be implemented if required
    - The pollution control and treatment facilities will be installed and the monitoring network including instrumentation and procedures established prior to construction activities taking place on the ground in the vicinity of watercourses and sensitive surface and groundwater receptors. It is envisaged that the pollution control facilities will be monitored daily to ensure their continued function

10.6.2.2 Receptor specific mitigation measures

A number of mitigation measures have been developed specifically for groundwater dependent receptors. These are detailed below for aquifer, supply wells and habitats.

10.6.2.2.1 Aquifer Specific Mitigation Measures

Aquifer specific mitigation measures are implemented where karst or high permeability zones are encountered during the construction programme.

In the event of karst being encountered the Karst Protocol shall be implemented, which is documented in the CEMP (**Appendix A.7.5**). Application of the Karst Protocol are summarised below to detail where they will be implemented:

- Where karst features are encountered during construction works these will be assessed by a hydrogeologist and an engineering geologist. These features will require their extent across the proposed road development to be delineated. In the case of excavations (road cuttings, tunnels, bridge pier excavations) then the karst feature shall be excavated and backfilled with course fill and sealed. This will prevent runoff draining into the feature and therefore protect against accidental spillage. On this basis, construction runoff will not discharge to a karst pathway and will receive natural attenuation and dilution in the aquifer

- With regard to karst features being intercepted in excavations for earthworks (including viaducts, bridges and tunnels) and infiltration basins. The Karst Protocol preserves the hydraulic connectivity of the feature using granular material to fill but then seals the karst from the excavation using a liner (geotextile and or concrete depending on the site specifics) that will prevent linkage between excavation and the karst
- Where dewatering of the bedrock aquifer is proposed, groundwater level monitoring will be installed before construction, during the construction phase and 12 months following construction to enable potential effects from dewatering to be identified. In the shallow cuts of the proposed road development there will be minimal dewatering of the bedrock aquifer required; nonetheless, a monitoring programme will be in place. If the monitoring indicates there is a measureable impact beyond that stated in this EIAR, then work with the potential to increase drawdown will be made safe and cease until the hydrogeological assessment is revised based on the site conditions and mitigation employed if appropriate
- In order to reduce potential contamination impacts, stockpiling of contaminated material and leachate generation will be prohibited. In the situation that potential contaminated material is encountered it will be tested and disposed of in an appropriate manner and in line with current water management legislation. If it is not possible to immediately remove contaminated material, then it will be stored on, and covered by, polythene sheeting to prevent rain water infiltrating through the material. The time frame between excavation and removal will be kept to an absolute minimum

10.6.2.2.2Mitigation measures specific for supply wells

The mitigation measures listed below will be adopted during the construction phase of the proposed road development:

- Five wells (W50-10, W50-12, W50-13, W50-14 and W50-15) will be lost during the construction of the proposed road development. These will each be mitigated by providing a replacement well, connecting to mains supply where available or by financial compensation. Where wells have to be abandoned as part of the proposed road development they will be sealed and abandoned in general accordance with Well Drilling Guidelines produced by the Institute of Geologists of Ireland (IGI 2007)
- Replacement wells, storage tank, associated pumping equipment and pipework for Wells W50-13 and W50-14 will be commissioned and tested to ensure adequate yield rates in advance of wells W50-13 and W50-14 being decommissioned.

- Wells outside of the proposed development boundary but within the drawdown zone of influence may be impacted by reduced groundwater levels during construction. All wells within 150m of the proposed development boundary (or 50m from the calculated drawdown ZoI if greater) will be monitored for water level on a monthly basis for 12 months before construction, during construction and for 12 months after construction. If the monitoring indicates that the proposed road development has impacted on a supply or geothermal well then mitigation will be applied
- Standard mitigation measures and aquifer specific mitigation measures are employed for protection of groundwater. To ensure the protection of quality of groundwater potable supplies, all wells within 150m of the proposed development boundary will be monitored for water quality on a monthly basis. All wells will be monitored for standard drinking water quality parameters on a monthly basis for 12 months before construction, during construction and for 12 months after construction. If the monitoring indicates that the proposed road development has impacted on a supply, then mitigation will be applied

10.6.2.2.3 Specific Mitigation measures for GWDTE

As presented in **Section 10.3.4** the proposed road development traverses groundwater bodies that supply a number of GWDTE. Those GWDTE that have been flagged as being at risk are all in areas where the groundwater pathways are karstic. In this regard the Karst Protocol, as detailed above in **Section 10.6.2.2.1**, forms part of mitigation to prevent groundwater quality or quantity being impacted. Additional mitigation is also employed to ensure that European sites are not impacted.

Construction activities represent a potential source of impact on the water quality of the Coolagh Lakes, which form part of the Lough Corrib cSAC, from uncontrolled construction site runoff and potential contamination of the groundwater from construction spillages. There will be no surface water discharges to the Coolagh lakes and all runoff will be treated before being discharged to ground at infiltration basins. Infiltration basins are designed to include settlement to remove sediment and have an appropriate thickness of subsoil below invert level.

Pouring of the concrete in excavations (River Corrib Bridge, Menlough Viaduct and Lackagh Tunnel) will only be undertaken when the excavation has been inspected by a qualified hydrogeologist. Inspection of the full depth and extent of each excavation will be undertaken to identify if any significant flow paths, such as the karst enhancement of the bedrock permeability, are present. If no significant flow paths are present, then the hydrogeologist will document accordingly and confirm that there is no risk to groundwater from concrete leakage. If significant pathways are present then impacts which may arise from flow along these pathways shall be designed by the hydrogeologist based on the karst mitigation plan, these may comprise of installing a high permeability zone to replace the groundwater pathways which would be removed by the foundations and / or sealing the linkage from excavation to protect the karst. The design of the mitigation measures shall be approved by a qualified hydrogeologist to confirm that there will be no negative impacts to groundwater.

These above measures will ensure that the risk of pollution of groundwater bodies is controlled. These mitigation measures are employed during construction, the impacts on groundwater quality beneath the site will be of Negligible Magnitude and Imperceptible Significance.

10.6.3 Operational Phase

During the operational phase of the proposed road development inspection and maintenance will occur to ensure that the infiltration basins continue to operate as intended for the design life of the proposed road development. A number of measures were incorporated into the design of the proposed road development to minimise their impact. These have been included in **Section 10.5.4** above and are repeated here for clarity.

In the drainage design, the infiltration basin design uses over excavation below the design invert to place subsoil of an appropriate thickness and material that meets TII Guidelines (TII HD45/15). All of the infiltration basins are more than 15m from surface karst mapped during the karst survey (refer to **Figure 10.1.002**) and will have sealed drainage up to the point of infiltration. All infiltration basins are designed to include the following features:

- A containment area
- A hydrocarbon interceptor
- A wetland

There is also a containment area in each drainage network that can manually be activated to contain spillage on the carriageway.

Networks S19a, S19b and S41 are located on the Lough Corrib Fen 1 (Menlough) GWB, which supports groundwater dependant terrestrial ecosystems (GWDTE) at Coolagh lakes. Due to the sensitivity of the Lough Corrib Fen 1 (Menlough) GWB those drainage networks that drain the carriageway above the GWB, which include S19a and S19b, also have a liner installed to ensure that the treated run-off percolates through the full thickness of the subsoil. S41 is located on a side road with a lower risk of accidental spillage and as such does not include this mitigation measure.

Infiltration basins require regular inspection to confirm that no observable subsidence in the infiltration has occurred due to karst. There are no guidelines on the inspection frequency for infiltration basins, however, based on the mitigation measures implemented the risk of subsidence occurring is considered to be low and inspection is recommended on 5-year frequency.

If karst features and potential pathways are found to be present during inspection, then the Karst Protocol developed for the construction phase will be implemented to ensure that no preferential pathways have formed within the infiltration basin.

10.7 Residual Impacts

The residual impacts are those that will occur after the proposed mitigation measures have taken effect and are shown in **Table 10.26** and **Table 10.27** below. There are no residual hydrogeological impacts to European sites.

Residual hydrogeological impacts remain for groundwater level drawdown impacts below the location of five Annex I habitats on the Galway Granite Batholith.

Table 26: Summary of hydrogeological residual impacts to receptors during the construction phase

10.7.1 Cumulative Impacts

Cumulative impacts are defined as the combination of many minor impacts creating one, larger, more significant impact (NRA, 2009 and EPA 2017). Cumulative impacts consider existing stresses on the natural environment as well as developments that are underway and in planning.

The baseline hydrogeology has identified that the groundwater bodies in the study area have a number of existing stresses in the form of discharges from wastewater treatment systems, septic tanks, road runoff, quarrying and agriculture. These potential pollutant sources have the potential to impact the groundwater environment in the form of reducing water quality by increased contaminants. On the basis of the design and mitigation measures employed for the proposed road development accommodate and maintain the existing GWB sub-catchments then there will be no alteration of groundwater pathways that could modify the impacts from existing pollutant sources.

The following developments being constructed or in planning are considered in terms of the cumulative hydrogeological impact with the proposed road development.

- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)
- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- Galway Harbour Port Extension (planning stage)
- Galway Transport Strategy (GTS)

The zone of influence from the N59 Maam Cross to Oughterard Road Project and N17/N18 projects occurs within separate groundwater sub catchments to those identified for the proposed road development and as such any impacts from these projects will not impact on the groundwater systems that the proposed road development straddles.

The proposed Galway Harbour Port Extension is located within the same GWB sub-catchment as the proposed road development but is located significantly downgradient of the proposed road development in transition coastal waters.

The Galway Transport Strategy includes some realignment of local roads but these do not incorporate cuttings or structures that could impact on groundwater.

The cumulative impact of the proposed road development with existing stresses on the hydrogeological environment and those in development or in planning has been considered. On the basis of the design and mitigation measures employed for the proposed road development there will be no alteration of groundwater pathways and hence no enhanced impact from existing pollutant sources within groundwater bodies. Furthermore, those new developments being constructed or proposed are located in different GWB sub catchments or located significantly downgradient so as not to cumulate impacts.

On this basis the cumulative impacts of the above developments with the proposed road development is negligible.

10.8 Summary

The hydrogeological study area is divided into two main areas on the basis of the contrasting aquifer properties for the two main geological rock types in the region; the Galway Granite Batholith in the west and the Visean Undifferentiated Limestone in the east.

In the western section underlain by granite is a poor aquifer that is only productive in local zones. The combination of poor aquifer and blanket bog cover, where rock is not exposed, limits the quantity of recharge that can infiltrate to ground. The groundwater table remains close to the surface and generally follows topography. The area is divided into two groundwater bodies the Spiddal GWB, which drains to Galway Bay and the Maam-Clonbur GWB which drains to the River Corrib. Groundwater flow in the Galway Granite Batholith is isolated to weathered zones and fracture zones and pathways generally tend to be up to 100m.

In the eastern section the Visean Undifferentiated Limestone is a regionally important karstified aquifer, which is dominated by conduit flow. The aquifer is capable of supplying regionally important abstractions and is associated with the presence of karst landforms and features but also the relatively low abundance of surface water features and man-made drainage. The Visean Undifferentiated Limestone is subdivided into groundwater bodies; Lough Corrib Fen 1 (Menlough), Lough Corrib Fen 3 & 4, Clarinbridge, Clare-Corrib and Ross Lake. Features within the groundwater bodies, including Coolagh Lakes, Ballindooley Lough and the Terryland River are located on valley fill which cause the features to become perched during low groundwater levels.

Groundwater receptors have been identified in both sections and include groundwater resources, groundwater abstractions, groundwater dependent habitat and groundwater dependent surface water features.

The potential impacts of the proposed road development on the hydrogeological receptors including groundwater resources, groundwater supplies, groundwater dependant terrestrial ecosystems and groundwater contributions to surface water have been assessed.

Groundwater Resources and Supplies

Where road cuttings are proposed then part of the aquifer will be removed, however, this amounts to a very small part of the aquifers and will have no perceptible impact on groundwater quantity. The water quality of the aquifers will not deteriorate due to the proposed road development and as such the proposed road development meets the requirements of the European Water Framework directive. The assessment highlights that five wells will be removed by the proposed road development. These wells will be decommissioned based on IGI guidelines.

All wells within 150m of the proposed development boundary (or within 150m of the drawdown zone of influence, whichever is the greater) will be monitored for 12 months before construction, during the duration of construction and for 12 months following completion.

Groundwater Dependant Terrestrial Ecosystems

Potential impacts from the proposed road development have been assessed for the hydrogeological setting of ecological habitats within the study area. The assessment has identified that karst is present in the Visean Undifferentiated Limestone and accordingly a karst protocol has been developed between geotechnical and hydrogeological specialists to mitigate against karst and to remove the risk of impact from the proposed road development encountering karst. There are no significant negative residual hydrogeological impacts to European sites due to the proposed road development.

Groundwater Contributions to Surface Water

Groundwater contributions to surface water have been assessed as part of this study, which has included identification of the surface water that groundwater bodies contribute to. The study has identified that there will be no significant negative impact in the groundwater contribution to surface water.

11 Hydrology

11.1 Introduction

This chapter of the EIAR consists of an appraisal of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, under the heading of hydrology.

This chapter initially sets out the methodology followed (**Section 11.2**), describes the receiving environment (**Section 11.3**) and summarises the main characteristics of the proposed road development which are of relevance to hydrology (**Section 11.4**). The evaluation of impacts of the proposed road development on hydrology are described. (**Section 11.5**). Measures are proposed to mitigate these impacts (**Section 11.6**) and residual impacts are described (**Section 11.7**). The chapter concludes with a summary (**Section 11.8**) and reference section (**Section 11.9**).

This chapter has utilised the information gathered during the constraints and route selection studies for the proposed road development to inform the hydrology impact appraisal. **Sections 4.6, 6.5.4** and **7.6.4 of the Route Selection Report** considered the hydrology constraints within the scheme study area and compared the potential of hydrology impacts of the proposed route options respectively. These assessments and sections of the Route Selection Report contributed to the design of the proposed road development which this chapter appraises.

11.2 Methodology

11.2.1 Introduction

The following section outlines the legislation and guidelines considered and the adopted methodology for the preparing of this chapter.

11.2.2 Guidelines

This chapter has been prepared having due regard to the following guidance documents:

- Environmental Protection Agency (EPA) Guidelines on the Information to be contained in Environmental Impact Statements, March 2002
- EPA Advice Notes on Current Practice in the preparation of Environmental Impact Statements, September 2003
- Draft EPA Guidelines on the Information to be contained in Environmental Impact Statements, September 2015
- Draft EPA Advice Notes on Current Practice in the preparation of Environmental Impact Statements, October 2015
- Draft EPA Guidelines on the Information to be Contained in Environmental Impact Assessment Reports, August 2017

- Surface Water and Drainage Guidance in the National Roads Authority Design Manual for Roads and Bridges
- National Road Authority (NRA) Guidelines on Procedures for the Assessment and Treatment of Geology, Hydrology and Hydrogeology for National Road Schemes (referred to as TII Guidelines in this chapter)
- NRA Environmental Impact Assessment of National Roads Schemes – A Practical Guide, November 2008
- DoEHLG (Nov 2009) Flood Risk Management and the Planning System Guidance document
- Inland Fisheries Ireland (IFI) (2016) Guidelines on protection of fisheries during construction works in and adjacent to waters

The methodology follows the guidance outlined in Section 5.6 of the NRA Guidelines on Procedures for the Assessment and Treatment of Geology, Hydrology and Hydrogeology for National Road Schemes pertaining to the treatment of Hydrology. The impact category, duration and nature of impact have been considered in this assessment. The range criteria for assessing the importance of hydrological features within the study area and the criteria for quantifying the magnitude of impacts are assessed in accordance with the guidelines.

11.2.3 Data Sources and Consultations

The following list of data sources were reviewed as part of this assessment of the impacts on hydrology:

Ordnance Survey Ireland (OSi)

- Discovery Series Mapping (1:50,000) 2017
- Six Inch Raster Maps (1:10,560)
- Six Inch and 25inch OS Vector Mapping
- Orthographic Aerial Mapping 2012 and 2016

Environmental Protection Agency (EPA)

- Teagasc Subsoil Classification Mapping
- Water Quality Monitoring Database and Reports
- Water Framework Directive Classification 2015
- EPA Hydrometric Data System 2017

Office of Public Works (OPW)

- Arterial Drainage scheme land benefitting Mapping for Ireland
- OPW and Drainage District Arterial Drainage Channels and Maintained Channels
- OPW hydrometric Data website 2017
- OPW Floodmaps.ie website 2017

- OPW FSU (Flood Studies Update) Web Portal Site for Flood Flow Estimation
- OPW Preliminary Flood Risk Assessment Mapping (pFRA) 2011
- OPW Draft CFRAM Flood Risk Mapping, draft hydrology, hydraulics and flood risk management reports 2016

Galway County/City Council

- Galway County Development Plan (2015 – 2021)
- Galway City Development Plan (2017 – 2023)
- Galway Transport Strategy (2016)
- Planning Register
- Water Services Section

National Parks and Wildlife Service (NPWS)

- Designated Areas Mapping
- Site Synopsis Reports
- Conservation Objectives Documents

Other sources

- Western River Basin Management Plan (2009 – 2015)
- Aerial survey photography and Lidar
- Geological Survey of Ireland (GSI) Web Mapping
- Specially commissioned bathymetric surveys
- Topographical survey

Consultation took place with all relevant regulatory bodies including various departments of Galway County Council, Galway City Council, the OPW, GSI, National Parks and Wildlife Service (NPWS) and IFI.

11.2.4 Study Area and Baseline Data Collection

The extents of the study area are defined for the hydrology assessment as the lands within a 250m buffer of the proposed development boundary and the associated upstream and downstream catchments as shown on **Figures 11.101** to **11.114**.

Field surveys and walkover assessments were carried out to assess the hydrological impacts of the proposed road development. Detailed stream surveys (including topographical surveys where required) were undertaken at areas where hydrological impacts were likely to occur without appropriate mitigation. Specifically, all culvert and bridge crossing locations, proposed road drainage outfall locations and ecologically sensitive areas were visited and field measurements carried out along with reconnaissance of potential flood risk areas, including site visits during the December 2015/January 2016 winter flood event. The long duration rainfall and flooding in the River Corrib were notable and estimated flood flows in the River

Corrib were the worst since completion of the Salmon Weir Barrage in 1959 and the recorded flood magnitude at the Dangan Gauge represents c. 30 to 50year return period event.

Surface water quality monitoring was carried out of all main watercourses associated with the potential outfall receptors. Flow estimation in selected outfall streams was also conducted as were targeted bathymetric surveys of Coolagh Lakes, Ballindooley Lough and the River Corrib mainline channel.

11.2.5 Impact Assessment Methodology

The Hydrological Impact Assessment Methodology follows the guidance outlined in Section 5.6 of the TII Guidelines pertaining to the treatment of Hydrology. The Impact category, duration and nature of impact have been considered in this assessment. The range criteria for assessing the importance of hydrological features within the study area and the criteria for quantifying the magnitude of impacts are assessed in accordance with the TII Guidelines.

The hydrological assessment has been prepared by expanding and updating the desk study work carried out for constraints and route selection studies. It includes an assessment of published literature available from various sources including a web based search for relevant material. Site specific topographical information and aerial photography has been reviewed to locate any potential features of hydrological interest. These features have been investigated on the ground by walkover surveys to assess the significance of any likely environmental impacts on them.

Available topographical and hydrometric information (field and desk based) has been used to perform hydrological impact assessments of all required culvert crossings of existing watercourses and proposed outfall locations to existing streams and stormwater sewers. All watercourses and water bodies which could be affected directly (i.e. crossed or realigned/diverted) or indirectly (i.e. generally lie within 250m of the proposed development boundary or would receive storm runoff from the proposed road development) were assessed through a series of initial walkover visits followed up by a more detailed survey and hydrological assessment. Due to the nature of the hydrological environment, it is necessary to consider the larger river catchment environments that the proposed road development traverses.

The assessment of hydrological impacts for the proposed road development has been based on the analysis and interpretation of the data acquired during constraints and route selection studies, as well as site specific investigations undertaken as part of the EIA studies, including the ecological study, hydrogeological surveys, ground investigations, agricultural survey, topographical survey and hydrological walkover and surveys.

The key hydrological attributes identified along the proposed road development include:

- European designated sites including: Lough Corrib candidate Special Area of Conservation (cSAC), Galway Bay Complex cSAC, Inner Galway Bay SPA, and Lough Corrib SPA

- Annex I water dependant habitats
- Surface drinking water supply abstraction source from River Corrib at Jordan's Island
- Ecologically sensitive surface water features and catchment systems, fishery streams either locally or downstream, Fens, flushes and wetlands etc.
- Flood Risk Areas

These assessments included the potential hydrological impacts on European sites of the Galway Bay Complex cSAC), Inner Galway Bay SPA, Lough Corrib cSAC and Lough Corrib SPA and also of Ballindooley Lough which provides supporting habitat for birds within the Inner Galway Bay and Lough Corrib SPAs. Other neighbouring European sites such as Connemara Bog Complex cSAC, East Burren Complex cSAC, and Lough Fingall Complex cSAC are not hydrologically linked to the study area of the proposed road development. Other European sites such as, Black-Head-Pouallagh Complex cSAC and Inishmore cSAC, Inishmaan cSAC and Inis Oirr Islands cSAC which share the West of Ireland coastal waters are considered sufficiently remote that even a worst-case pollution event would have no perceptible impact given the travel time involved and the extensive dilution available.

The individual importance of these attributes has been then assessed with respect to their quality, extent / scale and rarity as set out in **Table 11.1** below.

Table 11.1: Criteria for Rating Site Attributes

Importance	Criteria
Extremely High	Attribute has a high quality or value on an international scale
Very High	Attribute has a high quality or value on a regional or national scale
High	Attribute has a high quality or value on a local scale
Medium	Attribute has a medium quality or value on a local scale
Low	Attribute has a low quality or value on a local scale

Types of hydrological impact fall into two broad categories of quantitative and qualitative impacts.

11.2.5.1 Quantitative Impacts

Hydraulic structures such as bridges, culverts, channel diversions and outfalls can, if not appropriately designed, impact negatively on upstream water levels and downstream flows. If a bridge or culvert opening is too narrow or a diversion channel undersized it may impede flow during times of floods thus causing water levels upstream of the structure to be raised above what would occur in the absence of the structure. If instream culvert structures and associated channel diversions and transitions are too wide or steep this can significantly affect the mean and low flow regime of the stream in terms of velocity and water depth changes resulting in low velocities and low water depths which can alter the local sedimentology and flow regime resulting in benthic impacts and potential fishery impacts.

In the design of the proposed road development, the adequacy of culvert sizes for local drainage areas and small river catchments is based on providing conveyance for the 100year return period flood event with recommended climate change allowance in accordance with OPW requirements. Blockage potential and maintenance requirements are also considered and are often the overriding design factor for small stream crossings. In this respect, the design flow used is based on gauged flow data, where available, and/or the upstream catchment characteristics of the crossing including:

- Catchment area
- Annual average rainfall for the catchment
- Mean channel slope (S1085)
- Soil type
- Flood Studies Report (FSR) 100-year flood growth factor of 1.96
- FSU catchment descriptors to estimate the annual index flood (Qmed)
- FSU pooling group flood growth factors

Each method included the standard factorial error for the related estimation method (Institute of Hydrology Report No. 124 3-variable equation (IH-124) = 1.65, Flood Studies Update (FSU) catchment descriptor flood estimation equation = 1.38). A climate change allowance of 20% increase on flows was also included in all flood flow estimations as is currently considered best practice.

Surface water drainage from the proposed carriageway, grassed margins/verges and embankment slopes can lead to localised increased flows and flooding in the receiving streams if not dealt with appropriately. The proposed drainage system is a combination of piped drains and carrier pipes, concrete surface water channels, slot drains, grassed surface water channels, and filter drains where permitted, which convey storm runoff to one of the various surface outfall locations located along the length of proposed road development.

11.2.5.2 Qualitative Impacts

Depending on the hydrological and ecological sensitivities of the receiving waters of the proposed drainage outfall, treatment of the storm water via online or offline detention / water quality improvement ponds are required upstream of the outfall to protect the water quality particularly from spillage and first flush events. The potential contaminant load and accidental spillage risk for a single outfall and sub-catchment area is a function of the design traffic and road pavement area and length.

11.3 Receiving Environment

11.3.1 Regional Overview of Hydrology

The proposed road development connects to the R336 Coast Road west of Bearna Village, passes to the north of Galway City and joins the existing N6 at Coolagh, Briarhill. It crosses the River Corrib near Menlo Castle on the eastern bank and on the western side it passes through National University of Ireland Galway (NUIG) Sporting Campus at Dangan. The River Corrib channel at the crossing site is within the Lough Corrib candidate Special Area of Conservation (cSAC) (000297) as are the Coolagh Lakes further to the southeast. The Lough Corrib SPA boundary includes Lough Corrib and extends down the River Corrib channel to north of Dangan. One proposed road drainage outfall from the proposed N59 Link Road North discharges into the Lough Corrib SPA and Lough Corrib cSAC designated waters. All remaining outfalls for the proposed road development are located downstream of the Lough Corrib SPA, with two proposed road drainage outfalls discharging directly into the Lough Corrib cSAC and the drainage from the proposed NUIG pitches also indirectly discharging to the Lough Corrib cSAC. The proposed road development lies within the OPW/EPA's hydrometric areas 29, 30 and 31.

The proposed road development intercepts several watercourses principally to the west of the River Corrib which will require culverting to maintain existing hydraulic connectivity. To the east of the River Corrib due to the highly karstic nature of the terrain there is a very sparse network of surface water drainage channels, ditches and stream channels. Rainwater generally infiltrates to ground through the limestone till and weathered karstified limestone bedrock, rather than directly running off as overland flow. Consequently, only one dry ditch was noted as being intercepted by the proposed road development near the Coolagh Lakes to the east of the River Corrib. Whereas, to the west of the River Corrib, the bedrock and quaternary changes to a more impervious type due to the underlying granite bedrock (east of N59 Moycullen Road) resulting in a much higher density of surface water drainage features with little ability for rainwater to infiltrate to groundwater. This gives rise to wetter conditions with peatlands and marshy areas quite common along the route of the proposed road development.

All of the rivers, streams, drains, lake features and groundwater bodies along the route of proposed road development eventually outfall into Galway Bay via the River Corrib Estuary or directly and indirectly to coastal and transitional waters via the coastal watercourses or via groundwater flow through both diffuse and preferential karst conduit flow pathways. The transitional waters (estuarine waters whose salinity is diluted by the River Corrib outflow and other smaller streams) are located between Salthill to the west and Roscam headland to the east and extend southwards to approximately 0.5 to 1km south of Mutton Island. The designated coastal waters of Galway Bay extend from Blackrock in Salthill east to Roscam Headland and Roscam Point. East of Roscam Point, the Oranmore Bay Transitional Waters are located.

The study area falls within the Western River Basin District (WRBD). The WRBD has classified the transitional coastal waters as good status, the coastal waters as moderate status and Lough Corrib as moderate lake quality (previously classified as poor). The majority of the watercourses and lakes within the study area do not have their status assigned (this includes Coolagh Lakes and Ballindooley Lough and all of the western watercourses). The only watercourses that have been classified are the Terryland River which has a water quality status of poor, the River Corrib which has a status of good and the lower reach of the Bearna Stream which was previously given a pass classification and is currently unassigned. However, all waterbodies within the study area, designated or otherwise, are treated as sensitive. The design approach to waterbodies is to maintain or improve the hydrological regime. This aligns with the objectives of the Water Framework Directive and the Western River Basin Management Plan to achieve Good status for all of its surface watercourses.

The groundwater bodies (GWBs) encountered by the proposed road development are the poorly productive bedrock GWB in the granite bedrock formations to the west of the N59 Moycullen Road and regionally important karst conduit flow limestone bedrock GWB to the east of the N59 Moycullen Road. The groundwater quality classification is good for the entire study area and wider catchment, but the karst GWB's are identified as at risk of not achieving good status whereas the poorly productive bedrock GWB to the west of the N59 Moycullen (Spiddal and Maam-Clonbur GWBs) are expected to achieve good status. For further details, refer to **Chapter 11, Hydrogeology**.

11.3.2 Climatological Data

The mean long term annual rainfall (SAAR) for the proposed road development varies slightly with a tendency for increased rainfall from east to west. The SAAR value for the Bearna area is typically 1275mm, whereas at the River Corrib crossing point, it is 1250mm and in the Ardaun / Doughiska area it is 1140mm.

The Annual Potential Evapotranspiration Rate based on the Athenry Meteorological Station is 508mm and for the Mace Head Station it is 562mm. The Athenry Station is considerably more suitably located to the proposed road development than the Mace Station and therefore considered more applicable. Combining this with the annual rainfall, the typical effective rainfall rate for recharge and runoff is calculated as 714mm.

The Met Éireann Rainstorm Depth-Duration-Frequency Model for the Galway City area is presented below in **Table 11.2** for durations of 0.25hrs to 25days and return periods of 2 to 200years (Annual Exceedance Probability (AEP) 50% to 0.5%).

Table 11.2: Rainstorm Depth-Duration-Frequency Relationship for the Galway City Area

11.3.3 Hydrological Drainage Features

There are five principal hydrological drainage catchments and their sub-catchments intercepted/potentially impacted by the proposed road development which are labelled from west to east as follows (refer to **Figures 11.1.101** and **11.1.114**):

1. Sruthán Na Libeirtí Stream
2. Trusky Stream
3. Bearna Stream
4. Knocknacarra Stream
5. Corrib Catchment
    a. River Corrib
    b. Coolagh Lakes
    c. Terryland River
    d. Ballindooley Lough System

There are six downstream sub-catchments that also discharge to the Galway Bay Complex cSAC and Inner Galway Bay SPA, namely Lough Atalia, Doughiska, Curragreen, Galway City Coastal, Roscam and Glenascaul drainage areas. These small drainage catchments are located on the eastern side of the River Corrib within the karst limestone bedrock formation and do not have surface drainage features. Effective rainfall from these catchments drains to groundwater or is intercepted by the existing urban storm drainage systems.

Two very minor coastal streams / drains exist at An Baile Nua, Bearna which drain directly into the sea at Bearna.

11.3.4 Hydrological Catchments

11.3.4.1 Sruthán na Libeirtí

Sruthán na Libeirtí is a small stream which rises in a peatland land area 2km north of the R336 Coast Road and flows southwards to the coast outfalling to Galway Bay 2km west of Bearna Village at Cora na Libeirtí at An Baile Nua. This stream is unmaintained, narrow (typically 0.5m to 1m wide) and shallow < 0.5m.

Sruthán na Libeirtí has a catchment area of 1.5 km^2 and high percentage runoff due to its generally impermeable overburden cover and shallow bedrock. There are no sources of gauged flood flow information for this stream given its very minor scale, but this watercourse has been included in the Flood Studies Update (FSU) for flood flow estimation of the index Flood flow magnitude (mean and median flow magnitude) based on catchment descriptors for a number of prediction points along the stream reach.

Table 11.4: FSR Catchment Characteristics for the Sruthán na Libeirtí

Catchment Characteristic	
AREA (km^2)	1.47
Annual Rainfall SAAR (mm)	1300
Winter Rainfall Acceptance potential SOIL Index	0.3 (type 2)
Channel Flood Slope S1085 (m/km)	25.0
URBAN – fraction of catchment	0%

Table 11.5: FSU Catchment Descriptors for the Sruthán na Libeirtí (Source OPW FSU Web Portal Site)

Catchment Characteristic	
AREA (km^2)	1.47
Annual Rainfall SAAR (mm)	1281
FARL	1.0
BFISOIL Baseflow Index of Soils	0.4512
Drainage Density DRAIND km per km^2	2.999
Channel Flood Slope S1085 (m/km)	25.08
Arterial Drainage Factor ARTDRAIN2	0.0
URBAN – fraction of catchment	0.0098

QMED rate =1.135cumec (0.77cumec per km2 representing a moderately high runoff rate)

Note FSR is the Flood Studies Report completed in 1975 and supplementary studies carried out in the late 1970's, 1980's and 1990's for estimating flood flow magnitudes ingauged and ungauged catchments and the FSU represents the OPW Flood Study Update method completed in 2105 succeeds the FSR method.

11.3.4.2 Trusky Stream

The Trusky Stream which flows through Bearna is a relatively small stream having a catchment area of $3.3km^2$ and outfalls to Galway Bay at Bearna Harbour. This stream has two main branches, one to the east of the harbour road and one to the west. The stream channel has been culverted and modified through Bearna Village and crosses under the R336 Coast Road in two culverts; an original arch culvert near the Twelve Pins Hotel and a concrete piped culvert, located approximately 170m to the east. This stream potentially represents a flood risk to the village and R336 Coast Road at these culvert crossings as a result of potential debris blockage. This stream rises in peatland to the south of Lough Inch and flows typically southwards 2.5km to the harbour. The channel is not maintained, very vegetated and varying in width (0.5 to 1m channel widths) in its middle and upper reaches. The channel through the lower reach has been significantly modified with sections of culverting and new channel to facilitate urban development. Unlike the Sruthán na Libeirtí, the percentage runoff is moderate to low.

Table 11.6: FSR Catchment Characteristics of the Trusky Stream

Catchment Characteristic	
AREA (km^2)	3.3
Annual Rainfall SAAR (mm)	1300
Winter Rainfall Acceptance potential SOIL Index	0.3 (Type 2)
Channel Flood Slope S1085 (m/km)	21.9
URBAN – fraction of catchment	0%

Table 11.7: FSU Catchment Descriptors of the Trusky Stream (Source OPW FSU Web Portal Site)

Catchment Characteristic	
AREA (km^2) (corrected error in FSU)	3.3
Annual Rainfall SAAR (mm)	1293
FARL	1.0
BFISOIL Baseflow Index of Soils	0.6877
Drainage Density DRAIND km per km^2	1.128
Channel Flood Slope S1085 (m/km)	18.4
Arterial Drainage Factor ARTDRAIN2	0
URBAN – fraction of catchment	0.0622

The median flood flow (Qmed) estimate for this stream from the FSU is 1.26cumec (representing a runoff rate of 0.38cumec per km^2 which is a moderate to low flood runoff rate).

11.3.4.3 Bearna Stream

The Bearna Stream is the largest of the small watercourses encountered by the proposed road development entering Galway Bay cSAC and Inner Galway Bay SPA near Rusheen Bay. Its catchment area measures only 9.1km^2 to its sea outfall in Rusheen Bay and its main tributaries are the An Sruthán Dubh and the Tonabrocky Streams. This river system rises in the townlands of Pollnaclogha, Drum and Tonabrocky 4km to the north. It is an unmaintained stream which in sections is very overgrown particularly in its middle and upper reaches. Flooding is not a significant issue for this stream. The percentage runoff based on overburden and land slope is moderate to low in magnitude.

Table 11.8: FSR Catchment Characteristics of the Bearna Stream

Catchment Characteristic	
AREA (km^2)	9.1
Annual Rainfall SAAR (mm)	1290
Winter Rainfall Acceptance potential SOIL Index	0.3 (Type 2)
Channel Flood Slope S1085 (m/km)	13.5
URBAN – fraction of catchment	0.5%

Table 11.9: FSU Catchment Descriptors of the Bearna Stream (Source OPW FSU Web Portal Site)

Catchment Characteristic	
AREA (km^2)	9.14
Annual Rainfall SAAR (mm)	1292
FARL	0.979
BFISOIL Baseflow Index of Soils	0.601
Drainage Density DRAIND km per km^2	1.422
Channel Flood Slope S1085 (m/km)	0.1
Arterial Drainage Factor ARTDRAIN2	0.0
URBAN – fraction of catchment	0.05

The estimated QMED median Flood flow is 3.41cumec representing a moderate to low runoff rate of 0.37cumec per km^2.

11.3.4.4 Knocknacarra Stream

The Knocknacarra Stream is a small and highly urbanised stream that discharges to Galway Bay Complex cSAC and Inner Galway Bay SPA near Blakes Hill in Salthill. A large portion of its lower reach is culverted almost to its sea outfall and forms part of the Galway City storm drainage system. It rises to the north of Rahoon at Letteragh and flows southwards over a distance of 3km to the sea. It would be considered a highly urbanised watercourse with an urban fraction of almost 50%.

Table 11.10: FSR Catchment Characteristics of the Knocknacarra Stream

Catchment Characteristic	
AREA (km2)	4.4
Annual Rainfall SAAR (mm)	1240
Winter Rainfall Acceptance potential SOIL Index	0.3 (Type 2)
Channel Flood Slope S1085 (m/km)	10.0
URBAN – fraction of catchment	49%

Table 11.11: FSU Catchment Descriptors of the Knocknacarra Stream River (Source OPW FSU Web Portal Site)

Catchment Characteristic	
AREA (km^2)	4.38
Annual Rainfall SAAR (mm)	1239.6
FARL	1.0
BFISOIL Baseflow Index of Soils	0.61
Drainage Density DRAIND km per km^2	0.757
Channel Flood Slope S1085 (m/km)	10.01
Arterial Drainage Factor ARTDRAIN2	0.0

Catchment Characteristic	
URBAN – fraction of catchment	0.5

The estimated QMED median Flood flow is 2.82cumec representing a moderate runoff rate of 0.644cumec per km^2. This runoff rate almost doubled over the rural greenfield runoff due to significant size of the urbanised catchment fraction.

11.3.4.5 Terryland River

The Terryland River also known as the Sandy River is a small drainage system that essentially drains the Terryland Basin with a total catchment area of 6.75km^2. The stream's outlet is to groundwater via two swallow-holes located at Poulavourleen, west of Castlegar Village. Old historic maps of Galway (Grand Jury Map 1819) show that this stream was a spur off the River Corrib channel and the valley floor was almost a lake bed during winter flooding. Arterial drainage works as part of a Public Works Corrib Drainage and Navigation Scheme were carried out in the 1850's and as part of these works constructed the Dyke Road embankment to prevent flooding from the River Corrib and allow the reclamation of the Terryland Valley for farmland. Today, this embankment and the Salmon weirs gated controls protect important commercial, industrial and retail developments that include the Galway Retail Park, Galway Shopping Centre, Terryland Shopping Centre, Terryland Retail Park and Liosbán Industrial Estate.

A water intake from the River Corrib, near Jordan's Island, provides controlled inflow from the River Corrib to feed the city water supply at the Terryland Galway City Water Treatment Works with the excess discharging to the Terryland River. This inflow from the River Corrib to the Terryland River in terms of stream flow is relatively small and not significant in respect to flood flow contribution. The watercourse is partially tidal with the tidal signal (0.7 to 0.8m range on spring tides and 0.3 to 0.4m range on neap tides upstream of the swallow-holes) evident and particularly so on spring tides which produces an almost reversal in flow direction coinciding with the flooding and ebbing spring tides (Terryland River Valley Drainage Scheme Report, 1998). These swallow holes are believed to discharge to Galway Bay but the location of the outlet in Galway Bay is unknown. The integrity of these swallow holes is unknown. Ballindooley Lough is considered to be part of the Terryland catchment but this connection has not been proven. The connection may be possible through the groundwater flow as Ballindooley Lough is at the base of an enclosed depression.

The inflow from the River Corrib is via a manmade channel referred to as the Galway Bore which is also the abstraction / intake channel to the Terryland Water Treatment Plant. The excess flow overspills with a fall of 3m to the Terryland River Basin. Historical maps (1819) show the entire Terryland River Valley as inundated and part of the River Corrib system. The capacity of the swallow-holes is unknown and a previous 1998 KT Cullen Study for Galway City Council recommended that development levels are set above 7m OD which is equivalent to the River Corrib level in severe flood (> 100year Return Period in River Corrib upstream of Salmon Weir Barrage). The CFRAM model study makes certain assumptions with predicted levels significantly lower at 3.4 and 4.94m OD for the 100 and 1000-year events for the Terryland River Valley.

Table 11.12: FSR Catchment Characteristics of the Terryland River

Catchment Characteristic	
AREA (km^2)	6.75
Annual Rainfall SAAR (mm)	1160
Winter Rainfall Acceptance potential SOIL Index	0.15 (type 1)
Channel Flood Slope S1085 (m/km)	0.4
URBAN – fraction of catchment	0.44

Table 11.13: FSU Catchment Descriptors of the Terryland River (Source OPW FSU Web Portal Site)

Catchment Characteristic	
AREA (km^2)	6.75
Annual Rainfall SAAR (mm)	1163
FARL	1
BFISOIL Baseflow Index of Soils	0.5726
Drainage Density DRAIND km per km^2	0.529
Channel Flood Slope S1085 (m/km)	0.435
Arterial Drainage Factor ARTDRAIN2	1.0
URBAN – fraction of catchment	0.435

The estimated QMED median flood flow is 1.92cumec representing a moderate flood runoff rate of 0.284cumec per km^2. This runoff rate almost doubled that of a greenfield rural catchment due to significance of the urbanised fraction at 43.5%. The capacity of the swallow-holes is unknown, but to date have been sufficiently ample as not to result in any significant inundation of the basin area.

11.3.4.6 River Corrib

The River Corrib is essentially a short outflow channel from the Lough Corrib to the sea at the Claddagh, Galway. The Corrib Navigation and Drainage Works (1848-1858) excavated a new wide outlet channel from Lough Corrib known as the Friar’s Cut which provides a more direct and deeper channel to service the lough than the meandering old channel (almost 1.5km shorter). Significant excavation of the River Corrib channel has taken place both during the original Corrib Drainage and Navigation Scheme and during the OPW Corrib-Clare Arterial Drainage Scheme (in the early 1960’s).

The area of the River Corrib catchment is approximately 3,136 km^2 to Wolfe Tone Bridge and 3121km^2 to Dangan Gauge based on DTM elevation data. This catchment area is quite large by Irish standards and is the biggest river system in the Western River Basin District. This includes a total lake surface area of approximately 314km^2 mainly due to Lough Corrib and Lough Mask but also includes Lough Carra, Finny Lakes and Maam Lakes which attenuate winter flood flows and sustain summer low flows. The register of hydrometric gauges has the catchment area to Wolfe Tone Bridge of 3111km^2 which is slightly less than the FSU estimate.

The River Corrib channel is a navigation channel and is reasonably wide, varying typically from 80m to 130m between river banks and typically 3 to 4 m deep. It is an impounded channel with levels maintained generally close to 6m OD Malin throughout the year by the gated weir at the Salmon Weir.

Table 11.14: Exceedance Percentile at Dangan Gauge

Exceedance Percentile at Dangan Gauge				
1%	5%	50%	95%	99%
6.75mOD	6.32mOD	5.91mOD	5.75mOD	5.70mOD

Much of the channel has been excavated with bed levels at the proposed road development crossing point at 2.75m OD, providing a flow area at summer 99-percentile low flow of 300m^2 and a channel velocity of 0.04m/s.

The River Corrib for flow estimation is gauged at Wolfe Tone Bridge which is a strategic location as it captures the total flow from the Corrib system before entering the bay. This site is tidally backwatered and the flow rating is considered only fair. Flow estimates from this gauge are currently not available due to difficulties and inconsistencies with the rating relationship identified in the gauged record dating back as far back as 2002. As part of the flood risk assessment for the proposed road development a reasonably consistent flood rating relationship was derived for the Dangan Gauge using the OPW flood rating measurements and recorded flood level flooding stage when all gates on the Salmon Weir are opened, which generally applies to winter maximum floods. This rating provided a QMED (2year return period) flow at Dangan of 264.4cumec (gauged period 1986 to 2015). The OPW CFRAM study produced a QMED estimate of 248cumec and the FSU estimate is 244cumec (both based on the Wolfe Tone Bridge gauge data for the record period pre 2002).

The statistical analysis of a derived annual maximum flood flow series for the Dangan of 264.4cumec is considered more reliable than the FSU and CFRAM estimates as it includes the more recent and wetter period post 2002 and avoids using the Wolfe Tone gauge whose rating is inconsistent. The flow duration curve for Wolfe Tone Bridge gauge (OPW hydrometric section) for the period 1970 to 1997 gave a median (50%) flow of 82cumec, a 95% low flow of 24.6cumec and a 99% low flow of 9.1cumec. The EPA Hydrological data publication (1995) for the record period 1970 to 1991 gave an average flow of 95.3cumec and a 95% low flow of 16.9cumec.

A study undertaken by the Department of Hydrology University College Galway (UCG) (now known as NUIG), (1985) as part of their investigation into the hydropower potential of the waterways of Galway City, developed a flow duration curve for the River Corrib at Wolfe Tone Bridge gauge (using OPW flow data from 1950 to 1980), which gave a mean flow rate of 82.5cumec and the lowest recorded flow of 8.9cumec (occurring in 1962). This flow duration curve gave median flow of 74.4cumec, 95-percentile low flow of 14.1cumec and a 99-percentile low flow of 12.13cumec. It should be noted that the period 1950 to 1980 in terms of rainfall would have represented a drier period than 1980 to present day and therefore the flow estimates are lower, particularly for the 1970's and 1950's which were the driest decades. For the purpose of this study, the lower estimates of low flow using a 99-percentile of 12cumec and a 95-percentile of 14cumec will be used. These low flow estimates assume the worst case dilution volumes for the receiving water body in respect to proposed road drainage discharges.

Table 11.15: FSU Catchment Descriptors of the River Corrib to Dangan (Source OPW FSU Web Portal Site)

Catchment Characteristic	
AREA (km^2)	3121
Annual Rainfall SAAR (mm)	1423.6
FARL	0.661
BFISOIL Baseflow Index of Soils	0.781
Drainage Density DRAIND km per km^2	0.94
Channel Flood Slope S1085 (m/km)	0.568
Arterial Drainage Factor ARTDRAIN2	0.411
URBAN – fraction of catchment	0.004

The FSU estimated QMED flood flow for the Corrib at Wolfe Tone is 244cumec representing a relatively low flood runoff rate of approximately 0.078cumec per km^2. The recommended QMED estimate based on the Dangan Gauge is 264.4 giving a slightly higher flood runoff rate of 0.085cumec per km^2.

The typical winter-summer water level range is 0.6m (typically 5.7m to 6.3m OD). The River Corrib channel at Dangan is approximately 110m wide and the channel bed invert near the crossing is typically 2.6 to 2.8m OD giving a flow depth of 3m and a total flow area of $312m^2$ at 5.7m OD and $403m^2$ at 6.3m OD. At a low flow (95-percentile) of 14cumec the average channel flow velocity is small at 0.044m/s and in typical winter flows the average velocity is 0.675m/s.

11.3.4.7 Ballindooley Lough

Ballindooley Lough is an enclosed lough located on the N84 Headford Road at Ballindooley, on the outskirts of Galway City. The lough forms at the floor of a large enclosed depression having a surrounding topographical catchment area of $2.25km^2$. The recent December 2015/January 2016 flood event, during which water levels peaked on the 2 Jan 2016, produced possibly the highest flood levels in at least 50 years both within this system and within the River Corrib system, with the maximum flood level recorded at 10.29m OD Malin. The typical summer lake low water level is approximately 1.5m lower at c.8.8m O.D. and in more severe drought conditions it is likely that lake levels fall below 8.5m O.D. This suggests that the more extreme annual range in lake level is of the order of 2m but for a typical year it is likely to be between 1 and 1.5m.

During the recent December 2015/January 2016 flood event, maximum winter flood levels both in the River Corrib and Lough Corrib reached 6.93m OD and

7.27m OD respectively and water levels in the Terryland Basin near Castlegar were below 4m OD.

A bathymetric survey of the Ballindooley Lough as part of this study showed that the deepest part of lake has a bed level of -2.5m OD Malin (i.e. 2.5m below mean sea level) whereas the overbank floodplain area is typically at an elevation of 9.3 to 9.5m O.D. This bed level suggests that at its deepest location, the water depth is 12m.

At the maximum recorded flood level of 10.29m OD, the surface area of the lake expands to 29.7ha and at the summer low water level of 8.5m OD it reduces to c. 4.5ha (4.2ha main lake and 0.3ha small pond to the southwest, both connected via a 3m wide and 250m long drain). There is over 2.4km of drainage channel draining the floodplain area of this lough, which feeds into the permanent lake. This drainage channel is reasonably maintained and typically the cross-section dimensions are 1.5 to 2m deep and 3m top width. The live storage volume between the winter high of 10.3m OD Malin and the summer low level of 8.5 is 271,500m^3. Approximately 500mm of rainfall (recorded at Met Éireann gauge in Athenry) fell in November and December 2015 and resulted in Ballindooley Lough rising by 1.3m from c. 9m OD to 10.3m OD. This represents a change in lake storage volume of almost 250,000m^3, which is 22% of the recorded rainfall depth over the 2.25km^2 catchment area.

The recession characteristics of the recorded lake levels indicate that the water level empties slowly (falls) by typically 0.8 to 1cm per day with almost similar recession characteristics at both high and low lake levels. In the summer period this fall is likely to represent evaporation losses from the lake surface. This slow almost constant like fall in levels suggests an emptying process influenced by the slower more continuous regional groundwater flow with the lake rising and falling with the groundwater table as opposed to a concentrated point (conduit flow via a swallow hole) outflows. The hydrological monitoring indicates that the lake is perched above the surrounding groundwater table in summer dry periods and influenced by the groundwater table in the wetter winter period. The proposed road development in terms of the groundwater table and groundwater flow is located down gradient of Ballindooley Lough. This feature is explained further in **Chapter 10, Hydrogeology**.

11.3.4.8 Coolagh Lakes

The Coolagh Lakes are part of the River Corrib system and are located within the Lough Corrib cSAC. The lake level within Coolagh Lakes is significantly influenced by the River Corrib water levels and the control imposed by the OPW at the Galway City Salmon Weirs Barrage (regulation 5.82 to 6.43m O.D. which is achieved approximately 85% of the time). This is not always achievable particularly during extreme flood events with lake levels exceeding the regulation levels. The periodic closure and opening of gates by the OPW creates inflow and outflow to the lakes in particular to the outer lake which provides additional flushing to the natural local catchment inflows. The water level in the Coolagh Lakes increases until it has positive head to outflow to the River Corrib channel upstream of Jordan’s Island via its small narrow outflow channel.

A bathymetric survey of the River Corrib and Coolagh Lakes revealed very deep bed levels within the middle of the two lakes with the deepest part of the lakes at c. -10 and -12m OD Malin respectively. This represents a maximum water depth of 16.5 and 18.5m for the inner and outer lakes respectively. Flow velocities within these lakes are very small with mixing principally by thermal differences and surface wind dynamics. These lakes are likely to represent a permanent sink for sediment if it were to enter such a system. The estimated winter 1-percentile water level for Coolagh Lakes is 6.75m OD producing an inundation area of 36ha, whereas the 99% exceedance summer low flow level is 5.73m OD with a lake area of 6.8ha.

The local catchment area draining to these lakes based on the topography is approximately 2.5km^2. Other deeper groundwater connections to karst areas to the northeast and east cannot be ruled out. Spring flow is evident in the Coolagh Lakes at two spring locations to the east and to the north. The mean annual inflow rate to the lakes is estimated to be approximately 30l/s based on water balance calculations. The low flow (95%-percentile) contribution is potentially as low as 2 to 3l/s. The bathymetric survey data for the lake is used to estimate the lake storage-stage relationship which for a summer low water level of 5.7m OD is c.630,000m^3 with a combined lake surface area upper and lower lakes) of c. 6.8ha (i.e. the permanent lake volume). Further storage volume and surface area statistics are presented below in **Table 11.16**.

Table 11.16: Percentile Lake levels, surface areas and storage volumes in the Coolagh Lakes system

Percentiles	1%	5%	50%	95%	99%
Lake level	6.64mOD	6.24mOD	5.86mOD	5.73mOD	5.70mOD
Area	36.0ha	30.4ha	10.9ha	7.2ha	6.8ha
Volume	801,000m^3	694,500m^3	649,000m^3	639,000m^3	637,000m^3

The annual winter-summer difference in storage volume (represented by the difference between the 1 and 99-percentile water levels) is 164,000m^3, therefore the average flushing ratio of this lake system by the River Corrib summer-winter water level variation is approximately 4 years at 5l/s. The natural flushing effect of recharge from the local catchment area is significantly higher at 0.7 years (250 days) at a mean annual inflow of 30l/s and the combined effect of the local recharge and the River Corrib is of the order of 35l/s producing an average hydraulic retention period of 215 days. These hydraulic retention times suggest moderate flushing time / exchange rate for a lake system.

The fringes of Coolagh Lakes dry out and only get inundated in winter by the River Corrib water levels. Alkaline fen habitat has been identified surrounding the lakes which are fed by groundwater flow and seepages. The waters within the lakes are quite alkaline with the hardness values recorded in excess of 200 mg/l $CaCO3$ and the pH at 7.8 to 8.2.

11.3.5 Surface Water Ecological Status

The locations of the watercourses and their catchment areas encountered along the proposed road development are given in **Figures 11.1.101** to **11.1.114**.

Given the European designation and salmonid status of the River Corrib (part of the Lough Corrib cSAC and Lough Corrib SPA) it is considered to be of International Status with an extremely high attribute value. The River Corrib catchment size is 3136km^2 to Wolfe Tone Bridge. The remaining watercourses encountered within the study area are all minor watercourses, with all such streams having catchment areas of well less than 10km^2, the streams are listed below:

- Coastal Streams at Baile Nua (<0.75km^2)
- Sruthán Na Libeirtí (1.5km^2)
- Trusky Stream (3.3km^2)
- Bearna Stream (9.14km^2)
- Knocknacarra Stream (4.4km^2)
- Terryland Stream (6.7km^2)

These watercourses generally have ecological attribute value of locally higher value.

The Galway Bay Complex cSAC and Inner Galway Bay SPA are coastal/transitional waters with the European designated waters commencing east of White Strand beach.

The Sruthán Na Libeirtí and Trusky Stream and the two minor watercourses at An Baile Nua, Bearna, that outfall to the sea near Bearna do not directly discharge to the Galway Bay Complex cSAC. The remaining streams, that the proposed road development traverse, all outfall directly into the Galway Bay Complex cSAC. The tidal circulation of the coastal waters off Bearna will eventually mix and on the flooding tides potentially enter the Galway Bay Complex cSAC. Therefore, the proposed drainage of the proposed road development will eventually drain into the Galway Bay Complex cSAC.

The Terryland River which has a water intake from the River Corrib at Jordan's Island drains the Terryland basin and disappears underground via karst swallow-holes near Castlegar. The outflow from these swallow holes is unknown but is likely to discharge to the Galway Bay Complex cSAC via submarine springs. The water level in the Terryland River shows a tidal response indicating its outflow point/points are within the tidal zone.

The majority of the above streams have either partially or extensively urbanised catchments. The fishery resource of these streams is assessed in detail in **Chapter 8, Biodiversity** and is summarised below:

- The two minor coastal streams at Baile Nua are not of fishery interest
- Sruthán na Libeirtí is categorised as of local importance (lower value) for European eel and with no salmonids present. The lower reaches have some moderate quality salmonid and European eel habitat

- The Trusky Stream is categorised to be of local importance (higher value) for salmonids, European eel and as a nursery for flounder in its lower reaches at Bearna. Some spawning habitat for trout exists in the lower reaches but this is limited
- The Bearna Stream is salmonid and is categorised to be of local importance (higher value) for Brown trout. Upper reaches are seasonal but moving downstream the habitat becomes an important salmonid river
- An Sruthán Dubh is a tributary of the Bearna Stream and is considered to be an excellent salmonid habitat throughout its upper reaches and is considered an excellent nursery salmonid stream with good numbers of juvenile Brown trout and small numbers of European eel. This is classified to be of local importance higher value for Brown trout and European eel
- The Knocknacarra Stream is categorised to be of local importance (higher value) for European eel and as a nursery for estuarine fish. Upper reaches are seasonal and of no fishery value but lower reaches near the estuary are of importance as a transitional habitat to estuarine fish and European eel
- The River Corrib is an important salmonid river system and is considered to be of International Status with an extremely high attribute value due to its European designation as part of the Lough Corrib cSAC and Lough Corrib SPA
- The Terryland River which continues to be impacted by urban pollution is considered to be of limited fisheries value and categorised to be of local importance (lower value) for European eel
- The Coolagh Lakes is categorised to be of local importance (lower value) for coarse fish species and European eel and despite its connection to the River Corrib is of limited or no value to salmonids
- Ballindooley Lough is considered to be an excellent coarse fishery, but not of importance as a salmonid fishery and is categorised to be of local importance (higher value) for coarse fish species

11.3.6 Surface Water Quality

11.3.6.1 Rivers

EPA Monitoring River Programme

The EPA carries out water quality assessments of rivers as part of a nationwide monitoring programme. Data is collected from physio-chemical and biological surveys, sampling both river water and the benthic substrate (sediment) in contact with the water.

Water sampling is carried out throughout the year and the main parameters analysed include: conductivity, pH, colour, alkalinity, hardness, dissolved oxygen, biochemical oxygen demand (BOD), ammonia, chloride, ortho-phosphate, oxidised nitrogen and temperature.

Biological surveys are normally carried out between the months of June and October. These examine the relationship between water quality and the relative abundance and composition of the macro-invertebrate communities in the sediment of rivers and streams. The macro-invertebrates include the aquatic stages of insects, shrimps, snails and bivalves, worms and leeches. It is generally found that the greater the diversity of species recorded, the better the water quality is.

The collated information relating the water quality and macro-invertebrate community composition is condensed to a numerical scale of Q-values or Biotic Index. The indices are grouped into four classes based on a river's suitability for beneficial uses such as water abstraction, fishery potential, amenity value, etc. (refer to **Table 11.17** below).

Table 11.17: Biological River Water Quality Classification System

Biotic Index (Q value)	Quality Status	Quality Class	Condition
Q5, Q4-5, Q4	Unpolluted	Class A	Satisfactory
Q3-4	Slightly Polluted / Eutrophic	Class B	Transitional
Q3, Q2-3	Moderately Polluted	Class C	Unsatisfactory
Q2, Q1-2, Q1	Seriously Polluted	Class D	Unsatisfactory

The River Corrib is monitored at Wolfe Tone Bridge and is currently categorised as having good status (Q4) for the period (2004 - 2015) and the Terryland River as having poor Status (Q2-3). No Other watercourses within the study area are currently monitored by the EPA as part of the EPA Monitoring River Programme.

11.3.6.2 Lakes

As part of a national water quality monitoring programme, a number of lakes throughout the country are sampled and the trophic status assessed. Lake water quality is most commonly assessed by reference to a scheme proposed by the Organisation for Economic Cooperation and Development (OECD, 1982). This scheme defines the traditional trophic categories by setting boundaries for the annual average values for total phosphorus, chlorophyll and water transparency, and for the maximum and minimum vales of the latter two parameters.

A modified version of these criteria is used in which annual maximum chlorophyll-a concentration is the only parameter used. This has been further subdivided into six water quality categories by reference to the maximum levels of planktonic algae measured during the period (refer to **Table 11.18**). Indicators relating to water quality and the probability of pollution are also shown.

Table 11.18: Trophic Classification Scheme for Lake Waters

Classification Scheme		**Category Description**				
Lake Trophic Category		**Annual Maximum Chl-a (mg/m^3)**	**Algal Growth**	**Degree of Deoxygenation in Hypolimnion**	**Level of Pollution**	**Impairment of Use of Lake**
Oligotrophic	(O)	<8	Low	Low	Very low	Probably none
Mesotrophic	(M)	8 – 25	Moderate	Moderate	Low	Very little
	Moderately (m-E)	25 – 35	Substantial	May be high	Significant	May be appreciable
Eutrophic	Strongly (s-E)	35 – 55	High	High	Strong	Appreciable
	Highly (h-E)	55 – 75	High	Probably total	High	High
Hypertrophic	(H)	>75	Very high	Probably total	Very high	Very high

The trophic status provides an indication as to what degree the lake is enriched by the presence of nutrients such as phosphorus and to a lesser extent nitrogen in the form of nitrate.

Lough Corrib is currently monitored as part of the EPA water quality reporting and is classified as Oligotrophic/Mesotrophic in terms of water quality indicating that nutrient enrichment is low and eutrophication is not a major concern.

11.3.6.3 Baseline Water Quality Sampling of Receiving Waters

Bi-monthly sampling of surface water quality, in the vicinity of the proposed road development, was carried out over a 14month period commencing November 2015 to December 2016. This was carried out to establish baseline water quality conditions in the receiving waters. The sampling locations are as follows:

1. Sruthán na Libeirtí at the R336 Coast Road culvert upstream
2. Trusky Stream East at the R336 Coast Road culvert upstream
3. Bearna Stream at Cappagh North
4. Bearna Stream at Cappagh South
5. River Corrib at Dangan Slip
6. River Corrib at Terryland Intake Channel, Jordan’s Island
7. Upper Coolagh Lake
8. Lower Coolagh Lake
9. Ballindooley Lough

The water quality sampling results are presented in **Appendix A.11.2**. The locations of the sampling points are identified on a set of figures within the appendix. The results show consistently good quality water at all of the sites with nutrient, BOD, sediments and heavy metal concentrations well within acceptable limits based on the surface water regulations. Bacterial faecal contamination was identified at all locations, possibly associated with the presence of agricultural activities, point septic tank and slurry pit sources within the respective catchments.

As expected the western watercourses (Bearna Stream, Trusky Stream and Sruthán na Libeirtí) associated with the granite bedrock and peatland areas showed slightly lower pH, lower alkalinity and hardness and elevated iron concentrations compared to the eastern limestone watercourses. The most alkaline and highest hardness waters were found within Ballindooley Lough followed by the Coolagh Lakes.

11.3.7 Water Supply Sources

11.3.7.1 Galway City Water Supply

The Galway City Water Supply Scheme at Terryland abstracts water from the River Corrib via an intake channel at Jordan’s Island. The Water Treatment plant has recently been upgraded so that it can treat and supply up to 55,000m^3 per day (0.64cumec). The source of this water is from Lough Corrib but also its downstream catchment area, including the Coolagh Lakes outflow to the River Corrib on the eastern bank of the River Corrib. This plant provides full treatment that includes screening, coagulation, flocculation and clarification, followed by gravity filtration, chlorination and UV-disinfection. The Galway City Council / Irish Water objective is to increase this supply and this is likely to require the relocation of the abstraction inlet point into the deeper River Corrib mainline channel possibly to the south of Jordan’s Island.

The source zone of contribution for this abstraction extends upstream and includes River Corrib, Lough Corrib and also includes Coolagh lakes.

The Regional Galway County Water supply abstraction and treatment is from the Lough Corrib at Luimnagh. This abstraction is located over 15km upstream of the proposed road development and therefore not within the zone of influence (ZoI) of the proposed road development.

11.4 Characteristics of the Proposed Development

A detailed description of the proposed road development and construction activities are provided in **Chapter 5, Description of Proposed Road Development** and **Chapter 7, Construction Activities**. This section outlines the characteristics and activities of the proposed road development of relevance to hydrology.

11.4.1 Operational Phase

11.4.1.1 Proposed Watercourse Crossings

Excluding the River Corrib there are a total of 17 stream road crossing sites that will require culverting, 16 of these culvert sites are located in the western section and one in the eastern section. The catchment areas of these watercourses is generally very small ranging from a number of hectares to the largest crossing of the Bearna Stream with an upstream catchment area of 5.5km^2. The majority of these watercourses flow in a southerly direction discharging into Galway Bay. The watercourses to the east of the Bearna Stream discharge to the designated Galway Bay Complex cSAC and watercourses to the west of the Bearna Stream discharge to Galway Bay outside of this cSAC. These watercourse crossings are summarised below in **Table 11.19**.

The proposed road development will involve a new bridge crossing of the River Corrib channel at Menlough/Dangan.

Table 11.19: Proposed Watercourse Crossing Locations

Culvert Reference	X	Y	Approx. Chainage	Catchment Area km^2	Qdesign cumec	Watercourse	Ecological Evaluation

The design flow presented in the above table includes the best flood flow estimate using either IH124 or the Flood Studies Update (FSU, 2015) method and multiplied by the factorial standard error of the equation and increased a further 20% to include for climate change allowance. Further details of the culvert crossings are discussed in **Section 11.5.3.1**.

11.4.1.2 Hydraulic Structures

Culverts

Table 11.20 summarises the propose crossing sizes, effective height and associated embedment depths for each of the proposed culverts at the crossing of watercourses.

Table 11.20: Preliminary Sizing of Watercourse -Crossing Culverts

Notes:

1. Suitable channel transition to and from culvert to be provided that allows for gentle flow transition into and from the culvert and protects against scour and deposition effects.
2. The sizes indicated above are full sizes inclusive of any increases required to accommodate depressed inverts or mammal ledges.

The above crossing sizes allow for pipe culverts and box section inverts to be buried beneath the existing bed level by depths of 150mm in respect to pipes and 300mm in respect to the box sections in fishery watercourses. All other watercourses (non-fisheries) traversed by the proposed road development are minor in flow requirements and therefore can be culverted using a standard nominal 1200mm or 900mm diameter concrete pipe or equivalent.

All of these culverts have been designed for the 100year flood and climate change allowance such that the impact on flood risk is rated at slight with a moderate residual flood risk associated with potential blockage by debris of the culvert barrel, inlet or outlet structures. The proposed regular maintenance and inspection program of the road drainage infrastructure minimises this residual flood risk impact reducing the flood risk to slight.

Under Section 50 of the Arterial Drainage Acts 1945 and 1995, culverting of streams by either new, upgraded or extended culverts/bridges requires approval from the OPW. This enables the OPW who are responsible for Flood Risk Management and Arterial Drainage to assess the implications of the proposed works. The minimum culvert size to be used in relation to the natural drainage is a 1200mm diameter pipe culvert which facilitates burying of the pipe by 150mm. From a hydraulic capacity, blockage potential and maintenance point of view, this minimum culvert size is acceptable and easily meets the OPW requirements. Section 50 approval has been obtained from the OPW in respect to all proposed watercourse culvert crossings described in **Table 11.20** above.

All culverts are designed to prevent permanent impact to the river morphology. A short term temporary impact may occur whilst on-line culverts are put in place. These impacts will be minimised through the incorporation of strict control procedures – refer to the Construction Environmental Management Plan (CEMP) in **Appendix A.7.5**. Permanent impacts on river morphology will be prevented by ensuring the river width is not exceeded or contracted by the proposed culvert or bridge and that reasonable transitions to and from the bridge or culvert is provided where approach and exit channels are skewed to the culvert alignment. In all fishery sensitive watercourses, the proposed culvert will be embedded into the channel to a depth of 300mm for box sections and a minimum of 150mm for pipe culverts (depending on hydraulic size requirements). Suitable local granular material will be placed to back fill the embedded culvert and sizing will be designed based on scour resistance requirements and in consultation with Inland Fisheries Ireland. In all fishery potential streams low flow channels through the culverts will be provided using appropriately sized natural sediments and baffles to assist the formation of such. The design of such measures must take into account the potential for scour.

All Culverts are designed with inlet and outlet structures that include headwall, wing walls and a buried concrete apron or armour stone to resist local scour of the stream bed at the inlet and outlet.

All crossings identified as potential salmonid rivers/streams and important for mammalian (otter) migration have been be designed to maintain the existing migratory routes as far as possible, in accordance with Guidelines for the crossing of Watercourses during the Construction of National Road Schemes, NRA 2008.

The culverts with mammal ledges have been identified and the effect of these ledges has been take into account in the Section 50 assessment.

Channel transitions are required to and from the culvert structure and this may require slight channel realignments to achieve a smooth transition and avoid local erosion and deposition sites due to the culvert.

River Corrib Bridge

The proposed road development crosses the River Corrib to the southwest of Menlo Castle on the eastern side and crosses through NUIG Sporting Campus at Dangan on the western side of the river. The proposed structure is a balanced cantilevered structure spanning over the river banks and provides a clear span between support piers of 153m. This clear span is sufficient to allow the support piers to be set back from the channel bank and thereby substantially reduces any potential encroachment of the River Corrib channel and its flood banks and allows for continuous access along the river bank edge on both banks. On the eastern bank the minimum setback distance from the pier face to channel edge is 5m and on the western bank the minimum setback is slightly more than 10m. Such setbacks meet IFI Fisheries requirements.

The bridge soffit level above the River Corrib Median flood level of 6.26m AOD is 14.1m AOD on the eastern bank edge, 17.8m AOD at the midspan of the channel and 15.5m OD on the western river bank edge. This ensures navigation requirements are easily met and such clearance reduces shadowing effects of the bridge structure.

A detailed hydraulic assessment of the River Corrib and the proposed bridge structure was carried out as part of the Section 50 application for the proposed bridge. This assessment involved development of a detailed 2-dimensional hydraulic model of the River Corrib reach from Menlough to the Salmon Weir and included the Jordan’s Island Channel and the Coolagh Lakes to predict flood levels and allow testing of various bridge configurations as part of the preliminary design and bridge options study. A summary of the predicted design flows and predicted design flood levels are presented in **Table 11.21** below.

Table 11.21: Estimated Design Flood Flows and Flood Levels at the Proposed River Corrib Bridge Crossing

Return Period years	**QT Flood Flow cumec**	**Computed Upstream Flood Level m OD**
2year (Median)	274.5	6.26
10year	389.3	6.72
100year	519.5	7.20
1000year	647.9	7.62
100year+CC	623.4	7.54

11.4.1.3 Proposed Road Drainage Features

There are 16 proposed mainline surface water outfalls discharging directly to surface watercourses, located primarily in the western section of the study area (over the western 10.15km of the mainline for the proposed road development). The remaining surface water outfalls from the 7.35km, to the east of the River Corrib will be discharged to groundwater or to existing public storm and foul sewer systems in the absence of surface water drainage features. The realigned N84 Headford Road and slip roads for the N84 Headford Road Junction will discharge to a small ditch that inflows to Ballindooley Lough. The two short sections of tunnel in the eastern section will discharge to the public foul sewer via pumping. Details of the overall breakdown of the proposed drainage network sections are shown on **Figures 11.6.101** to **11.6.115**.

The total surface drainage area for the proposed road development is estimated to be 94.85ha and the hard-paved area is 61.21ha. This gives the average percentage impervious area for the road of 64.5%. The total drainage area discharging to surface water outfalls is 55.96ha with hard paved area of 32.5ha and the total drainage area discharging to groundwater is 35.5ha with hard paved area of 19.2ha.

The proposed tunnelled sections are relatively short closed systems and the surface drainage from inside the tunnel is gravitated to a sump where it will be collected and discharged by pumping into the nearby public foul drainage system, which eventually arrives at the Mutton Island Waste Water treatment facility, where it is treated and disposed to sea. The tunnelled section will not receive any direct rainfall. An impounding sump of 25m^3, to collect accidental spillages from inside the tunnel is provided for both the Lackagh Tunnel and Galway Racecourse Tunnel.

The paved area contributing to the proposed road development drainage outfalls has an average pavement area of 1.2ha, which represents a reasonably small ratio of pavement area to outfall. The largest surface water outfall serves a paved area of 2.45ha and the largest groundwater outfall serves a paved area of 4.82ha. A summary of the proposed road development drainage outfalls discharging to surface watercourses is presented here in **Table 11.22** and those storm outfalls discharging to groundwater are presented in **Table 11.23**.

Table 11.22: Proposed Road Development Drainage Outfalls to Watercourses

The remaining drainage areas discharge to the existing public storm drainage infrastructure. The permissible discharge rates have been set based on consideration of natural greenfield runoff rates and the current capacity in the receiving storm drainage system. All of the proposed discharge rates to public storm sewers have been agreed with Galway City Council. A summary of the outfalls to the public sewer is provided in **Table 11.24** below.

Table 11.24: Proposed Road Development Outfalls to Public Storm Sewers

S45	15+200	1.736	1.44	750	241

Proper management and regular inspection and maintenance of these drainage discharge facilities will be undertaken as part of the operation and maintenance schedule during the operational phase of the proposed road development.

All rainfall runoff will be prevented from discharging directly to the receiving surface waters by the proposed road sustainable drainage system. Road runoff will only outfall to receiving surface waters at specified outfall locations. Catchment sizes are conserved as far as practicable by minimising diversion of run-off between sub-catchments. Attenuation ponds, treatment wetlands oil / petrol interceptors and silt traps will be installed at all major outfalls, to prevent pollutants from entering the receiving watercourses. The installation of emergency spill containment facilities with a minimum volume of 25m^3 will mitigate against any potential adverse impacts to the receiving surface waters arising from an accidental spillage associated with road haulage.

Attenuation storage and flow control have been provided for all mainline and new link road drainage areas so that the design flood discharge in the case of surface discharges achieves predetermined greenfield flood runoff rates. This prevents potential impacts to river morphology and surface water flow hydraulics of the receiving watercourses. In the case of groundwater, the storm water disposal rates meet the infiltration capacity of the infiltration basin. The proposed attenuation storage volumes are sized accordingly to accommodate any potential increase in surface water runoff rates up to the 100year return period storm event with climate change allowance. This ensures that there will be no increase to flood risk up to and including the 1 in 100year storm event as per TII drainage publications Clause 7.5 of DN-DNG-03022 Drainage Systems for National Roads. A departure from this standard applies to the two River Corrib outfalls (S18A and S18B) located on either bank, where flood attenuation is not necessary due to the significant difference in drainage catchment scale (with the River Corrib catchment over 70,000 times bigger) and timing of flood response (hours versus days). All outfall structures will be designed with an outlet structure that includes headwall, wing walls and a bed apron to prevent local scouring of the banks and the channel bed. All culverts are designed to allow for both aquatic species and mammal migration, and to maintain the existing river bed as far as possible, in accordance with “Guidelines for the Crossing of Watercourses During the Construction of National Road Schemes,” NRA, 2008. All culverts upstream and downstream of protected ecological areas (NHAs, SACs or SPAs) are designed to retain natural riverbed forms. **Section 11.4.1.1** discusses in greater detail the requirements of culverting for the protection of local ecology.

All culverts and the River Corrib Bridge are designed accordingly to prevent impact to watercourse morphology and to prevent impoundment or alteration of surface water flow hydrodynamics. All watercourse culverts and the River Corrib Bridge have obtained Section 50 approval from the OPW and therefore satisfy the OPW Flood Risk and impact requirements. For further details, refer to the Flood Risk Assessment Report in **Appendix A.11.1**.

The proposed River Corrib Bridge crossing is designed to prevent impact to the hydrodynamics of the river and its associated floodplain. It has been designed so as not to have any piers located within the effective floodplain area, within the channel, or within 5m of the river banks. The bridge is located in a stable, straight, reach section of the river (as evidenced by bankside vegetation), so it is expected to neither be sensitive to, nor impact on, local channel morphology.

No major river realignment work will be necessary as part of the proposed road development. Some minor stream and ditch realignment is required. The minor drain and stream diversions proposed for the proposed road development are summarised in **Table 11.25** below.

Table 11.25: Minor Watercourse Diversions

Stream	Approx. Chainage	Diversion Channel Length (m)	Location
Sruthan na Liberiti	0+700	35	Na Foraí Maola
Truskey Stream	2+800	50	Bearna to Moycullen Road
Tributary to Bearna Stream	3+375 to 3+900	525	Aille
Tonabrocky Stream	4+960 to 5+200	240	Keeraun
Drain	7+200 to 7+350	320	Letteragh Road

The proposed stream and drain realignments have been assessed as part of the culvert design. Localised design measures are included to prevent potential bank erosion at sites of bends which were found to coincide with a number of the proposed road culverts. This protection may be in the form of large boulders or rip-rap along the outer bank with a suitable filter material or geotextile placed inside the armouring to protect the native soil bank. All diversion channels will include fishery friendly requirements where they are identified as having fishery potential.

This may require the incorporation of meanders, riffles/shoals and pools within the channel bed and suitable sediment size provided within the new channel to resist scour under flood flow conditions. The flood capacity will be enhanced while importantly preserving the low flow channel characteristics. The inclusion of shoals and pools in the channel will assist the rehabilitation of the low flow channel at crossing and diversion/realignment sites. All stream re-alignment work shall create new channels that will achieve maximum ecological benefits and maintain or improve on the existing hydrological environment. The design of stream re-alignments was conducted in consultation with Inland Fisheries Ireland to ascertain their desired stream morphology to adequately address fishery habitats and passage. The principle aim of stream re-alignment is to promote ecology and ensure a more suitable stretch of stream for fisheries. Stream realignment will be conducted using the principles and guidance laid out by the Central Fisheries Board for the enhancement of rivers (O'Grady, 2006).

The use of persistent herbicides, pesticides or artificial fertilisers in any landscaping or subsequent maintenance within 2m of a watercourse is not permitted. Applications of herbicides or pesticides within a zone of 2m to 10m from any watercourse will be in accordance with manufacturer's recommendations and confined to periods when the vegetation is not wet from rainfall or dew.

11.4.1.4 Pollution Control Measures

The proposed drainage system design incorporates a range of pollution control features to limit the water quality impact to receiving waters. These include combined filter drains, detention ponds, grassed surface water channels, petrol and oil interceptors, wetlands and infiltration basins. The use of filter drains and grassed surface water channels are proposed in non-sensitive groundwater areas (granite bedrock areas west of N59 Moycullen Road) and closed (sealed) drainage systems are proposed in the highly vulnerable Karst Aquifer region east of the N59 Moycullen Road. A Treatment wetland will also be provided upstream or in combination with the attenuation pond at all proposed surface outfalls from the proposed mainline and new link road catchments and upstream of all infiltration basins, to provide primary treatment of road runoff. These wetlands systems will be suitably planted with aquatic plants for uptake of solutes including dissolved heavy metals and nutrients and will have a permanent pond depth of at least 500mm. A summary of the pollution control measures provided at each drainage outfall is summarised in **Table 11.26** below.

Table 11.26: Pollution Control Summary

Drainage Network Ref. No.	Outfalling to	Pollution Control Measure Provided
S1	Watercourse	Spillage Containment Pipe, Oil and Petrol Interceptor, Wetland, Attenuation Pond
S2	Watercourse	Spillage Containment Pipe, Oil and Petrol Interceptor, Wetland, Attenuation Pond
S3	Watercourse	Spillage Containment Pipe, Oil and Petrol Interceptor, Wetland, Attenuation Pond
S4A	Watercourse	Spillage Containment Area, Oil and petrol interceptor, Wetland, Attenuation Pond
S5A	Watercourse	Spillage Containment Area, Oil and Petrol Interceptor, Wetland, Attenuation Pond
S7A	Watercourse	Spillage Containment Pipe, Oil and Petrol Interceptor, Wetland, Attenuation Pond
S7B	Watercourse	Spillage containment Area, Oil and petrol interceptor, Wetland, Attenuation Pond
S8	Watercourse	Spillage containment Area, Oil and petrol interceptor, Wetland, Attenuation Pond

Drainage Network Ref. No.	Outfalling to	Pollution Control Measure Provided

S38	Existing Sewer	None Required, overlay of existing local road
S39	Existing Sewer	None Required, overlay of existing local road
S40	Infiltration Basin	Spillage Containment Area, Oil and Petrol Interceptor, Infiltration Basin
S41	Existing Sewer	None Required, overlay of existing local road
S44	Watercourse	None Required, synthetic playing pitch development only
S45	Existing Sewer	None Required, brown field development

Each of the mainline and new link road catchment attenuation ponds either includes or have immediately upstream a wetland treatment system which has been sized to cater for the first flush volume from the proposed road pavement (15mm rainfall event).

The attenuation ponds are sized to cater for the 100year storm event with 20% climate change allowance and discharge at the permissible greenfield flood outflow rate subject to a minimum discharge rate of 5l/s. These storages provide large detention times that allow effective settlement of sediments within the pond systems.

Spillage containment will be achieved using oil and petrol interceptors sized for the individual drainage catchment and located upstream of the wetland and attenuation ponds / infiltration basins to prevent any contamination from hydrocarbons entering the surface and groundwater systems. A minimum emergency spill containment volume of 25m^3 will be provided at all outfall locations where runoff can be diverted in the event of a spillage from a HGV.

To facilitate emergency response to serious spillages all pond and storage systems will be fitted with a manual penstock to close off the outfall and contain the spillage water within the pond/storage system for pumping out and appropriate treatment and disposal. Access will be provided to these facilities to enable ongoing inspection, maintenance and emergency response.

11.4.1.5 Material Deposition Areas

A total of 40 site areas have been identified as potential material deposition areas for the excess soft and unacceptable material along the route of the proposed road development. These sites are all within easy haulage distances from the location of large soft ground deposits and are detailed in the **Table 11.27** below. These sites provide a storage capacity in excess of the anticipated 370 thousand cubic metres of potentially excess unacceptable material which may be encountered along the proposed road development. Each area has been assessed, however they will not be fully utilised as there is excess capacity.

Table 11.27: Location of Potential Material Deposition Areas

Location	Approx. Chainage	Catchment Reference	Area (ha)	Approximate Capacity (m^3)
R336 Coast Road	0+050	Sruthán na Líbeirtí	0.089	1,200

Coolagh	16+500	Doughiska	0.782	35,000

These material deposition areas will be bunded or excavated sites and will have double erosion control fencing (silt fence) and a sediment settlement pond at the outlet which will be constructed in advance of their use as deposition areas. In addition, wheel wash facilities, will be provided at the entrance/exit as outlined in the CEMP – see **Appendix A.7.5**.

A 2.5m wide permanent maintenance access track will extend around the external perimeter of the peat restoration areas and combined with the foundation to the perimeter berm for access. Materials will initially be delivered to the working area for access roads and perimeter berm construction by low ground pressure vehicles such as tracked dumpers and light weight, wide track excavators.

Any local drains within these areas will be either diverted around the site or truncated to minimise the volume of water entering such areas to that of direct rainfall and the soil moisture of the material itself.

11.4.2 Construction Phase

The construction phase of the proposed road development involves temporary and permanent works in the vicinity of and within watercourses, generally associated with the construction of culverts and outfalls, realignment of drainage channels. The aspects of the construction phase that are relevant to hydrology are summarise below.

- Construction of 17 new culverts on watercourse crossings, refer to **Table 11.20** above
- Construction of all 25 road drainage outfalls discharging to surface water outfalls refer to **Table 11.22** above
- Construction of 10 road drainage outfalls discharging to groundwater via infiltration basins, refer to **Table 11.23** above
- Construction of 17 outfalls discharging to existing Public Storm sewer, refer to **Table 11.24** above
- Construction of 5 minor watercourse diversions, refer to **Table 11.25** (ranging in length from 35m to 525m)
- Construction of a new bridge over the River Corrib
- Construction of two tunnel sections at Lackagh Quarry and at Galway Racecourse
- General construction earthworks adjacent to watercourses including the construction of a replacement 3G all weather pitch and training pitch at NUIG Sporting Campus at Dangan
- Construction of wetland treatment systems, attenuation ponds and infiltration basins upstream of the proposed road drainage outfall
- Construction of permanent interceptor drains
- Construction of the proposed road drainage network including carrier drains, filter drains, grassed surface water channels
- Construction of retaining walls along route of the proposed road development

- Construction of flood relief mitigation measures at the N83 Tuam Road crossing location
- Construction of 13 site compounds within the proposed development boundary as set out in **Table 7.9** and shown on **Figures 7.101** to **7.123**
- Construction of material deposition areas - the provision of 40 material deposition sites along the route for surplus topsoil, U1 material (material that does not comply with the requirements outlined in TII Series 600 Cl. 601.1) and peat encountered during construction with the majority of peat material encountered on the west side of the River Corrib. Such material is not suitable as construction material and is excess material
- Construction of temporary drainage works such as sedimentation ponds and silt traps as required to treat soiled construction water. Temporary diversions and interceptor drains will be constructed to reduce the potential for soiled water runoff from the construction site. For further details of control of sediment and erosion refer to the CEMP in **Appendix A.7.5**

11.5 Evaluation of Impacts

11.5.1 Introduction

Given the scale and nature of the proposed road development there are potential significant impacts to the hydrological regime both during their construction and on-going operation. Consequently, detailed measures have been designed and incorporated to ensure that all potential significant impacts are avoided or mitigated.

The principal potential hydrological impacts to the character of the receiving waters are associated with the proposed crossing points and the potential for sediment loading and associated road drainage pollutants entering such watercourses during both construction and operational phases.

There is also potential for impacts to surface water hydrology from other sources which include:

- Impact to surface watercourses crossed by the proposed road development involving culvert and bridge structures and associated realignment of the watercourse channel
- Impact to surface watercourses discharged to via proposed road drainage outfalls and downstream impacts
- Impact to potential morphological changes to watercourses at channel crossings and proposed road development outfall discharge locations
- Impact to flooding and flood risk, upstream and downstream of proposed crossing points and floodplain encroachment at proposed crossing points, at material deposition areas and downstream impacts from storm outfall locations
- Impacts on sites of ecological importance in proximity to surface watercourses namely the River Corrib, Coolagh Lakes and Ballindooley Lough

- Impacts on Galway City public drinking water abstraction from the River Corrib at Jordan’s Island, which is located in the downstream reach from the proposed road development crossing of the River Corrib

11.5.2 Do Nothing Impact

In the event of the proposed road development not being constructed there would be no resulting impacts on the hydrology along the route of the proposed road development. The traffic will remain on the existing road network, which for many of the existing outfalls do not include a sustainable urban drainage system to protect surface and groundwater bodies from pollution and flood runoff.

11.5.3 Potential Impacts to Hydrological Receptors

Construction activities pose a significant risk to watercourses particularly from contaminated surface water runoff from construction activities entering nearby watercourses.

Construction activities within and alongside surface waters associated with bridge and culvert construction, outfalls and channel diversions can contribute to the deterioration of water quality and can physically alter the stream/river bed and bank morphology with the potential to alter erosion and deposition rates locally and downstream. Activities within or close to the watercourse channels can lead to increased turbidity through re-suspension of bed sediments and release of new sediments from earthworks. Consequently, in-stream works can potentially represent a severe disruption to aquatic ecology.

The main contaminants arising from construction runoff include:

- Elevated silt/sediment loading in construction site runoff. Elevated silt loading can lead to long-term damage to aquatic ecosystems by smothering spawning grounds and gravel beds and clogging the gills of fish. Increased silt load in receiving watercourses stunts aquatic plant growth, limits dissolved oxygen capacity and overall reduces the ecological quality with the most critical period associated with low flow conditions. Chemical contaminants in the watercourse can bind to silt which can lead to increased bioavailability of these contaminants
- Spillage of concrete, grout and other cement based products. These cement based products are highly alkaline (releasing fine highly alkaline silt) and extremely corrosive and can result in significant impact to watercourses altering the pH, smothering the stream bed and physically damaging fish through burning and clogging by the fine silt of gills
- Accidental spillage of hydrocarbons from construction plant and at storage depots / construction compounds
- Faecal contamination arising from inadequate treatment of on-site toilets and washing facilities

11.5.3.1 Hydraulic Structures

This sub-section considers the hydraulic impact of the proposed watercourse structures and stream realignments along the proposed road development.

Culvert Crossings

Table 11.19 presents a summary of the primary culvert crossings including upstream contributing catchment area and **Table 11.20** presents the proposed culvert sizes.

The majority of the streams intercepted have relatively small catchment areas and the recommended barrel dimension size provided is generally an increase over existing structures and stream channel dimensions and will not result in any significant contraction of the stream flow velocity or creation of upstream afflux. In a lot of cases the culvert dimensions have been increased to facilitate bat passage and mammal ledges. The Section 50 assessments show that all culverts provided are suitably sized to prevent any potential flood impacts both under present day statistics and in the short to medium term climate change conditions.

These structures can also have a negative impact on the flow regime in watercourses particularly those with fishery potential as often the wider dimension or increased channel gradients can locally result in insufficient water depth during mean and low flow conditions and such structures if not appropriately designed can lead to undesirable changes in channel morphology and thus potentially impact fish migration and sedimentation. The construction of these structures in watercourses, if not carefully managed, can lead to pollution of the watercourse both locally and in its downstream reaches through the potential for spillages from construction plant and equipment and potential release of cement based products, wood preservative from roadway timber fencing and the disturbance of bed and channel banks resulting in suspended sediment releases.

Without appropriate design measures the potential operational impact on hydrology and channel morphology is classified as slight for Local Low fishery watercourses and moderate for Local High watercourses. This is based on the fact that most of the streams are to be culverted are classified as locally higher value for fish in their downstream reaches. It is noted that all of the watercourses are valued as having Local High ecological value.

The potential constructional impacts without mitigation through potential release of sediments by disturbance of the channel bed and bank represent a short term local moderate to significant impact on water quality and bed sediment deposition rates that could impact fishery habitat potential of the downstream reach. As a result all construction works are to be carried out in accordance with OPW, EPA and IFI guidelines at appropriate times of the year and are to implement all necessary measures to limit the potential impact of the works on all stream/river ecology.

A summary of both operational and construction impact due to watercourse crossings is provided in **Table 11.28** below.

Table 11.28: Impact Assessment of Proposed Watercourse Culvert crossings

Ref.	Watercourse	Construction Phase Impact magnitude	Operational Phase Impact Magnitude
C00/01	Sruthán na Libeirtí	Short-term potential moderate impact on water quality and siltation locally and downstream reach	moderate local impact on channel flow regime and morphology
C00/02	Sruthán na Libeirtí	Short-term potential moderate impact on water quality and siltation locally and downstream reach	moderate local impact on channel flow regime and morphology
C01/01	Small coastal stream	Sort-term potential slight impact on water quality and siltation	slight local impact on channel flow regime and morphology
C02/01a	Trusky Stream	Short-term potential moderate impact on water quality and siltation in its downstream reach	moderate local impact on channel flow regime and morphology
C02/01b	Trusky Stream	Short-term potential moderate impact on water quality and siltation in its downstream reach	moderate local impact on channel flow regime and morphology
C03/01	Trusky minor drain	Short-term potential moderate impact on water quality and siltation in its downstream reach	slight local impact on channel flow regime and morphology
C03/02	Trusky minor drain	Short-term potential moderate impact on water quality and siltation in its downstream reach	slight local impact on channel flow regime and morphology
C03/03	Bearna Tributary	Short-term potential moderate impact on water quality and siltation locally and downstream reach	slight local impact on channel flow regime and morphology
C03/04	Bearna Tributary	Short-term potential moderate impact on water quality and siltation locally and downstream reach	slight local impact on channel flow regime and morphology
C04/01	Bearna Stream	Short-term potential significant impact on water quality and siltation locally and downstream reach	moderate local impact on channel flow regime and morphology
C04/02	Tonabrocky	Short-term potential moderate impact on water quality and siltation locally and downstream reach	moderate local impact on channel flow regime and morphology
C06/01	Knocknacarra Drain	Short-term potential slight impact on water quality and siltation	slight local impact on channel flow regime and morphology
C07/02B	Knocknacarra Drain	Short-term potential slight impact on water quality and siltation	slight local impact on channel flow regime and morphology

C07/01	Knocknacarra Drain	Short-term potential slight impact on water quality and siltation	slight local impact on channel flow regime and morphology

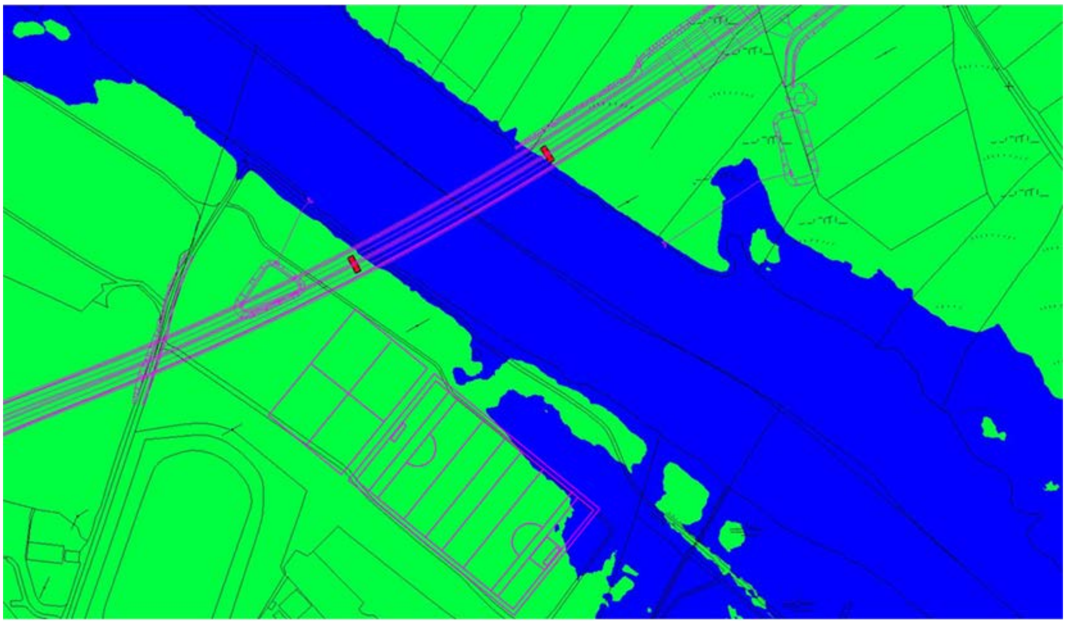
River Corrib Bridge Crossing

For the operational phase, the hydraulic modelling of return period flood flows (with inclusion for statistical error) provided estimates of flood levels at the proposed bridge site. Refer to **Table 11.26** above. This clearly demonstrates that the proposed bridge structure has no discernible impact on flood levels either upstream or downstream nor is there any flood risk issues for the proposed road development with the proposed bridge deck and the storm drainage system sufficiently elevated.

Hydraulic analysis shows no discernible impact on flood levels at the design flood event which is the 100year with inclusion of a climate change allowance of 20%. The predicted flood level for this design flood condition (100yr +CC) is 7.54m OD. At such a flood level, both river bank piers will be located just outside of the flood risk area. At the estimated 1000year flood level of 7.62m OD associated with a peak flood flow of 648cumec, the proposed bridge piers remain outside floodplain area in Flood Zone C, refer to **Plate 11.1** below and therefore no encroachment of the floodplain area will occur at the bridge crossing. The water quality / attenuation ponds remain outside the flood zone also.

There is little potential for bank erosion at the proposed River Corrib crossing location as the river channel is straight, regular and cut into bedrock.

Plate 11.1: 1 in 1,000 year return period flood inundation map of proposed bridge crossing with pier locations shown in red outside of the flood zone



During the construction phase, in order to avoid any potential scour risk associated with the construction of these bridge structures, abutments for bridges are sufficiently set back from the channel bank edge with foundations located at depth. This will protect the river channel from changes in morphology whereby the channel over time would naturally migrate towards one of the abutments. The proposed construction method for the River Corrib bridge crossing will essentially avoid works within the river channel, temporary or otherwise except for the installation of drainage outfalls 18A and 18B. The main risk will be associated with the construction of the support piers adjacent to the channel bank edge which are setback at least 10m on the western bank and 5m on the eastern bank. The River Corrib is sensitive as a salmonid river, major water supply source, European site designation and an important amenity, both locally and downstream through the city and canals. Potential construction accidental spillages of hydrocarbons from plant and spillage of concrete and associated chemicals with constructing the river side piers, bridge deck and storms outfalls represents a potential temporary impact to the waterbody and places risk to the water supply of Galway City, particularly activities on the eastern (left) bank and therefore is categorised as a potential moderate to significant impact in the absence of mitigation measures to protect the River Corrib from construction related pollution in the form of accidental spillages and soiled construction water runoff.

Construction sediment releases from construction activities associated with the bridge crossing represents a potential temporary impact on the River Corrib water quality both locally and downstream. The potential sediment plume will generally hug the river bank edge for quite a distance downstream (approximately 1 to 2km) before fully mixing across the channel width. There is generally good dilution in the River Corrib throughout the year to minimise the wider impact of sediment releases on fisheries, benthos and on the public water supply source. The low velocities associated with the River Corrib and particularly along its river edge provides the opportunity for released construction sediment to settle out rapidly along the bank edge giving rise to the potential for local smothering of the benthos.

Extensive earthworks will be associated with the development of the NUIG pitches at Dangan and given their close proximity to the River Corrib bank edge and to a local drain that discharges to the River Corrib a short distance downstream and the potential for partial flood inundation at the 100year flood a potential for construction runoff pollution of the River Corrib exists. Construction phase mitigation measures are required to protect the sensitive River Corrib waters.

There is a potential for construction impacts on the Coolagh Lakes and supporting habitat from construction site sediment runoff and construction spillages. The natural wetland habitat in the riparian zone of the lakes provides a good buffer between the construction area and the lakes. Notwithstanding this buffer zone, construction phase mitigation measures in the form of sediment and pollution control measures are required to protect this sensitive waterbody.

Mitigation which is outlined in the **Section 11.6** addresses these potential construction impacts through the proposed implementation of good construction practice procedures and environmental controls so as to minimise the opportunity for contaminated releases of construction water to the River Corrib, refer to the CEMP in **Appendix A.7.5**.

11.5.3.2 Stream Diversions and Realignments

The construction of watercourse crossings for the proposed road development will necessitate in some cases the localised diversion/realignment of the existing watercourses. Where feasible, these minor watercourse diversions/realignments will be carried out in the dry and when the channel has established, the watercourse will be diverted into them. The principal impact on a watercourse by a diversion is the change in the watercourse morphology. The general potential impacts can be:

- Slacker gradients: Slower flow velocities with resulting increased flow area and deposition, siltation promoting vegetation and weeds to grow in channels during periods of low flow
- Steeper gradients: Faster flow velocities, increased local bed erosion, shallower low flow depth
- Sharp bends and change in direction: Erosion and deposition with subsequent changes to the river channel morphology
- Lack of natural flood plains: Increase in upstream flood levels

Other potential impacts of watercourse diversions include:

- Change to natural low flow channels: Impact on fisheries and other animals
- Change to existing foliage and vegetation: Impact on fisheries and other species (otters, badgers etc.)

Stream diversions/realignments are not proposed on any locally sensitive salmonid streams. Details of the proposed stream diversions and realignments are presented in **Table 11.23** above. None of these realignments/diversions represent a transfer of stream flow between basins and are only local realignments to facilitate the proposed road development.

It is likely that all the proposed culverts will require some slight local channel realignment and regrading to facilitate the proposed road culvert barrel and to ensure gentle transition to and from the culvert and such transitions have been assessed as part of the culvert crossing assessment in **Table 11.28**.

The principal impact of these channel realignments is associated with the construction stage and the potential for soil erosion associated with the initial excavation works and the initial establishment of the flow channel. This soil erosion may give rise to potential water quality impacts and sedimentation downstream in the receiving waters, most of which are salmonid and of a local higher ecological value in their lower reaches. Therefore, in the unmitigated case, the potential impact of the constructional phase on salmonid potential downstream reaches with locally higher ecological value will represent a temporary moderate to significant water quality impact with potential for elevated suspended solids concentrations and potential for short-term sediment deposition.

The operational impact of the proposed watercourse realignments/diversions will be very localised to morphology changes in the stream channel during large floods and which will stabilise over time. The potential impact is rated to be a locally minor impact which can be further minimised through engineering design (trapezoidal channel with side slopes 1 in 2) of the channel and transitions including provision of culvert wing-walls and armoured bed and channel banks at such transitions. The significant realignment works to the Tonabrocky Stream represent a permanent moderate impact as the realignment diverts the stream channel in a relatively straight artificial channel that has relatively steep channel banks.

The drainage design has also identified that a number of minor drains/watercourses are intercepted by the proposed road development, principally in the western section of the proposed road development (i.e. west of the River Corrib). A number of the smaller field and roadside drains can, from a hydraulic and fisheries perspective, be truncated and the upstream portion diverted either to another existing drain close by or be connected into the road embankment drainage.

The relatively high density of the proposed road drainage outfalls will result in a very minor potential for significant diversion of drainage and recharge waters between neighbouring sub-catchments. The disturbance of field drainage systems represents a direct impact to the existing drainage regime. Following the detailed design this impact is considered to represent a residual slight to imperceptible and permanent in nature impact on the hydrology of adjacent wetland features, conservation areas and flood risk areas.

11.5.3.3 Flow Regime Impact from Drainage Outfalls

The drainage outfall discharges to surface watercourses represent point discharges. Therefore, locally, the discharges will change the flow rate, the flow depth and velocity in the receiving watercourse and generally cause an increase locally, but elsewhere it may cause a reduction. In general, there is not a significant transfer of catchment runoff between streams and tributaries and therefore the water balance is not negatively impacted. It is found that the impact to existing watercourses from the road storm discharge varies depending on the size of the natural catchment. The greater the natural catchment the lower the potential impact as the channels are better developed. Another reason for lower potential flow impact on the larger catchments is due to the smaller stormwater discharge volume relative to the natural stream and river volumes. The potential increase in the ambient water levels arising in larger catchment sizes therefore is reduced.

The impact to flood regime in the receiving watercourse represents potentially the more significant impact as road drainage can increase the rate and volume of flood runoff and cause potential flooding and scouring of the receiving watercourse locally. The design includes the provision of attenuation ponds and flow control to restrict the outfall discharge to a more natural greenfield flood runoff rate, thereby avoiding potential significant impacts to channel morphology and flow regime at the local scale. The potential impact magnitude is presented in **Table 11.29**.

Table 11.29: Impact Assessment of Storm Drainage on Receiving Waters in Respect to flow regime and Morphological Changes

Network Drainage Ref. No.	Outfall Chainage	Total Road Drainage Area (ha)	Receiving Water Catchment Area (ha)	Channel / Lake Capacity	Greenfield Mean Annual Maximum Flood Runoff Rate in Receiving Stream (m^3/s)	Potential Impact
S1	0+000	2.05	147	Narrow vegetated channel Low flood capacity constricted downstream by R336 culvert	1.132	Slight Local

11.5.4 Potential Impact to Water Quality

During the operational phase, the storm outfalls outlined in **Section 11.4.1.3** have a potential to adversely impact water quality in the receiving watercourse and groundwater from routine contaminants that are contained in road drainage waters. The water quality and ecological status of the receiving waters are also potentially threatened by contamination arising from large liquid spillages as a result of an accident on the proposed road development. These impacts are assessed by using the guidelines provided in the appropriate TII publications document DN-DNG-03065 (HD45) Road Drainage and the Water Environment. The outfalls discharging via infiltration basins to groundwater are assessed in **Chapter 10, Hydrogeology**. A summary of the paved area contributing from the proposed road drainage outfalls to the receiving surface watercourses are presented in **Table 11.30**.

The surface water storm outfalls also have the potential to impact the general flow and morphological regime of a receiving watercourse by increasing the volume and rate of runoff during storm events. The morphology of the stream is significantly influenced by ambient flow and flooding conditions in the stream. The potential increase in flow volume to the stream arises from an increased impervious area from the proposed road pavement area, the provision of road and embankment drainage with a direct pathway via the road drainage system to the receiving watercourse and potential interception of groundwater and diversion of drainage waters that would not otherwise have reached the outfall point. The hard-paved areas and the road drainage system reduces the time of concentration for rainwater to arrive at the outfall and thus increases the rate of runoff over the natural greenfield condition.

It is anticipated that the proposed road development will remove traffic from the existing road network which will provide some benefit as most these existing roads do not have sustainable urban drainage systems to protect surface and groundwater bodies from drainage water quality impacts.

Most of the surface watercourses being outfalled to by the proposed road drainage networks are only of high local value, but do eventually discharge to the European sites of the Lough Corrib cSAC and the Galway Bay Complex cSAC and Inner Galway Bay SPA. The N59 Link Road North outfall S15 eventually discharges to Lough Corrib cSAC and Lough Corrib SPA via an open drain at Dangan. Such watercourses provide a good buffer for attenuation and provide natural wetland treatment before reaching any of the European sites. Outfalls S18A and S18B discharge directly to the River Corrib channel, which is of high sensitivity being a salmonid river, European designated site and major public water supply source (Terryland Galway City water supply intake). All of the receiving watercourses have local higher attribute value further downstream in their lower reaches and all the outfalls to the Bearna, Knocknacarra and River Corrib Systems eventually discharge into the Galway Bay Complex cSAC and Inner Galway Bay SPA. Waters in the Sruthán na Libeirtí and the Trusky Stream at Bearna have the potential after mixing with the coastal waters to reach the tidal waters of the Galway Bay Complex cSAC and Inner Galway Bay SPA.

Outfalls S18A and S18B are located on the banks of River Corrib bank edge and represent very limited disturbance with the construction works to be carried out from the banks. Therefore water quality risks are significantly reduced. Construction works for outfalls S14A, S14B and S15 located at Dangan/Bushypark on its western bank discharge to the River Corrib via drainage ditches over distances of c.300 to 800m. These ditches provide an excellent wetland and settlement buffer to protect the River Corrib from construction runoff. Notwithstanding this buffer, the construction erosion and Sediment, Erosion and Pollution Control Plan, in the CEMP contained in **Appendix A.7.5** will apply to these watercourses designed to minimise the direct construction runoff to watercourses and minimise disturbance of sediment from in-stream and river bank works.

Table 11.30: Summary of Proposed Road Drainage Outfalls to Receiving Watercourses

Drainage Reference	Approx. Ch. Of Outfall	Road Section Ch. Start – Ch. End	Total Impervious Road Area (ha)	Receiving Catchment Area (km^2)	Mean Flow (cumec)	95% Low Flow (cumec)	Catchment	Comment and Fisheries Value

11.5.4.1 Accidental Spillages

During the operational phase of the proposed road development, the risk of pollution to both surface and groundwater resulting from accidental spillage is an issue to be considered. Trying to predict the occurrence of a spill with any degree of certainty is difficult. The risk is influenced by the type of roadway, length of road, the traffic volume, and proportion and type of heavy goods vehicles (HGV's), design speed and visibility. A spillage risk assessment of the proposed road development has been carried out in accordance with the TII publications document DN-DNG-03065 (HD45) – see **Table 11.31**.

The spillage assessment shows the proposed road development will have a very low magnitude of risk for individual outfalls or grouped catchment outfalls, and as such specific mitigation measures to lower this risk are not required under the TII publications road design standards.

The overall combined probability of a serious HGV spillage entering a watercourse from the proposed road development is low at 0.09%. This spillage risk analysis was based on the medium growth AADT Traffic figures, presented in **Chapter 6, Traffic Assessment and Route Cross-Section**, which indicate that HGV numbers are only 3 to 6% of the AADT number.

A similar assessment was carried out for the proposed outfalls to groundwater via infiltration basins and is presented in **Table 11.32** and similarly show very low probabilities.

Notwithstanding the very low spillage risk for this proposed road development, all storm outfalls will include pollution control facilities at their outfalls. All of the mainline drainage network outflows will pass through a suitably sized oil and petrol interceptor and then through a constructed wetland with a permanent pool followed by an attenuation pond or infiltration basin, depending on the design prior to discharging through its outfall. A penstock or similar online control restriction will be installed upstream of the petrol interceptor. In the event of a serious spill these controls can be put in place to block the outflow of contaminants allowing time for clean up to take place.

Table 11.31: Serious Spillage Pollution Risk Assessment at Proposed Outfalls to Surface Watercourses

Drainage Reference	Approx. Chainage	Watercourse	Outfall Risk (%)	Combined Risk (%)

11.5.4.2 Routine Road Runoff

Research has found that a broad band of potential pollutants are associated with routine runoff from road schemes arising from road traffic and road maintenance. These contaminants are generally associated with the particulate phase and are principally heavy metals, hydrocarbons and suspended solids and de-icing agents (salt and grit) and to a lesser extent nutrients, organics and faecal contamination. In terms of the potential impact to receiving watercourses research has found the first flush runoff (10 to 15mm rainfall runoff following an extended dry period) can produce elevated concentrations locally in the receiving waters. The impact of contaminants within routine road runoff depends on the loading (associated with traffic numbers) and the available dilution in the receiving watercourse.

The high density of outfall discharge points along the mainline of the proposed road development, disperses and reduces the potential pollutant point load from the proposed road drainage system. The design traffic volume in conjunction with the relatively small contributing road areas will not give rise to any potential significant hydraulic or pollutant loads on the receiving waters. The potential impact of routine runoff in the absence of storm drainage pollutant removal represents a localised impact on water quality of the receiving environment. The overall loading of heavy metals, sediments, hydrocarbons and other waste products on the receiving waters will be significantly reduced through the provision of various drainage design elements such as, petrol and oils interceptors, filter drains, grassed surface water channels, wetlands, infiltration area and storm attenuation ponds upstream of the outfalls designed to capture and treat the first flush rainfall runoff events.

TII publications document DN-DNG-03065 (HD45) gives guidance and assessment tools for the impact of road projects on the water environment, including the effects of runoff on surface waters. The Highways Agency Water Risk Assessment Tool (HAWRAT) is the tool used to assess the effects of road runoff on surface water quality and uses toxicity thresholds based on UK field research programmes which are consistent with the requirements of the Water Framework Directive (WFD) and appropriate for assessment of National Road Schemes in Ireland. The UK research programme has shown that pollution impacts from routine runoff on receiving waters are broadly correlated with Annual Average Daily Traffic (AADT) numbers.

A HAWRAT assessment has been carried out for all proposed mainline drainage outfalls directly discharging to surface watercourses along the proposed road development, including realigned and upgraded link roads and junctions, see **Table 11.33** below. The HAWRAT assessment tool uses the AADT category of 10,000 to 40,000 in the assessment process which is appropriate for the Design Year AADT numbers. Further to the west, as ADDT numbers reduce, this category is likely to be precautionary in terms of its water quality predictions as the ADDT numbers are much closer to 10,000 than 40,000. Anticipated traffic volumes on each section of the proposed road development are detailed in **Chapter 6, Traffic Assessment and Route Cross Section**.

It is also important to note that the HAWRAT assessment presented here is based on direct discharges to watercourses in the absence of proposed drainage design measures, that include petrol interceptors, water quality treatment ponds and wetlands and storm attenuation ponds, and therefore the predictions are worst case not including any treatment performance which have been designed to achieve well in excess of 60% reduction in suspended sediments and associated heavy metal contamination. The HAWRAT analysis was carried out on all of the proposed outfalls in the absence of proposed water quality and attenuation measures and the required level of treatment quantified, refer to **Table 11.33** below.

In cases where the road drainage outfall discharges to a drainage ditch with very limited drainage catchment, resulting in potentially dry / stagnant conditions during low flows, the local HAWRAT assessment will produce a FAIL result, as there is no dilution available for solutes nor flow velocities to disperse sediment away from the outfall. These failures in the HAWRAT analysis are not considered to represent an impact as such minor ditches are only serving as conduits to the larger stream and river channels. In these cases, the potential impact on watercourses is also assessed further downstream where it joins the larger stream channel, refer to outfall locations on **Figures 11.6.101** to **11.6.115**.

In general, HAWRAT is considered to provide a precautionary means to assess those proposed road outfall discharges in respect to soluble and sediment-bound pollutants. The screening parameters are sediment and the dissolved heavy metals of zinc and copper concentrations. These represent the primary waste constituents in the road drainage discharges and used as screening parameters for other pollutant substances such as de-icing agents of salt and grit, hydrocarbons, Cadmium, Pyrene, PAHs, nutrients and organics. The required treatment performance in terms of percentage reduction of soluble and sediment contaminants is also presented in **Table 11.33**.

Table 11.33: Results of the HAWRAT Road Outfall Water Quality Assessment of Receiving Surface Waters

Outfall No. Refer to Figures 11.6.101 to 11.6.115	**Water Hardness (mg/l $CaCO_3$)**	**Dissolved Copper (ug/l)**	**Dissolved Zinc (ug/l)**	**Sediment Deposition Index**	**Comment**

S18a	Med 50 – 200	<0.00	<0.00	1	Pass Solubles, Pass Sediment
S18b	Med 50 – 200	<0. 00	<0.00	2	Pass Solubles, Pass Sediment

A HAWRAT water quality toxicity analysis of the proposed road development discharges to the River Corrib was also carried out modelling the soluble heavy metal pollutants of copper and zinc from combined outfall sources. In this analysis the 95 percentile low river flow was specified, an AADT Class of >10,000 and < 40,000 and the combined load of all five outfalls having a total road impervious area of 7.08ha and a permeable (Grassed) area of 5.43ha. The annual rainfall catchment was taken as 1250mm, the base flow index as 0.5 the water hardness as medium (50 to 200 CaCO3 mg/l). A cumulated load from all of the outfall discharges (S14A, S14B, S15, S18A and S18B, ref **Figures 11.6.101** and **11.6.114**) was also specified in the HAWRAT assessment water quality toxicity analysis so as to include for the combined effects on the Dangan reach section of the River Corrib. Note that the outfall from the proposed NUIG pitches S44 was not assessed in this combination as this catchment is not a road, therefore routine road runoff water quality characteristics from traffic at this location is not applicable. This combined load simulation showed no discernible acute or chronic impacts on the water quality of River Corrib due to the high dilutions rates available in the River Corrib. The event statistics for the untreated effluent in the drainage runoff give the following event statistics, refer to **Tables 11.34** and **11.35**. These loadings are used as the mean concentration in the two-dimensional modelling of the River Corrib receiving waters presented latter in this section.

Table 11.34: Event Statistics for soluble heavy metal pollutants in untreated Road Drainage Runoff

	Dissolved Copper Cu (µg/l)	**Dissolved Zinc Zn (µg/l)**
Mean	24.00	67.53
90%	45.95	144.85
95%	57.54	191.09
99%	90.93	346.16

90%	0.00	0.01
95%	0.01	0.02
99%	0.03	0.08

The event statistics for this grouped discharge give a mean event concentration in the River Corrib of that is negligible (<0.00 (µg/l)) for copper and (<0.01 (µg/l)) for zinc and 99-percentile event statistics of 0.03 (µg/l) dissolved copper and 0.08 (µg/l) dissolved zinc which are considered to represent only trace concentrations and well below the maximum allowable concentrations of 30 and 100 µg/l as set out in the Surface Water Regulations. In the HAWRAT manual the runoff specific thresholds for short term exposure of organisms gives the following short-term exposure threshold values for dissolved copper and zinc.

Table 11.36: Maximum Short-term exposure threshold limits for dissolved copper and zinc (WRc 2007)

Exposure Duration	Copper (µg/l)	Zinc (µg/l)		
		Harness		
		Low (< 50mg/l CaCO3)	Medium (50 to 200 mg/l CaCO3)	High (>200mg/l CaCO3)
24 hour	21	60	92	385
6 hour	42	120	184	770

This assessment clearly shows that the dilution available in the River Corrib even at 95-percentile low flow conditions ensures that the potential toxicity impact from road runoff contaminants on this salmonid river will be negligible and well below allowable levels for dissolved copper and zinc set out in the Salmonid Waters Directive and in the Surface Waters Regulations and also well below the recommended short-term exposure thresholds presented in **Table 11.36** above.

It should be noted that the above assessment is carried out in the absence of proposed road drainage water quality and attenuation treatment and therefore the potential impact will be considerably lower after the designed treatment.

The provision of first flush treatment in a wetland system and the storage in the attenuation pond provides residence time for the sediment to settle out before being discharged to the watercourse. This storage also reduces the outfall discharge rate with the contaminated first flush event being stored and released gradually.

This grouped assessment was also carried out on Sruthán na Libeirtí, the Knocknacarra, Bearna and Trusky Streams and were found to satisfy the HAWRAT water quality assessment in the downstream fishery reaches. The impact on water chemistry downstream in the coastal waters will be negligible due to the significant mixing available in the downstream reaches of the watercourses and within the tidally flushed estuarine reaches.

For the various individual outfalls discharging to small drains and streams with limited upstream catchment, it is found that the majority of these outfalls fail the HAWRAT assessment (in absence of pollution control measures), simply because there is negligible flow for dilution during 95-percentile low flow design conditions. At these locations, these failures are not considered significant as locally these smaller drains are not fishery sensitive and further downstream in the receiving streams the flow rate and contributing catchment area increases which lessens any potential impact.

The proposed storm drainage design for all proposed new surface water outfalls discharging to watercourses includes a spillage containment area ($25m^3$), a petrol and oil interceptor, a surface flow (SF) wetland with a permanent pond depth of 0.6m (to take first flush volume 15mm) and an attenuation pond (typically having a storage volume of a further 70mm rainfall over the paved area). Such facilities will achieve a long hydraulic residence time for first flush pollutant events ensuring good settlement performance. Flood attenuation will not be provided at the direct outfalls to the River Corrib S18A and S18B as attenuation of the proposed road storm flow is not warranted given the immense scale of the River Corrib catchment and capacity of the channel relative to the proposed road drainage direct discharges at S18A and S18B. The other pollution control elements including spillage containment, wetland first flush treatment and petrol and oil interceptors will be provided to achieve storm water treatment and accidental spillage protection for these outfalls.

The expected performance of the designed pollution control measures is expected to achieve in excess of 60% settlement performance of particulate matter but for soluble substances unlikely to achieve above 30% reduction and lower performances during the non-growing season, refer to **Table 11.37** below. The design ensures no significant water quality impact on receiving designated waters of the Lough Corrib cSAC and Lough Corrib SPA and the downstream Galway Bay Complex cSAC and Inner Galway Bay SPA.

Table 11.37: Expected Pollutant Removal Performance of Vegetated systems extracted from TII DN-DNG-03063

Runoff Constituent	**Stormwater treatment system Performance**					
	Swales	**Infiltration Basins**	**SF Wetlands**	**SSF ** Wetlands**	**Detention / Retention Ponds**	**Sedimentation Ponds**
Sus Solids & associated heavy metals	Good	Good	Good	Good	Moderate	Good
Heavy Metals in solution *	Moderate - Good	Moderate - Good	Moderate - Good	Good	Poor	Poor - moderate
Oil and grease	Good	Moderate - Good	Good	Good	Moderate	Moderate
Nutrients	Poor	Poor	Moderate - Good	Good	Poor	Poor - moderate

Notes:

Poor represents < 30% removal efficiencies, Moderate represents 30 to 60% removal efficiency and Good represents > 60% removal efficiency

* applicable to Growing Season

** very limited operational life of SSF Wetlands due to clogging of substratum

In general, the most likely impact of untreated road runoff from the proposed road development is the increased total suspended solids loading to receiving waters and associated trace amounts of heavy metals (Cu, Zn) and hydrocarbons. At all proposed surface drainage outfalls, water quality treatment of the sediment load is provided for, which will reduce local impacts from sediment deposition accumulation and potential toxicity levels in the stream/drain channel immediately close to the outfall.

The two tunnel sections of the proposed road development do not receive direct surface water runoff, however small volumes of water could potentially be carried into the tunnel on tyres and bodies of wet vehicles. These volumes will be picked up by the internal sealed tunnel drainage and pumped to the foul sewer. This volume for treatment is miniscule (fraction of a percent) in comparison to the overall sewage and combined storm volume treated at the Mutton Island Plant and discharged to the Galway Bay via the Mutton Island marine outfall and therefore will have no perceptible effect of treatment performance of the Mutton Island Treatment Plant and the Galway Bay receiving waters.

The Water Quality Impact Assessment is presented in **Table 11.38** below:

Table 11.38: Water Quality Impact Assessment

Network Drainage Ref. No.	Outfall Chainage	Dilution Characteristics	Receiving Water Details	Water Quality Impact
S1	0+000	Low summer dilution available	Sruthán na Libeirtí	Slight Permanent Local Slight downstream
S2	0+625	Low summer dilution available	Sruthán na Libeirtí	Slight Permanent Local Slight downstream
S3	0+900	Low summer dilution available	Sruthán na Libeirtí	Moderate Permanent Local Slight downstream
S4A	1+550	Very Low summer dilution available	Trusky Tributary	Moderate Permanent Local Slight downstream
S5A	2+750	Low summer dilution available	Trusky Tributary	Slight Permanent Local Slight downstream
S7A	3+950	Very Low summer dilution available	Bearna Tributary	Moderate Permanent Local Slight downstream
S7B	3+950	Moderate summer dilution available	Bearna Stream	Slight Permanent Local Slight downstream
S8	4+000	Low summer dilution available	Bearna Tributary	Slight Permanent Local Slight downstream
S9	4+150	Moderate summer dilution available	Bearna Stream	Slight Permanent Local Slight downstream
S10	4+850	Low summer dilution available	Bearna Tributary Tonabrocky	Slight Permanent Local Slight downstream
S11	6+000	Very low summer low flow dilution available	Storm Sewer to Knocknacarra	Slight Permanent Local Slight downstream
S12	6+850	Low summer low flow dilution available	Knocknacarra Tributary	Moderate Permanent Local Slight downstream
S13	7+350	Very low summer low flow dilution available	Knocknacarra Tributary	Slight Permanent Local Slight downstream
S14A	8+300	Very low summer low flow dilution available	Minor River Corrib Stream	Moderate Permanent Local and imperceptible in downstream receiving Corrib waters
S14B	8+550	Very low summer low flow dilution	Minor River Corrib Stream	Slight Permanent Local and imperceptible in downstream receiving Corrib waters
S15	east of N59 link	Very Low summer dilution	Local drainage Ditch to River Corrib	Moderate Permanent Local and imperceptible in downstream receiving Corrib waters
S18A	9+250	Very High Summer low flow dilution	River Corrib	Slight Permanent Local

S18B	9+425	Very High Summer low flow dilution	River Corrib	Slight Permanent Local
S21A	12+250	Low Summer dilution Eventually drains to groundwater	Ballindooley Lough	Moderate Permanent Local

Detailed Assessment of River Corrib

River Corrib Channel

Two-dimensional transport and dispersion modelling of the outfall discharges in the River Corrib was carried out so as to assess the local impact effects of the plume near the inflow points and downstream, where full mixing with the receiving flow will not have fully occurred. Simulations were carried out modelling the two principal soluble heavy metal pollutants in the drainage effluent, namely copper and zinc and included the proposed first flush stormwater treatment in the wetland and attenuation ponds, which are designed to capture the first flush event of 15mm rainfall runoff and release slowly back to the River Corrib system so that a high percentage of the sediment is removed through settlement. Low flow conditions were modelled in the River Corrib with the river discharge rate set at the 95-percentile low flow of 14cumec (note median river flow is 82cumec) and the downstream water level upstream of the Salmon Weir barrage set at 5.7m OD (median 5.9mOD).

The event mean runoff concentrations from the HAWRAT model was specified as the storm effluent concentration at the outfalls of 24 µg/l Cu and 67.53 µg/l Zn. The simulation was run for combined outfall discharges on the western side of the River Corrib (outfalls 14A, 14B, 15 and 18A). An independent simulation for outfall S18B on the eastern bank of the River Corrib was also run and results combined with the western outfall simulations to predict the overall impact of the proposed road drainage discharge on the River Corrib. Note that the outfall from the proposed NUIG pitches S44 was not assessed as part of this analysis as this catchment is not a road, therefore routine road runoff water quality characteristics from traffic at this location is not applicable.

The drainage discharge plume in the River Corrib migrates with the flowing river downstream towards Galway Bay and therefore exposure duration is limited to hours as opposed to days. The maximum predicted concentrations throughout the model domain are presented below in **Plates 11.2** to **11.7** which show that the plume hugs the near bank side of the river for quite a distance downstream before fully mixing across the river channel. The simulations show that during the River Corrib low flow conditions the stormwater plume does not enter via the small channel east of Jordan’s Island and therefore has very limited effect on the Terryland Galway City water supply intake. It is also noted that the plume does not travel up in the Coolagh Lakes system under these conditions. The large dispersion provided by the River Corrib result in rapid dilution and low trace level pollutant concentrations in the receiving water. The potential impacts on water quality in Lough Corrib cSAC and Lough Corrib SPA arising from the plume are imperceptible.

The analysis shows that the potential soluble toxicity levels of copper and zinc in the receiving waters are negligible in terms of the threshold levels for 24-hour and 6-hour exposure periods. The available dilution in the River Corrib at low flow conditions is still very large and therefore the combined discharge from the various outfalls to the reach is very well diluted and does not impact the water quality or quantity in the receiving waters.

These simulations predict very low far-field concentrations of heavy metal pollutants under the River Corrib 95-percentile low flows of less than 0.05µg/l dissolved copper and less than 0.1µg/l dissolved zinc in the river channel near Jordan's Island. More elevated concentrations are predicted close to the outfalls of S18A and S18B on both River Corrib banks with predicted concentrations with a maximum local concentration of 1.75µg/l dissolved copper and 4.92µg/l dissolved zinc. These locally elevated concentrations are well below any potential exposure threshold levels for heavy metals (refer to **Table 11.36**) and easily satisfy the surface water and Salmonid Waters Regulations. At mean river flow the concentration both locally at the outfall and fully mixed downstream are significantly lower at almost six times lower than the River Corrib low-flow scenarios described above.

The potential impact of de-icing agents such as sodium chloride on the receiving water quality of the River Corrib will not result in a water quality impact as the dilution is large and particularly so during winter months, which is the high flow period with river flows generally above the median flow which dilutes and rapidly transports the salt load through the lower reaches of the River Corrib out to sea where they are imperceptible and have no effect.

The water quality impact of the proposed stormwater discharge on the River Corrib, given its high dilution and assimilative capacity, represents only a slight impact immediately local to the outfalls. The high water quality status of the River Corrib will not be affected by the proposed road development and its road drainage discharges.

The dispersion analyses show only trace pollutant concentrations reaching Jordan's Island channel and the Terryland Galway City water supply intake from the proposed road drainage discharges and can be concluded that the first flush impact of road drainage runoff on the water quality of the intake flow will be imperceptible.

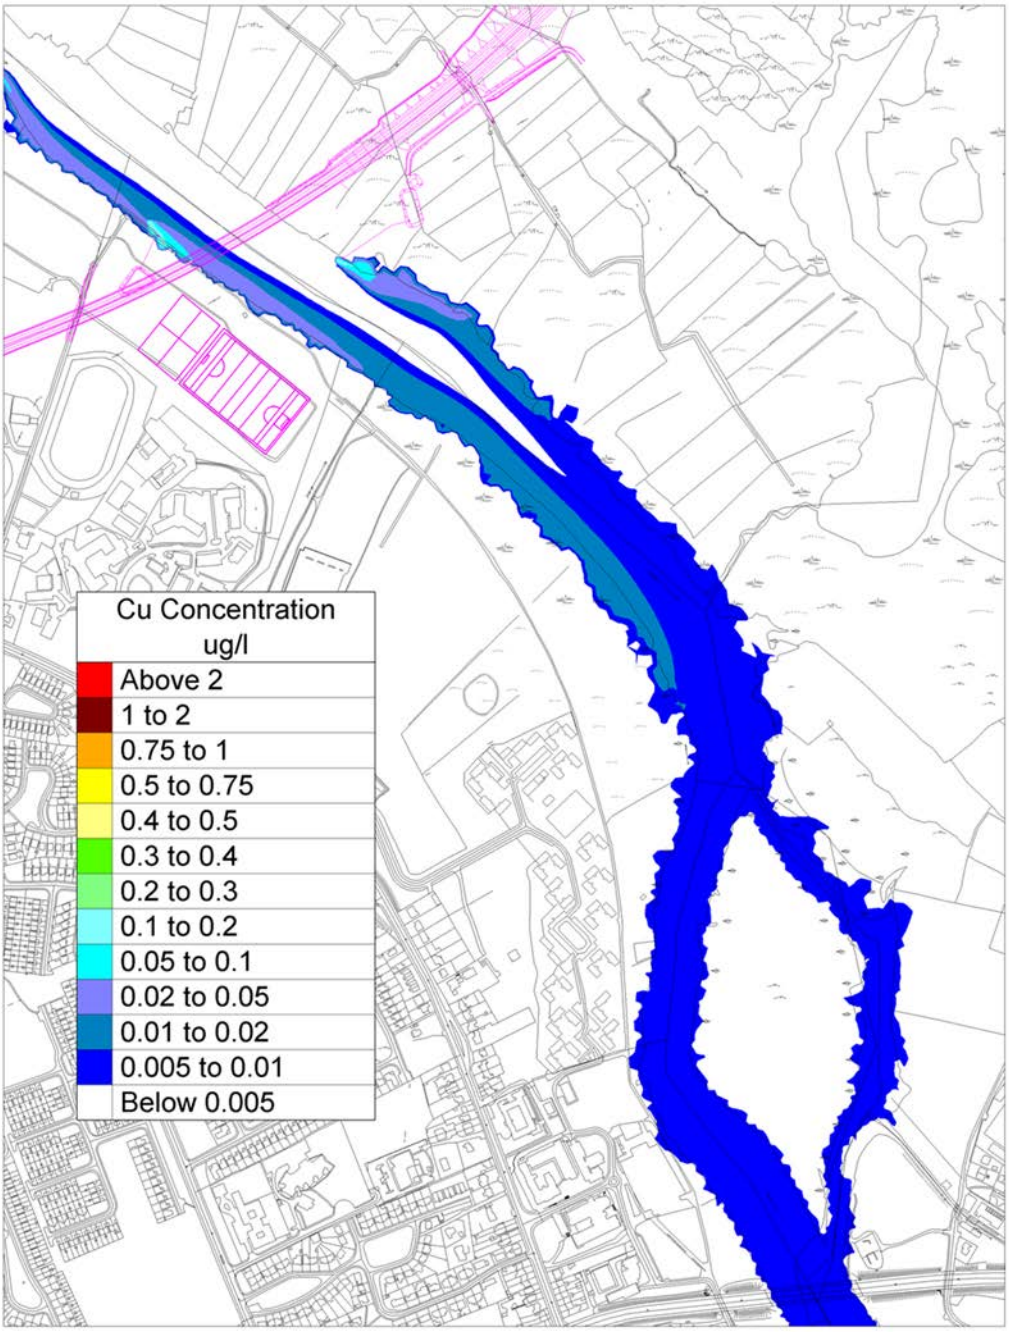

Plate 11.6: Maximum Dissolved Zinc Concentration for First Flush Rain Storm Event and 95% River Corrib Low Flow (14cumec) for all combined Outfalls (14A, 14B, 15, 18A and 18B)

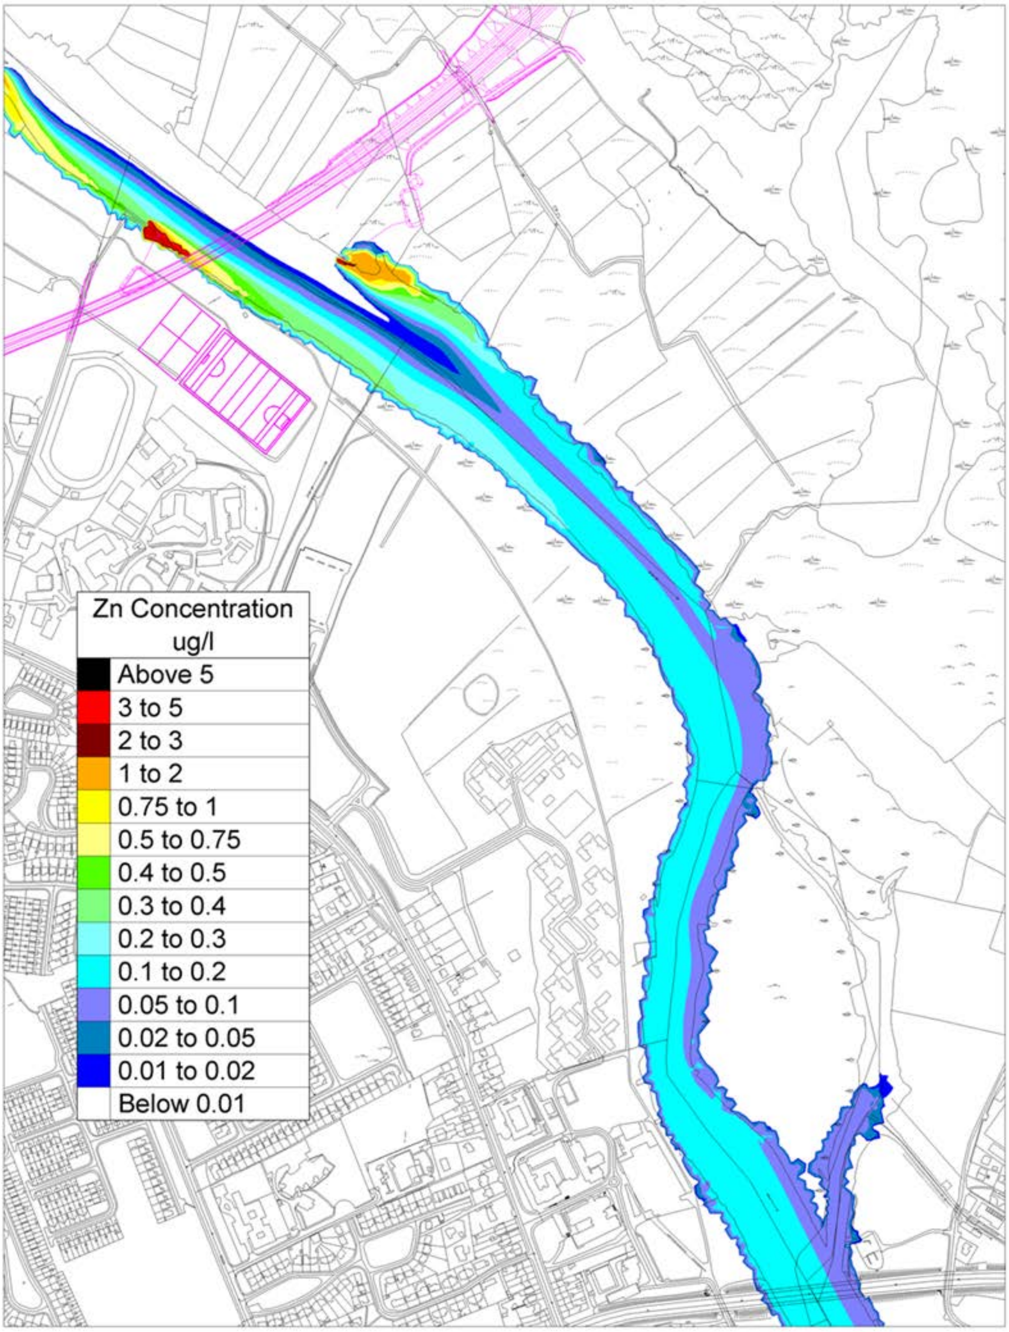

Plate 11.7: Maximum Dissolved Zinc Concentrations for First Flush Rain Storm Event and median River Corrib Flow (82cumec) for all combined Outfalls (14A, 14B, 15, 18A and 18B)

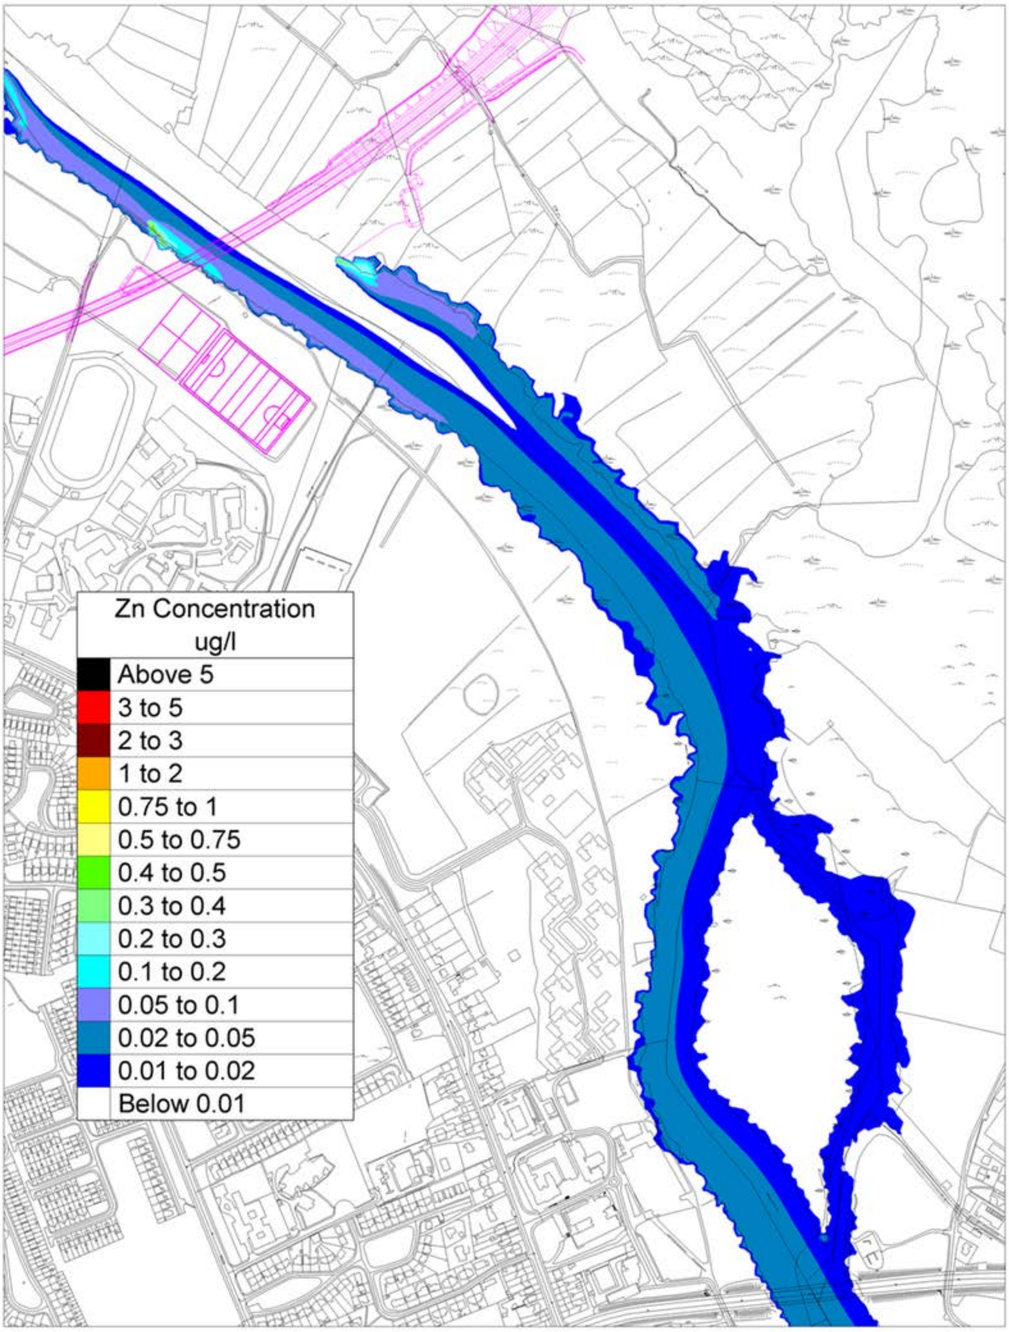

Detailed Assessment of Coolagh Lakes

The Coolagh Lakes and surrounding riparian lands form part of the Lough Corrib cSAC. The proposed road development traverses the Coolagh Lakes catchment from Ch. 9+700 to Ch. 11+800. There are no proposed direct storm water discharges to the Coolagh Lakes with all proposed road drainage discharges to groundwater via engineered infiltration basins. This runoff water drains into the limestone bedrock aquifer and ultimately some of this drainage water potentially recharges the Coolagh Lakes system. The protection of the groundwater quality is dealt with in detail in **Chapter 10, Hydrogeology**, with the infiltration basin and wetlands systems at each of these groundwater outfalls designed to remove pollutants and protect the highly vulnerable, regionally important, groundwater aquifer from adverse impacts by the proposed road drainage runoff. These groundwater quality design measures will also prevent impact to the hydrochemistry of the Coolagh Lakes through removal of pollutants via provision of a deep soil filter and generous infiltration areas at the relevant outfalls S19A and S19B and S20. The impact on the Coolagh Lakes water quality is rated as an imperceptible impact.

Detailed Assessment of Ballindooley Lough

The mainline section of the proposed road development from N84 Headford Road Junction to N83 Tuam Road Junction will be serviced by outfall S21B which is designed to discharge to groundwater in the vicinity of Ballindooley Lough where the groundwater flow gradient is southwards away from the lough. As a consequence, there will be no water quality or flow regime impacts on the lough from the mainline carriageway of proposed road development during the operational phase.

A single outfall S21A servicing the on-off slip roads and 250m of the existing N84 Headford Road at the N84 Headford Road Junction will discharge via a ditch to Ballindooley Lough system, entering the small lough to the southwest first which is connected to the bigger lough by a wide, straight c.200m long drainage channel. The total drainage area for this section is 3.31ha and the impervious road area is 1.36ha. This represents an average inflow rate of 0.3l/s and the annual average catchment drainage inflow is 20l/s from its 225ha catchment area presenting an average dilution of 67. Ballindooley Lough potentially represents a sink for sediment with the lake rising and falling with the groundwater table and in dry weather periods its water level remains perched above the receding groundwater table.

This proposed outfall is designed with pollution control measures that include a spillage containment volume, a petrol-oil interceptor, a wetland and an attenuation pond. These measures will reduce the potential sediment load on Ballindooley Lough by well over 60%. Circa 1.4km of the existing N84 Headford Road carriageway discharges untreated and uncontrolled surface water into Ballindooley Lough via road side trenches and storm pipes.

An assessment of the predicted loads and concentrations from road runoff from this outfall are presented in **Table 11.39** below. The annual mean concentrations of dissolved copper and zinc will rise by 0.399 and 1.417 µg/l respectively based on Event Mean concentrations and loads for significant road drainage pollutants in accordance with Table 3.1 of the TII publications DNS-03065. All other parameters considered below in **Table 11.39** represent minor increases and will not affect the water quality status of Ballindooley Lough.

Table 11.39: Predicted mean load of Stormwater Pollutants from Outfall S21A and predicted mean increase in pollutant concentration within Ballindooley Lough from S21A

Main Road Drainage Pollutants	Road Runoff Load	Road Runoff Event Mean Concentration	Pollution Control Performance	Lake mean storm Inflow Concentration	Mean Lake Concentration increase
	kg/yr	μg/l	%reduction	μg/l	μg/l
Total Copper	863	91.2	60%	36.48	0.547
Dissolved CU	296	31.3	15%	26.605	0.399
Total Zinc	3336	352.6	60%	141.04	2.116
Dissolved ZN	1051	111.1	15%	94.435	1.417
Total Cadmium	5.96	0.63	60%	0.252	0.004
Total Fluoranthene	9.65	1.02	60%	0.408	0.006
Total Pyrene	9.74	1.03	60%	0.412	0.006
Total PAH	71.1	7.52	60%	3.008	0.045

Please note the predicted lake concentrations in **Table 11.39** above do not take reducing factors such as filtration and absorption and settlement within the lake, or of plant uptake and natural biodegradation.

The proposed road development will have a negligible impact on the flow regime within the lake from the proposed road drainage outfall and the slight encroachment of the proposed road development into an extreme winter flood area. The overall water quality impact on the lake is classified as slight permanent impact and particularly as circa 1.4km of the N84 Headford Road already discharges uncontrolled and untreated to the lake catchment. The proposed road discharge is treated and the remaining sediment is likely to settle out locally within the small lake and this represents a potential moderate local impact on the lake sediments. The overall hydrological impact rating of the proposed road development on Ballindooley is classified as a local slight permanent impact.

11.5.5 Surface Water Supply Sources

There are two very large public surface water abstractions in proximity to the proposed road development. These are the Luimnagh regional water abstraction from Lough Corrib located over 15km upstream (north) of the proposed crossing point of the proposed road development of the River Corrib and the Terryland Galway City water supply abstraction from the River Corrib at Jordan's Island located 1.7km downstream of the crossing point on the eastern side of the river. The proposed road is not within the zone of contribution to the Luimnagh supply being located well downstream, whereas, the proposed road development is in close proximity to the Terryland Galway City supply intake having a travel time of potentially only 30 minutes to 2 hours to this abstraction point depending on the flow magnitude of the River Corrib. By virtue of the Luimnagh Lough Corrib abstraction being located over 15km upstream there will be no potential water quality impact from the proposed road development either during construction or operation phases.

The proposed road development will not have any perceptible impact on River Corrib flows and therefore will not impact the Terryland abstraction in terms of quantity of supply.

The close proximity of the proposed road development to the Terryland Galway City water supply intake, located within the immediate source contribution area, any pollution of the River Corrib by the proposed road development either during construction (construction runoff, construction accidental spillages (concrete, hydrocarbons), etc.) or during operation (spillages from road accident and routine road runoff) from the various contributing road drainage outfalls S14A, S14B, S15, S18A and S18B) has a high potential of reaching and contaminating the abstraction point at Jordan’s Island. This is particularly so for activities on or near the eastern bank. The abstraction is less sensitive to activities and discharges on the western bank but can still potentially be impacted given the right flow and meteorological conditions (southerly and westerly winds). The Terryland Galway City water supply is a fully treated water supply with tertiary treatment which provides some protection against significant impact by the proposed road development in the event of worst case spillage incident.

The dispersion analyses modelling of the River Corrib storm outfalls for the operational phase drainage discharges shows only trace pollutant concentrations reaching Jordan’s Island channel and the Terryland Galway City water supply intake under the critical first flush design conditions and can be concluded that the impact of routine road drainage runoff on the water quality of the Terryland Galway City water supply abstraction will be imperceptible.

The outfall spillage risk assessment indicates very low potential for serious accidental spillage and by the provision of outfall control facilities in the design, the potential impact from the operational phase of the proposed road development is rated as slight. Construction activities without adequate construction management mitigation measures, particularly on the eastern river bank have the potential to impact on this important abstraction which has a regionally important attribute value. Taking account of the good dilution available in the River Corrib, the avoidance of any major instream works in the channel, and the water treatment process available at the Terryland Galway City water supply treatment works to purify the water for public consumption, this construction impact is rated as a potential slight to moderate temporary impact. Notwithstanding this, a serious spillage has significant consequences and therefore mitigation measures to prevent construction based activities polluting the River Corrib are necessary.

Other water rights downstream are associated with the canals and various headraces both immediately to the east and west of the River Corrib channel through Galway City. The proposed road development will have an imperceptible impact on the flow regime and water quality of the River Corrib through Galway City and therefore will not impact flows and water quality in the various canals and main river channel.

11.5.6 Flood Risk

A Flood Risk Assessment (FRA) of the proposed road development in accordance with the Planning System and Flood Risk Management Guidelines (2009) was carried out and the FRA Report can be found in **Appendix A.11.1**. This assessment investigated the potential flood risk to the proposed road development itself and the potential flood impact arising from the proposed road development. A summary of the findings of the FRA is presented below.

Road developments by their nature traverse watercourses and flood risk areas along their selected route. The proposed road development will involve the crossing of 17 small watercourse channels requiring culverting, the local diversion/realignment of a number of these watercourses and road drainage outfall discharges to these watercourses at a proposed 23 number outfalls. The proposed road development involves a major bridge crossing over the River Corrib at Dangan, the encroachment of a number of small pluvial flood risk areas, wet grassland areas, the very slight encroachment of the River Corrib Floodplain adjacent to the Coolagh Lakes and the Ballindooley Lough floodplain. The proposed reconfiguration/redevelopment of the NUIG pitches at Dangan is shown to slightly encroach the River Corrib floodplain area. The most significant flood risk area that is encroached by the proposed road development is a large pluvial flood risk area adjacent to the N83 Tuam Road Junction at Twomileditch.

The vertical alignment of the proposed road development has been assessed against predicted fluvial, pluvial and groundwater flood levels and found to be sufficiently clear of flooding under both present day and future climate change scenarios. The proposed road development is not subject to any coastal flood risk being sufficient elevation naturally even with high range sea level rise of 1m.

The proposed bridge structure over the River Corrib is a 153m bridge span and avoids any instream piers and avoids the River Corrib floodplain width at the predicted 100year and 1000year flood levels. The potential impact of the proposed River Corrib bridge structure on flooding and flood risk has been shown through detailed modelling presented in the FRA Report in **Appendix A.11.1** to have no discernible impact on flood levels. The River Corrib Bridge crossing is considered not to present a residual flood risk as structure completely spans the floodplain width, no instream weirs and a soffit to flood level clearance of over 10m giving no opportunity of blockage by floating debris. Section 50 (1945 Arterial Drainage Act) approval has been granted by the OPW, who are the competent authority in respect to Flood Risk Management in Ireland, for the proposed River Corrib Bridge.

There is minor encroachment by the embankment of the proposed road development on the River Corrib floodplain near the Coolagh Lakes section at Ch. 9+890. This represents a very minor encroachment and will not result in a perceptible impact on flooding or on the active flow regime of the River Corrib and the Coolagh Lakes themselves and therefore such impact is rated as an imperceptible flood impact.

The proposed redevelopment of the NUIG pitches at Dangan represents a slight encroachment of the River Corrib’s 100-year and 1000-year flood zones at Dangan. The development of the pitches is likely to result in the raising of land so that the pitches are free from flooding and can drain effectively. The potential loss of floodplain storage is miniscule in comparison to the available flood storage in the River Corrib catchment and will not impact the flow regime in the River Corrib or affect flood risk elsewhere. Recreational/sports pitches are considered to be a suitable type of development within high and moderate flood zones A and B under the flood risk management planning guidelines.

At total of 16 small watercourses and drains will be crossed by the proposed road development and subsequently will be culverted. The topography and small catchment areas associated with these watercourses ensures that the associated flood zones for these streams is very localised having relatively narrow floodplain widths along these streams. The proposed culvert sizes are very generous and will not result in any constriction to flow and therefore any impact on flooding and flood risk is categorised as a slight permanent negative impact. Section 50 approval has been obtained from the OPW concerning flooding and flood capacity of all proposed culverts. The impact of all of the proposed culvert and bridge structures on flood water level and flood risk to properties is rated as imperceptible. All new culverts represent a residual flood risk in that serious blockage could cause local flooding.

A slight encroachment on the Ballindooley Lough flood zone by the embankment of the proposed road development is predicted and the effect of this has been assessed as minor and the impact on flooding assessed as a slight permanent impact.

There is a potential flood risk to the proposed Lackagh Tunnel from elevated groundwater table combined with pluvial flooding within the quarry. This risk is associated with the potential for elevated flood levels within the quarry floor, under extreme 1000-year flood events and climate change conditions, to potentially enter the tunnel from the eastern portal entrance on the quarry side. As the proposed road development traverses through the quarry, it will reduce the available storage for rainfall and increase pluvial ponding depths contained within the lower bench of the quarry. This could potentially increase flood levels local to the quarry. The potential risk is significant but has been reduced to slight by design, through raising the minimum road level at the tunnel portal entrance by 1m above the recorded historical worst flooding event (highest recorded winter groundwater level is 15.7m OD. and lowest design road level is 16.735m OD). Such a clearance, given the limited drainage catchment area, is considered sufficient to minimise flood risk. Topographically the quarry area is self-contained and the proposed infilling as a result of the proposed road development will not result in flood waters spilling from the quarry and causing flooding elsewhere with flood waters retained and receding with the groundwater table. Permeable infill material is recommended for use within the quarry so as to maintain the drainage route to groundwater through it limestone base and sides.

Road drainage outfalls discharging to limited capacity (flow and infiltration capacity) surface and groundwaters sources are provided with suitably sized flow control and attenuation and infiltration basins. The flow controls are designed to achieve greenfield flood runoff rates in the case of surface water outfalls, and soil infiltration capacity in respect to groundwater outfalls. Flood attenuation for the River Corrib outfalls from S18A and S18B is not required due to the large scale of the River Corrib catchment and its flood response time relative to the proposed storm discharge. The potential impact rating of the storm drainage outfalls on the receiving waters with respect to flow regime and morphological changes, and as such flood risk is presented in **Table 11.29**. This generally represents slight to imperceptible permanent impacts. The provision of infiltration basins and attenuation ponds represents a residual flood risk in respect to the continued design performance in respect to preventing local flooding and flood impact.

The provision of infiltration basins and attenuation pond facilities throughout the proposed road development represent a potential new source of flood risk as by their nature they temporarily impound road drainage waters and release slowly to the receiving waters. These are engineered structures designed to deal with 1 in 100-year storm event with allowance for climate change and freeboard. Proposed design water depths vary from 1 to 1.85m and therefore represent a relatively low flood risk under normal operating conditions. In addition, infiltration basins are sized such that half of the basins volume will empty in 24 hours or less which facilitates space for consecutive storm events. However, such facilities may be subject to potential blockage and therefore overtop giving rise to potential local flooding. Flow control devices which have small orifice sizes in order to restrict flows to greenfield runoff rates can be prone to blockage.

The residual flood risk is minimised in the design as the following maintenance schedule for the proposed road development drainage infrastructure:

- Regular inspections of all drainage facilities that include, culverts, flow control devices, outfalls, attenuation ponds and infiltration basins and the road drainage network to ensure that the drainage system is in proper working order and performing as designed

Several small pluvial flood sources are encountered along the proposed road development associated with small local depressions which will be either fully or partially removed and are highlighted in the FRA Report in **Appendix A.11.1**. The assessment indicates that these pluvial flood sources are very minor in respect to contributing drainage area and the extent of the flood area and the infilling of these will not result in significant impact on flooding, with the potential impact assessed as slight to imperceptible.

A large pluvial flood risk area near the existing N83 Tuam Road at Twomileditch is encroached by the proposed road development. This area has a significant flood risk with up to seven dwellings and the existing carriageway of the N83 Tuam Road at high risk of flooding (currently). The existing road and a number of dwellings have experienced flooding in the recent past. The critical flood levels for flooding on the N83 Tuam Road and adjacent dwellings is 18.0m to 18.5m OD. The local authority regularly deploy pumps to clear flooding from the existing road in this area. The proposed road development potentially encroaches the pluvial Flood Zone A (high probability of flooding zone) with the potential for 21.2% to 22.4% loss in available flood storage within these pluvial flood prone lands at a flood level of 18m and 18.5m OD respectively. Without suitable mitigation, the proposed road development has a potential at this location to remove flood storage and potentially worsen the flood risk at this location. This loss of flood storage represents a significant permanent impact on flooding and flood risk and therefore requires specific flood mitigation. In addition to the loss of storage, the proposed road development will also introduce a significant additional paved area to the contributing catchment of this flood zone. However, the drainage of this paved runoff area is designed to dispose separately to groundwater via a number of appropriately located and sized infiltration basins which minimises the contribution of the road pavement runoff to flooding at this location. The specific flood mitigation measures are dealt with in detail below in Section 11.6.

The proposed N59 Link Road South from Ch. 1+550 to 2+200 and the proposed upgrade / realignment to the Gort Na Bró and the Rahoon to Western Distributer Road are shown to be extensively located in the fluvial Flood Risk Zone A (High Flood Risk) of the Knocknacarra Stream, based on the Galway City Strategic Flood Risk Assessment (SFRA) Flood Zone mapping prepared by JBA (30 September 2015) and the OPW pFRA mapping. Both the Galway City Council SFRA and the OPW pFRA mapping are very coarse and did not include details of the stream channel or its various culverts. The assessments used the EPA/OSI historic watercourse alignment which no longer exists having been replaced and realigned by a large storm water pipeline as part of land development initiative. This flood risk mapping only allowed for overland flow based on poor resolution DTM lidar data and did not include for channel / storm pipe conveyance. Examination of this flood risk mapping against the OPW lidar 2m DTM ground levels clearly indicates that this mapping is unrealistic and coarse as the flood outline does not follow the local contours. As part of the FRA for the proposed road development the Knocknacarra Stream storm pipe trunk main was modelled using the Microdrainage software program with pipe invert levels, pipe diameters, manhole locations and cover levels specified using the storm drainage data provided by Galway City Council. The estimated design flows from the FSU method were input at the various nodal points of the storm sewer model and the micro-drainage program ran. The model results showed ample capacity within the storm pipe at both the 100 and 1000-year flood events not to result in flooding in the vicinity of the proposed N59 Link Road South or the various realigned junctions at Gort Na Bró and the Rahoon to Western Distributer Road. It is concluded that the proposed road development does not encroach the floodplain area or the flood risk zones of the Knocknacarra Stream and therefore will not impact on flooding. In keeping with the Galway City Sustainable Urban Drainage policy all storm discharge from the proposed road development to the Knocknacarra Stream will be attenuated to the natural greenfield runoff rates and therefore will not impact flood flows and flooding.

11.5.7 European Sites

Lough Corrib cSAC and Lough Corrib SPA

A summary of the potential hydrological impacts on the Lough Corrib cSAC are provided in in **Table 11.39**. The proposed road development via its drainage outfalls will provide a pathway for road runoff pollutants to enter the Lough Corrib cSAC and Lough Corrib SPA during construction and operational phases. Only one outfall S15 from the N59 Link Road North has a potential pathway via a drainage ditch that discharges to the River Corrib in the vicinity of the southern extent of the Lough Corrib SPA. The potential impacts from the operational phase have been reduced in the design process to minor and imperceptible both in respect to flow regime changes and water quality impact.

The potential impact of the proposed road development on the surface hydrology of the Coolagh Lakes system will be imperceptible. The proposed road development represents a potential pollution hazard and has a residual risk of pollution via contamination of the groundwater at its proposed infiltration basin. Proper management and regular inspection and maintenance of these drainage discharge facilities will significantly reduce the risk of pollution impact on the groundwater and the Coolagh Lakes system.

Galway Bay Complex cSAC and Inner Galway Bay SPA

A summary of the potential hydrological impacts on the Lough Corrib cSAC are provided in in **Table 11.40**.

The proposed road drainage treatment, the good natural buffering from the receiving watercourses before reaching the Galway Bay Complex cSAC and Inner Galway Bay SPA and the natural high dilution within the coastal and transitional waters of these European sites ensures that the residual impact on flow and water quality within the Galway Bay Complex cSAC and Inner Galway Bay SPA both locally and regionally will be negligible.

Construction impacts arising from the proposed road development represent a low risk to water quality within the Galway Bay Complex cSAC and Inner Galway Bay SPA due to the available buffering by the watercourses and by the high dilution within these European sites.

11.5.8 Water dependent habitats outside of a European site

The proposed road development traverses through and adjacent to the various water dependent habitats located outside of the European site. These habitats types encountered which have been mapped and described in **Chapter 8, Biodiversity** are summarised below in **Table 11.40**.

Table 11.40: Summary of water dependent habitats

Habitat Code	Habitat Name	Status
Fossitt Code PF1	Rich Fen and Flush	Non-Annex
Fossitt Code PF2	Poor Fen and Flush	Non-Annex
Annex Code 4010	Wet Heath	Annex I
Annex Code 6410	Molina Meadows	Annex I
Annex Code 7130	Blanket Bog (active)	Annex I
Annex Code 7140	Transition Mire	Annex I
Annex Code 7150	Rhynchosporion Depression	Annex I

The proposed road development has the potential to impact the water balance of water dependent wetland habitats through the potential diversion of overland and interflow that supplies these wetlands either through interception in the embankment toe drains, the subsurface filter drains, interceptor drain and by drainage in the road formation layer. **Table 11.41** presents an assessment of the impact to adjacent wetland habitats.

Table 11.41: Hydrological Impact Assessment on Water dependent habitats outside of a European site

Wetland Code	Habitat	Approx. Chainage	Location	Potential Impact
4030/4010	Mosaic of dry and Wet heath	0+700	Within proposed development boundary and to northwest	A toe drain of the proposed road development will drain a small section of this habitat, the potential hydrological impact will not extend beyond the hydrogeology ZOI
4010	Wet heath	0+700	Extends to within 30m north of the proposed development boundary	Wet heath located up gradient of the proposed road surface drainage. This habitat will not be impacted hydrologically
PF2/GS4	Poor Fen and Flush and wet grassland	0+750	Extends to within 20m north of the proposed development boundary	Located up gradient of the proposed road surface drainage. This habitat will not be impacted
4010	Wet heath	0+950	Within proposed development boundary	Habitat removed / lost. Refer to **Chapter 8, Biodiversity** for full details on habitat loss or removal
6410	Molinia Meadows	0+900	North of road	Located up gradient of the proposed road surface drainage. This habitat will not be impacted hydrologically
4010	Wet heath	1+250	Within proposed development boundary	Habitat removed / lost. Refer to **Chapter 8, Biodiversity** for full details on habitat loss or removal
4010	Wet heath	1+350	Within proposed development boundary	Slight encroachment and local drainage impact. The surface drainage impact will not extend beyond the hydrogeology ZOI
4010	Wet heath	1+450	Extends to within 30m Southwest of Road proposed development boundary	Located up gradient of the proposed road surface drainage. This habitat will not be impacted hydrologically
4010	Wet heath	1+400 - Na Foraí Maola to Troscaigh Link Road	Extends to within 8m north of Road proposed development boundary	Located up gradient of the proposed road surface drainage. This habitat will not be impacted hydrologically

Wetland Code	Habitat	Approx. Chainage	Location	Potential Impact
4010	Wet heath	1+750 to 2+400	Extends typically to within 50m north of Road proposed development boundary	Located up gradient of the proposed road surface drainage. This habitat will not be impacted hydrologically
4010	Wet heath	1+850 to 2+100	Located within and immediately north and south of proposed development boundary. Topography generally flat.	Habitat removed and local drainage effect both north and south of the proposed road toe drains. The surface drainage impact will not extend beyond the hydrogeology ZOI
4010	Wet heath	2+700	South(60m) and 40m west of Bearna-Moycullen Road	Located up gradient of the proposed road surface drainage. This habitat will not be impacted
6410	Molinia Meadows	2+850 to 2+950	130m south	Surface drainage at this habitat will not be impact by the proposed road development
4010	Wet heath	3+450 to 3+700	Extends to within 50m southeast of Road proposed development boundary. Habitat located downgradient and within the ZOI of the road	A small local drain that runs along the downstream boundary of this habitat will be diverted. The proposed road drainage and formation layer will capture and divert contributing overland and interflow away from this habitat. Potential Moderate Impact on the surface hydrology of this habitat. The groundwater ZoI does not extend downstream to this habitat and therefore it is likely that this habitat will not be lost
6410	Molinia Meadows	3+600	west of proposed development boundary	Located up gradient of the proposed road surface drainage. This habitat will not be impacted hydrologically
6410	Molinia Meadows	3+600	30m east of proposed development boundary	Habitat located downgradient with potential drying effect through interception of overland and interflow by road drainage and road construction. The hydrogeological ZoI does

Wetland Code	Habitat	Approx. Chainage	Location	Potential Impact
				not extend downstream to this habitat and therefore it is likely that this habitat will not be lost. Potential Slight Impact on the surface hydrology of this habitat
4010	Wet heath	3+650 to 3+800	Habitat within proposed development boundary	Habitat removed / lost. Refer to **Chapter 8, Biodiversity** for full details on habitat loss or removal
4030/4010	Mosaic and dry and Wet heath	3+750	Habitat generally Northwest and slightly within proposed development boundary	The proposed road development is in a cutting with drainage effect by interceptor drains and road filter drains. The surface drainage impact will not extend beyond the hydrogeology ZOI
4030/4010	Mosaic and dry and Wet heath	4+925	Habitat Northwest and slightly within proposed development boundary	The effect of the proposed road development drainage will not extend beyond the hydrogeology ZOI at this location
4010	Wet heath	5+075	located South and slightly within proposed development boundary	Slight local surface drainage effect on habitat by the proposed road development. The effect of the proposed road development drainage will not extend beyond the hydrogeology ZOI
4010	Wet heath	5+200	Extends to within 60m North of Road proposed development boundary	Located up gradient of the proposed road surface drainage. This habitat will not be impacted hydrologically
4030/4010	Mosaic and dry and Wet heath	5+250	Slight encroachment of Habitat within Fence Line	The effect of the proposed road development drainage will not extend beyond the hydrogeology ZOI
4010	Wet heath	5+850	Extends to within 110m North of proposed development boundary	No hydrological impact as habitat not within ZoI of road and surface drainage in area serviced by existing storm sewer

Wetland Code	Habitat	Approx. Chainage	Location	Potential Impact
7140	Transition Mire	7+450 and N59 0+700	80m NW of proposed development boundary and proposed construction compound area	No hydrological impact as habitat not within ZoI of Road being fed from the Northwest and North
7130	Blanket Bog (active)	7+550 and N59 0+650	10m NW of proposed development boundary and proposed construction compound area	No hydrological impact as habitat not within ZoI of Road being fed from the Northwest and North
PF2	Poor Fen and Flush	7+850	north and within proposed development boundary	The effect of the proposed road development drainage will not extend beyond the hydrogeology ZoI
6410	Molina Meadows	12+250	within and downstream near Ballindooley Lough	The effect of the proposed road development drainage will not extend beyond the hydrogeology ZoI
PF1	Rich Fen and Flush	12+350	Extends to within 70m NW of proposed development boundary	The surface drainage of this Habitat will not be impacted by the proposed road development

Local impacts to the local water chemistry in terms of changing the pH may apply where limestone derived alkaline material is placed over granite bedrock. Surface water run-off, interflow or groundwater movements through such material has the potential to impact local areas of peatland habitats by changing the pH of the recharge water particularly where this alkaline material is saturated (below the groundwater table). This potential impact will only apply to adjacent wetland habitats within hydrogeological Zone of Influence of the proposed road development. The use of limestone based road material for the pavement and capping layers is permitted as such layers will be protected from direct surface water and groundwater infiltration and located in the unsaturated zone above the groundwater table. This capping protection is provided by the road bitumen surface and the use of native topsoil capping along the grass verge and embankment section of the road construction. Restriction on the use of limestone derived formation material will apply locally to road sections in the vicinity of water dependent habitats within the granite bedrock area (west of the existing N59 Moycullen Road), refer to **Chapter 9, Soils and Geology** for details of mitigation.

A summary of the potential impacts on the Lough Corrib cSAC and Lough Corrib SPA is provided in **Table 11.42** below.

Table 11.42: Hydrological Impacts on Lough Corrib cSAC and Lough Corrib SPA

Attribute	Impact Stage	Nature of Impact	Impact description	Potential Impact Magnitude
Lough Corrib cSAC (00297), and Lough Corrib SPA (004042) River Corrib	Construction	Spillages (hydrocarbons, cement etc.) into watercourses and onto wetlands.	A major bridge construction is proposed across the River Corrib and associated with the bridge deck and the bridge piers will be the pouring of concrete and the use of chemical and grouting agents in close proximity to an internationally important waterbody. Due to the major public water abstraction located only 1.7km downstream on the east bank makes it highly sensitive to construction pollution and potential accidental spillages.	Moderate to Significant Temporary Impact requiring mitigation
Lough Corrib cSAC (000297), Lough Corrib SPA (004042) River Corrib Coolagh Lakes	Construction	Silts and sediments arising from works adjacent to watercourses and construction site runoff	Within the River Corrib Catchment, the various streams/drains encountered provide a pathway for silts and sediment laden runoff water from the construction site to reach the Lough Corrib cSAC and cause local increase in suspended solids and turbidity. These activities adjacent to the River Corrib and its floodplain provide a significant source and pathway for sediment laden runoff to enter the River Corrib with little buffer time available for natural filtering and settlement. The River Corrib Bridge crossing of the Lough Corrib cSAC at Menlo/Dangan will not involve any in-stream works but bridge piers are to be located on either bank close to the river edge which can give rise to site runoff entering the river during works. Two bank side drainage outfalls are to be constructed which given their proximity the river flow make it difficult to prevent local disturbance of sediments. Good dilution in the River Corrib significantly lessens the potential impact on the receiving waters The proposed construction of the NUIG pitches as part of the accommodation works for the Road has the potential during construction to pollute given their proximity of the pitches to the Corrib river bank and to a local drainage ditch to the southeast that discharges directly into the River Corrib. A section of the	Moderate to Significant Temporary Impact requiring mitigation

Attribute	Impact Stage	Nature of Impact	Impact description	Potential Impact Magnitude
			Pitch is shown to be within the 1 in 100year flood contour and therefore there is a small risk of flood inundation during construction which could further exacerbate sediment runoff to the Corrib There is potential for construction impact in the form sediment runoff and pollution associated with the road construction in vicinity of the Coolagh/Corrib Floodplain at Ch. 9+850.	
Lough Corrib cSAC (000297), Lough Corrib SPA (004042) River Corrib Coolagh Lakes	Operational	Changes to Flow regime within the River Corrib	The proposed road development slightly encroaches the River Corrib floodplain near Menlo / Coolagh Lakes at Ch. 9+850 to Ch. 9+900. The area of encroachment at the 1000year flood level is 0.27ha and at the 100year it is 0.11ha. The proposed encroachment will not have any perceptible impact on flooding or on the hydrological flow regime. Potential encroachment of the 100year flood extents will also occur at Dangan associated with the redevelopment of the NUIG pitches. The Pitches infill this floodplain area to achieve a free draining pitch These encroachments are very small and the potential flood storage loss from infilling will be miniscule in relation to the Corrib Flood area and flood volume and will no perceptible impact on flooding or flow regime in the Corrib and the Corrib cSAC and Corrib SPA. A number of road outfalls discharge directly and indirectly to the Corrib cSAC (outfalls S14A, S14B, S15, S18A, S18B) and Corrib SPA (outfall S15). These outfalls relatively to the Corrib drain a miniscule area and will have no perceptible effect on the flow rate and water depth of the Corrib River.	Slight to imperceptible permanent impact

Attribute	Impact Stage	Nature of Impact	Impact description	Potential Impact Magnitude
Lough Corrib cSAC (000297), Lough Corrib SPA (004042) River Corrib Coolagh Lakes	Operational	Impact on Receiving Water Quality of Corrib from Road Drainage at proposed road drainage outfalls	Within the River Corrib Catchment, the various streams/drains encountered provide a permanent pathway for pollutants from the road drainage waters to enter the River Corrib. The potential impact by the road drainage outfalls on the Lough Corrib cSAC and SPA have been assessed as local minor to imperceptible impact and will not affect the “Good” water quality status of the Corrib River. The potential risk of impact to the River Corrib by serious accidental road spillage has been assessed as extremely low risk and further reduced in the design process through the provision of containment facilities in the form of petrol and oil interceptors and wetland area upstream of the drainage outfalls	Slight permanent impact

A summary of the potential impacts on the Galway Bay Complex cSAC and Inner Galway Bay SPA is provided in **Table 11.43** below.

Table 11.43: Hydrological Impacts on Galway Bay Complex cSAC and Inner Galway Bay SPA

Attribute	Phase	Source	Impact description	Potential Impact Magnitude
Galway Bay Complex cSAC (00268) Inner Galway Bay SPA (04031)	Construction	Silts and sediments arising from in stream works and works adjacent to watercourses and construction site runoff.	The various streams encountered all along the proposed road development provide a pathway for silts and sediments runoff from the construction site to reach the Galway Bay Complex cSAC and Inner Galway Bay SPA at Galway City which is typically located 1 to 2km downstream of the proposed road development and therefore at risk of indirect water quality impacts.	Slight Temporary Impact
	Construction	Spillages (hydrocarbons, cement etc.) into watercourses and onto wetlands.	Construction spillages similar to silts and sediments can reach the Galway Bay Complex cSAC and Inner Galway Bay SPA at Galway City via surface runoff and via groundwater.	Slight Temporary Impact

Attribute	**Phase**	**Source**	**Impact description**	**Potential Impact Magnitude**
	Construction	Disturbance due to construction machinery and carrying out of temporary works (cofferdams, culverts, channel diversions, sediment ponds, silt fences etc.).	There is no direct encroachment of the Galway Bay Complex cSAC and Inner Galway Bay SPA at Galway City by the proposed road development.	None
	Operational	Road drainage and outfalls impacting on the water quality Regime: - Routine road runoff discharges - Accidental fuel spills from road	There are no direct discharges from road drainage outfalls to the Galway Bay Complex cSAC and Inner Galway Bay SPA at Galway City but most the road outfalls discharge to watercourses and groundwater aquifer that outfall to this cSAC/SPA and therefore provide a pathway for contaminants to reach the cSAC/SPA. The probability of accidental road accident spillages is shown to be very low and sufficient dilution available to minimise the impact of routine runoff on the Galway Bay Complex cSAC and Inner Galway Bay SPA at Galway City.	None
	Operational	Changes to watercourse channel morphology because of culverting, diversions, channel regrading works and outfall discharges giving rise to short term erosion and deposition and morphological changes.	The proposed road development will not impact on morphological processes in the Galway Bay Complex cSAC and Inner Galway Bay SPA and particularly so as outfall discharges will be attenuated which will limit any local increase in flood runoff rates that could cause increased channel erosion. The sediment yield to the Galway Bay Complex cSAC and Inner Galway Bay SPA at Galway City will not be perceptibly changed given the proposed works involved and the scale of the overall contributing catchments to the Galway Bay Complex cSAC and Inner Galway Bay SPA at Galway City relative to the footprint of the proposed road development.	None

11.5.9 Material Deposition Areas

A total of 40 site areas have been identified as potential material deposition areas for the excess soft and unacceptable material along the route of the proposed road development, refer to **Table 11.27**.

These potential material deposition areas if not correctly constructed, could represent a serious source of pollution to an adjacent watercourse should untreated runoff waters containing high concentration of sediment from these facilities enter the watercourse.

These material deposition areas will be bunded or excavated sites and will have double erosion control fencing (silt fence) and a sediment settlement pond at the outlet which will be constructed in advance of their use as deposition areas. In addition, wheel wash facilities will be provided at the entrance/exit as outlined in the CEMP – see **Appendix A.7.5**.

Runoff from the material deposition areas will be treated in temporary settlement ponds which will be provided upstream of the outfall to the receiving watercourse or sewer. These ponds will be maintained until the material deposition areas have stabilised and become adequately vegetated. In addition, the specific construction sequence for these areas (described below) will allow for settlement of sediment prior to discharge to the receiving watercourse. The construction sequence of each of the material deposition areas is such that the area allocated for material deposition is compartmentalised to allow a deposition area to be first established in one compartment, while the runoff water from this compartment flows into and is contained within an adjacent compartment. This will allow settlement of sediment to take place. Once settlement of the sediments has occurred, this settlement area is then itself filled with peat and the adjacent compartment acts as the settlement area for the runoff from this section. This process is repeated as the works advance.

The construction sequencing and design of the material deposition areas will ensure that there will be negligible impact on adjacent watercourses. As part of the CEMP a plan for erosion and sediment control has been developed which deals specifically with the potential impacts of the material deposition areas and this is attached in **Appendix A.7.5**.

11.6 Mitigation Measures

11.6.1 Introduction

This section outlines the proposed mitigation measures for hydrology. Mitigation measures follow the principles of avoidance, reduction and remedy. The most effective measure of avoidance is dealt with during the route selection and design stage, by moving the proposed road development either laterally or vertically within the Emerging Preferred Route Corridor, to ensure that it does not traverse or pass near to sensitive hydrological attributes. As set out throughout **Section 11.4**, appropriate measures have been incorporated into the design of the proposed road development to avoid impacts where possible.

Where avoidance of the feature has not been possible, consideration has been given to locally modifying the proposed road development so as to reduce / minimise the extent of the impact. If any modifications are proposed to reduce hydrological impacts, it is necessary to also consider any associated impacts to the hydrogeological and ecological regimes.

11.6.2 Construction Phase

As is normal practice the Construction Environmental Management Plan (CEMP) included in **Appendix A.7.5** will be finalised by the Contractor in advance of the commencement of construction and the following will be implemented as part this plan:

- An Incident Response Plan detailing the procedures to be undertaken in the event of spillage of chemical, fuel or other hazardous wastes, logging of non-compliance incidents and any such risks that could lead to a pollution incident, including flood risks (Refer to Section 10 of the CEMP in **Appendix A.7.5**)
- A Sediment Erosion and Pollution Control Plan (Refer to Section 8 of the CEMP in **Appendix A.7.5**). This shall include water quality monitoring and method statements to ensure compliance with environmental quality standards specified in the relevant legislation (i.e. surface water regulations and Salmonid Regulations 1988)
- All necessary permits and licenses for instream construction works associated with the provision of culverts, bridges and outfalls. OPW Section 50 consent has been received for all culverts and bridges proposed in the EIAR. Changes to these structures as part of the detailed design and construction stage will require new Section 50 consent to be obtained
- Inform and consult with OPW Western Arterial Drainage Section who have responsibility for the Corrib-Mask Arterial Drainage scheme and the ongoing control of river and lake levels at the Salmon Weir Barrage in Galway City
- Continue to Inform and consult with Inland Fisheries Ireland (IFI)
- Continue to Inform and consult with National Parks and Wildlife Service (NPWS)

Construction activities will be required to take cognisance of the following guidance documents for construction work on, over or near water:

- Guidelines on Protection of Fisheries During Construction Works in and Adjacent to Waters (Inland Fisheries Ireland, 2016)
- Shannon Regional Fisheries Board – Protection and Conservation of Fisheries Habitat with particular reference to Road Construction
- Requirements for the Protection of Fisheries Habitat during Construction and Development Works at River Sites (Eastern Regional Fisheries Board)
- Central Fisheries Board Channels and Challenges – The Enhancement of Salmonid Rivers
- CIRIA C793 The SuDS Manual
- CIRIA C624 Development and Flood Risk – guidance for the construction industry
- CIRIA C532 Control of Water Pollution from Construction Sites Guidance for Consultants and Contractors
- CIRIA C648 Control of Water Pollution from Linear Construction Projects, technical guidance
- CIRIA C649 Control of Water Pollution from Linear Construction Projects, site guide
- Guidelines for the Crossing of Watercourses during the Construction of National Road schemes (NRA, 2006)
- Road Drainage and the Water Environment DN-DNG-03065 (TII, June 2015)
- Vegetated Drainage Systems for Road Runoff DN-DNG-03063 (TII, June 2015)

Based on the above guidance documents concerning control of construction impacts on the water environment, the following outlines the principal mitigation measures that will be prescribed for the construction phase in order to protect all catchment, watercourse and ecologically protected areas from direct and indirect impacts:

- All constructional compound areas will be required to be located on dry land and set back from river and stream channels and out of floodplain areas. Floodplain areas include the Flood Risk Zones A and B (i.e. outside of the present day 100year and 1000year flood extents)
- The storage of oils, fuel, chemicals, hydraulic fluids, etc. will not occur within 100m of the River Corrib or within the Floodplain Area as defined above
- Surface water flowing onto the construction area will be minimised through the provision of temporary berms, diversion channels and cut-off ditches, where appropriate
- Management of excess material stockpiles to prevent siltation of watercourse systems through runoff during rainstorms will be undertaken. This may involve allowing the establishment of vegetation on the exposed soil and the diversion of runoff water off these stockpiles to the construction settlement ponds and avoiding stockpiling of material in vicinity of sensitive watercourses

- Where construction works are carried out adjacent to turloughs, fens, stream and river channels and lakes, protection of such waterbodies from silt load shall be carried out through use of reserved grassed buffer areas, timber fencing with silt fences or earthen berms. These measures will provide adequate treatment of constructional site runoff waters before reaching the watercourses
- Use of settlement ponds, silt traps and bunds and minimising construction activities within watercourses. Where pumping of water is to be carried out, filters will be used at intake points and discharge will be through a sediment trap or sedi-mat
- All watercourses that occur in areas of land that will be used for site compound/storage facilities will be fenced off at a minimum distance of 5m. In addition, measures will be implemented to ensure that silt laden or contaminated surface water runoff from the compound site does not discharge directly to the watercourse. Compounds shall not be constructed on lands designated as Flood Zone A or B in accordance with the OPW's The Planning System and Flood Risk Management Guidelines (November 2009). Site compounds will not be permitted in a European Sites (i.e. Lough Corrib cSAC)
- Protection measures will be put in place to ensure that all hydrocarbons used during the construction phase are appropriately handled, stored and disposed of in accordance with the TII document "Guidelines for the crossing of watercourses during the construction of National Road Schemes". All chemical and fuel filling locations will be contained within bunded areas and set back a minimum of 10m from watercourses
- Foul drainage from all site offices and construction facilities will be contained and disposed of in an appropriate manner to prevent pollution
- The construction discharge will be treated such that it will not reduce the environmental quality standard of the receiving watercourses
- Riparian vegetation along the identified sensitive watercourses will be fenced off to provide a buffer zone for its protection to a minimum distance of 5m except for proposed crossing points
- The use and management of concrete (which has a deleterious effect on water chemistry and aquatic habitats and species) in or close to watercourses will be carefully controlled to avoid spillage. Where on-site batching is proposed, this activity will be carried out well away from watercourses. Washout from such mixing plants will be carried out only in a designated contained impermeable area
- All material deposition areas must be adequately bunded and compartmentalised such that the rainwater outflow from these facilities is adequately controlled and treated prior to reaching the receiving surface watercourses. The sediment control requirements are set out in the in the Sediment, Erosion and Pollution Control Construction Management Plan section of the CEMP (refer to **Appendix A.7.5**).

The potential for constructional phase impacts on water quality in receiving streams and lakes has been reduced to slight and imperceptible through the implementation of a Sediment Erosion and Pollution Control Management Plan included in the CEMP in **Appendix A.7.5**.

The potential for constructional phase impacts on water quality in the Lough Corrib cSAC has been reduced to slight and imperceptible through the implementation of a Sediment Erosion and Pollution Control Management Plan., included in the CEMP in **Appendix A.7.5**.

To minimise the risk of contamination to the Galway Bay Complex cSAC a detailed Sediment, Erosion and Pollution Control Management Plan for the construction phase has been developed and included in the CEMP in **Appendix A.7.5**, which provides for avoidance, reduction, mitigation and monitoring. Construction hydrological and water quality impacts on the Galway Bay Complex cSAC and Inner Galway Bay SPA will be avoided.

11.6.3 Operational Phase

11.6.3.1 Flood Risk Mitigation

A single flood risk area adjacent to the N83 Tuam Road at Twomileditch is identified as being significantly impacted by the proposed road development with a potential loss of 21% of the available flood storage. This potential impact is identified as significant as the loss of flood storage will increase the extreme flood levels and increase the probability of flooding within an existing flood risk area where seven houses and the N83 Tuam Road are identified to be at high flood risk.

Without suitable mitigation the proposed road development will have a significant impact on pluvial flooding on these lands and will increase the flood risk to other properties.

The 100-year return period flood event with a 20% allowance for climate change design flood level for the proposed flood relief measures is 17.5m OD Malin which will prevent flooding of the driveways to the dwellings and the N83 Tuam Road.

The flood relief mitigation measures to eliminate the flood impact of the proposed road development and reduce the existing flood risk in this area are described as follows (refer also to Drawing GCOB-500-D-600):

- Prevent the upgraded portion of the N83 Tuam Road from spilling laterally northwards into the driveways of existing flood risk houses by:
  - Upgrade and provide effective road drainage network along the existing N83 Tuam Road. The proposed upgraded road drainage for the N83 portion is extends for a length of 780m
  - Provide interceptor drain to capture rapid hill slope runoff from the southeast reaching the N83 Tuam Road
  - Provide for infiltration of this interceptor drain for the less severe rain storm events
  - Connect this interceptor drain to the proposed flood compensation storage

- Compensate flood storage lost by providing compensation storage of 8,030m^3 in the form of an excavated rectangular engineered storage pond. The base elevation of 16m OD and a top design water level elevation of 17.5m OD
- Connect this compensation storage to the remaining low-lying natural flood storage area located to the northwest of the proposed road development so that both storage areas are hydraulically linked via culverts
- Provide for permanent a pumping station and rising mains from the proposed compensation flood storage facility to discharge to the existing storm sewer with maximum pumping capacity of 250l/s

Table 11.44 Outlines the required storage volumes required for the catchment for a range of return periods and durations events. The critical volumes for each return period are shown in bold text.

Table 11.44: Flood Mitigation Storage Volumes

Duration	Pumping	Storage Volume Required		
hours	**250 l/s**	**2yr**	**10yr**	**100yr**
1	900	5138	8208	13428
2	1800	6029	9662	15649
3	2700	6408	10451	16898
4	3600	**6532**	10830	18001
6	5400	6420	**11128**	19459
9	8100	5665	10833	20439
12	10800	4500	10267	**20687**
18	16200	1607	8659	19904
24	21600	0	6112	18008
48	43200	0	0	6388

The required flood storage with pumping of 0.25cumec is 20,700m^3 for the 100year event and including 20% climate change the storage required is 24,800m^3.

The available storage at a top water level of 17.5m OD is compensation storage of 8,030m^3 and remaining (with proposed road development) natural storage of 18,470m^3 giving a total available flood storage of 26,500m^3, which is sufficient to achieve that design standards.

Overall the proposed road development with this mitigation will provided a significant positive impact on flooding and flood risk in N83 Tuam Road in the Twomileditch flood risk area.

To minimise the residual flood risk associated with the blockage of flood relief culverts and associated drainage assets, the following operational mitigation measure is recommended:

- Regular (monthly) inspection of N83 Flood Relief facilities be carried out to ensure that the system is in proper working order and performing as designed.

11.7 Residual Impacts

The residual hydrological impacts associated with the proposed road development can be grouped as follows:

- Drainage and flood risk
- Water quality
- Channel morphology
- Potential impacts on key ecological receptors

11.7.1 Drainage and Flood Risk

There is a potential to increase peak flow rates and runoff volumes due to the increased impermeable area associated with the proposed road development and the collecting drainage system which discharges at outfall points. The implementation of SuDS through the incorporation of engineered wetlands, attenuation ponds, infiltration basins and controlled discharges at all outfalls will control storm runoff rates to greenfield flood runoff rates and will not exacerbate flooding and flood risk in the receiving watercourses. As part of the proposed drainage design attenuation storage has been sized to accommodate the 100-year storm event with 20% climate change allowance.

In the karst aquifer section east of the River Corrib, where surface drainage watercourse features are non-existent, the proposed road drainage system will convey rainfall from the impervious road pavement as drainage runoff to discharge, virtually a point source, to groundwater via engineered infiltration basins. Sizing of these basins, with facility for surcharging within the basin, has been designed to cater for the 100year flood event with 20% climate change allowance.

The provision of infiltration basins and attenuation pond facilities throughout the proposed road development represent a potential new source of flood risk as they by their nature impound road drainage waters and release slowly to the receiving waters. Such facilities may be subject to potential blockage and therefore overtop giving rise to potential for local flooding. The residual risk is low due to the standard regular inspections of such facilities, that include, culverts, flow control devices, outfalls, attenuation ponds and infiltration basins to ensure that system is in proper working order and performing as designed. Such facilities are considered to represent a slight magnitude permanent impact to flooding and flood risk.

With the relatively high density of drainage outfalls along the proposed road development there is limited opportunity for significant diversion of drainage flows between catchments and sub-catchments with the overall residual impact on flow regime categorised as local slight to imperceptible as only very minor land drains and recharge from the road pavement are potentially diverted.

The disturbance of field drainage systems represents a direct impact to the existing drainage regime. The drainage has been designed sympathetic to the natural drainage pathways maintaining where feasible existing drainage runs by culverting or slightly realigning the local drains across the proposed road development. The overall impact on surface drainage along the proposed road development is a slight to imperceptible residual impact.

No negative residual impacts on flood risk due to loss of conveyance are anticipated at the River Corrib and the various culverted watercourse crossings. All culvert design flows include large factors for uncertainty associated with flood estimation in small ungauged catchments and thus the proposed culvert sizes are conservatively large and in all cases substantially exceed the existing culvert sizes on such streams and therefore avoid any conveyance capacity issues. There will be no residual impact from the proposed road development.

The loss of floodplain storage where the proposed road development crosses such areas is minor relative to the catchment flood flows and existing flood storage volumes within the floodplain. The assessment identifies a slight reduction of flood storage at the River Corrib crossing adjacent to the Coolagh Lakes and at Ballindooley Lough both of which are considered to represent an imperceptible impact on flood risk and flow regime of the Coolagh Lakes and Ballindooley Lough.

The proposed flood mitigation measure for the N83 Tuam Road Junction to mitigate loss of flood storage from a pluvial flood risk area will provide a moderate to significant positive residual impact on flooding and flood risk at N83 Tuam Road Twomileditch area, as the proposed mitigation measure will reduce the flood risk to the existing road and to the six remaining houses.

However negative residual flood impacts associated with the N83 flood relief measures will remain:

- Discharge of flood water into the Terryland Basin at 250 l/s resulting in slight increase in flood levels within the Terryland River channel. The impact of this discharge on flood levels in the Terryland Basin is minor representing a slight permanent residual impact on flood levels
- Reduction of available capacity within the existing storm sewer located to immediately south in the City North Business Park (the full bore capacity in the pipe is estimated to be 900l/s and therefore the proposed maximum discharge of 250l/s will reduce the available capacity by 27% This is considered a slight impact
- Residual flood risk at the N83 Tuam Road associated with potential breakdown of the storm water pumping station, and blockage of storage area and associated drains and outfalls. This is considered slight in light of regular monthly inspections proposed

11.7.2 Water Quality

The proposed road drainage will be collected and discharged to watercourses resulting in localised water quality impact at the outfall sites. This impact is minimised by utilising best practice design using sustainable drainage systems (SuDS). These include filter drains and grassed surface water channels where permitted, vegetated lined wetlands, attenuation ponds and infiltration basins. The vegetated wetlands, are sized to cater for the potentially contaminated first flush volume 15mm effective rainfall. Further detention storage of runoff water, provided within the attenuation pond systems and infiltration basins, will permit further settlement of suspended pollutants. The impacts of reduction of water quality in streams receiving routine runoff is considered to represent slight and imperceptible permanent residual impacts.

All pollution control facilities and attenuation areas will be fitted with oil and petrol interceptor and a penstock or similar restriction at the outfall to the receiving channel and groundwater basin. The overall risk assessment to quantify the likelihood of a serious accidental spillage indicates a cumulative risk for the entire road length discharging to surface water courses as 0.07% which represents a very low risk of serious contamination. For most watercourse receptors, this potential spillage risk for individual outfalls is much smaller and therefore represents an imperceptible risk. The risk decreases westward along the route of the proposed road development.

The impact from an accidental spillage should it occur on all stream outfalls will be reduced using oil and petrol interceptors upstream of the ponds and outfall. A penstock control and spillage containment area which can be closed off in the event of a serious pollution incident arising will be provided for all mainline and new link road catchments. As a consequence of the design there will be an imperceptible residual impact from accidental spillages along the proposed road development.

The proposed road development discharges to the River Corrib near the bridge crossing a short distance 1.7m upstream of the Terryland Intake from the River Corrib at Jordan’s Island. 2.625km of proposed road development mainline and 0.625km of N59 Link Road North representing 7.1ha of road pavement area contributes to the proposed River Corrib outfalls at (S14A, S14B, S18A, S18B and S15) at the location of the intake. Routine road drainage discharges will have imperceptible impact on water quality of the Terryland Galway City water supply abstraction. A risk assessment of serious spillage for this section of the proposed road development indicated very low risk of spillage (0.042%). The provision of oil petrol interceptor, wetland treatment system and outflow control further reduces the risk of impact to the water supply to imperceptible.

11.7.3 Morphology

No significant local impacts to stream and river morphology are anticipated, as all practicable design measures for bridges, culverts, channel realignments and drainage outfalls are to be implemented which are designed to minimise the potential for local scouring and flow regime changes. The residual impact on river and stream channel morphology is classed as local slight permanent impact at the various culvert crossing and outfalls and classed as an imperceptible impact the

River Corrib crossing as there are no in-stream piers or in-stream works to be carried out.

11.7.4 Key Ecological Receptors

The key ecological receptors sensitive to surface hydrology impacts are Ballindooley Lough, Lough Corrib cSAC including the Coolagh Lakes and River Corrib channel, the various salmonid potential streams (including downstream reaches of the Bearna, Trusky and Knocknacarra Streams) and the coastal/transitional waters of the Galway Bay Complex cSAC. The key water dependent wetland receptors sensitive to surface hydrology include Blanket bogs, Transitional mires, Wet heath, Rich fen and flush, and Molinia Meadows.

The rating of these receptors varies from locally high for the watercourses and Ballindooley Lough and extremely high for the Lough Corrib cSAC including Coolagh Lakes and the River Corrib channel and Galway Bay Complex cSAC. The hydrological residual impact on these receptors is rated as imperceptible for the Coolagh Lakes, Ballindooley Lough and Galway Bay Complex cSAC.

The hydrological residual impact represents a slight local magnitude impact on the River Corrib channel. The impact is associated with the outfall discharges and the construction of two river bank drainage outfalls. There is a slight residual impact for the salmonid potential in local higher value streams associated with flooding, flow regime change, water quality and morphology changes all of which are localised and minor. The overall residual impact from the proposed road development and its drainage system on the Lough Corrib cSAC and Lough Corrib SPA is rated as an imperceptible residual impact. This rating is achieved through design of appropriate pollution control measures at the proposed road drainage outfalls and at appropriate design of the proposed bridge and culvert crossings.

The proposed road development and its drainage system will have an imperceptible residual hydrological impact on Galway Bay Complex cSAC and Inner Galway Bay SPA. This is achieved through design of appropriate pollution control measures at its road drainage outfalls.

Surface drainage impacts to water dependent wetland habitats have been identified where the proposed road development traverses through such a habitat or passes in close proximity upstream of such habitats. Overall the zone of influence (ZoI) on surface drainage by the proposed road development on these habitats does not exceed the hydrogeological ZOI. The exception to this is the potential impact to a downstream Wet Heath (4010) located 50m southeast of the proposed development boundary between Ch. 3+450 to Ch. 3+700 and Molinia Meadows (6410) located 30m east of the proposed development boundary at Ch. 3+800. In both cases, the proposed road development which is in a large cutting will intercept the local surface drainage partially supplying these wetlands and divert into the proposed road drainage to outfall elsewhere resulting in a potential reduction in the surface water supplying these wetlands. The hydrogeological ZOI from the proposed road development does not extend to these wetland features and therefore the groundwater table and flow is unlikely to be altered. The residual hydrological impact on these two wetland habitats represents moderate and slight permanent impact respectively.

11.7.5 Cumulative Impacts

Cumulative impacts are defined as the combination of many minor impacts creating one, larger, more significant impact (NRA, 2009 and EPA 2017). Cumulative impacts consider existing stresses on the natural environment as well as developments that are underway and in planning.

The baseline hydrology has identified that the surface water features in the study area have a number of existing stresses in the form of discharges from surface water drainage systems, road runoff and agricultural activities and loss of natural flood plains. These sources have the potential to impact the existing hydrological environment in the form of reducing water quality by increased contaminants or by increasing flood risk. On the basis that the design and mitigation measures employed for the proposed road development to maintain or improve water quality in existing catchments, there are no significant hydrological residual impacts associated with the proposed road development.

The Galway County Development Plan 2015-2021, Galway City Development Plan 2017-2023, Bearna Local Area Plan 2007-2017, Gaeltacht Local Area Plan 2008–2018 and Ardaun Local Area Plan 2018–2024 set out a series of objectives for appropriate management of surface water and water quality of the existing environment. This will ensure that future planning applications are developed using design criteria to ensure that no there is no hydrological impact on receiving watercourses or surface water sewers associated with planned developments. This will typically be achieved in terms of flood risk and stream morphology by utilising sustainable drainage systems (SUDS) and restricting surface water runoff discharge rates to meet that of greenfield runoff rates and volumes. Therefore, the residual impact associated with future proposed or planned developments on the hydrological environment is imperceptible.

The residual impacts associated with the following major projects and plans that are currently underway or in planning have also been assessed in more detail. These projects include:

- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)
- N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction)
- Proposed Galway Harbour Port Extension (planning stage)
- Galway Transport Strategy (GTS)

The M17/M18 Tuam to Gort Motorway Project has recently completed construction. The portion of the M17 and Tuam Bypass (circa 26km) that lies north of the existing R339 Galway to Caltra Road, lies within the catchment of the River Corrib. The portion of the M17 M18 to the south of the R339 lies within the catchment of Galway Bay for the Oranmore River, Clarin River, Kilcolgan River, Gort River and Lough Coole turlough system. This M17/M18 scheme has been designed with a modern road drainage system and construction methods that reduce the potential impact on the receiving environment. Where residual local impacts arise at various road outfalls, culvert crossings and displacement of flood storage, the impacts do not translate downstream in the River Corrib or to Galway Bay as perceptible impacts that would combine with residual impacts from the proposed road development, given the very large dilution available and the travel distances involved.

There will be no perceptible hydrological cumulative impact between the M17/M18 Tuam to Gort Motorway Scheme and the proposed road development.

The N59 Oughterard to Maam Cross Road Scheme and N59 Moycullen Road Scheme also lie within the catchment of the River Corrib upstream of the proposed road development. Both N59 road schemes have been designed with modern road drainage systems and construction methods that reduce the potential impact on the receiving environment. Where local impacts arise at various road outfalls and culvert crossings and displacement of flood storage and changes to river and stream morphology, these impacts do not translate downstream in the River Corrib (given the very large dilution available and the travel distances involved) as perceptible impacts that would combine with residual impacts from the proposed road development. There will be no perceptible hydrological cumulative impact between the N59 Oughterard to Maam Cross Road Scheme and the N59 Moycullen Road Scheme with the proposed road development.

The proposed Galway Harbour Expansion Project is located in the Galway City Coastal catchment and at the mouth of the River Corrib Estuary downstream of the proposed road development. The following hydrological residual impacts have been extracted from the summary of residual impacts from the Galway Harbour Company, Galway Harbour Extension Environmental Impact Statement:

- *Alteration of salinity levels in vicinity of the River Corrib outflow during construction as a result of increased current velocities or changes in current direction due to the construction of the proposed development – Permanent Slight Positive Impact*
- *Alteration to current velocities at the proposed development site will impact the sedimentary environment resulting in a shift of existing scouring and deposition sites and subsequent alteration of benthic habitat resulting from construction of the proposed development in the intertidal and subtidal zone in proximity to the River Corrib outflow – Permanent Slight Negative Impact*
- *Alteration to current directions at the proposed development site will impact the sedimentary environment resulting in a shift of existing scouring and deposition sites and a subsequent alteration of benthic habitat types as a result of construction of proposed development in the intertidal and subtidal zone in proximity to the River Corrib outflow – Permanent Imperceptible Impact*
- *Release of grey water from construction site as a result of construction activities – Temporary Slight Negative Impact*
- *Release of sewage from construction site resulting from leakage from construction site and vessels – Temporary Slight Negative*

- *Release of diesel from construction site resulting from leakage from construction site – Temporary Slight Negative*
- *Oil Spills and other accidental release of fluids/solids during loading/off-loading of vessels as a result of accidental spillage – Temporary High Negative Impact*
- *Impacts from maintenance dredging as a result of sedimentation and smothering arising from dredging and disposal – Short Term Serial Localised Negative Impacts*
- *Changes in wave climate as a result of increases and decreases due to new structure – Permanent Low Impact*

The proposed road development will have no noticeable effect on the flow regime, salinity, sedimentation process or water quality downstream in the River Corrib Estuary and Inner Galway Bay, both during construction and operation stages. Therefore, no cumulative hydrological impacts will occur between the Galway Harbour Expansion project and the proposed road development, even if the construction phases for both projects were to coincide.

There are a number of elements of the Galway Transport Strategy (GTS) located within the same hydrological catchments as the proposed road development.

The relevant elements of the Galway Transport Strategy that could have an impact on hydrology include:

- the upgrading of pedestrian network
- the upgrading of cycle network which includes the Bearna Greenway, the Galway to Dublin Cycleway (Galway City to Oranmore)[1], the Galway to Oughterard Greenway[2] and non-greenway elements
- Expansion of Public Bike Hire Scheme (currently under construction)
- The upgrading of public transport network including increased frequency of buses and a new cross city access link (including the N83 Tuam Bus Corridor Scheme)
- the upgrading of road network which includes modifications to the existing road infrastructure and the proposed road development

The GTS is at the plan stage so each individual project element of the design will be subject to further detail design. The detailed design shall be in compliance with the surface water management and water quality objectives set out in the various development plans. Therefore, there should be no cumulative impacts associated with this development.

[1] The GTS includes that portion of the Galway to Dublin Cycleway between Galway City and Oranmore.
[2] The GTS includes that portion of the Galway to Oughterard Greenway between Galway City and Moycullen.

11.8 Summary

The proposed road development, passes through three hydrometric areas 29 - Galway Bay South East, 30 - Corrib and 31 - Galway Bay North along its 17.4km length. Within the study area there are two distinct regions of hydrological response, with the area to the west of the N59 Moycullen Road associated with the granite bedrock having high surface run-off characteristics and the area to the east of the N59 Moycullen Road having low surface run-off associated with karst permeable limestone bedrock. This results in a reasonably dense network of surface drains in the western section and a very sparse non-existent surface drain network in the eastern section. Consequently, the drainage solution for the proposed road development is challenging in the eastern section requiring infiltration to groundwater for safe disposal of road drainage waters.

The proposed road development traverses only one major watercourse, namely the River Corrib which is of international importance being part of the Lough Corrib cSAC and Lough Corrib SPA. The remaining watercourses encountered, principally to the west are minor, the majority of which are intersected close to their upstream watersheds. Therefore, these watercourses have limited contributing catchment areas, and consequently are of low capacity. They are poorly established stream channels and generally not maintained. The attribute rating of these small watercourses, which include the Trusky Stream, Bearna Stream and Knocknacarra Stream is one of local higher and of fishery interest/potential in their downstream reaches closer to the coast. Other watercourses/drains encountered are of limited fisheries importance but are also classified as local higher ecological value which include the Sruthán na Libertí.

The proposed road development will involve 17 culvert crossings and one major bridge crossing. All of the 17 culvert crossings are crossing small watercourses, with the largest catchment being less than 5 km², which is the Bearna Stream. A number of local diversion and realignments are associated with the various culvert crossings so as to facilitate channel transition to and from the new culverts. These have a potential for constructional impact and more permanent local morphological changes. A realignment is proposed for the Tonabrocky Stream to facilitate the proposed road development and to avoid a significant length of culvert beneath the proposed road development. Mitigation for this realignment is to incorporate fish friendly design incorporating shoals, pools and meanders.

The drainage system for the proposed road development will include 54 road drainage outfalls, which comprise the following:

- 25 to surface watercourses at new storm outfalls
- 9 to groundwater via new infiltration basins
- 17 to existing public surface water sewers
- 2 (tunnel sections) to be pumped to the public foul sewer
- 1 to an existing N6 road infiltration basin

The proposed surface water outfalls and culvert crossings represent a potential for local flood impact, morphological changes and water quality impacts both during construction and operation phases. This is described further below.

The major bridge crossing of the River Corrib from Dangan to Menlough is designed to clear span the main river channel and provide as a minimum 5m setback from the river edge for its two banksides piers. The clear spanning of River Corrib avoids the need for in-stream works at the construction stage which lessens the potential for constructional and operational (permanent piers) impacts. The River Corrib is the source to a major public drinking water abstraction that supplies Galway City, located downstream at Terryland, off Jordan's Island. The abstraction point is only 1.7km downstream of the proposed road development. There is therefore, a high pollution risk (in the absence of mitigation measures) from the proposed road development to water quality, particularly during the construction phase.

Stringent mitigation and control of potential polluting activities associated with construction activities is proposed which will significantly reduce this pollution risk. Stringent controls are proposed to limit the risk of untreated sediment run-off entering the water body and to minimise the risk of construction spillages of concrete and hydrocarbons into these waters. Refer to the CEMP in **Appendix A.7.5**. Specifically, there will be no in-stream works at the River Corrib channel associated with the construction of the river bridge crossing that fully spans the River Corrib channel, so as to protect both the Lough Corrib cSAC and SPA and the major downstream drinking water abstraction to the Galway City Water Treatment Plant at Terryland.

The operational phase also presents a pollution risk to the Terryland water supply both from accidental spillages and from routine road run-off discharges. However, design pollution control measures have been put in place to significantly reduce the risk.

In conclusion, residual construction and operational pollution impacts on the River Corrib will be slight to imperceptible. Elsewhere, construction impacts on water quality are reduced from having potentially moderate and significant temporary impacts to having slight and imperceptible temporary impacts through mitigation with the implementation of the CEMP in **Appendix A.7.5**.

During the operational phase, water quality in the receiving streams (which have been identified as of generally good quality status) will be protected from proposed road drainage discharges. Oil and petrol interceptors along with wetland treatment systems will be placed upstream of all surface water outfalls and groundwater infiltration basins. These are designed to capture first flush rainfall events and provide protection against both minor or large road spillages. An operational spillage assessment for the proposed road development was carried out for all outfalls, both surface and groundwater, and the results show low risk of impact from serious accidental spillage involving a HGV. In conclusion, residual water quality impacts on these watercourses will be slight during the operational phase.

The proposed road development passes close to the Coolagh Lakes and Ballindooley Lough. There is only a very slight encroachment by the proposed road embankment of the extreme floodplain area of these lakes and there will be no direct surface water discharge to the Coolagh Lakes. There is a single small treated surface discharge from the N84 Headford Road to Ballindooley Lough. The overall hydrological impact on these features is rated as slight to imperceptible with the construction phase representing the greater risk to the lakes. Similar to other sensitive aquatic locations, such as the River Corrib crossing, stringent mitigation and control of potential polluting activities associated with construction activities is proposed which will significantly reduce the risk of impact to a slight temporary impact.

The proposed road development as part of the EIAR has undergone a detailed Flood Risk Assessment in accordance with the DoEHLG Planning System and Flood Risk Management Guidelines for Planning Authorities. The assessment identified the sources of flood risk to the proposed road development from fluvial, pluvial and groundwater sources, but not from a coastal source as the proposed road development is sufficiently set back and elevated above the coastal zone. Overall the assessment has concluded that the proposed road development design minimises flood risk to the development itself and is rated as having a low probability of flooding.

A potential significant flood risk impact has been identified in the vicinity of the N83 Tuam Road Junction resulting in the permanent encroachment and loss of flood storage from this flood risk area. Flood relief mitigation measures involving improved land and road drainage, provision of compensation storage and storm water pumping to the Terryland Basin have been designed which when implemented will result in providing a residual moderate to significant positive benefit by reducing the risk of serious flooding in this area.

At all other locations along the proposed road development, there will only be slight to imperceptible impacts on flood risk as very minimal encroachment of floodplains occur and design measures in the form of large culverts and stormwater attenuation ponds are proposed. Residual flood risks exist at the drainage outfalls and their associated attenuation ponds and at the various culverts from potential blockages. This impact through the design of the proposed road development has been assessed as a slight residual flood risk achieved by the proposed program of regular inspections and maintenance of these assets and for the ponds the inclusion of controlled overflow systems in the event of a blockage. The culverts are all generously sized and blockage potential is minimised.

The proposed road development satisfies the requirements of the Water Framework Directive in terms of maintain, protecting and enhancing the water quality status of the receiving watercourses and groundwater. Protection is achieved through the provision of storm water treatment and controlled discharge at the proposed road drainage outfalls and enhancement is achieved by taking road traffic from unprotected roads where uncontrolled road runoff enters adjacent watercourses and the groundwater aquifers.

Potential hydrological impacts from the proposed road development have been identified and assessed. Appropriate design and mitigation measures have been incorporated to remove any risk of significant hydrological impact on the receiving environment. There are no significant negative residual hydrological effects due to the proposed road development.

The overall residual hydrological impact from the proposed road development on the Lough Corrib cSAC and SPA and the Galway Bay Complex cSAC and Inner Galway Bay SPA is rated as imperceptible. This is achieved through design of appropriate pollution control measures at the proposed road drainage outfalls, the proposed full spanning bridge structure of the River Corrib channel and effective floodplain area and the proposed implementation of the CEMP during construction. Refer to **Appendix A.7.5**.

There are no significant cumulative hydrological impacts associated with this proposed road development in combination with other projects either granted or in planning.

12 Landscape and Visual

12.1 Introduction

This chapter of the EIAR consists of an appraisal of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, under the heading of landscape and visual aspects.

This chapter initially sets out the methodology followed in carrying out the appraisal (**Section 12.2**), describes the existing landscape and visual environment (**Section 12.3**), and summarises the main characteristics of the proposed road development that are of relevance to landscape and visual aspects (**Section 12.4**). The evaluation of impacts of the proposed road development on the landscape and visual environment are described (**Section 12.5**), measures are proposed to mitigate these impacts (**Section 12.6**), and residual impacts are described (**Section 12.7**). The chapter concludes with a summary (**Section 12.8**) and reference section (**Section 12.9**).

This chapter has utilised the information gathered during the constraints and route selections studies for the proposed road development to inform the landscape and visual impact appraisal. **Sections 4.7**, **6.5.5** and **7.6.5** of the **Route Selection Report** considered the landscape and visual constraints within the scheme study area and compared the potential landscape and visual impacts of the proposed route corridors respectively. These assessments and sections of the Route Selection Report contributed to the design of the proposed road development which this chapter assesses.

12.2 Methodology

12.2.1 Introduction

Landscape has two separate but closely related aspects. The first is **visual impact**, *i.e.* the extent to which new development can be seen in the landscape. The second is **impact on landscape character**, *i.e.* effects of new development on the fabric or structure of the landscape.

The visual impact assessment considers visual receptors along the proposed road development. The majority of receptors involve residential properties, however, cultural and heritage properties, community facilities, *e.g.* churches, amenities and recreational facilities, open spaces, walkways, and other viewers within the environment are also considered.

Landscape character is derived from the appearance of the land, and takes account of natural and man-made features such as topography, landform, vegetation, land uses and built environment and their interaction to create specific patterns that are distinctive to particular localities. Therefore, aspects such as landscape character and landscape designations are also considered in the description of the receiving landscape.

12.2.2 Legislation and Guidelines

The methodology has regard to Sections 50(2) and 50(3) of the Roads Act 1993 as amended, and the following guidance publications:

- EPA: Guidelines on the Information to be contained in Environmental Impact Statements, 2002
- EPA: Advice Notes on Current Practice (in the preparation of Environmental Impact Statements) 2003
- EPA: Draft Guidelines on the Information to be contained in Environmental Impact Assessment Reports, 2017
- EPA: Draft Advice Notes for Preparing Environmental Impact Statements, Consultation 2015
- LI/IEMA: Guidelines for Landscape and Visual Impact Assessment, 3rd Edition, 2013
- NRA: Environmental Impact Assessment of National Road Schemes - A Practical Guide
- NRA: A Guide to Landscape Treatments for National Road Schemes in Ireland
- NRA: Guidelines on the Implementation of Landscape Treatments on National Road Schemes in Ireland
- NRA: Guidelines for Protection and Preservation of Trees, Hedgerows and Scrub Prior to, during and Post Construction of National Road Schemes
- NRA: Design Manual for Roads and Bridges

12.2.3 Data Sources and Consultations

The findings and recommendations of other chapters of this EIAR have also been considered in the preparation of this assessment. Particular liaison and consultation has taken place with the relevant specialists in the project team in terms of the design for the proposed road development and with particular respect to aspects such as Archaeological, Architectural and Cultural Heritage, Biodiversity, Noise and Vibration, Human Beings and Construction Activities.

12.2.4 Scheme Study area and Baseline Data Collection

The landscape setting for the proposed road development covers a wide corridor comprising a part rural, part peri-urban and part suburban landscape extending from west of Bearna Village around the north and east of Galway City to a tie-in with the existing N6 between Dougishka and Coolagh-Briarhill.

Baseline data collection involved reviewing desktop information including statutory planning documents, landscape character assessments and other landscape and visual related publications and sources in order to identify likely significant and sensitive landscape and visual receptors. The findings of the desktop data collection stage was augmented, refined and verified during a series of survey visits, undertaken at different times during the year, to the landscape corridor of the proposed road development. This allowed for identification of visual receptors, landscape features, vegetation, and for analysis of local landscape and visual character.

12.2.5 Impact Assessment Methodology

The significance criteria as set out in the EPA Guidelines have been used for the purpose of this assessment, see **Table 12.1** Landscape and Visual Impact Assessment Criteria. The criteria have been modified to take account of the current Draft EPA Guidelines (2017) and other references used in the assessment methodology.

The significance of landscapes is considered against their designation (*i.e.* national, county, local, *etc*.). Where not designated or otherwise protected, landscapes are considered as being of local significance. Therefore, landscape assessments take account of the receiving environment, its character and features, as well as landscape planning designations and listings.

Views from properties are all considered on an equal basis without varying degrees of significance or sensitivity. All properties located within 200m of the centreline of the proposed road development are considered, together with any property outside of 200m, which for reasons of openness, or otherwise, are considered to have potential for significant impact. For the most part, properties outside 200m of the centreline of the proposed road development that have no potential for impact have not been included in the assessment. While these properties may have sight of the proposed road development, due to a combination of distance, context, elevation or intervening topography, the proposed road development comprises a small element of the overall panorama and will not give rise to an adverse impact. Visual impact from properties other than residences is also considered and as such, schools, community facilities and recreational and other amenities are also included.

Visual assessments for properties are tabulated in the Visual Impact Schedule (VIS) Tables in **Appendix A.12.1** and are illustrated on the Landscape and Visual figures (Refer to **Figures 12.1.01** to **12.1.14**). The properties are numbered using sequential chainage-based references in approximate geographical order from west to east along the proposed road development.

Visual impacts are assessed at three key stages:

Construction Stage: considers the period of active construction of the proposed road development up to completion of the works.

Pre-establishment Stage: considers the period of initial operation of the proposed road development where new landscape measures are unlikely to provide effective mitigation. All works, including new boundaries, barriers, screens, seeding, *etc*. are complete and while planting will be in place, it would require a period of time to establish as effective mitigation. The impact is assessed in the year the proposed road development would open to traffic.

Post-establishment Stage: considers the impact after such time as proposed planting has established and is providing effective landscape and visual mitigation.

This usually requires a period of five to seven years after planting. The impact is assessed c.15 years after the proposed road development would open to traffic.

Table 12.1: Classification of Significance of Impacts

		Existing Environment Significance / Sensitivity			
		High	**Medium**	**Low**	**Negligible**
Description of Impact Character / Magnitude / Duration / Probability/ Consequences	**High**	Profound	Very Significant	Significant / Moderate	Moderate / Slight
	Medium	Very Significant / Significant	Significant / Moderate	Moderate	Slight / Not Significant
	Low	Significant / Moderate	Moderate / Slight	Slight / Not Significant	Not Significant / Imperceptible
	Negligible	Slight / Not Significant	Not Significant	Not Significant / Imperceptible	Imperceptible

These impacts[1], which in quality may be positive, neutral or negative/adverse, are described as follows:

- **Imperceptible:** An effect capable of measurement but without noticeable consequences
- **Not significant:** An effect which causes noticeable changes in the character of the environment but without noticeable consequences
- **Slight:** An effect which causes noticeable changes in the character of the environment without affecting its sensitivities
- **Moderate:** An effect that alters the character of the environment in a manner that is consistent with existing and emerging trends
- **Significant:** An effect which, by its character, magnitude, duration or intensity alters a sensitive aspect of the environment
- **Very Significant:** An effect which, by its character, magnitude, duration or intensity significantly alters the majority of a sensitive aspect of the environment
- **Profound:** An effect which obliterates sensitive characteristics

In terms of **duration**, effects are considered as follows:

- **Brief:** lasting up to one day
- **Temporary:** lasting up to one year
- **Short-term:** lasting one to seven years
- **Medium-term:** lasting seven to fifteen years

1 It should be noted that throughout this chapter of the EIAR, the terms impact and effect are interchangeable and should be read to have the same meaning.

- **Long-term:** lasting fifteen to sixty years
- **Permanent:** lasting over sixty years

Further aspects including do-nothing, worse-case, cumulative, interactive, indirect and residual impacts are also considered, where appropriate, in the assessment.

12.3 Receiving Environment

12.3.1 Landscape Context and Character

12.3.1.1 General

Galway City is situated on the River Corrib, a short c.6km river linking Lough Corrib in the north to Galway Bay in the south. The historic city and the city core is centred on the southern extent (mouth) of the river but the city has also extended significantly both eastwards towards Oranmore and westwards towards Bearna. While city expansion to the north has been constrained by Lough Corrib, development has extended along the corridors of the various national, regional and local roads that radiate out west, northwest, northeast and east from the city centre.

The landscape along the proposed road development is divided into two distinct sections by the River Corrib at Dangan/Menlough. The west side of the river valley (along the existing N59 Moycullen Road) is also the boundary of a clear geographical divide between the underlying granite geology to the west and limestone to the east.

In general, the landscape to the west of the river is characterised by a pattern of irregular shaped, undulating enclosed fields delineated by drystone granite walls. Stretches of Blanket bog are also common and many fields, particularly in the vicinity of Bearna, are increasingly overgrown with scrub and bramble.

The landscape to the east is characterised by a pattern of larger, usually rectangular fields of improved grassland. The notable exceptions to this are the overgrown and wooded demesne landscape of Menlo Castle, the areas of bare Limestone pavement with surrounding dense hazel scrub, and the presence of large limestone quarries at Coolough (Lackagh Quarry) and at Ballygarraun/Pollkeen (Roadstone Quarry, off the N83 at Twomileditch).

The landscape within the city and north along the wider River Corrib corridor is low-lying typically being lower than 30m above ordnance datum (OD). Within the extended city, the landscape rises gradually to the east to circa 70m OD at Briarhill (Dougishka) where the local high point is topped by a reservoir. To the west of the N6/Bóthar na dTreabh, Dougishka includes established residential estates (Garrán Ard, Maigh Rua, Garran Íseal, Sraith Fhada, An Sean Bhaile) – many of which openly overlook the existing N6/Bóthar na dTreabh. To the east the landscape is open, rural and increasingly flat with limestone walls. The village of Coolagh-Briarhill lies to the immediate north of the existing N6 approach to the city.

To the northeast, the landscape undulates over shallow valleys and low ridges towards Lough Corrib. The ridges at Ballygarraun/Pollkeen and

Ballindooley/Coolough are topped with limestone quarries and exposed limestone pavement and limestone walls are also a feature of the wider area from Ballindooley through to Menlough. Much of this area is covered with hazel scrub with limited tree cover. The villages of Castlegar and Coolough-Menlough retain a distinctive village character despite the increasing expansion of the city into their immediate context.

The ruin of Menlo Castle and its associated grounds provide an attractive landmark feature on the east side of the river close to where it leaves Lough Corrib. Menlough Village, also located on the east bank of the river, has an attractive and historic network of narrow rural roads with a dense network of individual and clustered residential properties.

North of the city the River Corrib forms a broad and attractive watercourse set within a landscape mosaic of grassland and marginal grassland, sports areas (*e.g.* National University of Galway (NUIG) Sports Campus and Glenlo Abbey Golf Course) and areas of wetland/marsh (especially at the northern reaches of the river approaching Lough Corrib) scrub and woodland plantings. The entire valley is low-lying and the immediate river valley is below 10m OD.

West of the River Corrib, the landscape rises to the northwest of the city where a local high point at Tonabrocky (111m OD) is marked with telecommunication masts. From Tonabrocky the landscape falls gradually south and southwest to the coastal corridor extending either side of Bearna Village.

A large lake, Lough Inch, is located circa 1.5km northwest of Bearna Village. Large areas of bogs/peatlands are located west/northwest of Bearna, including around Lough Inch and at Tonabrocky Bog further north.

Extensive residential development is a particular feature along the R336 Coast Road and along other local roads in the wider area around Bearna Village.

Extensive residential, community and mixed developments is also a feature along the N59 Moycullen Road corridor extending northwest from the city. This includes developments such as Dangan Business Park, the NUIG Sports Campus and the hotel and golf course resort at Glenlo Abbey.

12.3.1.2 Landscape along Proposed Road Development

The overall length of the proposed road development is c.17.54km and includes for other new and re-aligned link roads and realigned sections of existing roads, as well as for over 2.2km of N59 Link Road from Bushypark on the existing N9 Moycullen Road in the north, to the Rahoon Road in the south. Refer to **Chapter 5, Description of Proposed Road Development** for further details.

The route of the proposed road development skirts the peri-urban landscape that lies between the developed western, northern and eastern suburbs of the city and the surrounding rural hinterland. Many sections of the route of the proposed road development are overgrown with blackthorn, gorse and hazel scrub and bramble.

The landscape along the initial western section of the proposed road development is a rugged lowland landscape of small fields, marginal grassland, extensive and increasing areas of scrub, granite stone walls in a variety of condition, and residential development prominently located along the main and local roads throughout.

To the northwest the route of the proposed road development passes through Cappagh, Mincloon, Letteragh and Barnacranny on the exposed lower southern slopes of ground that rises gradually towards Tonabrocky Hill.

To the north of the city, the route of the proposed road development leaves high ground at Dangan, which includes extensive residential and recreational/sports development, and crosses the wide lowland valley of the River Corrib before moving onto gradually rising ground east of Menlo Castle. The ivy-covered castle ruin, located north of the proposed crossing location is a prominent landmark feature along the river corridor.

To the northeast the route of the proposed road development crosses the rolling drumlin and valley landscape between Coolough (and Lackagh Quarry), Ballinfoile and Castlegar. The route passes immediately south of Ballindooley Lough and through a residential area at Castlegar. The route is north of the defined settlement area of Castlegar Village, as identified on the Land Use Zoning and Specific Objectives Map of Galway City Development Plan 2017-2023. Residential development is a prominent feature in the existing landscape both where the proposed road development crosses the N84 Headford Road at Ballindooley and passes through Castlegar.

To the east of the city, the route of the proposed road development passes to the immediate east of Galway Racecourse before turning south and east around the village of Coolagh-Briarhill to tie-in to the existing N6 and the R446 Bother na dTreabh south of the village and east of Dougishka.

The main landscape features along the proposed road development include the diversity of ecological/landscape and cultural areas, the mosaic of open grassland, limestone pavement, marsh, wetland, river corridor/lake edge, scrub/and occasional tree plantings; the presence of significant recreational and sports grounds (including Galway Racecourse and NUIG Sports Campus) and other open spaces; and the overall high quality of the landscape – especially along the River Corrib corridor and east through to Ballindooley. These features add to overall diversity and interest of the landscape as well as to its sensitivity and significance.

As noted while there are extensive areas of scrub, including gorse and blackthorn to the west and hazel and blackthorn to the northeast, the plantings are generally low and the landscape is often visually open and tree and woodland planting is notably limited along the proposed road development. The presence of mature trees and blocks of trees is most notable within the River Corrib valley, including around residential and sports facilities on the west bank of the river and on rising ground east of Menlo Castle on the east bank.

Given the city edge location, the presence of residential properties is a notable and prominent visual feature along the entirety of the route of the proposed road development. In addition, there are a variety of community and social amenities as well as rural villages located close to the proposed road development. Visual significance also applies to features of archaeological, architectural and cultural heritage, *e.g.* Menlo Castle, Bushypark House, *etc*., as described under **Chapter 13, Archaeological, Architectural and Cultural Heritage**.

12.3.1.3 Landscape Character Assessment

The Landscape and Landscape Character Assessment for County Galway[2] (2003) sub-divides the county into 25 large landscape character areas (LCAs). Landscape values and sensitivity ratings have also been applied to each of the LCAs. Only five of the LCAs (3, 5, 9, 11 & 12) pertain to the route of the proposed road development (refer to **Plate 12.1** and **Table 12.2**).

The western portion of the proposed road development is located within:

- Landscape Character Area 9: *Inverin to Galway City Coastline, which covers the southwestern portion of the study area in and around Bearna and City Coastline*

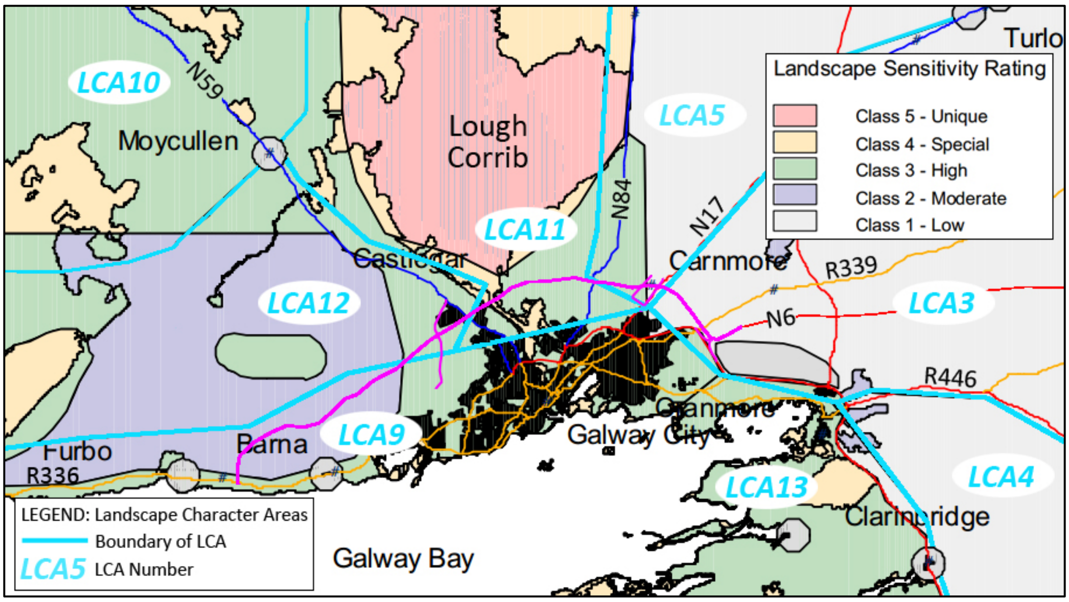
Thereafter continuing clockwise, the proposed route development passes through the edge of the following LCAs:

- LCA 12: *South foothills of east Connemara Mountains (west of Salthill to Rossaveel)*
- LCA 11: *Lough Corrib and environs*
- LCA 5: *Northeast Galway (Tuam environs)*
- LCA 3: *East Central Galway (Athenry, Ballinasloe to Portumna)*

The Lough Corrib LCA (11), which covers the central section of the proposed road development (north of the city), is the most sensitive, being described as '*wide dramatic expanse of water including many islands supporting deciduous woodland. The land … surrounding the southern section is flat, open grassland. The landscape of the Lough and its surrounds is highly scenic and includes many facilities for visitors*.' (Section 2.13 of Landscape and Landscape Character Assessment for County Galway).

[2] Included as Environmental Support Document to Galway County Development Plan 2015-2021 (http://www.galway.ie/en/services/planning/developmentplansandpolicy/galwaycountydevelopmentplan2015-2021/)

Plate 12.1: LCAs and Sensitivity Ratings with proposed road development indicated in Pink *(source: Extract of Figure 3 of Landscape and Landscape Character Assessment of Galway County – annotated to show LCAs, LCA Numbers and alignment of proposed road development (indicated in pink))*



Each of these county-wide LCAs represents a broad landscape area, and as such in the course of carrying out this assessment, the landscape along the route of the proposed road development has been further sub-divided into Local Landscape Character Units (LLCUs), which highlight more immediate and distinctive landscapes characteristics. The LLCUs are described in **Table 12.2** and illustrated on **Figures 12.2.01** and **12.2.02** Landscape Character.

While somewhat distant from the immediate line of the proposed road development, both Lough Corrib and Galway Bay are considered waters of national tourism significance[3].

[3] Determination of Waters of National Tourism Significance and Associated Water Quality Status, Fáilte Ireland (2009)

Table 12.2: Landscape Character Areas (LCAs) and Local Landscape Character Units (LLCUs)

LCA, Approx. Chainage & Length	Landscape Character Area (LCA) Description, Value and Sensitivity	Local Landscape Character Units (LLCU)	LLCU Landscape Description, Value and Sensitivity
LCA 9 Ch. 0+000 to Ch. 7+200 (c.7.2km)	**Inverin to Galway City Coastline:** The coast is flat, comprising rocks and sand merging with natural grassland, towards the R336. The coast line commands striking views of County Clare and the Aran Islands. Further inland from the R336 route, there are residential and some light industrial developments which have lowered the scenic value in this area. **High Landscape Value and High Landscape Sensitivity with parallel strip of Special Sensitivity**.	**Coastal Fringe – Bearna:** Ch. 0+000 to Ch. 0+250 (c.0.25km)	Open grassland with sea views and granite stone walls. Increasingly coarse-grained marginal grassland with extensive scrub north of the R336. **Moderate Value and High Sensitivity north of R336. High Value and Special Sensitivity south of R336**.
		Undulating Western Lowlands: Ch. 0+250 to Ch. 6+300 (c.6.05km)	Marginal coarse grassland/peatland with extensive scrub and overgrown granite stone walls. **Moderate Value and Moderate Sensitivity**.
LCA 12 Ch. 7+200 to Ch. 7+700 (c.0.5km)	**South foothills of east Connemara Mountains:** The landscape of the foothills is undulating heath and scrubland with regular rocky outcrops. The area is generally undeveloped and have expansive views in a southerly direction across Galway Bay towards County Clare. **Medium Landscape Value and approximately half High Landscape Sensitivity and half Special Sensitivity**.	**Open Western Uplands:** Ch. 6+300 to Ch. 8+000 (c.1.7km)	Increasingly open and elevated landscape on rising slopes. Some granite stone walls and limited hedgerows. **High Value and High Sensitivity**.
LCA 11 Ch. 7+700 to Ch. 13+100 (c.5.4km)	**Lough Corrib and Environs:** Lough Corrib is a wide, dramatic expanse of water including many islands supporting deciduous woodland. The land around the northern part of the Lough is undulating heath bog and coniferous forestry whereas the land surrounding the southern section	**West Galway Suburbs:** Ch. 8+000 to Ch. 8+800 (c.0.8km)	Elevated lands dominated by residential (and some other) development. **Moderate Value and Moderate Sensitivity**.
		Institutional City Lands: Ch. 8+800 to Ch. 9+100 (c.0.3km)	Amenity, recreational and sports-related lands – with open public access.

LCA, Approx. Chainage & Length	Landscape Character Area (LCA) Description, Value and Sensitivity	Local Landscape Character Units (LLCU)	LLCU Landscape Description, Value and Sensitivity
	is flat, open grassland. The landscape of the Lough and its surrounds is highly scenic and includes many facilities for visitors. **Outstanding Landscape Value and Unique Landscape Sensitivity with pockets of High and Special Sensitivity**.		**High Value and Special Sensitivity.**
		Corrib River Valley: Ch. 9+100 to Ch. 9+900 (c.0.8km)	Broad lowland river with large expanse of slow-moving water fringed by mosaic of wetland, amenity, grassland and woodland landscapes. Accentuated by presence of significant castle ruin. **High Value and Unique Sensitivity**.
		Limestone Lowlands: Ch. 9+900 to Ch. 11+200 (c.1.3km)	Scrub dominated areas of limestone pavement, grassland and stone walls. **High Value and Special Sensitivity**.
LCA 5 Ch.13+100 to Ch.14+200 (1.1km)	**Northeast Galway:** Landscape is flat, fertile pastoral land bound with field hedgerows. There is little or no coniferous forestry or deciduous woodland. There are no areas of particular scenic value. **Low Landscape Value and Low Landscape Sensitivity with pockets of Moderate Sensitivity**.	**Undulating Limestone Lowlands:** Ch. 11+200 to Ch. 14+100 (c.2.9km)	Prominent rolling drumlin ridges and valley grassland landscape with hedgerows. Large limestone rock quarries on open ridges and lough with surrounding wetlands in valley. **High Value and High Sensitivity**.
LCA 3 Ch.14+200 to Ch.17+540 (3.34km)	**East Central Galway:** The landscape is flat, coarse grassland, occasional clumps of coniferous forestry between 1–3km^2 in size, fields defined principally by stone walls. There are no areas of particular scenic value although the stone walls are quite distinct.	**East Galway Suburbs:** Ch. 14+100 to Ch. 14+500 (c.0.4km) & Ch. 15+400 to Ch. 16+000 (c.0.6km)	Lands dominated by residential and business park development. **Moderate Value and Moderate Sensitivity**.
		Galway Racecourse: Ch. 14+500 to Ch. 15+400 (c.0.9km)	Flat open landscape and significant city and region amenity. **High Value and Special Sensitivity**.

LCA, Approx. Chainage & Length	Landscape Character Area (LCA) Description, Value and Sensitivity	Local Landscape Character Units (LLCU)	LLCU Landscape Description, Value and Sensitivity
	Low Landscape Value and Low Landscape Sensitivity with pockets of Moderate Sensitivity.	**Open Limestone Lowlands:** Ch. 16+000 to Ch. 17+540 (c.1.54km).	Increasingly flat open grassland landscape with limestone walls and occasional mature trees. **High Value and Moderate Sensitivity**.

12.3.1.4 Galway City Development Plan 2017-2023

The provision of the proposed road development is an integrated part of the Galway Transport Strategy (GTS). The GTS, and hence the proposed road development has been incorporated into both Galway City Development Plan 2017-2023 and Galway County Development Plan 2015-2021 as varied.

The provision of the proposed road development as part of the integrated GTS is a stated objective of Galway City Development Plan. This objective is supported in particular by Policies 3.3, 3.4, and 3.7 as well as by the Specific Objectives outlined under Section 3.10 of the Plan. The corridor of the proposed road development is also expressed on the Land Use Zoning and Specific Objectives Map of Galway City Development Plan and described as 'N6 Galway City Ring Road (N6 GCRR)'.

In terms of land use zoning in the Galway City Development Plan it is stated that the '*strategic objectives which include the plan commitments to preserve the N6GCRR Preferred Route Corridor and the associated land requirements will take priority over other land uses and objectives.*' (page 14, Galway City Development Plan 2017-2023).

In terms of landscape and visual considerations, Chapter 2 of the Galway City Development Plan addresses **Housing and Sustainable Neighbourhoods** and sets out various policies and specific objectives to develop, enhance, protect and regenerate existing and proposed residential areas, including those within the outer suburbs (Section 2.5) and established suburbs (Section 2.6). Section 2.10 of Galway City Development Plan addresses **Village Envelopes/Areas**, and recognises four village settlement areas with distinct characters within the Plan area. These are Menlough, Castlegar, Coolagh-Briarhill and Coolagh-Menlough as shown on **Figures 12.3.01** and **12.3.02**. Policy 2.10 seeks to strengthen the character of these villages and to protect and enhance their amenity and identity.

Chapter 4 of Galway City Development Plan sets out the policies and objectives in relation to **Natural Heritage, Recreation and Amenity**. This Plan identifies the green network of the city and the spaces that comprise this network (refer to Table 4.1 of Plan and to **Plate 12.2** of this chapter of the EIAR). The network is promoted and supported by Policy 4.1.

The network includes **protected spaces** (i.e. SACs, SPAs, NHAs, pNHAs and local biodiversity areas); **blue spaces** (Coastal area, River Corrib, canals and other waterways, Lough Corrib and lakes, enclosed marine and wetlands); **green spaces** (citywide and city centre parks and neighbourhood parks); **community spaces** (greenways, recreational facilities and playgrounds, and protected views of special amenity value and interest); and **open spaces** (which includes institutional open space, recreation and amenity zoned lands and agricultural and high amenity lands).

This green network includes the River Corrib, lands at Menlo Castle, Galway Racecourse, NUIG Sports Campus, Cappagh Park, Ballinfoile Park, Ballindooley Lough as well as agricultural and high amenity zoned lands.

Plate 12.2 and **Plate 12.3** provide an overlay of the proposed road development onto the green network and green spaces/park network respectively. Further detail is also provided on **Figures 12.3.01** and **12.3.02**: Landscape Planning Aspects.

Section 4.4 of Galway City Development Plan discusses **Green Spaces** and Figure 4.4 of the Plan (refer to **Plate 2.3**) identifies the extent of parks within the city area.

To the northwest and north, most of the lands outside of the developed city are identified as part of the green network. The majority of the proposed road development is located within these areas.

These are also shown on **Figures 12.3.01** and **12.3.02**: Landscape Planning Aspects, which indicates that the proposed road development crosses lands zoned for 'recreational and amenity use' along the Bearna Stream (Ch. 5+230 - between Cappagh and Ballymoneen Roads) and at NUIG Sports Campus (Ch. 8+900) on the west side of the River Corrib. The proposed road development also crosses a large area of land zoned for agriculture and high amenity on the east side of the River Corrib.

Section 4.4.1 **Urban Woodland Parks and Trees** and Policy 4.4.1 seeks to manage, develop and integrate existing trees and hedgerows, including on development sites.

Section 4.5.1 **Greenways and Public Rights of Way** promotes the development of such linkages, including through the NUIG campus on the west bank of the River Corrib. The proposed road development would cross this greenway and other such links proposed to the northwest of the city (refer to **Figures 12.3.01** and **12.3.02**).

Plate 12.2: Green Network (within City Area) overlain with the proposed road development *(source: Figure 4.1 from City Development Plan with proposed road development overlain in black)*

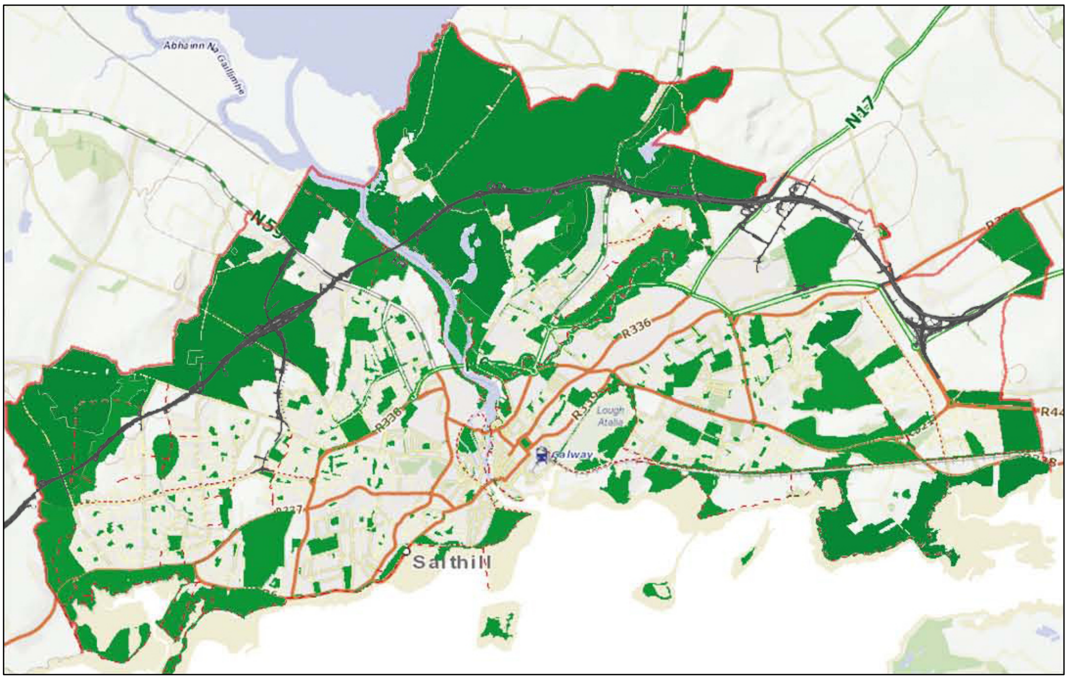


Plate 12.3: Park Network (within City Area) overlain with the Proposed Road Development *(source: Figure 4.4 from City Development Plan with proposed road development overlain in black)*

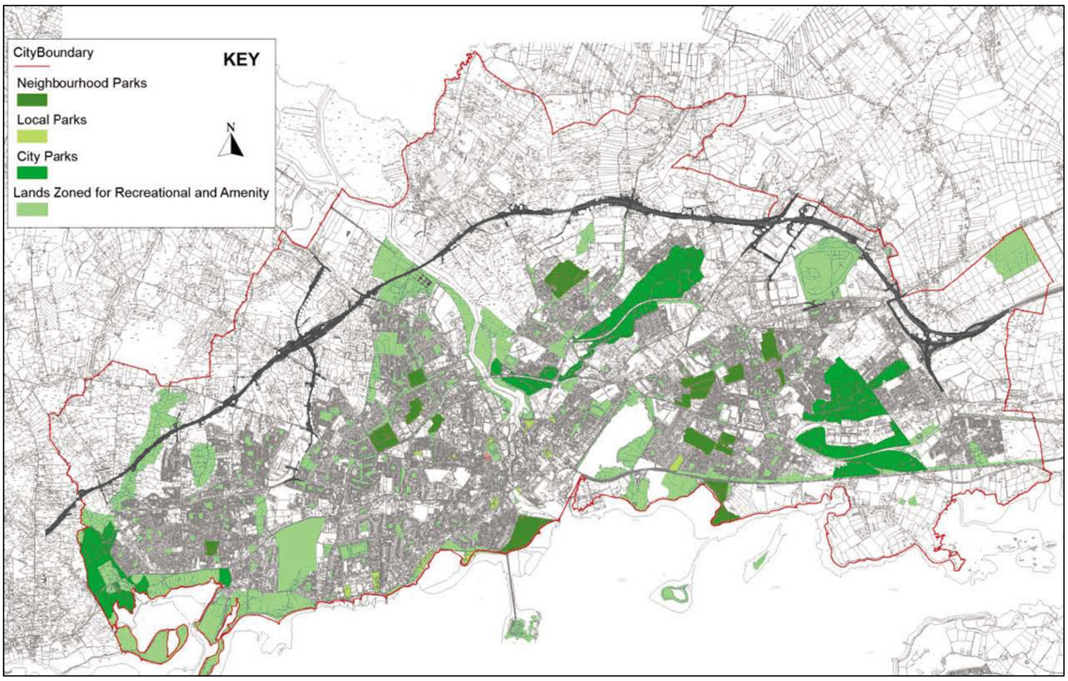


Section 4.5.3: **Views of Special Amenity Value and Interest**, identifies panoramic (V.1 to V.9) and linear protected views (V.10 to V.19). The location of the views are shown on **Figures 12.3.01** and **12.3.02** and views relevant to the proposed road development are listed in **Table 12.3**.

Table 12.3: Selected Panoramic Protected Views and Linear Protected Views

Panoramic Protected Views	
V.1	Panoramic views of the city and the River Corrib from Circular Road
V.2	Views from Dyke Road and Coolagh Road encompassing the River Corrib and Coolagh fen
V.6	Panoramic views of the city, and the Terryland Valley from parts of the Castlegar-Ballindooley Road
V.7	Views encompassing Lough Corrib from parts of the Quarry Road and Monument Road
Linear Protected Views	
V.10	Views from Galway-Moycullen Road (N59) of the River Corrib
V.14	Views northwards encompassing the River Corrib and adjoining lands from Quincentenary Bridge
V.19	Views encompassing Ballindooley Lough from parts of the Headford Road

Section 4.6.2: **Agricultural Lands** discusses general agricultural lands (zoned A) and high amenity agricultural lands (zoned G). The latter areas are illustrated on **Figures 12.3.01** and **12.3.02** and indicate that the proposed road development crosses this high amenity designation on the east side of the River Corrib. Policy

4.6.2 aims to prevent development that would give rise to environmental pollution or injury to general amenities, and also restricts the location of structures (other than structures with essential links to the waterway and public utilities) within ten metres of the River Corrib, in G zoned lands.

Section 4.7 of the plan sets out further **Specific Objectives** in relation to Natural heritage, Recreation and Amenity. These include:

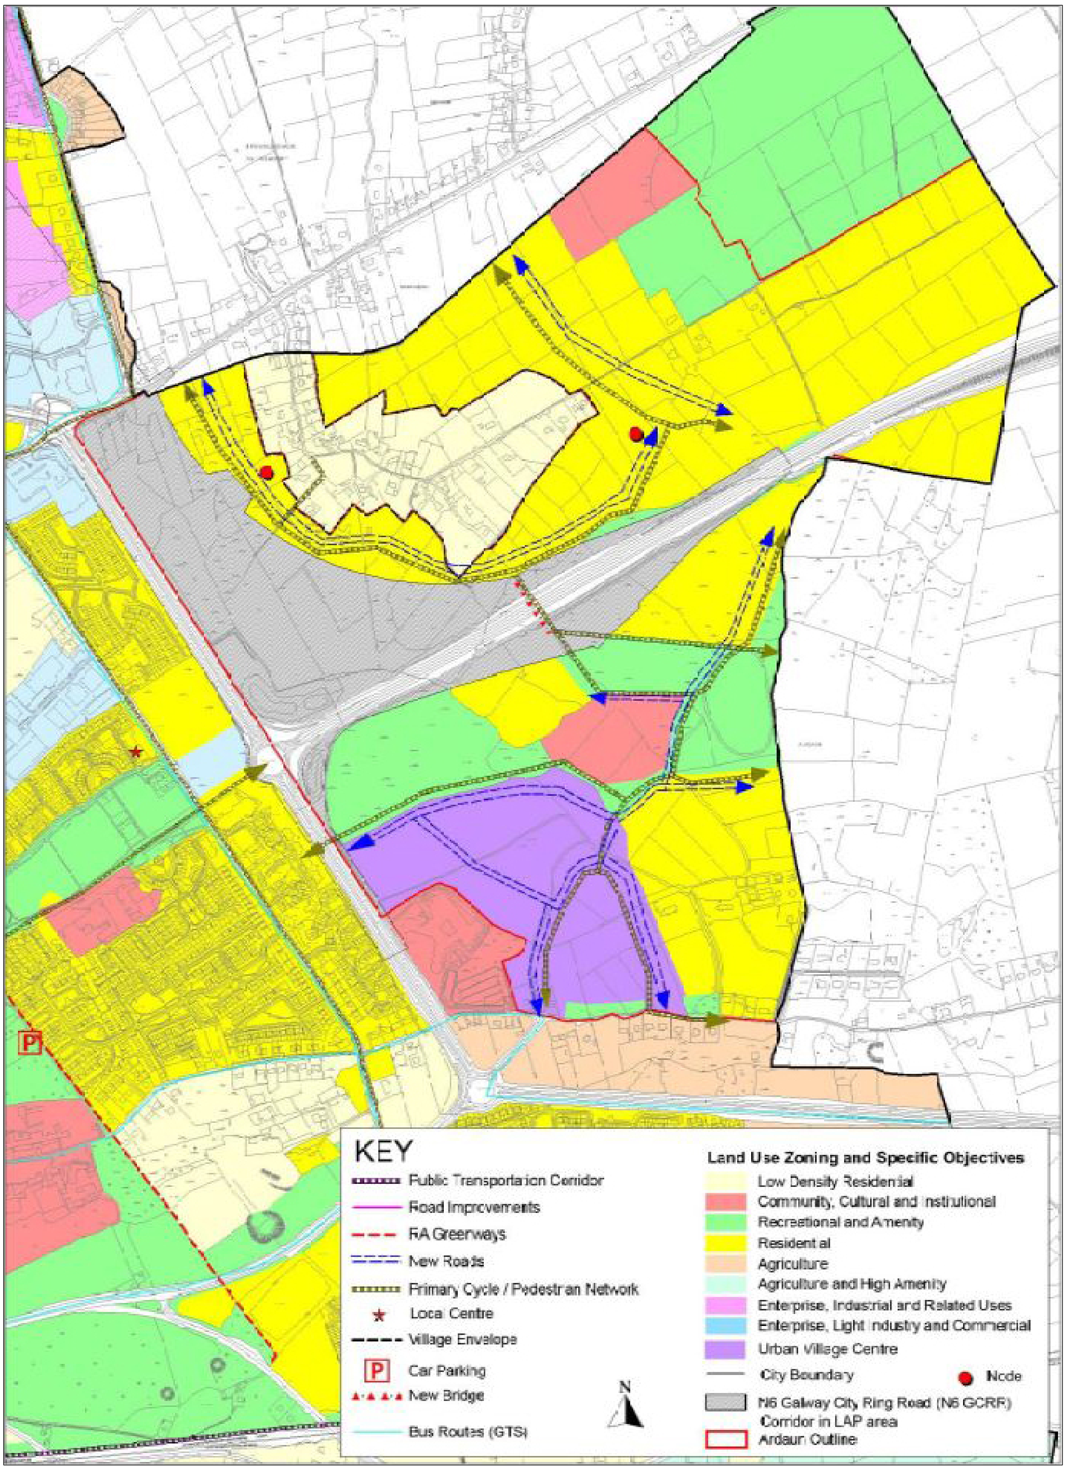
- A medium/long term objective to explore the potential for developing lands adjacent to Menlo Castle incorporating Menlough Woods as a park.
- A medium/long term objective to develop a walk along the eastern side of the River Corrib from the Dyke Road to the pier at Menlough.

Section 9.11 of Galway City Development Plan addresses **Light Pollution** and Policy 9.11 seeks to Ensure the design of external lighting minimises the incidence of light pollution, glare and spillage into the surrounding environment and has due regard to the visual and residential amenities of surrounding areas.

12.3.1.5 Ardaun Local Area Plan 2018-2024

The western section of the existing M6/N6 Galway to Dublin Motorway and the eastern end of the proposed road development falls within the area covered by the Arduan Local Area Plan (LAP). The LAP acknowledges that the '*N6 Galway City Ring Road route corridor reservation traverses the north-western section of the area*' (refer to Section 4 Ardaun Local Area Plan, page 8) and does not include development proposals within the corridor of the proposed road development. The Draft LAP proposes major development in the area, including new residential and commercial developments on c.81 hectares of an overall LAP area of c.164 hectares. The Draft LAP envisages significant changes to the landscape and visual setting of the area, which will be delivered on a phased basis over a long period of time.

Plate 12.4: Ardaun LAP – Land Use Zoning *(source: Figure 23 from Ardaun Local Area Plan 2018-2024)*



12.3.1.6 Galway County Development Plan 2015-2021

The Galway Transport Strategy (GTS) and the proposed road development are incorporated within Galway County Development Plan, as varied, and discussed in detail in Sections 5.3.4 and 5.3.4.6 of the Plan respectively. The GTS and the proposed road development are supported by Land Use Integration and Sustainable Transportation Policies TI-2 and TI-8 and Objectives TI-1 and TI-15.

In terms of landscape and visual considerations, Chapter 9 of Galway County Development Plan sets out policies and objectives in relation to **Heritage, Landscape and Environmental Management**. The strategic aims of the Plan (page 148) are to:

- To promote appropriate enhancement of the built and natural environment as an integral part of any development
- To promote a reasonable balance between conservation measures and development needs in the interests of promoting orderly and sustainable development
- To protect the landscape categories within the county and avoid negative impacts upon the natural environment
- To promote appropriate enhancement of the natural environment as an integral part of any development

Section 9.3 of Galway County Development Plan sets out General Heritage Policies, while Sections 9.4, 9.5, 9.6 and 9.7 relate to **Built Heritage, Architectural Heritage, and Archaeological Heritage**.

Objective AH 9 – 'Local Landscape and Place Assessment' supports local communities and residents in analysing character of local places and promotes its regeneration for the use and enjoyment of locals and visitors.

Objective AH 10 – 'Designed Landscapes' addresses surviving designed landscapes and promotes the conservation of their essential character, both built and natural.

Section 9.9 of Galway County Development Plan sets out a range of **Natural Heritage and Biodiversity** Policies and Objectives, which seek to protect, conserve and enhance the natural heritage and biodiversity of designated and non-designated sites, ecological networks and linear features such as hedgerows, stonewalls, water resources, geological and geomorphological systems, bats and bat habitats, eskers, the coastal zone, inland waterways, riparian zones and soil and groundwater; to promote green infrastructure; to implement national and county heritage plans and biodiversity plans; to support measures for prevention, recording and eradication of invasive species; to promote the use of native species; and to take account of Management Plans prepared for European sites by the National Parks and Wildlife Service (NPWS).

Objective NHB 11 – 'Trees, Parkland/Woodland, Stonewalls and Hedgerows' seeks to: protect important trees and hedgerows; to promote the use of native species; and to retain natural boundaries, including stone walls and hedgerows, wherever possible or to replace with a similar boundary where removal is unavoidable.

Sections 9.10 and 9.11 of Galway County Development Plan sets out Policies and Objectives in relation to **Landscape Conservation and Management** and to the consideration of landscape character, and where appropriate, to the preservation and enhancement of character, views and prospects, amenities of places and features of natural beauty or interest.

Section 9.10 of Galway County Development Plan notes that County Galway has been sub-divided into 25 **Landscape Character Areas** (LCAs), each of which has been attributed landscape values and sensitivity ratings. As landscape character relates to both county and city administrative areas this is discussed in further detail in **Section 12.3.1.2** of this chapter.

Section 9.12 and 9.13 of Galway County Development Plan refers to **Focal Points and Views** and to Objective FPC 1 – Development Management, which seeks to preserve focal points and views as listed in Map FPV1 of Galway County Development Plan. It is noted that this objective shall be balanced against the need to develop key infrastructure to meet the strategic aims of the Plan, and have regard to the zoning objectives of serviced development land within Galway Metropolitan Area.

Focal Points/Views Map FPV1 (of Galway County Development Plan) indicates that there are 5 focal points/views on or close to the proposed road development (Refer to **Figures 12.3.01** and **12.3.02**). These are:

71 – View of Headland Illaunafamona (700m+ from proposed road development).

72 – View of the sea from north of Bearna (750m section of proposed road development (Ch. 2+600 to Ch. 3+350) passes through northern extent of area from which view is identified).

73 – View of Lough Inch from the surrounding Third Class Roads (proposed road development passes immediately south of area from which view is identified)

74 – View of North Clare Coast (westernmost 2.85km section of proposed road development (Ch. 0+000 to Ch. 2+850) crosses into eastern portion of area from which view is identified).

75 – View of Loch Bhain Ui Choinc

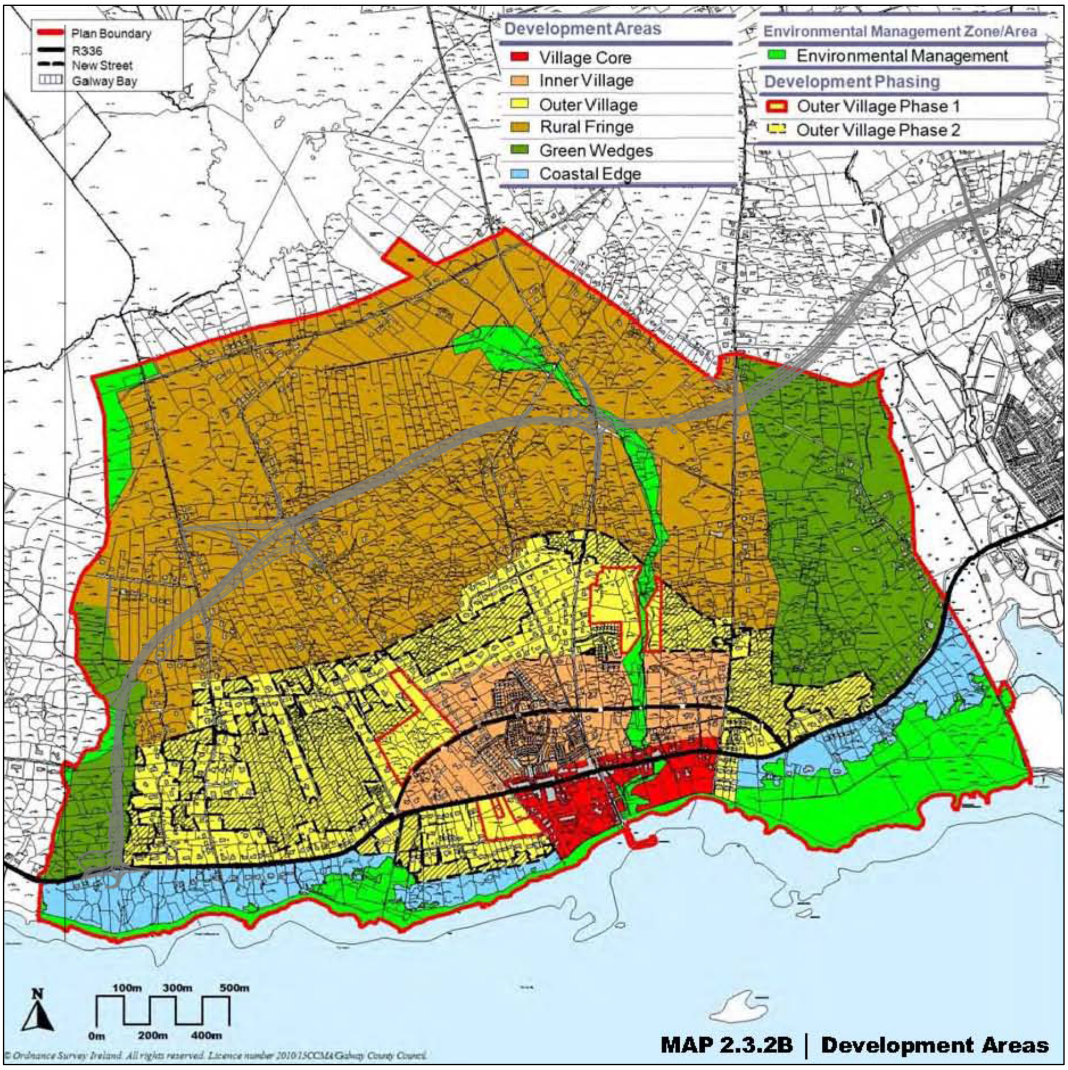
76 – View of Lough Corrib (1.45km section of proposed road development (Ch. 8+200 to Ch. 9+650) passes through southern end of area from which view is identified).

12.3.1.7 Bearna Local Area Plan 2007-2017

Section 2 of the Bearna Local Area Plan sets out the policies and objectives in relation to **Development Strategy**. Sub-section 2.3.2 discusses Land Use Strategy and identifies landscape designations. The designations are overlain with the proposed road development on **Plate 12.5**. The designations/land use objectives include:

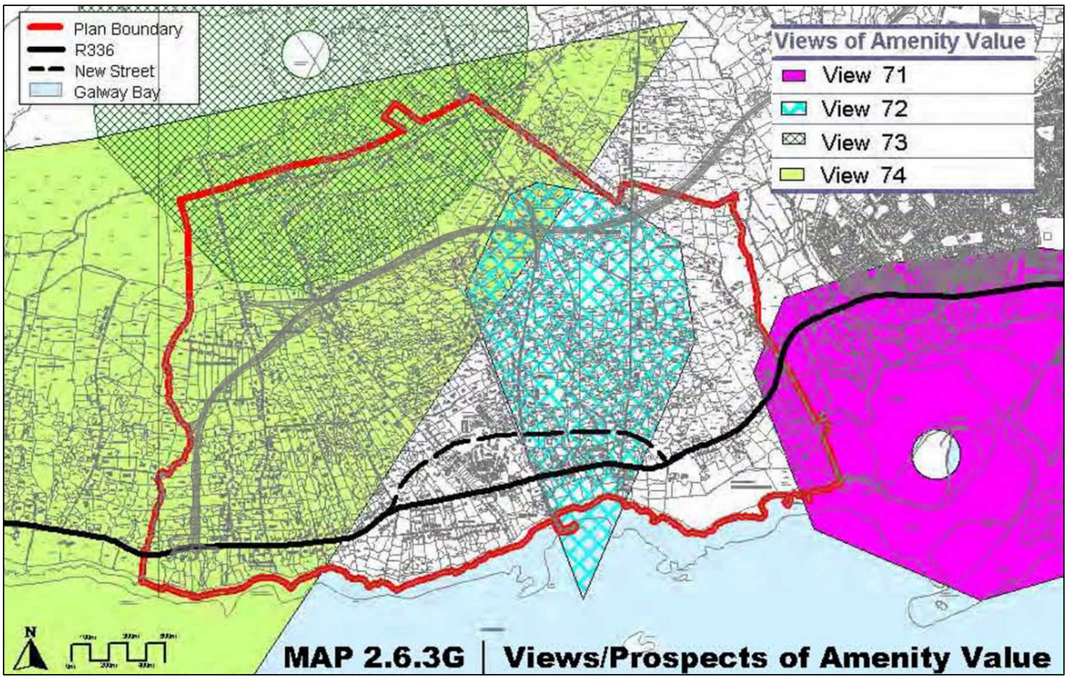
- Objective LU6: ‘Rural Fringe Area’, which seeks to protect the rural landscape north of Bearna from inappropriate and ribbon development. This area is also described in more detail in Sub-section 3.4 of the Bearna Local Area Plan. The proposed road development passes through centre of the rural fringe area.
- Objective LU7: ‘Green Wedges Area’, which seeks to retain areas adjacent to Sruthán Na Libeirtí (west) and Barna Woods (east) as green landscape wedges separating Bearna from Na Forbacha in the west and from Galway City to the east. These areas are also described in more detail in Sub-section 3.5 of the LAP. The proposed road development passes north south through western green wedge along Sruthán Na Libeirtí.
- Objective LU8: ‘Coastal Edge Area’ seeks to protect the coastal edge and high amenity area and retain potential for recreation, amenity, conservation and visual amenity. This area is also described in more detail in Sub-section 3.6 of the Bearna Local Area Plan. The proposed road development ties in to existing R336 at northern boundary of coastal edge area.
- Objective LU9: ‘Environmental Management Zone/Area’ seeks to protect areas with high biodiversity, landscape, amenity, and/or flood risk potential. These areas are also described in more detail in Sub-section 3.7 of the Bearna Local Area Plan. A c.150m section of the proposed road development passes through an environmental management zone/area along the Sruthán Na Libeirtí (Ch. 0+500). A further short section (c.100m) of the proposed road development at the proposed Bearna East Roundabout also crosses a narrow section of a second environmental management zone/area located along the Trusky Stream (Ch. 2+800).

Plate 12.5: Development Area Map from Bearna LAP overlain with proposed road development (in Grey)



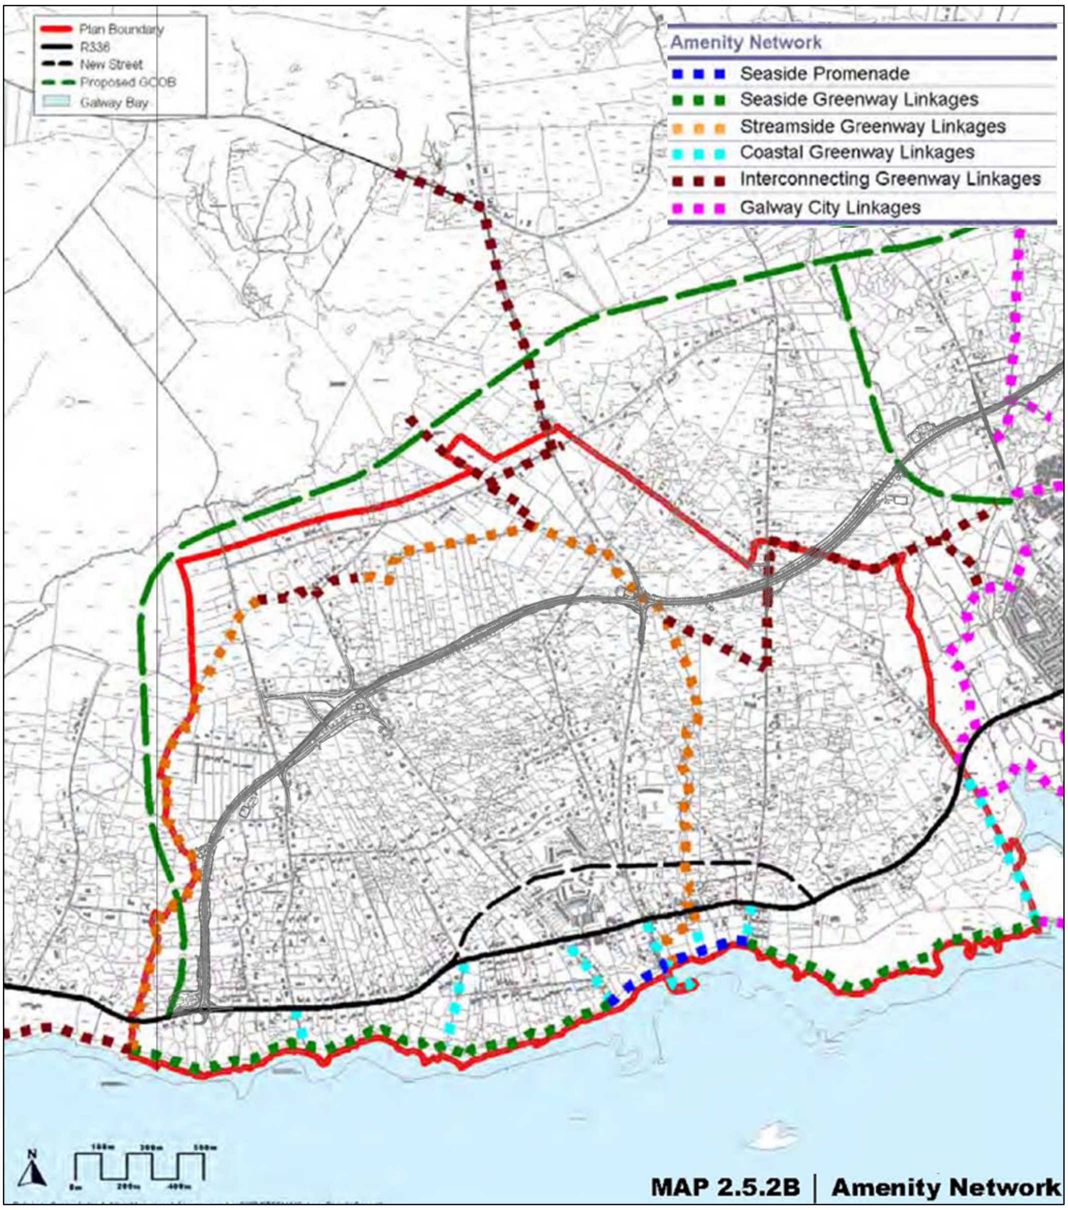
Policy 2.4.2B and Objectives VD12 to VD17 of the local area plan, which relate to **Landscape, Open Space, Views and Prospects**, seek to enhance green networks, integrate new development with the landscape, and landscape features, including streams, trees and hedgerows, and promote ecological landscaping. Objective VD14 Views and Prospects reflects the policy of Galway County Development Plan in relation to the protection of Views 71, 72, 73 and 74 as discussed under **Section 12.3.1.3** above (refer to **Plate 12.6** and **Figures 12.3.01** and **12.3.02** also).

Plate 12.6: Prospects Map from Bearna LAP overlain with proposed road development (in Grey)



Policy 2.5.2B and Objectives CF13 to CF19 of the local area plan relate to the **Amenity Network**. In particular Objectives CF15 and CF17 seek to promote streamside greenway linkages, loops and interconnections along Trusky Stream and Sruthán Na Libeirtí and on to a potential future coastal amenity park/promenade. These objectives are further supported by Objective CF18 which promotes the use of existing boreens and field or property boundaries or other routes as appropriate/agreed to improve the amenity network. The proposed road development crosses streamside greenways and interconnecting greenway linkages – refer to **Plate 12.7**.

Plate 12.7: Amenity Network Map from Bearna LAP overlain with proposed road development (in Grey) *(Note: Route of previous N6 Galway Outer Bypass (2006) is shown in dashed green line)*



Policy 2.6.3D and Objectives NH10 to NH13 of the local area plan, which relate to the **Nature Conservation and Biodiversity**, address designated and non-designated sites, tree protection, interconnectivity and the retention, replacement of natural boundaries, including stone walls.

Likewise, Policy 2.6.3F and Objectives NH19 to NH22 of the local area plan, which relate to the **Field Patterns, Hedgerows and Stone Walls**, also address retention, where possible of field patterns and boundaries, including hedgerows and stone walls.

Policy 2.6.3I and Objectives Nh32 to NH35 of the local area plan relate to **Landscape Character and Views**; to the landscape value and sensitivity of such character; to designated views and prospects, and to the scenic qualities of the coastal zone (particularly 50m either side of the coastal road). Objective NH32 also notes potential for consideration of designation of this coastal zone as an Area of Special Amenity or as a Landscape Conservation area. The tie-in of the proposed road development with the existing R336 falls within the stated corridor of 50m to either side of the coast road. This area has not been designated as an Area of Special Amenity or as a Landscape Conservation area.

Policy 2.6.3J and Objectives NH36 to NH44 of the local area plan relate to the **Coastal Zone**, and to its sensitivities, protection and conservation, as well as to its potential for amenity/linkages/walkways.

12.3.1.8 Gaeltacht Local Area Plan 2008-2018

In an overall sense, the Gaeltacht LAP reiterates the landscape and visual considerations and objectives as set out in the Galway County Development Plan 2015-2021. In particular, Environmental Policies PL1, PL2 and PL3 refer to landscape and Policy OHE5 addresses biodiversity and ecological networks. Part of the proposed road development falls within District F Imeall Na Cathrach/An Eachréid, which abuts and surrounds Galway City. The Plan notes that "*It is the area under greatest pressure from City growth and must cope not only with the changes to its language and culture but with the constant demand for infrastructure and services which this now peri-urban area*."

12.3.1.9 Historic Gardens and Designed Landscapes

The National Inventory of Architectural Heritage (NIAH) records properties under Historic Gardens and Designed Landscapes. The properties listed are given a historic feature richness index rating (FRI) ranging between 0 to 16 depending on the quality of the extant features and the state of their preservation. Where no, or virtually no recognisable features remain, properties are considered as having '0' FRI. Properties with a low rating (*i.e.* FRI of less than 5) will have experienced significant loss and/or alteration of the original layout of the historic garden and/or designed landscape. Nevertheless, even where a lower rating has been recorded, individual features may continue to have local landscape significance, *e.g.* peripheral mature woodland, avenues, parkland trees *etc*. Where the FRI rating is 5, or above, landscape elements retained on the ground continue to show significant features of the original landscape design intent and structure.

The properties listed in **Table 12.4** lie on or close to the proposed road development. However, not all of these historic properties are directly impacted or even indirectly impacted, *e.g.* in terms of impact on their setting. Historic demesnes with houses that have potential for visual impact have also been assessed, together with all other properties, within the visual impact schedule in **Appendix A.12.1** and within **Section 12.5.3.6** and **Section 12.5.4.6** of this chapter. A more detailed consideration of all aspects of architectural and cultural heritage is provided under **Chapter 13, Archaeological, Architectural and Cultural Heritage**.

Table 12.4: Historic Gardens and Designed Landscapes located along the Proposed Road Development (PRD)

Figure Ref.	Name and location relative to PRD:	FRI Index	NIAH Comments & Principal Retained Features
P008-043 (**Figure 12.1.12**)	Bushypark House demesne. Mainline of PRD over 600m+ from house. Proposed N59 Link Road North ties into existing N59 Moycullen Road along southern demesne boundary.	2	NIAH Comments: Main features substantially present - peripheral features unrecognisable. Much of the structural footprint of the designed landscape shown on the 1836 - 1846 OS map is visible in aerial photography but features are in a degraded condition. Note: The principal structure, 'Bushypark House', is still extant and is listed as a protected structure. Some limited residential development has taken place within the demesne lands.
N/A	Ashley Park demesne. 300m+ from PRD.	1	NIAH Comments: Virtually no recognisable features. Housing has been constructed on this site. Virtually no features of the designed landscape shown on the 1836 - 1846 OS map are visible in aerial photography.
P009-001 (Dangan House – 2nd Ed. Mapping) (**Figure 12.1.07**)	Dangan Cottage, Dangan House, Dangan Nunnery, Mary Ville demesnes. (Effectively forming one combined or conjoined landscape). PRD passes through northern portion of original conjoined demesne lands.	1	NIAH Comments: Virtually no recognisable features remain. Industrial and sporting facilities have been constructed on this site. Note: NIAH garden survey only includes an entry for Dangan House, which, like Nunnery, on the first edition map was located on the edge of the River Corrib. Neither property survives today or are indicated on second edition mapping. Dangan Cottage appears in the same place on both first and second edition mapping. However, the property is no longer present and a sports pitch has been constructed on the location

Figure Ref.	Name and location relative to PRD:	FRI Index	NIAH Comments & Principal Retained Features
			Mary Ville is not shown on first edition mapping, but does appear on second edition mapping, together with a new reference for Dangan House in a different location to that shown on the first edition mapping.
P009-003 (**Figure 12.1.07**)	Menlo Castle demesne. PRD passes through southeast portion of original demesne – c.150m from castle ruins.	6	NIAH Comments: Main features unrecognisable – peripheral features visible. A river runs alongside this site. Much of the parkland shown on the 1836 - 1846 OS map has been divided into smaller fields. Note: Today the principal castle structure survives as a dramatic ruin on the edge of the river (P009-003). The principal structure and its entrance are both protected structures.
PG14-016 (site of) (**Figure 12.1.14**)	Ballybrit House demesne. 1km+ from PRD. City East Business Park Junction works are within demesne.	0	NIAH Comments: Virtually no recognisable features. Note: Today the demesne is completely covered by industrial and residential development and the site of the house lies beneath Bóthar na dTreabh (N6).

12.3.1.10 Landscape and Visual Significance and Sensitivity

The main features of significance and sensitivity in the receiving landscape (in general west to east order) are:

- The semi-natural landscape character of marginal grasslands, scrub plantings, small stream valleys and stone walls to the west and north of Bearna Village
- Environmental Management and Open Space Areas, protected views and prospects, and proposed greenways and linkages west and north of Bearna Village
- The open rising landscape, including open space lands, northwest of Galway City
- The River Corrib corridor and its wider landscape setting, which includes the prominent ruins of Menlo Castle, as well as a diverse mosaic of semi-natural and man-influenced landscapes, riparian plantings, grasslands, scrub and woodland. Protected views and prospects and lands on east bank designated as High Amenity Agriculture

- The recreation, sports and amenity lands of NUIG Sports Campus and surrounding areas. Lands on west bank of River Corrib designated as Recreation, Open Space
- The limestone, grassland and scrub landscape with stone walls northeast of Galway City
- The wider drumlin and valley landscape setting with protected views and prospects around Ballindooley Lough
- The open recreational lands of Galway Racecourse and surrounding areas

The main features of visual significance and sensitivity in the receiving landscape (in a general west to east order) are:

- The presence, prominence and visual amenity of residential property and development in general, especially at the:
    - west and north of Bearna, at Foraí Maola Road, at Troscaigh Road and at Ann Gibbons and Bearna to N59 Moycullen Road
    - west/northwest of the city, at Aille Road, Cappagh Road, and Ballymoneen
    - northwest of the city, at Rahoon Road and Clybaun Road, Letteragh Road and at Chloch Scoilte.
    - to either side of the N59 Moycullen Road north of the city, at Knocknafroska, Barnacranny, Upper Dangan and Aughnacurra and also at Ballagh and Bushypark
    - north/northeast of the city, at Bóthar Nua, Seanbóthar
    - northeast of the city, at N84 Headford Road and at Hynes' Bóithrín, Spellman's Bóithrín and School Road and setting of Castlegar Village
    - east of the city, at N83 Tuam Road, Racecourse Avenue, Ballybrit Crescent, and the village of Coolagh-Briarhill
- The location of a number of protected views and prospects.
- The visual amenity associated with NUIG Sports Campus.
- The visual amenity associated with the River Corrib corridor, including the setting of Menlo Castle.
- The visual amenity associated with Galway Racecourse.

12.4 Characteristics of the Proposed Development

A detailed description of the proposed road development and construction activities are provided in **Chapter 5, Description of Proposed Road Development** and **Chapter 7, Construction Activities**.

The main characteristics of the proposed road development of relevance to the landscape and visual assessment are outlined under construction and operation phases in the following.

12.4.1 Construction Phase

The main characteristics of the construction stage of the proposed road development that have potential for landscape and visual impact are:

- Site mobilisation and establishment, tree and vegetation removal, fencing of lands, provision of site compounds
- Removal of properties, boundaries, amenities
- Normal landscape disturbance and activity, including removal of topsoil, general earthworks and operation of construction traffic
- Construction of significant earthworks, including cuttings and rock cuttings (< 3m deep) and embankments (< 3m high)
- Construction of the new road, link roads and associated local road re-alignments, including provision of noise barriers, lighting, gantries signage, *etc*.
- Construction of new structures, including under and overbridges, culverts, a c.650m long bridge crossing of the River Corrib and its valley, a c.310m length of viaduct, and 2 separate sections of tunnel – one of c.270m length at Lackagh Quarry, and a second of c.240m length at Galway Racecourse.
- Demolition and modification of part of NUIG Sports Pavilion, provision of new sport pitches at NUIG Sports campus and provision of re-organised stabling and parking facilities at Galway Racecourse.
- Other related works, including diversion of existing services, provision of new services, provision of attenuation and wetland ponds, drainage facilities, new road boundaries and landscape works, *etc*.

12.4.2 Operational Phase

The main characteristics of the operation stage of the proposed road development that have potential for landscape and visual impact are:

- The presence and operation (traffic) of the road and its proximity to residential, amenity and other property
- The prominence of embankments and cuttings in the landscape
- The prominence of elevated structures such as bridges and the viaduct
- The presence of noise barriers, gantries signage, *etc*.

- The presence of additional roadside lighting
- The movement of traffic on the proposed road development, including on bridges, embankments, tunnel portals *etc*.

12.5 Evaluation of Impacts

12.5.1 Introduction

The proposed road development crosses a diverse rural/sub-urban edge landscape to the west, north and east of typical city development. Residential properties are a common feature along most sections of the proposed road development, particularly at the crossing of local roads west and northwest of Galway, at the crossing of the N59 Moycullen Road, at the N84 at Ballindooley, at Castlegar, and at Ballybrit, Dougishka and Coolagh-Briarhill.

Within this landscape, the construction associated with the proposed road development will give rise to significant and profound negative impacts in terms of disturbance to the existing landscape and visual character of the area and to properties located close to the proposed road development.

While landscape and visual impacts will tend to be most pronounced during the construction and early operation stages, the proposed road development will, as with all road schemes, also have some degree of residual permanent effect on its landscape and visual environment.

12.5.2 Do Nothing Impact

Landscapes and properties along the proposed road development would not experience the negative landscape and visual impacts that are associated with the proposed road development and their existing setting would experience little or no change in the short to medium-term other than from likely further residential and city-related development.

12.5.3 Potential Construction Impacts

Details of the anticipated three-year construction period of the proposed road development is set out in **Chapter 7, Construction Activities**.

Potentially impacted features and landscape and visual impacts are described on a section by section basis below. An assessment of the overall construction stage visual Impact is also discussed separately in the **Section 12.5.3.6** of this chapter. Potentially impacted properties are indicated on **Figures 12.1.01** to **12.1.14** and recorded in **Appendix A.12.1**.

12.5.3.1 Ch. 0+000 to Ch. 6+300 (Landscape Character Area 9)

The following construction-related aspects give rise to potential for landscape and visual impacts within this section of the proposed road development:

- **Properties:** Ten residential properties are to be acquired with consequent impact on existing community and landscape/visual setting (refer to **Figures 12.1.01** to **12.1.05**). These are mainly located at the crossing of local roads where ribbon-style residential development is a feature along such roads.

  Locally significant short-term negative impact

- **Vegetation:** Removal of vegetation is very limited and is primarily focused on areas of scrub vegetation, short sections of gappy hedgerows and occasional small trees – often around properties to be acquired (refer **Figures 12.4.01** to **12.4.05**).

  No significant impact arises

- **Landscape Features:** There is substantial impact on, and removal of, stone field boundary walls. While often dilapidated and overgrown with scrub, these walls are a notable feature of this relatively open, rough-grained landscape.

  Locally significant short-term negative impact

- **Embankments:** Significant embankments (i.e. >3m high) are limited in extent and scale. While some short sections of lower embankments (i.e. < 3m high) are required to cross local low points, the main sections of embankment (total c.2.55km) with approximate maximum heights are:

  - Ch. 0+550 to Ch. 1+150 (up to c.6m high)
  - Ch. 1+200 to Ch. 1+600 including Troscaigh/Foraí Maola Overbridge Link (up to c.7m high)
  - Ch. 1+900 to Ch. 2+250 (up to c.7m high)
  - Ch. 2+800 to Ch. 3+050 (up to c.6m high)
  - Ch. 3+900 to Ch. 4+000 (up to c.7m high)
  - Ch. 4+100 to Ch. 4+350 (up to c.5m high)
  - Ch. 4+750 to Ch. 5+000 (up to c.6m high)
  - Ch. 5+950 to Ch. 6+300 (up to c.9m high)

  Locally significant short-term negative impacts

- **Cuttings:** Significant cuttings (i.e. > 3m deep) are limited in extent and scale. While some short sections of shallow cut (i.e. < 3m deep) are required to cross local ridges/high points, the main sections of cut (total c.0.95km) with approximate maximum depth are:

  - Ch. 3+150 to Ch. 3+900 (up to c.5m cut – rock expected at lower depths)
  - Ch. 5+350 to Ch. 5+530 (up to c.9m cut – rock expected at lower depths)

  Locally moderate short-term negative impacts

- **Visual Impacts:** Significant negative visual impacts arise for residential properties, especially in the crossing of local roads (at R336, Foraí Maola, Troscaigh, Ann Gibbons, Aille, Cappagh, Ballymoneen, Rahoon and Letteragh) and at the proposed Troscaigh/Foraí Maola Overbridge Link (Ch. 1+380). Refer to **Section 12.5.3.6** and **Figures 12.1.01** to **12.1.05**.

  Overall there will be a significant short-term negative visual impact

- **Landscape Planning:** Construction of part of the proposed road development is sited within a Green Wedge Ch. 0+000 to Ch. 0+750) and also passes through a short section of an Environmental Management Zone[4] (at Ch. 0+550) located along Sruthán Na Libeirtí. The construction of the proposed road development also crosses a further narrow section of an Environmental Management Zone at Trusky Stream (Ch. 2+850), as noted in the Bearna Local Area Plan.

Construction of part of the proposed road development crosses the northern edge of open space zoning (in Galway City Development Plan) east of Aille Road (Ch. 3+850); and again at Cappagh/Ballynahown/Keeraun (c.Ch. 4+700 to Ch. 5+300).

The proposed road development crosses the greenway link objectives at Trusky Stream (Ch. 2+850); at Aille Road (Ch. 3+300) and at Cappagh Road (Ch. 4+450), Boleybeg Bóithrín (Ch. 4+550) and at Keeraun Bóithrín (Ch. 5+950). Construction stage activities will result in temporary restrictions on the use of these local roads.

The construction of the proposed road development falls within the fore/middle-ground of View No. 74 - View of North Clare Coast and of View 72 – View of Sea from north of Bearna (as noted in Galway County Development Plan and Bearna LAP). Large-scale construction of the proposed road development will be visually distracting and incongruous in the foreground of the otherwise long range views.

<u>Overall there will be a significant short-term negative landscape planning impact</u>

- **Landscape Character:** Notwithstanding the extent of existing residential development, the construction of the proposed road development will give rise to substantial disruption of local landscape character – especially in the provision of the Troscaigh/Foraí Maola Overbridge Link. The construction will have limited impact on the more locally sensitive Bearna Coastal Fringe – especially south of the R336 Coast Road.

  The construction of proposed road development will have only slight to moderate negative impact on the overall Landscape Character Area (LCA 9).

  <u>Overall there will be a moderate to significant short-term negative impact on local landscape character</u>

12.5.3.2 Ch. 6+300 to Ch. 8+000 (Landscape Character Area 12)

The following construction-related aspects give rise to potential for landscape and visual impacts within this section of the proposed road development:

- **Properties:** Three residential properties are to be acquired with consequent impact on the existing community and landscape/visual setting (refer to **Figures 12.1.05** to **12.1.06** and **Figures 12.1.12** to **12.1.13**). These are located at Letteragh (1) and at the N59 Letteragh Junction (2).

  <u>Locally moderate short-term negative impact</u>

[4] for Environmental Management Zone: Refer to Objective LU9 of Bearna Local Area Plan and to Section 12.3.1.6 of this Chapter of the EIAR

- **Vegetation:** Removal of vegetation is limited and is primarily focused on areas of scrub vegetation, short sections of gappy hedgerows and occasional trees – generally around the proposed N59 Letteragh Junction (refer **Figures 12.4.05** to **12.4.06** and **Figures 12.4.12** to **12.4.13**).

  Locally slight short-term negative impact

- **Landscape Features:** There is considerable impact on, and removal of, stone field boundary walls. While often dilapidated and overgrown with scrub, these walls are a notable feature of this relatively open landscape.

  Locally moderate to significant short-term negative impact

- **Embankments:** Some significant embankments (i.e. > 3m high) arise. While some short sections of lower embankments (i.e. < 3m high) are also required to cross local low points, the main sections of embankment (total c.1.15km) with approximate maximum heights are:
  - Ch. 6+300 to Ch. 6+550 (up to c.12m high)
  - Ch. 6+800 to Ch. 6+950 (up to c.10m high)
  - Ch. 7+000 to Ch. 7+550 (various embankments associated with approach to and N59 Letteragh Junction - up to c.6m high)
  - Ch. 1+500 to Ch. 1+700 on N59 Link South (up to 7m high)

  Locally moderate short-term negative impacts

- **Cuttings:** Some significant cuttings (i.e. > 3m deep) arise. While some other short sections of shallow cut (i.e. < 3m deep) are required to cross local ridges/high points, the main sections of cut (total c.0.85km) with approximate maximum depth are:
  - Ch. 7+550 to Ch. 8+000 (various cuttings associated with N59 Letteragh Junction - up to c.11m cut. Rock expected at lower depths)
  - Ch. 0+050 to Ch. 0+450 on N59 Link North (up to 8m cut)

  Locally significant short-term negative impacts

- **Visual Impacts:** Significant negative visual impacts for residential properties, especially in the crossing of local roads at Letteragh and Rahoon and at the tie-in to the existing N59 Moycullen Road at Ballagh/Bushypark). Refer to **Section 12.5.3.6** and **Figures 12.1.05** to **12.1.06** and **Figures 12.1.12** to **12.1.13**.

  Overall there will be a significant short-term negative visual impact

- **Landscape Planning:** The construction of the proposed road development falls within the context of Linear View 10 of the River Corrib from the N59 Moycullen Road and County View 76 of Lough Corrib from the Ballagh / Bushypark area. Construction of the proposed N59 Link North will be visually distracting and incongruous in the foreground of longer range elevated views of Lough Corrib in View 76. No significant impact arises for View 10.

  Overall there will be a slight to moderate short-term negative landscape planning impact

- **Landscape Character:** Notwithstanding the rural/city edge nature of the landscape and the extent of residential development, the construction of the proposed road development will give rise to substantial disruption of the open elevated local landscape character.

The construction of proposed road development will have only slight to moderate negative impact on the overall Landscape Character Area (LCA 12).

Overall there will be a significant short-term negative impact on local landscape character

12.5.3.3 Ch. 8+000 to Ch. 11+800 (Landscape Character Area 11)

The following construction-related aspects give rise to potential for landscape and visual impacts within this section of the proposed road development:

- **Properties:** Thirteen residential properties are to be acquired with consequent significant impact on existing community and landscape/visual setting (refer to **Figures 12.1.06** to **12.1.08**). These properties are mainly located to either side of the N59 Moycullen road at Knockadoney/Bushypark (2), Ard na Locha (3) and Aughnacurra (6) on the east bank of the River Corrib, and at Bóthar Nua (2) on the west bank. A temporary acquisition of the NUIG Sports Pavilion is also proposed to allow for modification of the building to facilitate the proposed road development.

  Locally very significant/profound short-term negative impact at N59 Moycullen Road/Aughnacurra, and otherwise significant

- **Vegetation:** Substantial removal of vegetation within Aughnacurra residential estate and NUIG Sports Campus on the west bank; and southest of Menlo Castle; and in sections across limestone landscape of Menlough/Coolough on the east bank (refer **Figures 12.4.06** to **12.4.08**). Significant impact on woodland block south of Menlo Castle is particularly notable.

  Locally significant/very significant short-term negative impact

- **Landscape Features:** There is substantial impact on and removal of stone field boundary walls at Chloch Scoilte, Knocknabrona and Knocknafroska all west of the N59 Moycullen Road. There is a lesser impact on stone walls through the limestone areas of Menlough/Coolough on the east side of the river.

  Significant disruption and intrusion onto the recreational, amenity and sport grounds of NUIG Sports Campus; River Corrib watercourse and banks; distinctive setting of Menlo Castle; and the exposed limestone pavement areas in the east in Menlough/Coolough.

  Existing sports pitches impacted at NUIG Sports Campus are to be replaced with all-weather facilities.

  Locally very significant/profound short-term negative impact

- **Embankments and Structures:** Some very significant embankments (i.e. > 3m high) and structures are required through this section. The main sections of embankment (total c.1.575km) and elevated structures (including 650m long bridge) with approximate maximum heights of embankment are:

- Ch. 8+350 to Ch. 9+000 (up to c.8m high). Embankment includes bridge over existing N59 Moycullen Road and significant sections of high retaining walls through retained residential areas
- Ch. 8+850 to Ch. 9+500 Major elevated bridge structure across River Corrib and immediate landscape setting
- Ch. 9+500 to Ch. 10+100 Eastern tie-in to River Corrib Bridge (up to 18m high)
- Ch. 10+105 to Ch. 10+425 Viaduct over limestone pavement
- Ch. 10+425 to Ch. 10+550 (up to c.10m high)
- Ch. 11+500 to Ch. 11+800 (up to 9m high – but located on excavated floor of Lackagh Quarry)

<u>Locally profound short-term negative impact</u>

- **Cuttings and Structures:** Cuttings are very limited through this section, and lead mainly to the proposed tunnel into Lackagh Quarry.

  The main sections of cut (total c.0.4km) and other structures with approximate maximum depth of cuttings are:

  - Ch. 10+950 to Ch. 11+150 (cutting leading to Lackagh Quarry - up to c.8m cut. Rock expected at lower depths) Ch. 11+150 to Ch. 11+350 Tunnel into Lackagh Quarry

  <u>Locally slight / moderate short-term negative impacts</u>

- **Visual Impacts:** Profound negative visual impacts for residential properties, especially to either side of N59 Moycullen Road; through NIUG Sports Campus; at crossing of River Corrib, including at Menlo Castle; as well as at Bóthar Nua and Seanbóthar on east bank of River Corrib. Construction of the bridge, associated embankments and viaduct will have a significant visual impact and give rise to city-wide attention and interest in the process. Refer to **Section 12.5.3.6** and **Figures 12.1.06** to **12.1.08**.

  <u>Overall profound short-term negative visual impact</u>

- **Landscape Planning:** The construction of the proposed road development crosses recreation and amenity zoned lands on west bank of River Corrib; and High Amenity Agricultural lands on east bank.

  The proposed river crossing is within context of County View 76 of Lough Corrib from the Dangan area. Construction of proposed bridge and associated earthworks will be visually prominent, distracting and incongruous in View 76.

  <u>Overall profound short-term negative landscape planning impact</u>

- **Landscape Character:** Construction of the bridge and associated works especially on east bank will have a significant impact on the local landscape character of this broad river valley landscape, on its feature castle ruin and on the semi-natural setting of the east bank. The proposed viaduct rises on to the locally elevated east side of the river valley corridor and as such the construction of the structure will be visible from more elevated locations on the west bank of the river.

  <u>Overall very significant/profound negative impact on local landscape character</u>

12.5.3.4 Ch. 11+800 to Ch. 14+200 (Part of Landscape Character Area 11 as well as Landscape Character Area 5)

The following construction-related aspects give rise to potential for landscape and visual impacts within this section of the proposed road development:

- **Properties:** Twenty-five residential properties are to be acquired with consequent significant impact on existing community and landscape/visual setting (refer to **Figures 12.1.08** to **12.1.10**). These properties are mainly located along the N84 Headford Road at Ballindooley/Castlegar (14) Castlegar Village (8) and N83 Tuam Road (3).

  <u>Locally profound short-term negative impact at Castlegar and local significant impact at N84 Headford Road and elsewhere</u>

- **Vegetation:** Limited removal of vegetation around residential areas at N84 Headford Road and Castlegar and along other limited sections (refer **Figures 12.4.08** to **12.4.10**).

  <u>Locally slight to moderate short-term negative impact</u>

- **Landscape Features:** There is moderate impact on and removal of stone field boundary walls through Castlegar.

  <u>Locally moderate short-term negative impact</u>

- **Embankments and Structures:** Series of embankments. The main sections of significant embankment (i.e. > 3m high) and elevated structures with approximate maximum heights of embankment (c.1.0km overall) are:
  - Ch. 11+950 to Ch. 12+500 (up to c.14m high). Embankment includes bridge over existing N84 Headford Road
  - Ch. 13+650 to Ch. 14+150. Embankment (up to 12m high) includes bridge over existing N83 Tuam Road

  <u>Locally very significant short-term negative impact</u>

- **Cuttings and Structures:** Various significant cuttings (i.e. > 3m deep) through this section – including deep cutting southwards out of Lackagh Quarry (Ch. 11+800 to Ch. 11+950).

  The main sections of cut (total c.1.0km) with approximate maximum depth are:
  - Ch. 11+800 to Ch. 11+950 (cutting out of Lackagh Quarry - up to c.18m cut. Rock expected through most of depth)
  - Ch. 12+550 to Ch. 12+850 through ridge at Castlegar (up to 7m deep – rock at lower levels)
  - Ch. 13+050 to Ch. 13+600 through ridge at Castlegar (up to 12m deep – rock at lower levels)

  <u>Locally very significant short-term negative impacts</u>

- **Visual Impacts:** Very significant/profound negative visual impacts for residential properties, especially to east of crossing of N84 Headford Road and through Castlegar generally. Refer to **Section 12.5.3.6** and **Figures 12.1.08** to **12.1.10**.

  <u>Overall profound short-term negative visual impact</u>

- **Landscape Planning:** The protected historic settlement of Castlegar Village lies to the south of the proposed road development.

  The landscape surrounding Ballindooley Lough immediately north of the proposed road development is designated as High Amenity Agriculture.

  The construction of the proposed road development falls within the context of protected views V6 and V19.

  <u>Overall moderate - significant short-term negative landscape planning impact</u>

- **Landscape Character:** Construction of proposed embankments, cuttings as well as a c.650m long bridge structure and a c.320m long viaduct structure will have a substantial impact on the rolling hill and valley nature of the local landscape character.

  <u>Overall significant/very significant negative impact on local landscape character</u>

12.5.3.5 Ch. 14+300 to Ch. 17+540 (Landscape Character Area 3)

The following construction-related aspects give rise to potential for landscape and visual impacts within this section of the proposed road development:

- **Properties:** Three residential properties are to be acquired with consequent minor impact on existing community and landscape/visual setting (refer to **Figures 12.1.10**, **12.1.11** and **12.1.14**). These properties are located along Racecourse Avenue and the R339 Monivea Road.

  <u>Locally slight short-term negative impact</u>

- **Vegetation:** Limited removal of scrub vegetation west of Coolagh-Briarhill (refer **Figures 12.4.10**, **12.4.11** and **12.4.14**).

  <u>Locally slight short-term negative impact</u>

- **Landscape Features:** There is substantial impact on and removal of stone field boundary walls at Ballybrit and Coolagh-Briarhill. The proposed road development crosses the line of an old mass path at Parkmore (Ch. 1+010 on Parkmore Link Road).

  <u>Locally moderate to significant short-term negative impact</u>

- **Embankments and Structures:** Series of embankments. The main sections of embankment (c.1.0km overall) and elevated structures with approximate maximum heights of significant embankment (i.e. > 3.0m high) are:
  - Ch. 14+200 to Ch. 14+400 (up to c.6m high). Embankments up to 15m high associated with loop link roads
  - Ch. 15+550 to End. Series of embankments up to 12m high with bridges and sections of retaining wall leading to and comprising proposed Coolagh Junction

  <u>Locally significant short-term negative impact</u>

- **Cuttings and Structures:** Various significant cuttings (i.e. >3.0m deep) through this section – including deep cutting into Lackagh Quarry (Ch. 11+800 to Ch. 11+950).

  The main sections of cut (total c.1.0km) with approximate maximum depth are:

  - Ch. 14+150 to Ch. 14+950 (up to c.10m deep). Cutting leading to Galway Racecourse Tunnel
  - Ch. 14+950 to Ch. 15+200 Cut and cover tunnel structure at Galway Racecourse
  - Ch. 15+200 to Ch. 15+400 (up to c.8m deep). Cutting leading from Galway Racecourse Tunnel

  <u>Locally significant short-term negative impacts</u>

- **Visual Impacts:** Very significant/profound negative visual impacts for residential properties, at Racecourse Avenue/Ballybrit Crescent and significant at Coolagh-Briarhill. Slight to moderate negative visual impacts at Dougishka. Refer to **Section 12.5.3.6** and **Figures 12.1.10**, **12.1.11** and **12.1.14**.

  <u>Overall very significant short-term negative visual impact</u>

- **Landscape Planning:** The historic settlement of Coolagh-Briarhill Village lies to the immediate northeast of the proposed road development. This village already overlooks existing smaller N6 junction.

  The landscape surrounding Ballybrit is designated for Recreation and Amenity land use.

  <u>Overall significant short-term negative landscape planning impact</u>

- **Landscape Character:** Construction of proposed embankments, cuttings and structures will have a substantial impact on the open recreational and amenity character of Galway Racecourse.

  <u>Overall significant negative impact on local landscape character</u>

12.5.3.6 Visual Impact

Visual impact tends to be most pronounced during the construction phase when the initial disturbance is both unfamiliar and substantial and may often be in close proximity to properties. At the same time, effective visual mitigation may also be limited and therefore, significant negative temporary and short-term visual impacts will arise.

Construction stage impacts will arise primarily from visual disturbance and visual intrusion resulting from the initial loss of vegetation and boundary screening, from earthworks, alteration of ground levels and from normal construction activity and traffic. Issues such as noise and construction activity and the location of construction compounds will also have the effect of drawing visual attention to the works, thereby increasing the perceived visual impact associated with visual disturbance.

The construction stage visual impact of the proposed road development has been assessed and is set out in detail in the Visual Impact Schedule (VIS) Table in **Appendix A.12.1**. The findings are summarised in **Table 12.5** below.

In overall terms, some 406 locations have been assessed along the proposed road development. Of these 54 residential properties will be acquired (44 of which will be demolished), together with a temporary acquisition of the NUIG Sports Pavilion, and the remaining 352 properties and landscape locations have been assessed for visual impact during construction. Refer to **Chapter, 15 Material Assets – Non Agriculture** for further details on acquisitions.

During the construction stage, 36 of the 352 locations (c.10%) will have an imperceptible impact. A further 169 locations (c.49%) will have a not significant, slight or moderate short-term impact. One hundred and five locations (c.30%) will have significant or very significant short-term visual impact. The remaining 42 locations (c.11%) will experience profound temporary or short-term negative visual impact associated with the construction stage of the proposed road development.

Table 12.5: Visual Impacts Construction Stage

Impact	Construction Stage
Imperceptible	36
Not Significant/Slight	79
Moderate	90
Significant	80
Very Significant	25
Profound	42
Total	352

12.5.4 Potential Operational Impacts

Potentially impacted features and general landscape and visual impacts are described on a section by section basis in the following. An assessment of the overall operational stage visual impact is also discussed separately in the **Section 12.5.4.6**.

12.5.4.1 Ch. 0+000 to Ch. 6+300 (Landscape Character Area 9)

- **Landscape Character:** In its operational phase the proposed road development, with its various sections of embankment and related road infrastructure will contrast significantly with the open exposed nature of the existing landscape, the small-scale and narrow nature of existing roads and the extent of residential development located along such existing roads. The proposed road development will tend to integrate over time within this generally small scale coarse landscape.

  Lighting at the proposed R336 Coast Road and lighting from traffic will also introduce a significant new element into the landscape corridor of the proposed road development. The corridor of the existing R336 – especially along the northern side – is being increasingly developed resulting in an on-going change to its background rural character.

The introduction of short sections of roadside lighting at the proposed Bearna East Roundabout and the proposed Cappagh Road Junction will also accentuate the degree of change in the background rural landscape. Roadside lighting at the proposed Ballymoneen Road Junction will tie-in to existing roadside lighting to the immediate south along the Ballymoneen Road.

Local significant short-term and locally moderate medium-term negative impact

- **Visual Impacts:** Significant negative visual impacts will continue to arise for residential properties close to the proposed road development, especially in the crossing of local roads (at R336, Foraí Maola, Troscaigh, Ann Gibbons, Aille, Cappagh, Ballymoneen, Rahoon and Letteragh) and Troscaigh/Foraí Maola Overbridge Link. Refer to **Section 12.5.4.6** and **Figures 12.1.01** to **12.1.05**.

  Overall significant short-term and locally moderate medium-term negative impact

- **Landscape Planning:** The proposed road development will have a significant impact on the Green Wedge and Environmental Management Zone located along the Sruthán Na Libeirtí, in that it impacts on a substantial portion of the designations. Nevertheless, the most significant portion of the designations are retained along the more sensitive corridor of Sruthán Na Libeirtí. The proposed road development will not have a significant impact the Environmental Management Zone at either the Trusky Stream (Ch. 2+850).

  The proposed road development will not have a significant impact on the proposed large areas of open spaces east of Aille Road (Ch. 3+850); and at Cappagh/Ballynahown/Keeraun (c.Ch. 4+700 to Ch. 5+300).

  The proposed road development will not have a significant impact on proposed greenway link objectives. The proposed road development will allow for and facilitate crossing and tie-in to proposed greenway link objectives at Trusky Stream (Ch. 2+850); at Aille Road (Ch. 3+300) and at Cappagh Road (Ch. 4+450); Boleybeg Bóithrín (Ch. 4+550) and at Keeraun Bóithrín (Ch. 5+950).

  While traffic on the proposed road development will introduce a moving and distracting element within the foreground of protected views 72 and 74, it will not detract from the longer-range focus of the views – which is the sea and the north Clare coast. In addition, the proposed road development will open up significant new views of the coast and the sea – especially travelling from Na Foraí Maola Thair, south to the R336.

  Moderate short-term and slight medium-term negative landscape planning impact

12.5.4.2 Ch. 6+300 to Ch. 8+000 (Landscape Character Area 12)

- **Landscape Character:** In its operational phase the proposed road development, with its various sections of embankments and cuttings (latter especially at Ballagh/Bushypark) and major junction at Letteragh will contrast significantly with the open exposed, sometimes remote and elevated nature of the existing landscape and the small-scale and narrow nature of existing roads. Residential development is prominent along local existing local roads and the area is increasingly under the influence of expanding city development. The proposed road development will tend to integrate over time within this increasingly urban influenced landscape.

Roadside lighting at the proposed N59 Letteragh Junction and along the proposed N59 Link Road North together with lighting from traffic will also introduce a significant new element into the landscape corridor of the proposed road development.

Roadside lighting is already present on the N59 Moycullen Road at the location proposed N59 Bushypark Junction. Likewise roadside lighting is already present between Gateway Retail Park – Rahoon Road – Rosán Glas – Bun A Chnoic, which accounts for much of the corridor of the proposed N59 Link Road South.

<u>Significant short-term and moderate medium-term negative impact on local landscape character</u>

- **Visual Impacts:** Significant negative visual impacts will continue to arise for residential properties, especially in the crossing of local roads at Letteragh and Rahoon and at tie-in to existing N59 Moycullen Road at Ballagh/Bushypark). Refer to **Section 12.5.4.6** and **Figures 12.1.05** to **12.1.06** and **Figures 12.1.12** to **12.1.13**.

  <u>Overall significant short-term and moderate medium-term negative visual impact</u>

- **Landscape Planning:** The proposed road development falls within the context of Linear View 10 of the River Corrib from the N59 Moycullen Road and County View 76 of Lough Corrib from the Ballagh/Bushypark area. However, the proposed road development will not detract from the focus of the protected views (River Corrib and Lough Corrib) from these locations.

  <u>Slight short-term negative and no medium-term landscape planning impact</u>

12.5.4.3 Ch. 8+000 to Ch. 11+800 (Landscape Character Area 11)

- **Landscape Character:** The proposed road development, including major new c.650m long bridge, high embankments and a c.320m long viaduct will introduce a dominant new feature into its landscape corridor. The new bridge will be prominent along the River Corrib and NIUG Sports Campus and from Menlo Castle, while the embankments and viaduct on the east of the River Corrib cross a very remote and elevated semi-natural landscape. The bridge and viaduct, and particularly traffic on the structures, will also be visible where elevated vantage points on the west side of the river allow for viewing across the River Corrib valley.

  Given the existing environment, and the nature of this section of the proposed road development, integration of the development will be slow and structures such as the bridge and viaduct will permanently influence landscape character.

  Other than at the portal entrance to Lackagh Tunnel and within Lackagh Quarry itself, is not proposed to provide roadside lighting along this section of the proposed road development. Nevertheless, a level of lighting will be introduced from traffic movements particularly along elevated sections. Floodlight facilities will also to be provided in association with the proposed all-weather sports pitch at NUIG Sports Campus. The floodlighting will allow for evening use of the facilities during darker evening months and will not have extended or night-time use.

<u>Profound short-term and very significant medium negative impact on local landscape character</u>

- **Visual Impacts:** Profound negative visual impacts will continue for residential properties, especially to either side of N59 Moycullen Road; through NIUG Sports Campus; at crossing of River Corrib, including at Menlo Castle; as well as at Bóthar Nua and Seanbóthar on east bank of River Corrib. Many properties are retained close to the elevated proposed road development both east and west of the N59 Moycullen Road (Ch. 8+300 to Ch. 8+700). This necessitates the use of retaining walls to minimise landtake and the presence of retaining structures will increase the visual impact of the development in these areas. Noise barriers are also provided along sections of the proposed road development. Whilst they will screen traffic, where they are located on the top of an embankment they will also accentuate the overall visual impact. The proposed noise barriers on the River Corrib Bridge will be transparent. Refer to **Section 12.5.4.6** and **Figures 12.1.06** to **12.1.08**.

  <u>Overall profound short-term negative visual impact and very significant medium-term impact</u>

- **Landscape Planning:** The proposed road development crosses recreation and amenity zoned lands on west bank of River Corrib; the river itself and High Amenity Agricultural lands on east bank. While this will change the character of the area the proposed road development will not preclude on-going objectives for the landscape planning of the area.

  The river crossing is not significant within the context of protected County View 76 of Lough Corrib from the Dangan area.

  <u>Significant short-term and moderate medium-term negative landscape planning impact</u>

12.5.4.4 Ch. 11+800 to Ch. 14+200 (Part of Landscape Character Area 11 as well as Landscape Character Area 5)

- **Landscape Character:** The proposed road development, which includes two major junctions (N84 Headford Road and N83 Tuam) and significant embankments and cuttings cuts across a rolling drumlin valley landscape and is within the wider setting for Ballindooley Lough. Traffic on elevated embankments will be particularly prominent from higher ground further east/northeast. Nevertheless, the landscape corridor of the proposed road development is also being increasingly influenced by urban edge development – especially along the N84 Headford Road and N83 Tuam Road.

- This section includes for the introduction of significant extent of proposed roadside lighting across an area, which is currently outside the limit of roadside lighting in adjoining suburban areas. Notwithstanding proximity to the developed suburbs, roadside lighting, as well as lighting associated with traffic, will have the effect accentuating the presence of the proposed road development and emphasising the degree of change in the background rural/suburban edge landscape.

<u>Significant short-term and moderate medium-term negative impact on local landscape character</u>

- **Visual Impacts:** Very significant/profound negative visual impacts will continue for residential properties, especially to east of the crossing on Headford Road and through Castlegar generally. Refer to **Section 12.5.4.6** and **Figures 12.1.08** to **12.1.10**.

  <u>Profound short-term and very significant medium-term negative visual impact</u>

- **Landscape Planning:** Impact will arise for the high amenity setting of Ballindooley Lough and from the historic village settlement of Castlegar.

  The proposed road development will not have a significant impact on protected views V6 and V19.

  <u>Significant short-term and moderate medium-term negative landscape planning impact</u>

12.5.4.5 Ch. 14+300 to Ch. 17+540 (Landscape Character Area 3)

The following operation-related aspects give rise to potential for landscape and visual impacts within this section of the proposed road development:

- **Landscape Character:** This section of the proposed road development is set within an urban influenced landscape. Nevertheless, the significant road infrastructure will give rise to impacts on local character – especially through the open recreational and amenity character of Galway Racecourse and to a lesser degree at Dougishka and Coolagh-Briarhill – which are already impacted by the existing N6 and city development.
- While roadside lighting is proposed through this area, much of the area already lies within the suburban context of the outer city where roadside lighting is a feature of the background landscape.

  <u>Significant short-term and slight medium-term negative impact on local landscape character</u>

- **Visual Impacts:** Very significant negative visual impacts will continue for residential properties at Racecourse Avenue/Ballybrit Crescent and to a lesser degree at Coolagh-Briarhill. Refer to **Section 12.5.4.6** and **Figures 12.1.10** to **12.1.11** and **12.1.14**.

  <u>Very significant short-term and moderate medium-term negative visual impact</u>

- **Landscape Planning:** Proposed road development passes through the edge of the recreation and amenity zoned landscape of Galway Racecourse and to the west and south of the historic village settlement of Coolagh-Briarhill Village already overlooks existing smaller N6 junction.

<u>Moderate short-term and slight medium-term negative landscape planning impact</u>

12.5.4.6 Visual Impact

On completion of construction, aspects such as earthworks, construction activity and disturbance are removed as impacting features. Nevertheless, impacts will continue to arise from the presence of the proposed road development which will remain prominent in the landscape until such stage as landscape proposals established and become effective. As such, operational-stage visual impacts will be most pronounced in the short-term after construction (*i.e.* pre-establishment stage), however, negative visual impact will also continue to arise for residential and other properties located close to or adjoining the boundary of the proposed road development for some considerable period of time (*i.e.* post-establishment stage).

During the operation stage, visual impacts will continue to arise from the physical built presence of the proposed road development, including its significant structures, elevated embankments, deep cuttings, traffic usage and additional illumination both fixed and from vehicles, especially where the proposed road development is on embankment or at junctions and bridging locations. In open views, embankments have the potential for visual obstruction and significant visual intrusion. Deep cuttings can also result in significant change to the visual nature of landscape continuity.

Measures for the mitigation of potential noise impact will be required at a number of locations along the proposed road development, especially where residential properties are in close proximity to the carriageway. Such noise impacts and mitigation measures are considered in detail in **Chapter 17, Noise and Vibration**. Mitigation measures will involve the provision of barriers or earth bunds or a combination of such features. While initially these features may increase the visual presence of the proposed road development, they also provide for immediate visual screening of the proposed road development and its associated traffic. In the majority of circumstances these features can also be appropriately incorporated into the proposed landscaping measures.

The proposed road development also includes for realignments/tie-ins to existing national, regional and local roads, together with drainage works and accommodation measures, all of which have potential for localised visual impacts. Local road realignment is important as many residential properties tend to be located along such roads and local direct impacts can arise.

A full schedule and description of visual impacts on properties is set out in the Visual Impact Schedule (VIS) Tables in **Appendix A.12.1** and on **Figures 12.1.01** to **12.1.14**. The findings are summarised in **Table 12.6** below.

In the pre-establishment stage 71 of the 352 locations (c.20%) will have an imperceptible impact. A further 166 locations (c.47%) will have a slight or moderate short-term impact. Eighty-five locations (c.24%) will have significant or very significant short-term visual impact. The remaining 30 locations (c.9%) will experience profound short-term negative visual impact associated with the presence and early operation stage of the proposed road development. Refer to **Figures 12.1.01** to **12.1.14** for locations of properties.

As landscape measures establish and mature the level of visual impact will gradually recede so that in the post-establishment stage some 152 locations (c.43%) will have an imperceptible impact. A further 145 locations (c.41%) will have a slight or moderate medium-term impact. Thirty-two locations (c.9%) will have significant or very significant medium-term visual impact. The remaining 23 locations (c.7%) will continue to experience profound medium and longer-term negative visual impact associated with the proposed road development. Refer to **Figures 12.1.01** to **12.1.14** for locations of properties.

The properties with on-going significant and very significant visual impact are either located in more remote and rural areas and are in proximity to the proposed road development, or are in suburban areas and are located directly adjacent to the proposed road development.

Table 12.6: Summary of Visual Impacts

Impact	Construction Stage	Pre-establishment Stage	Post-establishment Stage
Imperceptible	36	71	152
Not Significant/Slight	79	82	74
Moderate	90	84	71
Significant	80	67	32
Very Significant	25	18	0
Profound	42	30	23
Total	352	352	352

12.5.4.7 Photomontages

Photomontages have been prepared of the proposed River Corrib Bridge and for other areas along the route of the proposed road development.

The Photomontages of the proposed River Corrib Bridge and associated infrastructural works from the surrounding landscape are included in **Appendix A.12.2**. For some locations the views are summer-time, for others the views are winter-time and for some locations both summer and winter views are used. In any case, it is clear that the density of vegetation in the local landscape means that the potential for increased winter-time visibility is not so pronounced in this landscape setting.

For each view three options are presented starting with the ‘As Existing’ view. Thereafter, a view is shown with the proposed road development simply ‘overlaid’ on the existing view. This assists the viewer in accurately locating the proposed road development in the view before it is set into the image. The final version is an ‘As Proposed’ view and this shows what, if any, of the proposed road development will be visible.

A feature of all of the more distant views is the extent to which the landscape visually absorbs the proposed road development and bridge. This characteristic ensures that the proposed road development will not dominated views within its wider landscape setting. As such the proposed road development and bridge is either entirely screened or only partly glimpsed in views from Quincentenary Bridge (View 1); from the Coolough-Menlough Road (Views 2, 3 & 4); from Glenlo Abbey (View 8); and from the N59 Moycullen Road in the vicinity of Bushypark House (Views 9, 10, 11 & 12); and from more southern parts of the NIUG Sports Campus (View 15).

The bridge becomes an increasingly prominent feature in closer range views, especially from the river bank (Views 6, 7, 16, 20, 21 & 22); from Menlo Castle (Views 5, 6, 20 & 21); and from the grounds of NUIG Sports Campus (Views 14, 16, 17, 18, 19). That said the wooded nature of the background river edge landscape means that the structure appears out of a wooded backdrop to openly cross the wide river in a simple single span. The effect is to maintain open views along the river corridor and to/from Menlo Castle.

The greatest impact is from the existing sports grounds of NUIG on the west bank of the river where users of the sports facilities and the river-side amenities gain direct access to the underside of this large structure.

Photomontages have also been prepared from a range of other areas along the route of the proposed road development. These views, which are included in **Appendix A.12.3**, are presented in two formats: first showing landscape works immediately after planting and second: with established planting c.15 years after planting. The views help illustrate the nature of the physical and visual changes, as well as the associated effects likely to arise as a result of the proposed road development.

12.5.5 Landscape and Visual Impact of related or associated developments

Other aspects of the construction and operation of the proposed road development have potential for landscape and visual impacts. Construction-related aspects such as site compounds, construction traffic on the local roads, temporary road closures and diversions, works associated with local road tie-ins, provision of footpaths and cycleways, stream diversions, culverts, drainage works, drainage ponds, service diversions, including diversion of overhead transmission lines will give rise to slight to moderate localised temporary impacts.

ESB’s 110kV overhead transmission lines are to be locally modified and/or diverted at four locations namely Cappagh, Castlegar, Parkmore, and Coolagh, Briarhill, as indicated on **Figures 15.1.1** to **15.1.15** (e.g. Ch. 13+525; Ch. 14+200 to Ch. 14+450 – Parkmore Link Road Junction; Ch. 16+20 to Ch. 17+100 – Coolagh Junction). These minor modifications/diversions will give rise to imperceptible to slight landscape or visual impacts.

Minor adjustments, including short re-alignments, undergrounding, provision of new poles and local raising of existing low voltage transmissions lines (10kV, 38kV) is also proposed at a number of locations as indicated on **Figures 15.1.1** to **15.1.15** (e.g. Ch. 3+780; Ch. 3+875; Ch. 6+675; Ch. 8+250 to Ch. 8+500; Ch.

2+025 – N59 Link Road South & Parkmore Link Road). These will not give rise to adverse landscape or visual impacts. Refer to **Chapter 15**, **Material Assets Non-Agriculture** for further details.

As well as the mainline, the proposed road development will involve the construction of roundabouts, at-grade junctions, grade-separated junctions, local roads, tunnel service buildings and a c.30m wide wildlife overbridge at Castlegar (Ch. 12+700).

East of the River Corrib roadside lighting is to be provided at the main junctions between the R336 Bearna West Roundabout and the N59 Letteragh Junction; along the full length of the N59 Link Road South, including around the Gateway Retail Park Junction; along the full length of the N59 Link Road North, including at the Bushypark Junction on the N59 Moycullen Road. Roadside lighting is already present along the part of the corridor of the N59 Link Road South between Gateway Retail Park – Rahoon Road – Rosán Glas and Bun A Chnoic. Roadside lighting is also already present along the N59 Moycullen Road at Bushypark.

West of the River Corrib roadside lighting is to be provided at the Lackagh Tunnel Portal; along the full length of the mainline of the proposed road development from Lackagh Tunnel, via the N84 Headford Road Junction to the N83 Tuam Road; along the City North Business Park Link; the Parkmore Link Road; at the Galway Racecourse Tunnel Portals; and along the Briarhill Business Park Road, the Ballybrit Crescent Junction, the R339 Monivea Road, Lynch Junction, Briarhill Link, Coolagh Junction and section of R446 within the proposed road development. Roadside lighting is already present along the N83 Tuam Road, within Parkmore Business Park, along Ballybrit Crescent, along R339 Monivea Road, along Briarhill Business Park Road, and along Bóthar na dTreabh, at the Coolagh Roundabout, and for 300m east along the existing N6.

Where not already a feature of the landscape, the introduction of roadside lighting will emphasise the degree of change in the rural landscape brought about by the proposed road development and associated traffic use. In many central and eastern areas the proposed road development passes through a suburban or suburban edge landscape where roadside lighting is already a feature. The most significant area of additional roadside lighting runs from Lackagh Quarry east to the proposed N83 Tuam Road Junction.

Operational aspects such as gantries and other signs, lighting columns, noise barriers, safety barriers, boundary and other fencing are all features typical of road development. In general, such aspects will give rise to slight localised and short-term impacts, however, taller noise barriers (>2.5m) on elevated sections of embankment located to either side of the N59 Moycullen Road crossing will further accentuate already significant visual impact for residential properties in this area. Where present, noise barriers will also have a beneficial effect in reducing the visibility of traffic from nearby residential properties. Transparent noise barriers will be used on the proposed River Corrib Bridge. Tunnel service buildings are to be provided adjacent to the two tunnels at Lackagh Quarry (Ch. 11+300) and Galway Racecourse (Ch. 14+950). The former building is to be located within the excavated quarry floor and will have no landscape or visual impact. The latter building is to be provided close to the boundary with Racecourse Business Park, where it will not give rise to landscape or visual impact. Likewise, the proposed re-organised stabling and parking at Galway Racecourse is in keeping with the surrounding context and will not give rise to adverse landscape or visual effects. Tunnel portals are associated with the two tunnels – however, these features are set into the landscape (as in Lackagh Quarry) or set low in the landscape (as at Galway Racecourse). The proposed wildlife overpass at Castlegar (Structure S12/02, Ch.12+700) will provide a wide landscape/planted bridge for connection of local habitats. The proposed new sports pitches at NUIG Sports Campus are located on existing pitches and while floodlighting is also to be provided, this is not out of place in the context of the surrounding sport campus.

12.6 Mitigation Measures

12.6.1 Introduction

Consideration was given to avoidance of significant landscape and visual impacts during the route corridor selection and during the design process for the proposed road development. Nevertheless, all road construction projects give rise to some degree of unavoidable landscape and visual impacts.

Mitigation of landscape and visual impacts for the proposed road development shall have regard to the approach as set out in the following NRA/TII guidance documents:

- Guidelines for the Creation and Maintenance of an Environmental Operating Plan (2007)
- A Guide to Landscape Treatments for National Road Schemes in Ireland (2006)
- Guidelines on the Implementation of Landscape Treatments on National Road Schemes in Ireland (2012)
- Guidelines for the Protection and Preservation of Trees, Hedgerows and Scrub Prior to, During and Post Construction of National Road Schemes (2006)
- Guidelines on the Management of Noxious Weeds and Non-Native Invasive Plant Species on National Roads (Revision 1, 2010)
- Standard Construction Details (2000-2017)
- Specification for Works (2000-2017)

In the following sections detailed mitigation proposals are set out for both the Construction Stage and Operational Stage

Landscape mitigation proposals shall take account of the approaches and principles as set out in A Guide to Landscape Treatments for National Road Schemes in Ireland, in particular to Chapter 4: Components of the Roadside Landscape; Chapter 5: Soil Geographic Factors; and Chapter 6: Landscape Treatments. Unless otherwise qualified in the following or in **Chapter 8, Biodiversity**, seeding and planting proposals, including species and planting type and species shall be in accordance with Chapter 6 of the Landscape Guidelines, adapted as required for local environmental and landscape conditions.

12.6.2 Construction Phase

During the construction stage, the Construction Environmental Management Plan (CEMP) in **Appendix A.7.5** will be finalised and adopted by the Contractor'. Adherence to the CEMP will be a contract requirement and this will ensure good working practices are followed so as to minimise and manage any significant, negative environmental impacts arising from construction. As well as other items, the CEMP includes the mitigation set out within this chapter and incorporates these measures as part of their implementation.

Mitigation will ensure that the works will have continuous monitoring under the Construction Environmental Management Plan so as to ensure adequate protection of areas outside of the construction works.

Specific measures shall ensure that:

- Site machinery shall operate within the proposed road development construction area
- Storage areas shall be located so as to avoid impacting further on existing residential and other property, woodlands, trees, hedgerows, drainage patterns, etc.
- Solid site hoarding of minimum 2.0m in height shall be provided alongside construction works adjoining residential property or recreational amenities
- Solid hoarding or similar, of minimum 2.0m in height shall be provided along any side of a proposed construction compounds, where they are located within 100m of residential properties
- Construction compounds shall be fully-decommissioned and reinstated to their pre-construction condition at the end of the construction contract
- Side slopes and other landscape areas along the proposed road development shall be prepared for soiling, and either seeded and/or planted at the earliest possible opportunity. As such, some scope may exist for undertaking significant areas of seeding and planting prior to the end of the construction works. However, due to construction programming and seasonal restrictions, it is also likely that significant planting works will not be undertaken until the end of the major construction phase

12.6.3 Operational Phase

Measures proposed to mitigate the landscape and visual impacts of the operation stage of the proposed road development are considered under Project-wide Measures and Specific Measures. Project-wide measures are described in the following section and in **Table 12.7**, while specific measures are set out in detail in **Table 12.8**. The measures are also identified on **Figures 12.4.01** to **12.4.14**.

12.6.3.1 Project-wide Landscape Measures

Project-wide measures will be applied over the entire proposed road development, depending on the nature of the particular road section. Where feasible such measures shall include for the re-connection of existing field boundaries and hedgerows along the proposed road development. Where appropriate trees species as noted in Mitigation **Tables 12.7** and **12.8**, shall be randomly spaced in a visually naturalistic manner within such hedgerows.

This approach will be locally modified to incorporate other landscape treatments, which may negate the requirement for the hedgerow, *e.g.* blocks of native woodland planting (see Landscape Guidelines, Section 6.2: Tree and Shrub Treatments) or semi-natural meadows (see Landscape Guidelines, Section 6.1: Grassland Treatments) where it is considered appropriate to have open sections along the proposed carriageway. Open sections shall allow for views to the wider landscape where they do not impinge on requirements for screening for residential properties or other amenities.

Proposals will ensure that planting is distributed along the proposed road development and the associated local road realignments and will vary from locally appropriate hedgerow reinstatement, with tree-planting, where appropriate; to wider plantings of landscape and screen planting; to the establishment of larger areas of scrub/shrub planting and new woodland for integration of the development within the wider landscape. The approach will provide a density and diversity of plantings and improve the biodiversity structure of the new landscape (see Landscape Guidelines, Section 6.2: Tree and Shrub Treatments).

Treatments will take into consideration the assessment and recommendations of **Chapter 8, Biodiversity** and will ensure that, species which are locally indigenous and native are utilised in the proposed plantings. However, detailed proposals in terms of their nature and approach will consider the locally impacted environment and in terms of species may include non-invasive, non-native plants, *e.g.* within residential areas where existing garden plantings are disturbed.

Where areas are in cut or fill, a grass or meadow sward will be established over the slope except in areas of cutting through stable rock (see Landscape Guidelines, Section 4.2: Cuttings and Embankments). It is not proposed to plant either cut or fill slopes in their entirety, but to encourage a more naturalistic and locally sympathetic grouping of plantings within a semi-natural grass sward. Slopes may also be seeded to wildflower grassland and hydro-seeding may be utilised for seeding of steep slopes. It is expected that significant extent of rock cutting will arise on the proposed road development. Stable rock slopes will be retained as an exposed face for natural colonisation and as a local landscape features.

Along the length of the proposed road development, landscape areas within junctions and small areas of severed fields, plots or other property acquired for the construction of the proposed road development will be varyingly treated including being planted in a semi-natural copse like scrub plantings and native woodland species (see Landscape Guidelines, Section 4.6: Additional Plots and Other Areas). Such planted blocks dispersed along the proposed road development will assist in the improvement of the longer-term visual character of the proposed road development and local surrounds. Particular attention shall be given to an appropriate extent and scale of planting in and surrounding junctions (see Landscape Guidelines, Section 4.3: Junctions, Interchanges and Roundabouts) and embankments (see Landscape Guidelines, Section 4.2.2: Embankments).

Certain areas along the length of the proposed road development have been set aside for drainage requirements/pollution control/attenuation. Where proposed these will be securely fenced and planted with locally appropriate hedgerows, shrubs and/or screen planting located along the proposed development boundary to minimise any visual impact from off road areas. However, it is noted that these features also offer the potential to provide for improved landscape diversity and habitat.

Proposed planting will generally be established using bare-root transplants, whips and feathered plants which adapt readily to disturbed ground conditions. A proportion, totalling not less than 5% of 'Half-standard' (6-8cm girth & 200cm-250cm tall) and a further 5% 'Standard' (8-10cm girth & 250cm-300cm tall) trees shall be used to supplement these plantings, especially in the vicinity of residential areas. All planting mixes will take cognisance of, and include native and local species as identified in the **Chapter 8, Biodiversity**. These requirements have been adapted and further detailed as appropriate to particular areas as set out in **Table 12.8**.

Where used, tree species will be selected from a list of primarily native, naturalised and indigenous species, which will include alder, common ash (*subject to planting restrictions at time of works*), common birches, common oaks, mountain ash, Scots pine and willow species. Planting sizes will be from 75cm to 400cm in height and tree species will be planted at average 2.0m centres within the wider planting mix.

Shrub planting species utilised will be selected from a list of primarily native and indigenous species, which will include, blackthorn, elder, hawthorn, hazel, holly, guelder rose, spindle, willows and other plants found naturalised in the affected localities. Planting sizes will vary from 30 to 75cm in height and shrub species will be planted at between 1.0 and 1.5m centres depending of landscape type, see **Table 12.8**.

Hedge planting will be primarily of blackthorn and hawthorn interspersed with other species such as elder, hazel, holly and those found locally. Hawthorn within hedgerows shall be planted at between 75 to 90cm in height and at 500mm centres in each of 2 double staggered rows or wider plantings where a more dense effect is required. The hedgerow will be interspersed with standard-sized randomly spaced tree species such as alder, common ash and oaks, as appropriate to particular locality.

Areas to be seeded to meadow will be thinly topsoiled (5cm layer) and seeded with a locally appropriate seed mix. Mainline and side road verges will be cultivated, topsoiled minimum 200mm deep and stone buried to remove stones down to 25mm diameter prior to seeding to a low-maintenance grass seed mix.

Where lighting is proposed, the lighting design shall meet the requirements of BS EN 13201-2:2003 and BS5489-1: 2003, Code of Practice for Design of Road Lighting. Lighting of Roads and Public Amenity Areas and shall comply with the requirements of the DMRB TD 34-91. The detailed lighting design shall be completed in a manner, which will minimise glare and will ensure that light-spill effect is minimised.

In specific locations barriers and/or earth bunds may be provided to reduce the impact of noise. Such barriers will also have the effect of providing immediate visual screening of traffic from properties. Such features shall, wherever possible, be integrated within the proposed landscaping measures. **Chapter 17, Noise and Vibration** outlines the assessment of noise impact and the requirements for such mitigation.

Table 12.7: Project-wide Landscape and Visual Mitigation Elements and Treatments (Note Proposed Road Development has been abbreviated to PRD in the following table)

Reference	Description of Measures
Cut slopes on mainline, link roads and local roads	Cut slopes shall be finished to even gradients, topsoiled unless otherwise stated in this table or elsewhere in the EIAR. Slopes shall be free of rubble and stones over 50mm diameter. All such rubble/stone shall be removed or buried. Unless otherwise stated slopes shall be seeded to a low maintenance non-agricultural grassland or to a diverse grass/wildflower sward, as appropriate. Steep slopes may be hydro-seeded. Where exposed, stable rock cuttings / slopes will be retained as a landscape feature along the proposed road corridor.
Embankments on mainline, link roads, and local roads	Embankments shall be finished to even gradients, topsoiled unless otherwise stated in this table or elsewhere in the EIAR. Slopes shall be free of rubble and stones over 50mm diameter. All such rubble/stone shall be removed or buried. Unless otherwise stated slopes shall be seeded to a low maintenance non-agricultural grassland or to a diverse grass/wildflower sward, as appropriate. Steep slopes may be hydro-seeded.
Verges & Roundabouts on mainline, link roads, and local roads	Verges will be provided along both sides of mainline. Verges will also be provided around junctions and along local road re-alignments and tie-ins. Verges and roundabouts shall be finished to even or gently flowing gradients, with minimum 200mm topsoil. Areas shall be stone buried or raked will be free of rubble and stones over 25mm diameter. Verges and roundabouts will be seeded to low-maintenance seed mix.
Ponds, swales, 'V-drains' etc.	All slopes shall be evenly graded and free of rubble and stones over 50mm diameter. Slopes shall be seeded to low maintenance non-agricultural grassland or to a grass/wildflower sward, allowing for natural development over time. Steep slopes on pond edges and 'V-drains' may be hydro-seeded. Areas around ponds shall be a diverse landscape of low maintenance grassland/species-rich grass wildflower sward and plantings of scrub planting and/or low-canopy woodland and shrub planting. Hedgerows of blackthorn and hawthorn, hazel

Reference	Description of Measures
	and holly, without tree species, shall be established along non-roadside boundaries. Non-palisade type fencing (*e.g.* paladin or timber and anti-climb netwire fencing) shall be secure pond areas.
Noise barriers / bunds	Where possible hedgerow scrub and shrub planting and/or low-canopy woodland of native species shall be established as either a narrow planting of 3.0m minimum width or double-staggered hedgerow along the full off-road face of barriers. Low-canopy and/or shrub planting of native species shall be established on the off road face of bunds. The planting shall include ash*, birch, blackthorn, elder, hawthorn, hazel, holly, rowan and/or willow species as appropriate. Plants shall be 90 to 120cm in height at planting. *** Note**: Due to the risk of Ash Dieback (*Chalara fraxinea*) and until further notice, ash (*Fraxinus* species) is no longer approved by the TII for planting schemes. This does not impact on the use of Mountain ash – also known as rowan (*Sorbus aucuparia*). Transparent noise barriers will be used on the River Corrib Bridge
Plants and planting areas	All tree species over 150cm in height together with all Pine shall be appropriately staked and tied. All failed, dead or defective plants shall be replaced before the end of each and every year of defect aftercare. Full planting area will be free of stones over 50mm in diameter.
Grass areas	Grass areas shall provide full sward cover within 12 months of seeding. Any failed, bare or defective areas shall be re-seeded between March – May and/or August – September in each and every year of defect aftercare.
Unauthorised access, parking and/or encampment	Landscape proposals shall avoid creating areas considered as being suitable for unauthorised parking and shall use landscape proposals to deter and prevent such use.
Remnant areas	Any post-construction remnant lands shall be treated to a diverse range of grassland and/or planting proposals to include a minimum 30% planting, amended as locally appropriate. The remaining area shall be treated as locally appropriate low maintenance grass/species-rich sward.

12.6.3.2 Specific Landscape Measures

Specific mitigation measures are set out on **Figures 12.4.01** to **12.4.14** and in **Table 12.8**. The measures include construction-related aspects such as avoidance/minimising impact on property boundaries and landscape features as well as provision of solid screen hoarding during the construction phase for those properties particularly impacted by the works.

All of the following specific mitigation measures will be taken account of in the detailed design and implementation of landscape measures:

- Location of cut-off drains at the top of cuttings and at the bottom of embankments
- The location and requirements for maintenance access along the mainline of the proposed road development
- Locations where rock is encountered in cuttings. Such rock faces may be retained as geological features of the corridor of the proposed road development
- The location and integration of noise barriers within the landscape design
- Clearance zones (TD19 - Safety Barrier Standards)
- Sight-lines, including at junctions and to carriageway signage, *etc*.

A series of significant retaining walls, and a bridge over the N59 Moycullen Road, are proposed in the Dangan area between Ch. 8+300 and Ch. 8+670. This is both an existing residential area and a gateway into the city. Where feasible reinforced earth retaining wall approaches will be incorporated so as allow for a green landscape finish to all or part of the retaining structures. A limestone finish will be used where structural walls are required and for the abutments of the proposed bridge over the N59 Moycullen Road. The stone will consist of natural limestone, matching the character of the local stone, with a strong horizontal axis of between 5 to 1 and 7 to 1 (*i.e.* horizontal to vertical dimension).

Landscape Measures also take account of the specific protection and mitigation measures detailed in **Chapter 8, Biodiversity**. In particular, the measures include:

- Retained habitats, trees and hedgerows on land-take boundaries, *etc*. will be fenced-off and protected during construction works
- Specific measures are proposed at a number of locations for mitigation of potential impact on Bat species. This includes:
    - the provision of artificial bat roosts – with specific planting to encourage use
    - the provision of a planted wildlife overbridge (Ch. 12+700) with tie-in planting to local hedgerows and proposed planting on the boundary of the proposed road development, which will maximise potential benefit and use
    - dense planting, with trees for improvement of connectivity along the boundary of the proposed road development:
        - west of the crossing of the L1323 Letteragh (Ch. 7+200 – Ch. 7+280)

    - along embankments to either side of the proposed bridge over the River Corrib
    - between the crossing of the N84 Headford Road at Ballindooley and School Road at Castlegar
  - hedgerow planting for improvement of connectivity of habitats to the east of Menlo Castle
  - hedgerow and copse planting for enhancement of foraging habitat to the north of Menlo Castle
- In order to deter Barn Owls from foraging close to the proposed road development, embankments and cuttings, other than rock cuttings or cut slopes left to naturally regenerate, will be densely planted with low growing scrub (e.g. blackthorn, hawthorn) from Ch. 8+550 to Ch. 17+500
- In order to deter Barn Owls from over flying the proposed road development, planting of closely-spaced trees (approx. 2m centres) greater than 3m in height will be established along the top of the embankments between Ch. 9+600 and Ch. 10+100
- All mitigation planting will take place at the earliest opportunity feasible during the construction stage so as to maximise establishment prior to road opening

Table 12.8: Specific Landscape and Visual Mitigation Elements and Treatments
(Note Proposed Road Development has been abbreviated to PRD in the following Table)

Reference	Location	Description of Measures
6.0m wide Screen Planting	Planting at 1.0m centres for visual screening shall be of a minimum of 6m in width. The planting shall extend for a minimum of 100m to either side of any adjoining residential property or amenity. (refer to **Figures 12.4.01** to **12.4.14**)	Planting will include a dense planting at 1m centres of alder, birch, blackthorn, elder, geulder rose, holly, hawthorn, hazel, rowan, and willow species. Shrubs shall be planted at between 60 to 90cm in height. Scots pine of minimum 60cm in height at planting shall comprise 20% of the overall plant numbers and holly at a minimum of 45cm in height shall comprise a further 15%. Tree species, planted equally at half-standard (6-8cm girth) and standard size (8-10cm girth), shall comprise minimum 10% of the mix.
3.0m wide Screen Planting	Where space is limited planting at 1.0m centres for visual screening shall be of a minimum of 3m in width. The planting shall extend for a minimum of 100m to either side of any adjoining residential property or amenity. (refer to **Figures 12.4.01** to **12.4.14**)	Planting will include a dense planting at 1m centres of alder, birch, blackthorn, elder, geulder rose, holly, hawthorn, hazel, rowan, and willow species. Shrubs shall be planted at between 60 to 90cm in height. Scots pine of minimum 60cm in height at planting shall comprise 20% of the overall plant numbers and holly at a minimum of 45cm in height shall comprise a further 15%.

Reference	Location	Description of Measures
		Tree species, planted equally at half-standard (6-8cm girth) and standard size (8-10cm girth), shall comprise minimum 20% of the mix.
Stone Wall Boundaries	Stone walls as indicated on **Figures 12.4.01** to **12.4.15**)	Where indicated stone walls will be replaced along impacted sections of property and road boundaries on local roads. The stone from the disturbed sections of existing walls will be retained and re-used (generally granite to west; limestone to east) where possible to reinstate these new boundaries. The boundary walls may be backed by hedgerows of locally appropriate species, i.e. blackthorn, hawthorn and holly to west and hazel, hawthorn and holly to east. Elsewhere, where stone walls are removed the stone will be retained and made available for re-use by the adjacent property owners for the construction of a new stone wall on their side of the proposed development boundary if they wish.
Boundary Hedgerow	Typical double staggered hedgerow with tree planting, where locally appropriate	Primarily blackthorn (30%), hawthorn (40%) and holly (10%) hedgerow in west interspersed with other species (20%) such as elder, willow, and those found locally. Primarily hazel (30%), hawthorn (40%) and holly (10%) hedgerow to east interspersed with other species (20%) such as blackthorn elder, willow, and those found locally. Hawthorn plants shall be of c.90cm in height and planted at 50cm centres in each of two double staggered rows, 25cm apart. Other plants of c.50cm in height shall be interspersed. The hedgerow may be interspersed with 'half-standard-sized' (6-8cm girth) alder, birch and/or oak trees planted at random spacings but averaging a min. of 1 tree per 25 linear metre. Limited tree species, such as birch and mountain ash may also be included as 'whips' at 150cm in height.
Retaining Walls and structure over the N59 Moycullen Road	Use of reinforced earth retaining systems and limestone finishes for structural elements. Retaining Wall Structures R08/01; R08/02; R08/07 & R08/04; and Bridge Structure S08/02 (Ch. 8+300 to Ch. 8+670)	Where feasible reinforced earth retaining wall approaches will be incorporated so as allow for a green landscape finish to all or part of the retaining structures. Planting of trees shall also be provided along the base of the structure. These shall include smaller growing species such as alder, birch and rowan planted as Selected Standards (i.e. 14cm girth or greater) A limestone finish will be used for the external finish of the abutments for the proposed bridge over the N59 Moycullen Road and where structural walls are required. The stone will consist of natural limestone, matching the character of

Reference	Location	Description of Measures
		local stone, with a strong horizontal axis of between 5 to 1 and 7 to 1 (i.e. horizontal to vertical dimension).
Bat habitat enhancement	New 2m wide tree and shrub hedgerow, with occasional planted copses located north and east of Menlo Castle.	New hedgerow of native species will be established with plants at 0.5m staggered centres in each of 5 rows located 0.5m apart to sub-divide existing open fields. Standard-sized trees species (min 8-10cm girth, 2.4m high) will be planted at 15m staggered centres in each of the 3 central rows. Diverse range of shrub species will be planted between trees in the central rows and throughout the outer 2 rows. Circa 15m diameter woodland copses will be established within open fields using similar approach, densities and species. Planting will be protected by stock-proof fence, c.1.25m high located at 1.0m offset to either side of the outer row of the new hedgerow. Tree species to include alder, birch, oak, rowan, planted as standards (as above) and whips (1.25m high). Shrubs to comprise mainly blackthorn, hawthorn and hazel (combined 60%), with elder, holly, spindle, willow etc. Hawthorn plants shall be of between c.90cm in height and all other shrubs shall be c.60cm in height.
Wildlife Overpass	Ballindooley / Castlegar Structure S12/02 (Ch. 12+700)	Wildlife overpass (c.30m wide) will be landscaped to provide for connective habitat across proposed road development. Planting to consist of a central narrow grass path bounded on either side by tree-lined hedgerows of native species. Soil depths to vary from minimum c.45cm depth at edges to c.1.5m depth along centre-line of both hedgerows. Planted element of both hedgerow lines will be c.2m wide with standard-sized trees (min 8-10cm girth, 2.4m high) planted at 3m staggered centres in each of 2 rows in each hedgerow. Diverse range of shrub species will be planted between trees and along the line of each hedgerow. Planting to tie-in to proposed planting leading east and west on upper slopes of cuttings on both sides of the proposed road development. This will form a continuous hedgerow/planted network.

Reference	Location	Description of Measures
		Tree species to include alder, birch, oak, rowan, planted as standards (as above) and whips (1.25m high). Shrubs to comprise mainly blackthorn, hawthorn and hazel (combined 60%), with elder, holly, spindle, willow etc. Hawthorn plants shall be of between c.90cm in height and all other shrubs shall be c.60cm in height.
Barn Owl Tree Planting	Typical double staggered treeline with dense underplanting, between Ch. 9+600 and Ch. 10+100.	Deterrent tree planting to comprise alder, birch and/or rowan planted at 3m in height (min 12-14cm girth) and at 2.0m centres in each of 2 rows 1.5m apart. Dense low scrub planting to comprise blackthorn (50%), hawthorn (20%), hazel (10%) and holly (10%) interspersed with other species (10%) such as elder, willow, and those found locally. Hawthorn plants shall be of c.90cm in height and planted at 50cm centres. Blackthorn and other plants shall be of c.50cm in height and planted at 50cm centres in staggered rows, 50cm apart.
Barn Owl Scrub Planting	Dense low scrub planting on all embankments and cut slopes (other than rock cuttings or cut slopes left to naturally regenerate) from Ch. 8+550 to Ch.17+540.	Dense low scrub planting to comprise blackthorn (50%), hawthorn (20%) hazel (10%) and holly (10%) interspersed with other species (10%) such as elder, willow, and those found locally. Hawthorn plants shall be of c.90cm in height and planted at 50cm centres. Blackthorn and other plants shall be of c.50cm in height and planted at 50cm centres in staggered rows, 50cm apart.
Compensatory Habitat Areas (CHA)	Along Proposed Road Development Refer to 'CHA' locations on **Figures 12.4.01** to **12.4.14**)	Areas identified for compensatory habitat for mitigation of potential ecological impacts. Refer to **Chapter 8, Biodiversity** for further detail.

*** Note**: Due to the risk of Ash Dieback (*Chalara fraxinea*) and until further notice, ash (*Fraxinus* species) is no longer approved by the TII for planting schemes. This does not impact on the use of Mountain ash – also known as rowan (*Sorbus aucuparia*).

12.7 Residual Impacts

12.7.1 Introduction

Residual Impacts are outlined separately in the following sections under Construction Phase and Operational Phase.

12.7.2 Construction Phase

In landscape and visual terms, proposed mitigation measures will have limited effect during the construction stage, and relate more to the orderly development, protection of landscape on and external to the landtake and to minimisation of visual disruption and impact, where possible. For this reason, it is considered that the potential negative landscape and visual impacts as outlined in **Section 12.5.3** of this chapter will continue to arise, even with mitigation, during the temporary and short-term construction phase of the proposed road development.

12.7.3 Operational Phase

During the initial operation stage landscape and visual impacts will continue to arise from the physical presence and operation of the proposed road development. The proposed road development will be a significant and prominent new element in the landscape – at least until such stage as landscape mitigation proposals establish and become increasingly effective. As such, initial operational-stage landscape and visual impacts will continue to be pronounced and negative in the short-term (*i.e.* pre-establishment stage). With the development of mitigation planting, the significance and severity of landscape and visual impacts will gradually abate over time.

Negative visual impact will also continue to arise for residential and other properties located close to or adjoining the boundary of the proposed road development for some time (*i.e.* post-establishment stage).

Therefore, significant or notable residual landscape impacts will continue to arise:

- Along the edge of Sruthán Na Libeirtí, Bearna
- On the open elevated landscapes of Ballagh, Rahoon, Letteragh, Barnacranny and Dangan Upper
- On the recreation sports and amenity landscape of NUIG Sports Campus
- On the lowland landscape valley of the River Corrib, and the setting of Menlo Castle
- On the limestone landscape of Menlough and Coolough
- On the rolling landscape through Castlegar, south of Ballindooley Lough

Locations of these significant landscape impacts are provided on **Figures 12.4.01** to **12.4.14**.

Significant or notable residual visual impacts will continue to arise for properties:

- At the crossing of local roads north and northeast of Bearna (Foraí Maola Road, Troscaigh Road, Ann Gibbons Road, Aille Road)
- At the crossing of local roads northwest of Galway (Cappagh Road, Ballymoneen Road, Rahoon Road and Letteragh Road)
- To either side of the crossing of the N59 Moycullen Road north of Galway (The Heath, Barnacranny, Ard na Locha, Aughnacurra and at Bushypark/Ballagh)
- On the recreation sports and amenity landscape of NUIG Sports Campus
- On the lowland landscape valley of the River Corrib, and setting of Menlo Castle
- At the crossing of Bóthar Nua and Seanbóthar north/northeast of Galway City
- At the crossing of the N84 Headford Road, at Castlegar, (including crossing of School Road) and at the N83 Tuam Road, northeast of Galway
- At Ballybrit/Parkmore, at Racecourse Avenue, Ballybrit Crescent, Monivea Road and Coolagh-Briarhill east of Galway

Details of the visual impacts are provided in **Table 12.6** above, in **Appendix A.12.1** and are indicated on **Figures 12.4.01** to **12.4.14**.

12.7.4 Cumulative Impacts

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant landscape and/or visual effects. The assessment has considered statutory city and county plans and associated planning registers; local area plans, including those for Bearna, Gaeltacht, and Ardaun and the Údarás na Gaeltachta' Strategic Plan.

The construction and operational stages of the proposed road development give rise to rise to significant, very significant and profound landscape and visual impacts. These impacts are generally focused within the immediate corridor of the proposed road development on the urban/rural edge of the city. To the west and north of the city much of the lands along the corridor are identified for agricultural and/or amenity uses. Further sports and amenity developments are likely within the grounds of NUIG Sports Campus on the west bank of the river. While there are some small areas of residential zoning at Ballymoneen, Rahoon, Letteragh, Ballindooley and Castlegar, development in these areas is unlikely to give rise to significant landscape and visual impacts or cumulative impacts. An area of enterprise, industrial and related zoning is indicated to the north and east of Galway Racecourse, but much of these lands are already developed within Parkmore Business Park.

The eastern end of the proposed road development falls within the area covered by the Arduan Local Area Plan (LAP). The LAP proposes major development in the area, including new residential and commercial developments on c.81 hectares of an overall LAP area of c.164 hectares on the east side of the city. The existing M6/N6 corridor runs through the centre of the LAP area and the proposed road development ties-in to the existing road infrastructure within the LAP area. While the LAP envisages significant changes to the landscape and visual setting of the area, it is likely that the measures proposed will be delivered on a phased basis over a long period of time. Nevertheless, depending on timing of delivery, scope exists for some limited or not significant cumulative landscape and visual impacts to arise.

The Galway Transport Strategy (GTS) also envisages further transport-related developments, including public transport and cycleway and greenway measures. However, these measures are unlikely to further adversely impact the landscape or visual setting along the proposed road development.

The Galway Harbour Port Extension project is at planning stage. However, if permitted, it is not expected that any significant cumulative landscape or visual effects will arise because of the separation distance between the proposed road development and the port location.

Other projects, such as the M17 Galway to Tuam Road Project (operational); the N18 Oranmore to Gort Road Project (operational); the N83 Tuam Bypass (operational); the M6 Motorway (operational); the M6 Motorway Service Area (pre-planning); the N59 Maam Cross to Oughterard Road Project (consented and pre-construction); and the N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction), are considered too distant from the proposed road development to give rise to cumulative landscape and/or visual effects.

In summary it is considered that there is limited potential for any significant cumulative impacts with other planned or potential developments and that these will not further increase the adverse or negative impacts associated with the proposed road development.

12.8 Summary

The proposed road development passes through a generally rural landscape on the western, northern and eastern edge of Galway City. Residential development is a prominent feature, especially along local roads from Bearna through to Letteragh; in suburban developments at Barnacranny and Dangan on north of the city; along the N84 Headford Road at Ballindooley and around the village settlement of Castlegar to the east/northeast of the city.

Some areas along the proposed road development are of very high landscape and visual quality and sensitivity - especially centred on the River Corrib and its broad lowland valley, with the riverside ruin of Menlo Castle and the high quality amenity and sports grounds of NUIG. The remote and semi-natural limestone and scrub covered landscapes of Menlough and Coolough are also of significant landscape quality and sensitivity, while Ballindooley Lough and Galway Racecourse are also of notable landscape quality.

Due to the nature of the baseline landscape, the construction and initial operational stage of the proposed road development will give rise to a range of significant, very significant and profound landscape and visual impacts, at least until such stage as the extensive landscape mitigation proposals establish and become effective. With the development of mitigation planting, the significance and severity of landscape and visual impacts will gradually abate.

Even with the development of mitigation planting, negative visual impact will continue to arise for residential and other properties located close to or adjoining the boundary of the proposed road development and where the proposed road development, including the major River Corrib Bridge, crosses sensitive landscape areas.

Therefore, the proposed road development will continue to have longer-term visual impacts for properties located immediately along the proposed road development where it is on high embankments and requires retaining walls. This is of particular note through Barnacranny/Dangan and at Castlegar as well as at dispersed locations along the proposed road development.

The proposed bridge and associated embankments and viaduct on the east bank of the river will have a permanent and significant impact on the semi-natural landscape valley and setting of the River Corrib as well as on the recreational and sports amenity of the northern end of NUIG Sports Campus.

13 Archaeological, Architectural and Cultural Heritage

13.1 Introduction

This chapter of the EIAR consists of an appraisal of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, under the heading of archaeological, architectural and cultural heritage.

This chapter initially sets out the methodology followed in carrying out the appraisal (**Section 13.2**), describes the receiving environment (**Section 13.3**), and summarises the main characteristics of the proposed road development which are of relevance to the archaeological, architectural and cultural heritage (**Section 13.4**). The evaluation of impacts of the proposed road development on archaeological, architectural and cultural heritage are described (**Section 13.5**), measures are proposed to mitigate these impacts (**Section 13.6**), and residual impacts are described (**Section 13.7**). The chapter concludes with a summary (**Section 13.8**) and reference section (**Section 13.9**).

This chapter has utilised the information gathered during the constraints and route selections studies for proposed road development to inform the archaeological, architectural and cultural heritage impact appraisal. **Sections 4.11, 6.5.6** and **7.6.6** of the **Route Selection Report** examined the archaeological, architectural and cultural heritage constraints within the scheme study area and compared the potential of archaeological, architectural and cultural heritage impacts of the respective route options. These sections of the Route Selection Report contributed to the design of the proposed road development which this chapter appraises. It has also involved further detailed analysis of the archaeological, architectural and cultural heritage resources, including a full field inspection which is further discussed below.

13.2 Methodology

13.2.1 Introduction

This study determines, as far as reasonably possible from existing records, the nature of the cultural heritage resource within the footprint of the proposed road development and in the vicinity of the proposed road development using appropriate methods of study. Desk-based assessment is defined as a programme of study of the historic environment within a specified area or site that addresses agreed research and/or conservation objectives. It consists of an analysis of existing written, graphic, photographic and electronic information in order to identify the likely heritage assets, their interests and significance and the character of the study area, including appropriate consideration of the settings of heritage assets (IFA[1] 2012). This leads to the following:

- Determining the presence of known archaeological and built heritage sites that may be affected by the proposed road development
- Assessment of the likelihood of finding previously unrecorded archaeological remains during the construction programme
- Determining the impact upon the setting of known cultural heritage sites in the surrounding area (receiving environment)
- Suggested mitigation measures based upon the results of the above research

Research for the EIAR has been undertaken in two phases. The first phase comprised a paper survey of all available archaeological, architectural, historical and cartographic sources. The second phase involved a field inspection of the proposed road development.

The study involved detailed interrogation of the archaeological, historical and architectural nature of the receiving environment of the proposed road development. This included information from the Record of Monuments and Places of County Galway, the County and City Development Plans, the topographical files of the National Museum of Ireland and cartographic and documentary records. Aerial photographs of the study area were also consulted. Field inspections were carried out along the route of the proposed road development in December 2015 and July 2016 in an attempt to identify any known cultural heritage sites and previously unrecorded features, structures and portable finds within the footprint of the proposed road development.

The receiving environment is defined as an area measuring c. 250m from the edge (proposed development boundary) of the proposed road development [2] Measurements are taken from the proposed development boundary to the upstanding remains of a site or structure. Where there are no upstanding remains, the measurement is taken to the centre of the site as indicated within **Figures 13.1** to **13.14**.

13.2.2 Legislation and Guidelines

The study has been carried out in accordance with the Code of Practice that was agreed between the Transport Infrastructure Ireland (TII) and the Minister for Arts, Heritage, Gaeltacht and the Islands (now the Department of Culture, Heritage and the Gaeltacht, DoCHG) and EPA Guidelines and advice notes (2003 & 2017).

The following legislation, standards and guidelines were also consulted as part of the assessment.

- National Monuments Act 1930 to 2014
- The Planning and Development Acts 2000 to 2017

[1] Institution of Field Archaeologists
[2] NRA guidelines (page 57) recommend a minimum of 50m either side of the road centreline

- Heritage Act, 1995, as amended
- Guidelines on the information to be contained in Environmental Impact Statements, 2003, EPA
- Advice Notes on Current Practice (in preparation of Environmental Impact Statements), 2003, EPA
- Draft Advice Notes on Current Practice (in preparation of Environmental Impact Statements), 2015, EPA
- Guidelines on the information to be contained in Environmental Impact Statements, Draft 2015, EPA
- Guidelines on the information to be contained in environmental impact assessment reports (Draft August 2017), EPA
- Frameworks and Principles for the Protection of the Archaeological Heritage, 1999, (formerly) Department of Arts, Heritage, Gaeltacht and Islands
- Architectural Heritage (National Inventory) and Historic Monuments (Miscellaneous Provisions) Act, 2000 and the Local Government (Planning and Development) Act 2000
- Code of Practice for Archaeology agreed between the Minister for Arts, Heritage, Regional, Rural and Gaeltacht Affairs (now the Department of Culture, Heritage and the Gaeltacht) and Transport Infrastructure Ireland, July 2017
- Guidelines for the Assessment of Archaeological & Architectural Heritage Impacts of National Road Schemes, 2005, NRA

13.2.3 Data Sources and Consultations

13.2.3.1 Consultations

Following the initial research, a number of statutory and voluntary bodies were consulted to gain further insight into the cultural background of the receiving environment and study area, as follows:

- Department of Culture, Heritage and the Gaeltacht – the Heritage Service, National Monuments and Historic Properties Section: Record of Monuments and Places; Sites and Monuments Record; Monuments in State Care Database; Preservation Orders; Register of Historic Monuments
- National Museum of Ireland, Irish Antiquities Division: topographical files of Ireland
- National Inventory of Architectural Heritage: County Galway
- Galway City and County Council: Planning Section
- Study Area and Baseline Data Collection

13.2.3.2 Paper Survey

This is a document search. The following sources were examined and a list of areas of archaeological, architectural and cultural heritage potential was compiled:

- Record of Monuments and Places for County Galway
- Sites and Monuments Record for County Galway
- Monuments in State Care Database
- Preservation Orders
- Register of Historic Monuments
- Topographical files of the National Museum of Ireland
- Cartographic and written sources relating to the study area
- Galway County Development Plan 2015 – 2021
- Galway City Development Plan 2011 – 2017 & 2017 – 2023
- Bearna Local Area Plan 2007 – 2017
- National Inventory of Architectural Heritage County Galway (Architectural & Garden Survey)
- Aerial photographs
- Excavations Bulletin (1970 – 2016)
- Place name analysis

Record of Monuments and Places (RMP) Section 12 (1) of the National Monuments Act (1994 amendment) provides that the Minister for Arts, Heritage, Gaeltacht and the Islands (now the Minister for Culture, Heritage and the Gaeltacht) shall establish and maintain a record of monuments and places (RMP) where it is known that such monuments exist. The record comprises of a list of monuments and relevant places and mapping showing each monument and relevant place in respect of each county in the State. Sites recorded on the Record of Monuments and Places all receive statutory protection under the National Monuments Act. All recorded monuments are referred to as Archaeological Heritage (AH sites) within this appraisal.

Sites and Monuments Record (SMR) holds documentary evidence and records of field inspections of all known archaeological sites and monuments. Some information is also held about archaeological sites and monuments whose precise location is not known e.g. only a site type and townland are recorded. These are known to the National Monuments Section as ‘un-located sites’ and cannot be afforded legal protection. As a result, these are omitted from the Record of Monuments and Places. SMR sites are also listed on a website maintained by the DoCHG – www.archaeology.ie. All Recorded Monuments are referred to as Archaeological Heritage (AH sites) within this assessment.

It should be noted that revisions are proposed to the RMP and SMR, with some sites listed as redundant records and proposed for removal and other, newly discovered sites, proposed for inclusion. Some of the recorded sites within the receiving environment of the proposed road development fall into this category. As the revisions have yet to take place, all current RMP/SMR sites are listed as AH sites within this assessment, with the relevant detail provided as to the nature and extent of each site included.

National Monuments in the State Care Database is a list of all the National Monuments in the State guardianship or ownership. Each is assigned a National Monument number whether in guardianship or ownership and has a brief description of each monument.

A National Monument receives statutory protection and is described as 'a monument or the remains of a monument the preservation of which is a matter of national importance by reason of the historical, architectural, traditional, artistic or archaeological interest attaching thereto' (National Monuments Act, 1930, Section 2).

The Minister for the Department of Environment, Heritage and Local Government (now the Minister for Culture, Heritage and the Gaeltacht) may acquire National Monuments by agreement or by compulsory order. The State or Local Authority may assume guardianship of any National Monument (other than dwellings). The owners of National Monuments (other than dwellings) may also appoint the Minister or the Local Authority as guardian of that monument if the State or Local Authority agrees. Once the site is in ownership or guardianship of the State, it may not be interfered with without the written consent of the Minister. There are no National Monuments located within the footprint of the proposed road development and its receiving environment.

Preservation Orders List and/or Temporary Preservation Orders, can be assigned to a site or sites that are deemed to be in danger of injury or destruction. Orders are allocated under the National Monuments Act, 1930. Preservation Orders make any interference with the site illegal. Temporary Preservation Orders can be attached under the National Monuments Act, 1954. These perform the same function as a Preservation Order but have a time limit of six months, after which the situation must be reviewed. Work may only be undertaken on or in the vicinity of sites under Preservation Orders with the written consent, and at the discretion, of the Minister (DoCHG). There are four sites that possess Preservation Orders within the receiving environment of the proposed road development under assessment. These are referred to as Archaeological Heritage (AH sites) within this assessment.

Register of Historic Monuments was established under Section 5 of the 1987 amendment to the 1930 National Monuments Act and requires the Minister to establish and maintain such a record. Historic monuments and archaeological areas included in the register are afforded statutory protection under the National Monuments Act 1987 amendment. The register also includes sites under Preservation Orders and Temporary Preservation Orders. All registered monuments are included in the Record of Monuments and Places.

Topographical files of the National Museum of Ireland is the national archive of all known finds recorded by the National Museum. This archive relates primarily to artefacts but also includes references to monuments and unique records of previous excavations. The find spots of artefacts are important sources of information on the discovery of sites of archaeological significance.

Cartographic sources are important in tracing land use development within the proposed road development area and its receiving environment as well as providing important topographical information on areas of archaeological potential and the construction of buildings. Cartographic analysis of all relevant maps has been made to identify any topographical anomalies or structures that no longer remain within the landscape. These included current and former townland and parish boundaries.

All sites of potential archaeological or architectural heritage merit identified during the map analysis are listed as Cultural Heritage (CH) sites within this assessment. All Townland Boundaries are listed as TB 1, 2 etc. In addition, all Areas of Archaeological Potential (AAPs) identified during the analysis of mapping (and other sources including field inspection) are referred to as AAPs within this assessment.

The cartographic sources consulted include:

- Down Survey Barony Map of Galway (1654 – 1656)
- Ordnance Survey 6” and 25” maps of Co. Galway (1841, 1895 – 1900, 1928 – 1929)

Documentary sources were consulted to compile background information on the archaeological, architectural and cultural heritage receiving environment of the proposed road development area.

Development Plans contain a catalogue of all the Protected Structures, archaeological sites and Architectural Conservation Areas within every county. The development plans for County Galway (2015 – 2021), Galway City (2011 – 2017 / 2017 – 2023) and the Bearna Local Area Plan (2007 – 2017) were examined as part of this assessment. All protected structures are referred to as Built Heritage sites (BH) as part of this assessment. There are no Architectural Conservation Areas located within the receiving environment of the proposed road development.

The National Inventory of Architectural Heritage (NIAH) is a government based organisation tasked with making a nationwide record of locally, regionally, nationally and internationally significant structures, which in turn provides county councils with a guide as to what structures to list within the Record of Protected Structures. The NIAH have also carried out a nationwide desk based survey of historic gardens, including demesnes that surround large houses. All NIAH structures are referred to as Built Heritage sites (BH) as part of this appraisal.

Whilst the NIAH Garden Survey was utilised as part of this assessment, this was carried out in conjunction with detailed analysis of the first edition OS maps and field inspection, in order to identify all designed landscapes (DL) within receiving environment of the proposed road development.

Aerial photographic coverage is an important source of information regarding the precise location of sites and their extent. It also provides information on the terrain and its likely potential for archaeology. Ordnance Survey aerial photographs (1995, 2000, 2005), Google Earth coverage (2003 – 2012) and Bing Maps were examined for this assessment. All sites identified during cartographic or aerial photographic assessment are identified as Cultural Heritage (CH) sites within this assessment. All

Areas of Archaeological Potential identified during the analysis are referred to as AAPs within this assessment.

Excavations Bulletin is a summary publication that has been produced every year since 1970. This summarises every archaeological excavation that has taken place in Ireland during that year up until 2010 and since 1987 has been edited by Isabel Bennett. This information is also available online (www.excavations.ie) from 1970 – 2016. Information from this resource is vital when examining the archaeological content of any area, which may not have been recorded under the SMR and RMP files.

Place Names are an important part in understanding both the archaeology, history and cultural heritage of an area. Place names can be used for generations and in some cases have been found to have their root deep in the historical past. The main references used for the place name analysis is *Irish Local Names Explained* by P.W Joyce (1870) and the Place Names Database of Ireland.

13.2.3.3 Field Inspection

Field inspection is necessary to determine the extent and nature of archaeological and architectural remains and can also lead to the identification of previously unrecorded or suspected sites and portable finds through topographical observation and local information.

The archaeological and architectural field inspection was carried out from the 30 of November to the 04 of December 2015 and during sunny conditions on the 26 of July 2016 and entailed:

- Noting and recording the terrain type and land usage
- Noting and recording the presence of known and previously unknown features of archaeological, architectural or cultural heritage significance
- Verifying the extent and condition of recorded sites and structures (RMPs/ RPS/ NIAH)
- Visually investigating any suspect landscape anomalies to determine the possibility of their being anthropogenic in origin and of archaeological, architectural or cultural heritage significance

13.2.3.4 Geophysical Survey

Geophysical survey is used to create ‘maps’ of subsurface archaeological features. Features are the non-portable part of the archaeological record, whether standing structures or traces of human activities left in the soil. Geophysical instruments can detect buried features when their electrical or magnetic properties contrast measurably with their surroundings. In some cases, individual artefacts especially metal, may be detected as well. Readings taken in a systematic pattern become a dataset that can be rendered as image maps. Survey results can be used to guide excavation and to give archaeologists insight into the patterning of non-excavated parts of the site. Unlike other archaeological methods, geophysical survey is not invasive or destructive.

As part of the assessment, a survey was carried out within one area of archaeological potential identified during the baseline assessment and field inspection. This area is located within the townland of Bushypark and the survey area including an area adjacent to a church and graveyard (BH 7) and a previously unknown platform in the landscape that may possess archaeological potential (CH 38).

The geophysical survey was carried out by Earthsound Archaeological Geophysics on behalf of IAC Ltd for Galway County Council and TII. It took place on the 17 and 18 of November 2016 under licence 16R0190.

13.2.4 Impact Evaluation Methodology

The quality and type of a potential impacts can vary to include the following (as per TII's Guidelines for the Assessment of Archaeological/Architectural Heritage Impacts of National Road Schemes (NRA, 2005, 25/54):

Negative Impact: A change that will detract from or permanently remove an archaeological/architectural monument/structure from the landscape.

Neutral Impact: A change that does not affect the archaeological/architectural heritage.

Positive Impact: A change that improves or enhances the setting of an archaeological/architectural monument/structure.

Direct Impact: Where an archaeological/architectural feature or site is physically located within the footprint of a potential route and entails the removal of part, or all of the monument or feature.

Indirect Impact: Where a feature or site of archaeological/architectural heritage merit or its setting is located in close proximity to the footprint of a potential route alignment.

No Predicted Impact: Where the potential route does not adversely or positively affect an archaeological/architectural heritage site.

It should be noted that whilst impact levels and definitions are applied consistently to the cultural heritage resource, direct impacts on sites that are subject to statutory protection are considered to be more significant than sites/structures not subject to statutory protection.

Impact Definitions (as outlined in the TII's Guidelines for the Assessment of Archaeological/Architectural Heritage Impacts of National Road Schemes (NRA, 2005, 54/21), are included in **Table 13.1** and **13.2** below. These have been supplemented with the additional impact definitions as per the most recent EPA guidelines (2017).

Table 13.1: Impact Definitions: Archaeology

Type of Impact	Definitions relating to sites of an archaeological nature
Profound	Applies where mitigation would be unlikely to remove adverse effects. Reserved for adverse, negative effects only. These effects arise when an archaeological site is completely and irreversibly destroyed by a proposed development
Very Significant	Effects which, by its character, magnitude, duration or intensity significantly alters the majority of a sensitive aspect of the environment
Significant	An impact which, by its magnitude, duration or intensity, alters an important aspect of the environment. An impact like this would be where part of a site would be permanently impacted upon, leading to a loss of character, integrity and data about the archaeological feature/site
Moderate	A moderate impact arises where a change to the site is proposed, which although noticeable, is not such that the archaeological integrity of the site is compromised and which is reversible. This arises where an archaeological feature can be incorporated into modern day development without damage and that all procedures used to facilitate this are reversible
Slight	An impact which causes changes to the character of the environment which are not significant or profound and do not directly impact or affect an archaeological feature or monument
Not significant	Effects which causes noticeable changes in the character of the environment but without noticeable consequences
Imperceptible	An impact capable of measurement but without noticeable consequences

Table 13.2: Impact Definitions: Architecture

Type of Impact	Definitions relating to sites of an architectural nature
Profound	An impact that obliterates the architectural heritage of a structure or feature of national or international importance. These effects arise where an architectural structure or feature is completely and irreversibly destroyed by the proposed development. Mitigation is unlikely to remove adverse effects
Very Significant	Effects which, by its character, magnitude, duration or intensity significantly alters the majority of a sensitive aspect of the environment
Significant	An impact that, by its, magnitude, duration or intensity alters the character and/or setting of the architectural heritage. These effects arise where an aspect or aspects of the architectural heritage is/are permanently impacted upon leading to a loss of character and integrity in the architectural structure or feature. Appropriate mitigation is likely to reduce the impact
Moderate	An impact that results in a change to the architectural heritage which, although noticeable, is not such that alters the integrity of the heritage. The change is likely to be consistent with existing and emerging trends. Impacts are probably reversible and may be of relatively short duration. Appropriate mitigation is very likely to reduce the impact
Slight	An impact that causes some minor change in the character of architectural heritage of local or regional importance without affecting its integrity or sensitivities. Although noticeable, the effects do not directly impact on the architectural structure or feature. Impacts are reversible and of relatively short duration. Appropriate mitigation will reduce the impact
Not significant	Effects which causes noticeable changes in the character of the environment but without noticeable consequences
Imperceptible	An impact on architectural heritage of local importance that is capable of measurement but without noticeable consequences

13.3 Receiving Environment

13.3.1 Results and Analysis

13.3.1.1 General

The proposed road development traverses the baronies, parishes and townlands listed in **Table 13.3** below. A detailed archaeological and historical background is provided in **Appendix A.13.1**.

Table 13.3: Baronies, Parishes and Townlands

Barony	Parish	Townland
Galway	Rahoon	Na hAille, Ballynahown East, Bushypark, An Cheapach, An Chloch Scoilte, Na Foraí Maola Thoir, Na Foraí Maola Thiar, Kentfield, Mincloon, An Baile Nua, Rahoon, Troscaigh Thoir, Troscaigh Thiar, Ballard West, Ballard East, Keeraun, Letteragh, Ballagh, Barnacranny, Dangan Upper, Dangan Lower
	St. Nicholas	An Caisleán Gearr, Cappanabornia, Parkmore, Ballybrit
Galway	Oranmore	Ballindooley, Mionlach, Pollkeen, Doughiska
Dunkellin		Breanloughaun, Coolagh

13.3.1.2 Recorded Monuments (AH sites) within the Receiving Environment

A total of 41 Archaeological Heritage sites (AH) are recorded within the receiving environment of the proposed road development (**Table 13.4**). However, the existing Sites and Monuments Record (SMR) and Record of Monuments and Places (RMP) is currently under review and a number of changes relating to some sites have been proposed in the record by the Department of Culture, Heritage and the Gaeltacht (www.archaeology.ie). As such, five redundant records are included within the 41 sites, which will be removed from the SMR. These sites have been classed by the DoCHG as being non-archaeological.

A further eight sites are proposed for removal due to their relatively recent date (AH 9, 10, 12, 17, 20, 27, 38, 39). Two sites will be removed from the Record as they are no longer extant having already been removed from the landscape due to quarrying (AH 18, 19). Two further sites will be removed from the record as they have been removed by modern development (AH 30, 31). One of the sites represents a series of probable prehistoric burnt mounds that have been excavated (AH 36). The entry is not proposed for removal from the record.

Four of the recorded sites within the townland of Ballybrit are further protected with Preservation Orders and as such are deemed to be of national importance (AH 32 - 35).

Of the 41 sites, nine are also classed as Protected Structures within the Galway City Development Plan (2017 – 2023). As such, these sites are also subject to statutory protection under the Planning and Development Act, 2000, as amended (AH 4, 15, 16, 22, 23, 25, 29, 33, 41).

The detail relating to each AH site is included in **Appendix A.13.2** of this EIAR and marked on **Figures 13.1.1** to **13.1.14**.

Table 13.4: Archaeological Heritage (AH) sites located within the receiving environment

AH No.	RMP No.:	Townland:	Classification:	Approx. Ch.	Dist. from proposed road development	Statutory protection
AH 1[3]	GA093-009	Na Foraí Maola Thiar	Redundant record: non-antiquity	0+500	9m east	None
AH 2	GA082-077	Rahoon	Bullaun Stone	6+850	0m	RMP
AH 3[4]	GA082-040	Dangan Lower	Redundant record: non-antiquity	8+350	57m southeast	None
AH 4[5]	GA094-047	Rahoon	House (Rahoon House) Also BH 18)	N59 Link Road South 3+350	153m southeast	RMP
AH 5	GA094-056	Rahoon	Designed Landscape Feature	Gort na Bró Road	61m southwest	RMP
AH 6	GA082-104	Bushypark	Enclosure	9+100	195m northwest	RMP
AH 7[6]	GA082-032	Dangan Lower	Redundant record: non-antiquity	8+750	86m northeast	None
AH 8	GA082-039	Dangan Lower	Children's Burial Ground	8+850	60m northeast	RMP
AH 9[7]	GA082-087	Mionlach	Settlement cluster	9+800	To the immediate north of the area proposed for habitat enhancement for bats. 573m northwest of proposed road development.	None

AH 41	GA082-070	Mionlach	Gate house (Also BH 21)	9+750	50m east of proposed habitat enhancement for bats. 406m northwest of proposed road development.	RMP

Of the 41 AH sites that have been identified seven of the sites are recorded within the footprint of the proposed road development. However, two of the sites have already been removed by quarrying (AH 18, 19); one site has been removed by existing development (AH 31) and one area has already been subject to archaeological excavation (AH 36). AH 24 is listed as a non-antiquity and AH 27 is listed as a quarry and as such does not possess archaeological significance. AH 2 is listed as the site of a bullaun stone; however, no trace of the feature has been identified during the course of this assessment.

Two further sites are located within the proposed development boundary which is outside the footprint of the proposed road development but required for habitat planting in Mionlach. AH 39 is listed as a designed landscape feature and is not considered to possess archaeological significance as it is scheduled for removal from the SMR/RMP. Similarly, AH 17, which is listed as a clearance cairn within this proposed habitat planting area is also scheduled for removal. A further designed landscape feature is located immediately adjacent to the proposed habitat planting area (AH 38), along with a recorded burial ground, located to the immediate west of the proposed habitat planting area (AH 40). Menlo Castle (AH 16) is located c. 140m northwest of the proposed road development. However, the edge of the habitat planting area is located to the immediate east of the castle structure.

13.3.1.3 National Museum of Ireland (NMI): Topographical Files

Information from the NMI topographical files listed a stone ard fragment (1987:184) and an iron axehead (1983:61) recovered from the townland of Dangan Lower. A number of lithic artefacts are listed under the townland of Mionlach, including seven stone axeheads of ‘Shannon type’ (KK131129, 2005C1:802, 1638:W307, 1637:W306, 1636:W305, 1635:W304, 1634:W303[22]); a collection of twenty blades of various geologies (1280:W5) and a chert blade (2005C1:801). A ‘beehive’ type quern top and base (2011:252) have also been recovered from the townland of An Caisleán Gearr. Details relating to the finds are listed in **Appendix A.13.3**.

[22] Polished stone axeheads of Neolithic date

13.3.1.4 Protected Structures (BH sites) within the Receiving Environment

A review of the Galway City Development Plan and Galway County Development Plan, has shown that a total of 27 Protected Structures (BH sites) are recorded within the study area of the proposed road development (**Table 13.5**). Six of the structures are also listed within the National Inventory of Architectural Heritage (NIAH) (see **Section 13.3.1.6**).

Of the 27 structures, nine are also classed as Recorded Monuments (BH 9, 10, 13, 14, 16, 17, 18, 21, 23). As such, these sites are also subject to statutory protection under the National Monuments Act.

The detail relating to each BH site is included in **Appendix A.13.4** of this EIAR and marked on **Figures 13.1.01** to **13.1.14**.

Table 13.5: Built Heritage (BH) sites located within the receiving environment

BH 23	5704	Mionlach	Pillar stone (Also AH 22)	9+850	530m northwest of proposed road development 68m north of area proposed for habitat planting	No
BH 24	5709	Mionlach	Thatched cottage	9+850	586m northwest of proposed road development.	Yes

BH No.:	RPS No.:	Townland:	Classification:	Approx. Ch.	Dist. from proposed road development	NIAH
					97m north of area proposed for habitat planting	
BH 25	5708	Mionlach	Thatched cottage	9+000	596m northwest of proposed road development. 163m north of area proposed for habitat planting	Yes
BH 26	5707	Mionlach	Thatched cottage	9+950	645m northwest of proposed road development. 191m north of area proposed for habitat planting	Yes
BH 27	5711	Mionlach	Thatched cottage	9+950	319m northwest of proposed road development. 200m northeast of area proposed for habitat planting	Yes

Of the 27 Protected Structures, one is located within the footprint of the proposed road development. This consists of a single storey thatched cottage within the townland of An Caisleán Gearr (BH 12). The structures identified at Mionlach (BH 21-27) are located within the receiving environment of the area proposed for habitat planting rather than the proposed road development.

13.3.1.5 National Inventory of Architectural Heritage structures (BH sites) within the Receiving Environment

A review of the National Inventory of Architectural Heritage (NIAH) has shown that there are 13 NIAH structures located within the receiving environment of the proposed road development (**Table 13.6**). All of these structures are listed as protected in the Galway City Development Plan. In addition, two of the buildings are also Recorded Monuments (Menlo Castle BH 10/AH 16 and Menlo Castle Gate house BH 21/AH 41).

Inclusion within the NIAH does not confer statutory protection. However, as the buildings are listed within the Record of Protected Structures, these buildings are subject to statutory protection under the Planning and Development Act (2000).

The detail relating to each BH site is included in **Appendix A.13.4** of this EIAR and marked on **Figures 13.1.01** to **13.1.14**.

Table 13.6: National Inventory of Architectural Heritage (BH) sites located within the receiving environment

BH No.	NIAH No.	Townland	Classification	Approx. Ch.	Dist. from proposed road development	RPS
BH 4	30408205	Barnacranny	Thatched cottage	8+450	6m southwest	Yes

BH 26	30408213	Mionlach	Thatched cottage	9+950	645m northwest of proposed road development. 191m north of area proposed for habitat planting	Yes
BH 27	30408217	Mionlach	Thatched cottage	9+950	319m northwest of proposed road development. 200m northeast of area proposed for habitat planting	Yes

13.3.1.6 Architectural Conservation Areas (ACAs) within the Receiving Environment

A review of the Galway City Development Plan and Galway County Development Plan, has shown that there are no ACAs located within the receiving environment of the proposed road development. The closest ACA, Bearna Village and environs, is located over 940m to the southeast of the proposed road development.

13.3.1.7 Designed Landscapes

A number of sources were reviewed in order to define the nature and extent of designed landscapes within the receiving environment of the proposed road development. These included the historic Ordnance Survey (OS) mapping, aerial photographic coverage, the NIAH Garden Survey, the Landed Estates Database and field inspections.

A total of nine designed landscapes have been identified within the receiving environment of the proposed road development (**Table 13.7**). Of these, four are associated with a principal structure that is listed as protected within the Galway City Development Plan. The landscapes are shown as shaded 'demesne' landscapes on the first edition OS mapping. These environments were intended to represent a natural parkland setting for a large house, a practice that became fashionable from the latter part of the 18th Century onwards. The landscapes, which can vary greatly in size, often possess specific features, such as long driveways, gate lodges, stately entrances, walled gardens, bodies of water and belts, avenues and clumps of deciduous and specimen trees.

The identified designed landscapes are listed in **Table 13.7** and described in more detail in **Appendix A.13.5** of this EIAR and shown on **Figures 13.1** to **13.14**.

Table 13.7: Designed Landscapes (DL) located within the receiving environment

DL No.:	Townland:	Description:
DL 1	Bearna, Cluain na nGabhar, Gort na Leice, An Roisín, An Seanbhaile Dubh, Baile an Mhóinín Thoir	Barna House and demesne. Marked as a substantial demesne on the first edition OS map covering several townlands. NIAH garden survey lists it as 'Main features unrecognisable – peripheral features visible'[25]. Barna House is a protected structure. The northwest corner of the demesne is located c. 143m southeast of the proposed road development.
DL 2	Rahoon	Rahoon House and demesne. The house and a large demesne landscape are marked on the first edition OS map. The principal structure does survive today and is a protected structure (BH 18), but is surrounded by modern residential development. As such, the demesne has almost completely lost its original character. NIAH garden survey lists it as 'Virtually no recognisable features'[26]. A proposed link road will run through the northwest corner of the original demesne.
DL 3	Kentfield	Glenlo Abbey demesne. The house is named as 'Glenlough' on the first edition OS map and occupies a large demesne landscape. The early 20th Century map shows it renamed as 'Glenlo Abbey'. The NIAH garden survey records it as 'Main features unrecognisable – peripheral features visible'[27]. The principal structure is not a protected structure. The southeast corner of the demesne is located to the immediate north of the proposed road development where it extends along the N59 Moycullen Road.
DL 4	Bushypark	Bushypark House demesne. Marked on the first edition OS map as a modest demesne. The NIAH garden survey lists it as 'Main features substantially present – peripheral features unrecognisable'[28]. The principal structure is still extant (BH 5) and is listed as a protected structure. The proposed link road will terminate to the immediate southwest of the demesne and associated drainage infrastructure will extent through the eastern portion of the demesne.
DL 5	Barnacranny	Lake View House and demesne. Shown on the first edition OS map but not shaded. Not included within the NIAH garden survey. The house is still extant today but the garden has been

[25] NIAH Garden Ref.: GA-45-M-248237
[26] NIAH Garden Ref.: GA-45-M-273253
[27] NIAH Garden Ref.: GA-45-M-267283
[28] NIAH Garden Ref.: GA-45-M-272278

DL No.:	Townland:	Description:
		impacted upon by modern residential development (CH 39). The north-eastern side of the demesne is located to the immediate south of the proposed road development where it extends along the N59 Moycullen Road.
DL 6	Dangan Upper	Ashley Park demesne. This house is marked within a demesne landscape on the first edition OS map. The NIAH garden survey records it as 'possessing virtually no recognisable features'[29]. Whilst the principal structure remains extant today (CH 40, the remainder of the landscape has been covered with residential development. The north-eastern side of the demesne is located to the immediate south of the proposed road development where it extends along the N59 Moycullen Road.
DL 7	Dangan Lower	Dangan Cottage, Dangan House, Dangan Nunnery, Mary Ville demesnes. The first edition OS map shows a large demesne landscape containing a number of large structures although the boundaries between them are not clear. The NIAH garden survey only includes an entry for Dangan House (which actually refers to Dangan Cottage). It reports 'virtually no recognisable features remain'[30]. The proposed road development travels in a north-east direction through the original demesne lands.
DL 8	Mionlach	Menlo Castle Demesne. The NIAH garden survey records it as 'Main features unrecognisable – peripheral features visible'[31]. Today the principal structure survives in ruins on the site (BH 10) and there has been a small amount of modern development in the northern part of the demesne. For the most part it remains as green fields, although has been subject to division to suit farming requirements. Some woodland survives within the former demesne, but only a small percentage when compared to the historic mapping. The principal structure and its entrance are both protected structures. The proposed road development travels in a north-east direction through the original demesne lands. The western part of the original demesne is located within an area of proposed for habitat enhancement.
DL 9	Ballybrit	Ballybrit House demesne. Today the demesne is completely covered by development and a road and as such nothing survives. The NIAH garden survey

[29] NIAH Garden Ref.: GA-45-M-283271
[30] NIAH Garden Ref.: GA-45-M-284274
[31] NIAH Garden Ref.: GA-45-M-284278

DL No.:	Townland:	Description:
		lists the area as possessing 'virtually no recognisable features'[32]. A short section of proposed existing infrastructure upgrade in located in the northeast corner of the original demesne landscape location.

13.3.1.8 Summary of Previous Archaeological Investigations within the Receiving Environment

A review of the Excavations Bulletin (1970 – 2016) has revealed that a number of archaeological investigations have been carried out within the receiving environment of the proposed road development. These are summarised below in **Table 13.8**.

Table 13.8: Summary of Previous Archaeological Fieldwork carried out within the receiving environment

Excavations Bulletin Ref.:	Licence Ref.:	Townland:	Description:
2001:497	01E0992	Coolagh/ An Caisleán Gearr/ Ballybrit/ Parkmore/ Cappanabornia/ Glenanail/ Ballybaan Beg,	Nothing of archaeological significance was identified during the course of monitoring 4.1km of pipeline construction.
2002:0724	02E1327	Dangan Lower	Archaeological testing adjacent to a recorded ring barrow (AH 11) revealed no features of archaeological significance.
2005:579 & 2006:779	Ministerial Dir.: A024/1.3 & A024/5 E2435	Coolagh	Archaeological testing and full excavation was carried out prior to the development of the existing N6. A possible cashel (53m x 60m) was identified in the townland of Coolagh within the footprint of the proposed road development (although an associated annex wall was noted to the south of the proposed development boundary). A secure date for the site was not obtained due to the lack of stratified finds. However, a red bead and fragments of lignite bracelet as well as two possible lime kilns were noted within the interior along with the oval foundations of a stone structure. It is possible the site represents an earlier medieval cashel. The site is located to the immediate east of the eastern end of the proposed road development where it extends along the existing N6.

[32] NIAH Garden Ref.: GA-46-M-333272

Excavations Bulletin Ref.:	Licence Ref.:	Townland:	Description:
2000:0368	00E0144	Ballinfoyle, Glenanail, An Caisleán Gearr	Monitoring of the Terryland drainage scheme in the landscape to the north of the existing N6 failed to identify any features of archaeological significance.
2005:592 2006:790	A024/1.1 E2052	Doughiska	A series of burnt mounds were found during testing and then excavated immediately adjacent to the current proposed road development (AH 36), as part of an earlier phase of construction associated with the existing N6. Only one shallow pit was found with the remains. Presumed to be prehistoric in date.
2008:540	E3588	Doughiska	During monitoring associated with the construction of the existing N6, a well was identified c. 100m SSW of the current proposed road development. It was deemed to be post medieval in date.
2012:279	12E0055	Na hAille, An Cheapach	Nothing of archaeological significance discovered during monitoring associated with an 110kv electricity line.
1997:194	97E0341	An Caisleán Gearr	Archaeological testing to the immediate west of AH 25/BH 13 failed to identify any features of archaeological significance.
1998:237	98E0498	An Caisleán Gearr	In 1998 archaeological testing was carried out at the site of a souterrain, which was identified in 1967 c.100m south of the current proposed road development. Reports of the time (1968) also indicated the discovery of a number of skeletons. However, testing in 1998 in the area failed to identify any archaeology – it is possible that previously identified archaeological remains were removed during the intervening years during land clearance.
N/a	14R0089	Ballybrit	As part of the constraints and route selection stage of the proposed road development, a geophysical survey was carried out at the centre of Galway Racecourse at Ballybrit in 2014. Both magnetometry & targeted electromagnetic induction (quadrature) survey were carried out. The survey indicated that widespread disturbance had taken place across the site. Some potential archaeological anomalies were noted in small areas across the site, but no responses were noted as being definitively archaeological.

13.3.1.9 Aerial Photographic Analysis

Analysis of a number of aerial photographic data sets was carried out as part of this appraisal. These included:

- Google Earth vertical aerial photographs, 2003, 2005, 2006, 2007, 2009, 2011, 2012
- Ordnance Survey Ireland vertical aerial photographs, 1995, 2000, 2005
- Bing.com vertical aerial photographs (Digital Globe), 2012

One site of archaeological potential was identified within the townland of Mionlach. This consists of a discrete circular anomaly visible within the Digital Globe data set (CH 46). The anomaly corresponds to a circular feature depicted on the 25-inch OS mapping (1895 – 1900). This feature may relate to the demesne landscape (DL 8) associated with Menlo Castle (AH 11/ BH 2).

13.3.1.10 Results of Field Inspection

The field inspection sought to assess the route of the proposed road development, its previous and current land use, the topography and to confirm the presence of any areas or sites of archaeological potential. During the course of the field investigation the full extent of the route of the proposed road development, and, where practicable, its immediate surrounding environs were inspected for known or previously unknown archaeological sites. The inspection was carried out in windy and wet conditions between the 30 of November to the 04 of December 2015 and during sunny conditions on the 26 of July 2016.

The route of the proposed road development traverses approximately 16.8km of ground which describes a generally northeast- southwest arcing corridor from the townland of An Baile Nua west of Bearna to Coolagh to the east of Galway City. The proposed road development traverses, for the most part, undeveloped, agricultural land. Extended areas of the route of the proposed road development are overgrown with gorse and bramble. The proposed road development is divided into two distinct sections by the River Corrib at Dangan/Menlough. This watercourse also represents the boundary of a clear geological divide between the western and eastern sections of the proposed road development. To the west of the N59 Moycullen Road, the underlying geology is granite and the landscape is characterised by a pattern of irregularly shaped, undulating enclosed fields delineated by drystone granite walls. Stretches of exhausted blanket bog are also common and many fields, particularly in the vicinity of Bearna have been left fallow and are entirely overgrown and inaccessible. To the east of the River Corrib, the underlying geology is limestone and the landscape is characterised by a pattern of larger, generally rectangular fields of improved bog pasture. The notable exceptions to this pattern were encountered within the overgrown demesne landscape of Menlough which comprises small overgrown fields covered in dense hazel and ivy growth and in the vicinity of the limestone quarry in Coolough, Lackagh Quarry, where extended areas of bare limestone pavement were observed.

A full record of the field inspection, including a summary of those areas that were not accessible, is included in **Appendix 13.6** of this EIAR. Photographs illustrating a variety of sites are included in **Appendix 13.7** and the route of the proposed road development and various sites are shown on **Figures 13.1.01** to **13.1.14**.

13.3.1.11 Previously Unrecorded Sites/ Structures of Cultural Heritage Merit

A number of previously unrecorded sites and structures of archaeological and architectural heritage merit have been identified during the course of this appraisal through the analysis of historic mapping, aerial photographs and field inspections. In order to reflect the fact that these sites are not subject to statutory protection, they have been listed as Cultural Heritage sites (CH). These are included in **Table 13.9** and shown on **Figures 13.1.01** to **13.1.14**.

Table 13.9: Previously Unrecorded sites of Cultural Heritage merit located within the receiving environment

CH No.	Townland:	Description:	Approx. Ch.	Dist. from proposed road development
CH 1	Na Foraí Maola Thiar	Site of vernacular structures marked on 1841 first edition map. No longer extant	0+150	15m west
CH 2	Na Foraí Maola Thiar	Site of vernacular structures marked on 1841 first edition OS map. No longer extant	0+130	0m
CH 3	Na Foraí Maola Thiar	Single storey vernacular cottage marked on the 1895 – 1900 25" OS map	0+175	145m east
CH 4	Na Foraí Maola Thiar	Sub-circular stone enclosure (Also AH 1 redundant record)	0+500	7m east
CH 5	Na Foraí Maola Thiar	Site of ruined vernacular structures marked on the 1841 first edition OS map	0+450	72m east
CH 6	Troscaigh Thiar	Single storey vernacular cottage marked on the 1895 – 1900 25" OS map	1+550	77m north-northwest
CH 7	Na Foraí Maola Thoir	Single storey vernacular cottage marked on the 1841 first edition OS map	1+500	10m south
CH 8	Troscaigh Thiar	Walled laneway marked on the 1841 first edition OS map	1+950	0m
CH 9	Troscaigh Thiar	Possible famine bridge	1+650	119m northeast
CH 10	Troscaigh Thiar	Site of a post medieval sheep fold. No longer extant	2+110	0m
CH 11	Troscaigh Thiar	Single storey vernacular cottage marked on the 1895 – 1900 25" OS map	2+250	17m west

CH No.	Townland:	Description:	Approx. Ch.	Dist. from proposed road development
CH 12	Troscaigh Thiar	Ruins of a vernacular building marked on the 1895 – 1900 25” OS map	2+150	140m west
CH 13	Troscaigh Thoir	Vernacular cottage and associated farm buildings. Some marked on the 1841 first edition OS map	2+400	33m south
CH 14	An Chloch Scoilte	Vernacular cottage. Marked on the 1895 – 1900 25” OS map	2+700	102m northwest
CH 15	An Chloch Scoilte	Ruins of a vernacular cottage. Marked on the 1895 – 1900 25” OS map.	2+800	210m north
CH 16	An Chloch Scoilte	The ruinous remains of the post medieval settlement of An Chloch Scoilte. The first edition OS map shows 18 structures in this area. By the time of the 1895-1900 25” OS map only six structures remain with a further two shown in ruins. Today four ruined structures survive along with one cottage that is still inhabited	2+900	191m north
CH 17	Troscaigh Thoir	Vernacular cottage, now extended. Marked on the 1895 –1900 25” OS map	3+075	146m south-southeast
CH 18	An Chloch Scoilte	Vernacular cottage, now extended. Marked on the 1895 –1900 25” OS map	3+260	0m
CH 19	An Cheapach	Vernacular cottage and associated farm building. Marked on the 1841 first edition OS map	4+350	116m north-northwest
CH 20	An Cheapach	Vernacular cottage and outbuildings. Marked on the 1895 – 1900 25” OS map	4+340	10m south
CH 21	An Cheapach	Site of vernacular structures marked on the 1841 first edition OS map. No longer appears to be extant	4+520	14m north
CH 22	An Cheapach	Group of ruined vernacular structures marked on the 1841 first edition OS map	4+450	20m east
CH 23	An Cheapach	Vernacular cottage marked on the 1895 – 1900 25” OS map. Now derelict but is upstanding and retains its pitched slate roof	4+600	6m southeast
CH 24	Ballynahown East	Ruins of a vernacular cottage marked on the 1841 first edition OS map	4+900	35m southeast

CH No.	Townland:	Description:	Approx. Ch.	Dist. from proposed road development
CH 25	Keeraun	Vernacular farm yard marked on the 1841 first edition OS map and the 1895 – 1900 25" OS map	5+500	24m northwest
CH 26	Keeraun	Vernacular cottage marked on the 1895 – 1900 25" OS map. Extended to the east with several concrete structures with corrugated roofs but the main cottage is now derelict	5+650	0m
CH 27	Keeraun	Vernacular cottage marked on the 1895 – 1900 25" OS map	5+700	23m west-northwest
CH 28	Keeraun	Vernacular cottage marked on the 1895 – 1900 25" OS map	5+900	217m north-northeast
CH 29	Mincloon	Site of vernacular structures marked on 1841 first edition OS map. No longer extant	6+300	0m
CH 30	Mincloon	Vernacular house and farmstead, marked on the 1895 – 1900 25" OS map	6+450	13m west
CH 31	Mincloon	A number of vernacular outbuildings marked on the 1895-1900 second edition OS map	6+500	75m east-southeast
CH 32	Mincloon	A stone outbuilding marked on the 1915 – 20 third edition OS map	6+500	0m
CH 33	Rahoon	Very well-built stone-walled laneway, marked on the 1841 first edition OS map	6+975	0m
CH 34	Rahoon	Site of vernacular structures marked on 1841 first edition OS map. No longer extant	7+280	0m
CH 35	Rahoon	Leitriff House. Two-storey farm house with four bays. Named and extended on 1895 – 1900 25" OS map	7+350	88m southeast
CH 36	Letteragh	A very well-built stone-walled laneway, marked on the 1841 first edition OS map	7+410	0m
CH 37	Dangan Upper	Well-built cairns from stone clearance. Not marked on the OS maps	7+600	0m
CH 38	Ballagh	Possible square enclosure. Not marked on the OS maps	N59 Link Road North 0+150	0m
CH 39	Barnacranny	Lake View House. Recently renovated two storey house.	8+350	39m southeast

CH No.	Townland:	Description:	Approx. Ch.	Dist. from proposed road development
		Marked on the 1841 first edition OS map		
CH 40	Dangan Upper	Ashley Park. Single storey house marked on the 1841 first edition OS map	8+700	19m southeast
CH 41	Dangan Lower	Mary Ville. Single storey house over rear basement with outbuildings. Marked on the 1895 – 1900 25” OS map	8+950	15m east
CH 42	Dangan Lower	Ruined stone outbuilding that is marked on the 1895 – 1900 25” OS map	8+725	8m southeast
CH 43	Dangan Lower	Site of Dangan Cottage. Marked on the 1841 first edition OS map, in ruins by the 1895 – 1900 25” OS map	8+800	27m southeast
CH 44	Dagan Lower	Site of walled garden and outbuildings associated with Dangan House (Nunnery). Shown the 1841 first edition OS map	9+100	38m northwest
CH 45	Mionlach	Possible boating inlet off the River Corrib. Shown on the 1895 – 1900 25” OS map but not annotated	9+450	33m southeast
CH 46	Mionlach	Possible circular enclosure identified during AP analysis and marked as a possible feature on the 1895-1900 25” OS map	9+600	28m southeast of alignment (within proposed habitat enhancement for bats)
CH 47	Mionlach	Possible vernacular animal shelter. Not marked on the historic mapping (2006 EIS)	9+700	34m northwest
CH 48	Mionlach	Possible consumption wall (2006 EIS)	9+600	24m northeast
CH 49	Mionlach	Possible prehistoric tomb (2006 EIS)	9+850	0m
CH 50	Mionlach	Possible circular feature (2006 EIS)	10+375	56m south
CH 51	Mionlach	Possible boulder of archaeological potential (2006 EIS)	10+500	0m
CH 52	Mionlach	Site of vernacular structures marked on the 1841 first edition OS map. No longer appear to be extant	10+600	0m
CH 53	An Caisleán Gearr	Ruins of a vernacular structures marked on the 1841 first edition OS map	13+225	97m south-southeast

CH No.	Townland:	Description:	Approx. Ch.	Dist. from proposed road development
CH 54	An Caisleán Gearr	Vernacular cottage marked on the 1895 – 1900 25” OS map	13+775	39m north
CH 55	Parkmore	Site of vernacular structures marked on 1895 – 1900 25” OS map. No longer extant	13+925	0m
CH 56	Parkmore	Site of vernacular structures marked on 1895 – 1900 25” map. No longer extant	14+120	0m
CH 57	Parkmore	Possible mass path. Sections of which are shown within historic mapping but not annotated	14+200	0m
CH 58	Coolagh	Site of vernacular structures, including a school, marked on the 1841 first edition OS map and the 1895 – 1900 25” OS map. No longer extant	15+850	0m
CH 59	Breanloughaun	Vernacular outbuilding. Marked on the 1895 – 1900 25” OS map	15+800	150m east-northeast
CH 60	Coolagh	Two storey vernacular farm house and associated outbuilding. Marked within the 25” OS map	16+400	169m northeast
CH 61	Coolagh	Renovated vernacular cottage and outbuilding. Marked on the 1895 – 1900 25” OS map	16+550	260m northeast
CH 62	Coolagh	Group of vernacular buildings comprising two single storey cottages, a two storey house and several outbuildings. One of the cottages is marked on the first edition OS map of 1841 and the remaining structures are shown on the 1895 – 1900 25” OS map. The structures are all upstanding but vary in condition	16+625	188m northwest
CH 63	Bushypark	Ruins of a vernacular structure shown on the 1895 – 1900 25” map	N59 Link Road North 0+000	3m northeast
CH 64	Letteragh	Vernacular cottage, now extended. Marked on the 1895 – 1900 25” OS map	N59 Link Road South 1+575	113m southeast
CH 65	Letteragh	Ruins of a vernacular cottage marked on the 1895 – 1900 25” OS map	N59 Link Road South 1+600	229m east-southeast
CH 66	Rahoon	Vernacular house, recently renovated. Marked on the 1895 – 1900 25” OS map	N59 Link Road	159m west-northwest

CH No.	Townland:	Description:	Approx. Ch.	Dist. from proposed road development
			South 2+050	
CH 67	Dangan Lower	Dangan House. A mid-19th century house in good condition. Likely under construction during compilation of the first edition OS map, as the structure is present but not labelled. By the time of the 1895 – 1900 25” OS map it is shown with outbuildings and annotated as ‘Dangan House’	9+100	199m southeast
CH 68	Bushypark	Disused railway	Pipeline wayleave	0m
CH 69	Bushypark	Potential mass rock	Pipeline wayleave	30m west-northwest
CH 70	Bushpark / Dangan Lower	Railway culvert	Pipeline wayleave	To the immediate east
CH 71	Mincloon	Walled trackway	6+200	0m
CH 72	Mionlach	Walled trackway	9+800	0m

13.3.1.12 Areas of Archaeological Potential (AAPs)

A number of areas of archaeological potential have been identified during the course of this appraisal through the analysis of historic mapping, aerial photographs and field inspections. These consist of features or areas within the receiving environment that often attract human activity, such as watercourses. The areas are described in **Table 13.10**.

Table 13.10: Areas of Archaeological Potential located within the receiving environment

AAP No.:	Townland:	Description:	Approx. Ch.	Dist. from proposed road development
AAP 1	Na Foraí Maola Thiar/ Cnoc na Gréine	Liberty Stream (TB 2)	0+430 - 0+650	0m
AAP 2	Troscaigh Thoir/ An Chloch Scoilte	Trusky Stream (TB 6)	2+650 - 2+950	0m
AAP 3	Na hAille/ An Cheapach	Barna Stream (TB 10)	3+850 - 4+150	0m
AAP 4	Ballynahown East	Stream (TB 12)	4+800 - 5+200	0m
AAP 5	Rahoon	Stream and boggy hollow	6+800 - 6+900	0m
AAP 6	Rahoon	Small stream	7+300 - 7+375	0m

AAP 7	Barnacranny	Small stream	7+500 - 7+675	0m
AAP 8	Barnacranny	Boggy, waterlogged marginal lands	N59 Link Road North 0+500 to 0+850	0m
AAP 9	Dangan Lower/ Mionlach	River Corrib (TB 22)	9+175 - 9+525	0m
AAP 10	An Caisleán Gearr	Boggy pasture – margins of *Lough an Dúlaigh*	12+200 - 12+450	0m
AAP 11	An Caisleán Gearr	Boggy hollow (AH 24)	12+975 - 13+075	0m
AAP 12	Bushypark	Site of 'Loughaunnafraska'	Pipeline wayleave	0m

13.3.1.13 Townland Boundaries

The proposed road development traverses a total of 33 townlands, three parishes and two baronies as listed in **Table 13.3**.

The townland is an Irish land unit of considerable longevity as many of the units are likely to correspond to much earlier land divisions. However, the term townland was not used to denote a unit of land until the Civil Survey of 1654. It bears no relation to the modern word 'town' but like the Irish word *baile* refers to a place. It is possible that the word is derived from the Old English *tun land* and meant 'the land forming an estate or manor' (Culleton 1999, 174).

Gaelic land ownership required a clear definition of the territories held by each sept[33] and a need for strong, permanent fences around their territories. It is possible that boundaries following ridge tops, streams or bog are more likely to be older in date than those composed of straight lines (*ibid.* 179).

The vast majority of townlands are referred to in the 17th Century, when land documentation records begin. Many of the townlands are mapped within the Down Survey of the 1650s, so called as all measurements were carefully 'laid downe' on paper at a scale of forty perches[34] to one inch. Therefore, most are in the context of pre-17th Century landscape organisation (McErlean 1983, 315).

In the 19th Century, some demesnes, deer parks or large farms were given townland status during the Ordnance Survey and some imprecise townland boundaries in areas such as bogs or lakes, were given more precise definition (*ibid.*). Larger tracks of land were divided into a number of townlands, and named Upper, Middle or Lower, as well as Beg and More (small and large) and north, east, south and west (Culleton 1999, 179). By the time the first Ordnance Survey had been completed a total of 62,000 townlands were recorded in Ireland.

The proposed road development will traverse 31 townlands. Some of the boundaries follow natural watercourses, but many were defined properly in the 19th Century

[33] A sept is a group or clan
[34] 1 perch = 5.0292m

and are marked with dry stone walls. The development of road infrastructure and the expansion of Galway City has already impacted upon the landscape and in some circumstances the townland boundaries are no longer extant.

Table 13.11: Townland Boundaries crossed by the proposed road development

TB No.:	Townland:	Description:	Approx. Ch.	Dist. from proposed road development
TB 1	An Baile Nua/ Na Foraí Maola Thiar	Sea Road (R336)	0+000	0m
TB 2	Na Foraí Maola Thiar/ Cnoc na Gréine	Liberty Stream (Also AAP 1)	0+450 – 0+650	0m
TB 3	Na Foraí Maola Thiar/ Na Foraí Maola Thoir	Local Road	1+100	0m
TB 4	Na Foraí Maola Thoir/ Troscaigh Thiar	Local Road	1+550	0m
TB 5	Troscaigh Thiar/ Troscaigh Thoir	Hedgerow & modern fence	2+425	0m
TB 6	Troscaigh Thoir/ An Chloch Scoilte	Former site of townland boundary including a portion of stream (AAP 2)	2+650 - 2+850	0m
TB 7	Troscaigh Thoir/ An Chloch Scoilte/ Ballard West	Stone wall	2+975 - 3+200	0m
TB 8	Ballard West/ Ballard East/ An Chloch Scoilte	Local road. Boundary between Ballard West and East not extant	3+250 - 3+350	0m
TB 9	Ballard East/ Na hAille	Stone wall	3+490	0m
TB 10	Na hAille/ An Cheapach	Barna Stream (AAP 3)	4+100	0m
TB 11	An Cheapach/ Ballynahown East	Stone walled laneway	4+700 – 4+800	0m
TB 12	Ballynahown East/ Keeraun	Stream (AAP 4) and field boundary (boundary completely overgrown)	4+800 – 5+250	0m
TB 13	Keeraun/ Ballyburke	Stone wall and hedgerow	5+660 – 5+725	0m
TB 14	Ballyburke/ Mincloon	Stone wall	6+050	0m
TB 15	Mincloon/ Rahoon	Stone wall	6+800	0m
TB 16	Rahoon/ Letteragh	Stone wall, sections of which have been removed	7+400	0m
TB 17	Letteragh/ Barnacranny	Stone wall	7+550	0m

TB 18	Barnacranny/ Dangan Upper	Stone wall	7+740	0m
TB 19	Barnacranny/ Dangan Upper	No access granted	8+200	0m
TB 20	Dangan Upper/ Dangan Lower/ Kentfield/ Ballagh/ Bushypark	N59 Moycullen Road (crossed at 2 points)	8+525	0m
TB 21	Barnacranny/ Ballagh	Stone wall and ditch	N59 Link Road North 0+550	0m
TB 22	Dangan Lower/ Menlough	River Corrib (AAP 9)	9+350	0m
TB 23	Mionlach /Ballindooley	Stone wall	10+725	0m
TB 24	Coolagh/ Ballindooley/ An Caisleán Gearr	Quarried away	11+600	0m
TB 25	Ballindooley/ An Caisleán Gearr	Stone wall and hedgerow	11+600 – 12+250	0m
TB 26	An Caisleán Gearr/ Parkmore	Tuam Road	13+900	0m
TB 27	An Caisleán Gearr/ Cappanabornia	Hedgerow	13+840	0m
TB 28	Cappanabornia/ Parkmore	Tuam Road	13+840	0m
TB 29	Parkmore/ Pollkeen	Stone wall	14+350	0m
TB 30	Parkmore/ Ballybrit	Removed	14+750	0m
TB 31	Ballybrit/ Doughiska	Removed	15+600	0m
TB 32	Doughiska/ Coolagh/ Breanloughaun	Stone wall and road	15+750 – 16+800	0m
TB 33	Rahoon/ Letteragh	Stone wall	N59 Link Road South 1+620	0m

13.3.1.14 Analysis of placenames within the receiving environment

Townland and topographic names are an invaluable source of information on topography, landownership and land use within the landscape. They also provide information on history; archaeological monuments and folklore of an area. A place name may refer to a long-forgotten site, and may indicate the possibility that the remains of certain sites may still survive below the ground surface. The Ordnance Survey surveyors recorded townland names in the 1830s and 1840s, when the entire country was mapped for the first time. Some of the townland names in the study area are of Irish origin and through time have been anglicised. The main references used for the place name analysis is *Irish Local Names Explained* by P.W Joyce (1870) and the Place Names Database of Ireland. A description and possible explanation of each townland name in the environs of the proposed road development are provided in the below table.

Table 13.12: Townland Names within the study area

Name (English)	Name (Irish)	Derivation	Possible Meaning
New Village	An Sráidbhaile Nua	N/a	Likely to relate to establishment of Bearna Village
Forramoyle East & West	Na Foraí Maola Thoir & Thiar	*Fauran-maola*	Spring on the flat topped hillock
Trusky West & East	Troscaigh Thiar & Thoir	*Triucha*	A cantred or district
Cloghscolita	An Chloch Scoilte	*Chloch-scoilte*	The split stone
Ballard West & East	An Baile Ard Thiar & Thoir	*Baile-ard*	The high town
Aille	An Aill	*Aill*	The cliff
Cappagh	An Cheapach	*Ceapach*	Plot of tillage land
Ballynahown East	Baile na hAbhann Thoir	*Baile-na-hAbhann*	Town of the river
Keeraun	An Caorán	*Caorán*	Moorland
Mincloon	Mionchluain	*Meen-cluain*	The small or fine meadow
Rahoon	Ráthún	*Rath-ún*	The fort
Letteragh	Leitreach	*Leitreach*	The hillside
Ballagh	An Bealach	*Bealach*	The way/pass
Kentfield	Baile an Cheantaigh	N/a	Likely to relate to the name of a landowner
Bushypark	Páirc na Sceach	*Bohy-pairc*	Field of the hut or tent
Dangan Lower & Upper	An Daingean Íochtair & Uachtair	*Daingean*	A fortress
Barnacranny	Barr na Crannaí	*Barr-na-crann*	Top of the tree
Menlough	Mionlach	*Meen-lach*	The small or smooth lake
Castlegar	An Caisleán Gearr	*Caisleán-Gearr*	The short castle
Ballindooley	Baile an Dúlaigh	*Baile-an-Dúlaigh*	Town/Homestead of Dúlaigh
Cappanabornia	Ceapach na Boirne	*Ceapach-na-boirne*	Land of the burren (area of rocky land)
Parkmore	An Pháirc Mhór	*Pháirc-mór*	The large field

Name (English)	Name (Irish)	Derivation	Possible Meaning
Ballybrit	Baile an Bhriotaigh	*Baile-an-Bhriotaigh*	The town of the Britons
Pollkeen	An Poll Caoin	*Poll-caoin*	The pleasant hole
Doughiska	Dabhach Uisce	*Dabhach-uisce*	The water tank
Breanloughaun	An Bréanlochán	*Bréan-lochán*	The foul lake
Coolagh	An Chuailleach	*Cualacha*	Corner field

13.3.1.15 Results of Geophysical Survey

As part of the assessment, a geophysical survey was carried out within one area of potential identified during the baseline assessment and field inspection. This area is located within the townland of Bushypark and the survey area included an area adjacent to a church and graveyard (BH 7) and a previously unknown platform in the landscape that may possess archaeological potential (CH 38).

The geophysical survey was carried out by Earthsound Archaeological Geophysics on behalf of IAC Ltd for Galway County Council and TII. It took place on the 17 and 18 of November 2016 under licence 16R0190. Magnetometer and EM Apparent Electrical Resistance surveys were conducted.

The survey revealed a number of possible ditches across the survey area. Many of these are linear in formation and are likely to form boundary features. The resistance survey suggests that some may have a bank or wall feature associated with them. A series of relict field boundaries were also detected.

Possible archaeological evidence includes a number of possible burning or industrial sites, a sub-rectangular ditch and ditches. Further anomalies are likely to be associated with soil or geological conditions on site and / or near surface geological outcrops. No anomalies were detected which appear to be associated with Bushypark Church and no evidence can be seen to suggest that the associated graveyard extends into the survey area. The full report has been included as **Appendix 13.12**.

13.4 Characteristics of the Proposed Development

13.4.1 Construction Phase

A detailed description of the proposed road development and construction activities are provided in **Chapter 5, Description of Proposed Road Development** and **Chapter 7, Construction Activities**. The characteristics of the proposed road development at construction stage, in relation to archaeology, architectural and cultural heritage, will involve the excavation of those lands made available (within the proposed development boundary) in order to facilitate the construction of the proposed road development. Physical changes to the existing ground level, including water courses, has the potential to impact on archaeological, built heritage and cultural heritage sites. The potential impacts related to such characteristics are provided in **Section 13.5** and detail on how impacts may occur is provided in **Appendix A.13.10**.

13.4.2 Operational Phase

At the operational stage of the proposed road development there is the potential to impact on the settings of archaeological, built and cultural heritage sites, due to physical changes to the receiving environment. The potential impacts related to such characteristics are provided in **Section 13.5** and detail on how impacts may occur is provided in **Appendix A.13.10**.

13.5 Evaluation of Impacts

13.5.1 Introduction

The evaluation of the potential impacts on archaeology, architectural and cultural heritage was undertaken in accordance with the criteria set out in **Section 13.2.4**. A summary of all sites, structures, potential impacts and proposed mitigation is included in **Tables 13.21** to **13.26** in **Section 13.8**.

13.5.2 Do-Nothing Impact

If the proposed road development were not to proceed, there would be no adverse impact on the archaeological, architectural and cultural heritage resource.

13.5.3 Potential Construction Impacts

Ground disturbances associated with the construction of the proposed road development, such as the removal of topsoil and the excavation of those lands made available have the potential to directly and negatively impact on the following sites (**Table 13.13**). No indirect impacts arising from vibration or dust associated with construction activities are anticipated.

This represents the recommended assessment of significance and impact descriptions for the purposes of informing the overall assessment of the likely impact on the archaeological, architectural and cultural heritage.

Table 13.13: Archaeological Heritage (AH): Potential Construction Impacts

Impact Significance

Areas of Archaeological Potential

Ground disturbances associated with the proposed road development have the potential to have a moderate, significant or profound direct and negative impact on as yet undiscovered archaeological features, deposits or artefacts that have the potential to survive beneath the current ground surface or water level within designated AAPs 1-12.

Townland Boundaries

Ground disturbances associated with the proposed road development have the potential to have a moderate direct and negative impact on sections of the 33 townland boundaries located within the proposed development boundary of the proposed road development.

General

Ground disturbances associated with the proposed road development have the potential to have a moderate, significant or profound direct and negative impact on archaeological features, deposits or artefacts that have the potential to survive beneath the current ground surface with no surface expression.

13.5.4 Potential Operational Impacts

The operation of the proposed road development has the potential to indirectly and negatively impact on the following sites:

Table 13.17: Archaeological Heritage (AH): Potential Operation Impacts

Impact Significance						
Profound	Very Significant	Significant	Moderate	Slight	Not Significant	Imperceptible
-	-	**AH 15** Summer house **AH 16** Menlo Castle	**AH 29** Cashel etc.	**AH 11** Barrow **AH 12** Site of House **AH 23** Site of chapel **AH 26** Children's burial ground	-	**AH 8** Children's burial ground **AH 14** Designed landscape feature

Impact Significance						
Profound	Very Significant	Significant	Moderate	Slight	Not Significant	Imperceptible
-	-	**CH 20** Vernacular buildings **CH 23** Vernacular cottage	**CH 4** Sub-circular enclosure **CH 25** Vernacular buildings **CH 30** Vernacular complex **CH 35** Leitriff House **CH 42** Stone outbuilding **CH 54** Vernacular Cottage	**CH 7** Vernacular cottage **CH 19** Vernacular buildings **CH 21** Site of vernacular buildings **CH 22** Ruined vernacular buildings **CH 24** Ruined vernacular building **CH 39** Lakeview House **CH 45** Possible boat inlet **CH 47** Vernacular animal shelter **CH 50** Possible circular feature **CH 53** Ruined vernacular buildings **CH 60** Vernacular complex **CH 61** Vernacular cottage **CH 62** Vernacular complex **CH 67** Dangan House **CH 69** Potential mass rock	-	**CH 1** Site of vernacular buildings **CH 3** Vernacular cottage **CH 5** Site of vernacular buildings **CH 6** Vernacular cottage **CH 27** Vernacular cottage **CH 31** Vernacular buildings **CH 48** Possible consumption wall **CH 64** Vernacular cottage

No indirect impacts during the operational phase on Areas of Archaeological Potential or Townland Boundaries have been identified.

13.5.5 Neutral/No Predicted Impacts

There are no predicted direct or indirect impacts for the following sites: AH 1, AH 3, AH 7, AH 9, AH 18, AH 19, AH 21, AH 22/ BH 23, AH 24, AH 30, AH 31, AH 36, AH 38, AH 39, AH 41/BH 21, AH 40, BH 22, BH 24, BH 25, BH 26, BH 27, DL 9, CH 43, CH 44, CH 46.

The potential impact has been deemed as neutral for the following sites: AH 4, AH 5, AH 6, AH 10, AH 13, AH 17, AH 20, AH 25, AH 28, AH 32, AH 33, AH 34, AH 35, AH 37.

BH 3, BH 4, BH 6, BH 8, BH 11, BH 13, BH 16, BH 18, BH 19, BH 20.

DL 1, DL 3, DL 5, DL 6.

CH 9, CH 11, CH 12, CH 14, CH 15, CH 16, CH 17, CH 28, CH 40, CH 41, CH 59, CH 63, CH 65, CH 66.

13.6 Mitigation Measures

13.6.1 Introduction

The proposed mitigation measures for the archaeological, architectural and cultural heritage are outlined below and detailed in **Appendix A.13.11**. A summary of all sites, structures, potential impacts and proposed mitigation is included in **Tables 13.21** to **13.26** in **Section 13.8**.

13.6.2 Construction Phase

The proposed mitigation measures for the construction phase are as follows:

- A programme of archaeological test trenching will be carried out within the footprint of the proposed road development prior to construction going ahead. This will target the sites and areas of archaeological and cultural heritage potential as outlined in **Section 13.5.3** as well as previously undisturbed areas within the proposed development boundary.
- Test trenching will be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be identified, if that is deemed the most appropriate manner in which to proceed.
- Prior to demolition, the thatched cottage BH 12 will be subject to a full measured, written and photographic survey. This will be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.

- Excavation of all previously recorded archaeological sites – where these fall, in whole or in part, within the footprint of the development – will be carried out under Ministerial Direction in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist
- The demesne landscape associated with Menlo Castle (DL 8), at Dangan Lower (DL7) and at Bushypark House (DL4) will be subject to a detailed photographic and written record prior to the construction of the proposed road development. This will be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.
- All Cultural Heritage (CH) sites listed in **Table 13.17** that include built heritage remains will be subject to a detailed written and photographic survey (to include test trenching where appropriate). This shall be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be identified, if that is deemed the most appropriate manner in which to proceed.
- Archaeological wade or underwater assessments will be carried out at any natural water courses (AAPs) to be impacted upon by the proposed road development by disturbance to their banks or beds. This shall be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be identified, if that is deemed the most appropriate manner in which to proceed.
- Any section of Townland Boundary to be impacted upon will be subject to a detailed written and photographic survey (to include test trenching where appropriate). This shall be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be identified, if that is deemed the most appropriate manner in which to proceed.

13.6.3 Operational Phase

The proposed mitigation measures for the operational phase are listed below. These measures are proposed to mitigate the indirect impacts of the operational phase of the proposed road development on these features. It is noted that these measures will be carried out during or prior to the construction phase.

- AH 15, 16, 29, 11, 12, 23 and 26 will be subject to a detailed photographic and written landscape record to preserve their current setting prior to the construction and operation of the proposed road development. This shall be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.

- BH 1, 7, 9, 10 and 17 will be subject to a detailed photographic and written landscape record to preserve their current setting prior to the construction and operation of the proposed road development. This shall be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.
- CH 20, 23, 8, 25, 30, 35, 42 and 54 will be subject to a detailed photographic and written landscape record to preserve their current setting prior to the construction of the proposed road development. This shall be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.

13.7 Residual Impacts

13.7.1 Introduction

13.7.2 Construction Phase

Once the recommended mitigation measures have been applied, there will be no residual impact on the archaeological, architectural or cultural heritage resource as a result of the construction of the proposed road development.

13.7.3 Operational Phase

Whilst the proposed mitigation measures will record the current context of those sites which will be indirectly impacted, they will not fully remove the residual impact of the proposed road development on the setting of the following sites:

- AH 15/ BH 19 Menlo Castle – post mitigation the operation of the proposed road development will have an indirect moderate negative impact on the castle
- AH 16/ BH 10 Summer House – post mitigation the operation of the proposed road development will have an indirect moderate negative impact on the castle

13.7.4 Cumulative Impacts

Cumulative impacts are defined as the combination of many minor impacts creating one, larger, more significant impact (NRA, 2009 and EPA 2017). Cumulative impacts consider existing stresses on the natural environment as well as developments that are underway and in planning.

The cumulative impacts of the proposed road development on archaeology, architecture and cultural heritage with the following projects and plans have been assessed:

- N59 Maam Cross to Oughterard Road Project
- M17 Galway to Tuam Road Project

- N18 Oranmore to Gort Road Project
- N17 Tuam Bypass
- M6 Motorway
- Proposed Galway Harbour Port Extension
- Galway Transport Strategy (GTS), which includes the following:
    - Investigate prospective sites to the east of the city for Park and Ride
    - Bearna Greenway
    - Galway to Oughterard (part of the Galway to Clifden) Greenway
    - Galway City to Oranmore (part of the Galway to Dublin) Cycleway
- Galway City Development Plan 2017 – 2023
- Galway County Development Plan 2015 – 2021

No proposed developments have been identified that will result in a significant negative cumulative impact with the addition the proposed road development upon the archaeological, architectural and cultural heritage resource.

The proposed Galway to Oughterard (part of the Galway to Clifden) Greenway will see the reopening of the railway line and potentially the repair of railway heritage features. The proposed road development will impact on a portion of the original railway line route where it passes through Dangan Lower. Sections of the railway line have been removed over the years due to differing activities, meaning that the proposed road development will result in a slight negative cumulative impact on the route of the original railway line. The proposed Galway to Oughterard Greenway scheme will have a positive impact on the cultural heritage of the area, which will help to offset the potential negative cumulative impact associated with the proposed road development. No negative residual impacts have been identified in association with the route of the former railway.

13.8 Summary

A summary of all sites, structures, potential impacts and proposed mitigation is included in **Tables 13.21** to **13.26** below.

One recorded monument (AH 2), which is listed as a Bullaun Stone will be profoundly and directly impacted upon as shown on **Figure 13.1.05**. However, it should be noted that the feature was not located during a field inspection and could not be previously located during a survey carried out by the Archaeological Survey of Ireland. The proposed road development will also have a moderate impact on the site of a quarry (AH 27). This site is post medieval in date and possesses little archaeological significance.

Ground disturbances associated with the proposed road development in general have the potential to have a moderate, significant or profound direct and negative impact on archaeological features, deposits or artefacts that have the potential to survive beneath the current ground surface with no surface expression.

One protected structure (BH 12) will be profoundly and directly impacted upon. This building, which consists of a single storey thatched structure, will be demolished (following a full architectural survey by suitably qualified staff) prior to the construction of the proposed road development.

The demesne landscape associated with Menlo Castle (DL 8) will be subject to a direct significant impact. The direct impact on the demesne landscape at Dangan Lower (DL 7) and at Bushypark House (DL 4) it is defined as moderate. Due to the developed nature of the environs at Rahoon House (DL 2) the impact, whilst direct, is imperceptible.

A total of 12 significant direct impacts on previously unrecorded sites or structures of cultural heritage significance were identified, along with nine moderate direct impacts.

A total of 12 Areas of Archaeological Potential have been identified during the course of this assessment. They are characterised by areas containing boggy ground and water courses, which are known to have attracted human activity in the past. Ground disturbances associated with the proposed road development have the potential to have a moderate, significant or profound direct and negative impact on archaeological features, deposits or artefacts that have the potential to survive beneath the current ground surface or water level within the designated AAPs.

A total of 33 Townland Boundaries will be crossed by the proposed road development. The impact upon these boundaries has been defined as direct and moderate in nature due to the relatively small percentage of a feature to be impacted upon.

As part of the proposed road development, an area of land within the townland of Menlough will be given over for the purpose of enhancing the habitat for bats – a population of which reside in the area, see **Chapter 8, Biodiversity** for further details. A number of sites outside of the receiving environment of the actual footprint of the proposed road development have been identified within this area, including Recorded Monuments and Protected Structures (AH 9, AH 22, AH 38-41, BH 21, BH 22-27). No predicted impacts are anticipated upon these sites as a result of the proposed habitat enhancement at Menlough.

A programme of archaeological testing, archaeological underwater or wade surveys, building surveys and townland boundary surveys have been recommended in order to mitigate the identified impacted during construction upon the archaeological, architectural and cultural heritage resource. All of the proposed surveys will be carried out by the appropriately qualified personnel under Ministerial Directions and in consultation with the Department of Culture, Heritage and Gaeltacht and a TII Project Archaeologist.

Predicted indirect operational impacts include significant negative impacts on the ruined summer house at Dangan Lower (AH 15/ BH 9) and Menlo Castle (AH 16/ BH 10). Moderate negative impacts are predicted at a recorded cashel site (AH 29/ BH 17). A thatched cottage (BH 1) and church (BH 7) will also be subject to indirect, moderate impacts.

The Designed Landscapes will all be subject to the same level of impacts during operation as during construction due to the impacts on setting. Similarly, two cultural heritage sites will experience significant indirect impacts and seven will experience moderate indirect impacts. No AAPs or Townland Boundaries will be indirectly impacted upon.

It should be noted that there are no predicted impacts at ten AH sites, one DL and three CH sites.

The impact has been deemed as neutral for 14 AH sites; ten BH sites; four DLs and 14 CH sites.

A programme of surveys has been recommended in order to record the current landscape context of sites and structures to be indirectly significantly or moderately impacted upon. These will be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.

Table 13.23: Designed Landscapes (DL): Summary of sites, impacts and mitigation

DL No.	Townland:	Detail:	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
DL 1	Bearna, Cluain na nGabhar, Gort na Leice, An Roisín, An Seanbhaile Dubh, Baile an Mhóinín Thoir	Barna House demesne. NIAH garden survey lists it as 'Main features unrecognisable – peripheral features visible'[37]. Barna House is a protected structure.	The northwest corner of the demesne is located c. 143m to the southeast	Neutral	N/a	None required
DL 2	Rahoon	Rahoon House demesne. NIAH garden survey lists it as 'Virtually no recognisable features'[38]. The main house is a protected structure (BH 18).	Proposed link road will run through the northwest corner of the original demesne	Direct	Imperceptible negative	None required
DL 3	Kentfield	Glenlo Abbey demesne. The NIAH garden survey records it as 'Main features unrecognisable – peripheral features visible'[39]. The main house is not a protected structure.	The southeast corner of the demesne is located to the immediate north of the proposed road development where it extends along the N59 Moycullen Road	Neutral	N/a	None required

[37] NIAH Garden Ref.: GA-45-M-248237
[38] NIAH Garden Ref.: GA-45-M-273253
[39] NIAH Garden Ref.: GA-45-M-267283

DL No.	Townland:	Detail:	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
DL 4	Bushypark	Bushypark House demesne. The NIAH garden survey lists it as 'Main features substantially present – peripheral features unrecognisable'[40]. The principal structure is still extant (BH 5) and is listed as a protected structure.	The proposed link road will terminate to the immediate southwest of the demesne and associated drainage infrastructure will extent through the eastern portion of the demesne	Direct	Moderate negative	Written and photographic landscape record prior to construction
DL 5	Barnacranny	Lake View House demesne. Not included within the NIAH garden survey. The house is still extant today (CH 39).	The north-eastern side of the demesne is located to the immediate south of the proposed road development where it extends along the N59 Moycullen Road	Neutral	N/a	None required
DL 6	Dangan Upper	Ashley Park demesne. The NIAH garden survey records it as 'possessing virtually no recognisable features'[41]. The principal structure remains extant today (CH 40)	The north-eastern side of the demesne is located to the immediate south of the proposed road development where it extends along the N59 Moycullen Road.	Neutral	N/a	None required
DL 7	Dangan Lower	Dangan Cottage, Dangan House, Dangan Nunnery, Mary Ville demesnes.	The proposed road development travels in a north-east direction	Direct	Moderate negative	Written and photographic landscape record prior to construction

[40] NIAH Garden Ref.: GA-45-M-272278
[41] NIAH Garden Ref.: GA-45-M-283271

DL No.	Townland:	Detail:	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
		The NIAH garden survey only includes an entry for Dangan House (which actually refers to Dangan Cottage). It reports 'virtually no recognisable features remain'[42].	through the original demesne lands.			
DL 8	Mionlach	Menlo Castle Demesne. NIAH garden survey records it as 'Main features unrecognisable – peripheral features visible'[43]. Today the principal structure survives in ruins on the site (BH 10). The principal structure and its entrance are both protected structures.	The proposed road development travels in a north-east direction through the original demesne lands. The western part of the original demesne is located within an area of proposed for habitat enhancement.	Direct	Significant negative	Written and photographic landscape record prior to construction
DL 9	Ballybrit	Ballybrit House demesne. The NIAH garden survey lists the area as possessing 'virtually no recognisable features'[44].	A short section of proposed existing infrastructure upgrade in located in the northeast corner of the original demesne landscape location.	No impact	N/a	None required

Table 13.24: Cultural Heritage (CH): Summary of sites, impacts and mitigation

CH No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
CH 1	Na Foraí Maola Thiar	Site of vernacular structures. No longer extant.	0+150	15m west	Indirect	Imperceptible negative	None required
CH 2	Na Foraí Maola Thiar	Site of vernacular structures. No longer extant.	0+130	0m	Direct	Significant negative	Archaeological testing prior to construction
CH 3	Na Foraí Maola Thiar	Single storey vernacular cottage.	0+175	145m east	Indirect	Imperceptible negative	None required
CH 4	Na Foraí Maola Thiar	Sub-circular stone enclosure (Also AH 1 redundant record).	0+500	7m east	Indirect	Moderate negative	Written and photographic landscape record prior to construction
CH 5	Na Foraí Maola Thiar	Site of ruined vernacular structures.	0+450	72m east	Indirect	Imperceptible negative	None required
CH 6	Troscaigh Thiar	Single storey vernacular cottage.	1+550	77m north-northwest	Indirect	Imperceptible negative	None required
CH 7	Na Foraí Maola Thoir	Single storey vernacular cottage.	1+500	10m south	Indirect	Slight negative	Written and photographic landscape record prior to construction
CH 8	Troscaigh Thiar	Walled laneway.	1+950	0m	Direct	Moderate negative	Written and photographic record prior to construction
CH 9	Troscaigh Thiar	Possible famine bridge.	1+650	119m northeast	Neutral	N/a	None required.

CH No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
CH 10	Troscaigh Thiar	Site of a post medieval sheep fold. No longer extant.	2+110	0m	Direct	Moderate negative	Archaeological testing prior to construction
CH 11	Troscaigh Thiar	Single storey vernacular cottage.	2+250	17m west	Neutral	N/a	None required.
CH 12	Troscaigh Thiar	Ruins of a vernacular building.	2+150	140m west	Neutral	N/a	None required.
CH 13	Troscaigh Thoir	Vernacular cottage and associated farm buildings.	2+400	33m south			
CH 14	An Chloch Scoilte	Vernacular cottage.	2+700	102m northwest	Neutral	N/a	None required.
CH 15	An Chloch Scoilte	Ruins of a vernacular cottage.	2+800	210m north	Neutral	N/a	None required.
CH 16	An Chloch Scoilte	The ruinous remains of the post medieval settlement of An Chloch Scoilte.	2+900	191m north	Neutral	N/a	None required.
CH 17	Troscaigh Thoir	Vernacular cottage, now extended.	3+075	146m south-southeast	Neutral	N/a	None required.
CH 18	An Chloch Scoilte	Vernacular cottage, now extended.	3+260	0m	Direct	Significant negative	Written and photographic record prior to construction
CH 19	An Cheapach	Vernacular cottage and associated farm building.	4+350	116m north-northwest	Indirect	Slight negative	Written and photographic landscape record prior to construction

CH No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
CH 20	An Cheapach	Vernacular cottage and outbuildings.	4+340	10m south	Indirect	Significant negative	Written and photographic record prior to construction
CH 21	An Cheapach	Site of vernacular structures. No longer appears to be extant.	4+520	14m north	Indirect	Slight negative	Written and photographic landscape record prior to construction
CH 22	An Cheapach	Group of ruined vernacular structures.	4+450	20m east	Indirect	Slight negative	Written and photographic landscape record prior to construction
CH 23	An Cheapach	Vernacular cottage. Now derelict.	4+600	6m southeast	Indirect	Significant negative	Written and photographic record prior to construction
CH 24	Ballynahown East	Ruins of a vernacular cottage.	4+900	35m southeast	Indirect	Slight negative	Written and photographic landscape record prior to construction
CH 25	Keeraun	Vernacular farm yard.	5+500	24m northwest	Indirect	Moderate negative	Written and photographic landscape record prior to construction
CH 26	Keeraun	Vernacular cottage, now derelict.	5+650	0m	Direct	Significant negative	Written and photographic record prior to construction
CH 27	Keeraun	Vernacular cottage.	5+700	23m west-northwest	Indirect	Imperceptible negative	None required
CH 28	Keeraun	Vernacular cottage.	5+900	217m north-northeast	Neutral	N/a	None required.

CH No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
CH 29	Mincloon	Site of vernacular structures. No longer extant.	6+300	0m	Direct	Significant negative	Archaeological testing prior to construction
CH 30	Mincloon	Vernacular house and farmstead.	6+450	13m west	Indirect	Moderate negative	Written and photographic landscape record prior to construction
CH 31	Mincloon	A number of vernacular outbuildings.	6+500	75m east-southeast	Indirect	Imperceptible negative	None required
CH 32	Mincloon	A stone outbuilding.	6+500	0m	Direct	Moderate negative	Written and photographic record prior to construction
CH 33	Rahoon	Stone-walled laneway.	6+975	0m	Direct	Moderate negative	Written and photographic record prior to construction
CH 34	Rahoon	Site of vernacular structures marked. No longer extant.	7+280	0m	Direct	Significant negative	Archaeological testing prior to construction
CH 35	Rahoon	Leitriff House.	7+350	88m southeast	Indirect	Moderate negative	Written and photographic landscape record prior to construction
CH 36	Letteragh	Stone-walled laneway.	7+410	0m	Direct	Moderate negative	Written and photographic record prior to construction

CH No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
CH 37	Dangan Upper	Well-built cairns from stone clearance.	7+600	0m	Direct	Moderate negative	Written and photographic record prior to construction
CH 38	Ballagh	Possible square enclosure.	N59 Link Road North 0+150	0m	Direct	Significant negative	Archaeological testing prior to construction
CH 39	Barnacranny	Lake View House.	8+350	39m southeast	Indirect	Slight negative	Written and photographic landscape record prior to construction
CH 40	Dangan Upper	Ashley Park.	8+700	19m southeast	Neutral	N/a	None required.
CH 41	Dangan Lower	Mary Ville.	8+950	15m east	Neutral	N/a	None required.
CH 42	Dangan Lower	Ruined stone outbuilding.	8+725	8m southeast	Indirect	Moderate negative	Written and photographic landscape record prior to construction
CH 43	Dangan Lower	Site of Dangan Cottage.	8+800	27m southeast	No impact	N/a	None required.
CH 44	Dagan Lower	Site of walled garden and outbuildings associated with Dangan House (Nunnery).	9+100	38m northwest	No impact	N/a	None required.
CH 45	Mionlach	Possible boating inlet off the River Corrib.	9+450	33m southeast	Indirect	Slight negative	Written and photographic landscape record prior to construction

CH No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
CH 46	Mionlach	Possible circular enclosure identified during AP analysis.	9+600	28m southeast of alignment (within proposed habitat enhancement for bats)	No impact	N/a	None required.
CH 47	Mionlach	Possible vernacular animal shelter.	9+700	34m northwest	Indirect	Slight negative	Written and photographic landscape record prior to construction
CH 48	Mionlach	Possible consumption wall.	9+600	24m northeast	Indirect	Imperceptible negative	None required
CH 49	Mionlach	Possible prehistoric tomb.	9+850	0m	Direct	Significant negative	Archaeological testing prior to construction
CH 50	Mionlach	Possible circular feature.	10+375	56m south	Indirect	Slight negative	Written and photographic landscape record prior to construction
CH 51	Mionlach	Possible boulder of archaeological potential.	10+500	0m	Direct	Moderate negative	Archaeological testing prior to construction
CH 52	Mionlach	Site of vernacular structures. No longer appear to be extant.	10+600	0m	Direct	Significant negative	Archaeological testing prior to construction
CH 53	An Caisleán Gearr	Ruins of a vernacular structures.	13+225	97m south-southeast	Indirect	Slight negative	Written and photographic landscape record prior to construction

CH No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
CH 54	An Caisleán Gearr	Vernacular cottage.	13+775	39m north	Indirect	Moderate negative	Written and photographic landscape record prior to construction
CH 55	Parkmore	Site of vernacular structures marked. No longer extant.	13+925	0m	Direct	Significant negative	Archaeological testing prior to construction
CH 56	Parkmore	Site of vernacular structures. No longer extant.	14+120	0m	Direct	Significant negative	Archaeological testing prior to construction
CH 57	Parkmore	Possible mass path.	14+200	0m	Direct	Significant negative	Archaeological testing & written and photographic record prior to construction
CH 58	Coolagh	Site of vernacular structures. No longer extant.	15+850	0m	Direct	Significant negative	Archaeological testing prior to construction
CH 59	Breanloughaun	Vernacular outbuilding.	15+800	150m east-northeast	Neutral	N/a	None required.
CH 60	Coolagh	Two storey vernacular farm house.	16+400	169m northeast	Indirect	Slight negative	Written and photographic landscape record prior to construction
CH 61	Coolagh	Renovated vernacular cottage and outbuilding.	16+550	260m northeast	Indirect	Slight negative	Written and photographic landscape record prior to construction

CH No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
CH 62	Coolagh	Group of vernacular buildings. The structures are all upstanding but vary in condition.	16+625	188m northwest	Indirect	Slight negative	Written and photographic landscape record prior to construction
CH 63	Bushypark	Ruins of a vernacular structure.	N59 Link Road North 0+000	3m northeast	Neutral	N/a	None required.
CH 64	Letteragh	Vernacular cottage, now extended.	N59 Link Road South 1+575	113m southeast	Indirect	Imperceptible negative	None required
CH 65	Letteragh	Ruins of a vernacular cottage.	N59 Link Road South 1+600	229m east-southeast	Neutral	N/a	None required.
CH 66	Rahoon	Vernacular house, recently renovated.	N59 Link Road South 2+050	159m west-northwest	Neutral	N/a	None required.
CH 67	Dangan Lower	Dangan House.	9+100	199m southeast	Indirect	Slight negative	Written and photographic landscape record prior to construction
CH 68	Bushypark	Disused railway	Pipeline wayleave	0m	Direct	Moderate negative	Written and photographic record prior to construction
CH 69	Bushypark	Potential mass rock	Pipeline wayleave	30m west-northwest	Indirect	Slight negative	Written and photographic landscape record prior to construction
CH 70	Bushpark/ Dangan Lower	Railway culvert	Pipeline wayleave	To the immediate east	Direct	Moderate negative	Written and photographic record prior to construction

CH No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
CH 71	Mincloon	Walled trackway	6+200	0m	Direct	Moderate negative	Written and photographic record prior to construction
CH 72	Mionlach	Walled trackway	9+800	0m	Direct	Moderate negative	Written and photographic record prior to construction

Table 13.25: Areas of Archaeological Potential (AAP): Summary of sites, impacts and mitigation

AAP No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
AAP 1	Na Foraí Maola Thiar/ Cnoc na Gréine	Liberty Stream (TB 2)	0+430 -0+650	0m	Direct	Moderate-profound negative	Underwater archaeological assessment prior to construction
AAP 2	Troscaigh Thoir/ An Chloch Scoilte	Trusky Stream (TB 6)	2+650 -2+950	0m	Direct	Moderate-profound negative	Underwater archaeological assessment prior to construction
AAP 3	Na hAille/ An Cheapach	Barna Stream (TB 10)	3+850 -4+150	0m	Direct	Moderate-profound negative	Underwater archaeological assessment prior to construction
AAP 4	Ballynahown East	Stream (TB 12)	4+800 -5+200	0m	Direct	Moderate-profound negative	Underwater archaeological assessment prior to construction

AAP No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
AAP 5	Rahoon	Stream and boggy hollow	6+800 -6+900	0m	Direct	Moderate-profound negative	Underwater archaeological assessment & archaeological testing prior to construction.
AAP 6	Rahoon	Small stream	7+300 – 7+375	0m	Direct	Moderate-profound negative	Underwater archaeological assessment prior to construction
AAP 7	Barnacranny	Small stream	7+500 -7+675	0m	Direct	Moderate-profound negative	Underwater archaeological assessment prior to construction
AAP 8	Barnacranny	Boggy, waterlogged marginal lands	N59 Link Road North 0+500 to 0+850	0m	Direct	Moderate-profound negative	Archaeological testing prior to construction
AAP 9	Dangan Lower/ Mionlach	River Corrib (TB 22)	9+175-9+525	0m	Direct	Moderate-profound negative	Underwater archaeological assessment prior to construction
AAP 10	An Caisleán Gearr	Boggy pasture – margins of *Lough an Dúlaigh*	12+200 - 12+450	0m	Direct	Moderate-profound negative	Archaeological testing prior to construction
AAP 11	An Caisleán Gearr	Boggy hollow (AH 24)	12+975 – 13+075	0m	Direct	Moderate-profound negative	Archaeological testing prior to construction.

AAP No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
AAP 12	Bushypark	Site of 'Loughaunnafraska'	Pipeline wayleave	0m	Direct	Moderate-profound negative	Archaeological testing prior to construction

Table 13.26: Townland Boundaries (TB): Summary of sites, impacts and mitigation

TB No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
TB 1	An Baile Nua/ Na Foraí Maola Thiar	Sea Road (R336)	0+000	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 2	Na Foraí Maola Thiar/ Cnoc na Gréine	Liberty Stream (Also AAP 1)	0+450 – 0+650	0m	Direct	Moderate negative	Written and photographic record & underwater archaeological assessment prior to construction
TB 3	Na Foraí Maola Thiar/ Na Foraí Maola Thoir	Local Road	1+100	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 4	Na Foraí Maola Thoir/ Troscaigh Thiar	Local Road	1+550	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 5	Troscaigh Thiar/ Troscaigh Thoir	Hedgerow & modern fence	2+425	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 6	Troscaigh Thoir/ An Chloch Scoilte	Former site of townland boundary	2+650 - 2+850	0m	Direct	Moderate negative	Written and photographic record, underwater archaeological assessment

TB No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
		including a portion of stream (AAP 2)					and archaeological testing prior to construction
TB 7	Troscaigh Thoir/ An Chloch Scoilte/ Ballard West	Stone wall	2+975 - 3+200	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 8	Ballard West/ Ballard East/ An Chloch Scoilte	Local road. Boundary between Ballard West and East not extant	3+250 - 3+350	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 9	Ballard East/ Na hAille	Stone wall	3+490	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 10	Na hAille/ An Cheapach	Barna Stream (AAP 3)	4+100	0m	Direct	Moderate negative	Written and photographic record & underwater archaeological assessment prior to construction
TB 11	An Cheapach/ Ballynahown East	Stone walled laneway	4+700 – 4+800	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 12	Ballynahown East/ Keeraun	Stream (AAP 4) and field boundary (boundary completely overgrown)	4+800-5+250	0m	Direct	Moderate negative	Written and photographic record & underwater archaeological assessment prior to construction
TB 13	Keeraun/ Ballyburke	Stone wall and hedgerow	5+660 - 5+725	0m	Direct	Moderate negative	Written and photographic record prior to construction

TB No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
TB 14	Ballyburke/ Mincloon	Stone wall	6+050	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 15	Mincloon/ Rahoon	Stone wall	6+800	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 16	Rahoon/ Letteragh	Stone wall, sections of which have been removed	7+400	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 17	Letteragh /Barnacranny	Stone wall	7+550	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 18	Barnacranny/ Dangan Upper	Stone wall	7+740	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 19	Barnacranny/ Dangan Upper	No access granted	8+200	0m	Direct	Moderate negative	Written and photographic record/ archaeological testing, prior to construction
TB 20	Dangan Upper/ Dangan Lower/ Kentfield/ Ballagh/ Bushypark	N59 Moycullen Road (crossed at 2 points)	8+525	0m	Direct	Moderate negative	Written and photographic record prior to construction
TB 21	Barnacranny/ Ballagh	Stone wall and ditch	N59 Link Road North 0+550	0m	Direct	Moderate negative	Written and photographic record & archaeological testing prior to construction
TB 22	Dangan Lower/ Menlough	River Corrib (AAP 9)	9+350	0m	Direct	Moderate negative	Underwater archaeological assessment

TB No.	Townland	Description	Approx. Ch.	Dist. from proposed road development	Impact type	Potential Impact level	Mitigation
							& written and photographic record prior to construction
TB 23	Mionlach/ Ballindooley	Stone wall	10+725	0m	Direct	Moderate negative	Written and photographic record prior to construction

14 Material Assets – Agriculture

14.1 Introduction

This chapter of the EIAR consists of an appraisal of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, under the heading of material assets - agriculture.

This chapter initially sets out the methodology followed (**Section 14.2**), describes the receiving environment (**Section 14.3**), and summarises the main characteristics of the proposed road development which are of relevance for material assets – agriculture (**Section 14.4**). The evaluation of impacts of the proposed road development on material assets-agriculture are described (**Section 14.5**). Measures are proposed to mitigate these impacts (**Section 14.6**) and residual impacts are described (**Section 14.7**). The chapter concludes with a summary (**Section 14.8**) and reference section (**Section 14.9**).

This chapter has utilised the information gathered during the previous phases of the proposed road development to inform the material assets-agriculture impact appraisal. **Sections 4.12**, **6.5.7** and **7.6.7** of the **Route Selection Report** considered the material assets agriculture constraints within the scheme study area and compared the potential material assets - agriculture impacts of the proposed route options respectively. These sections of the Route Selection Report contributed to the design of the proposed road development which this chapter appraises.

14.2 Methodology

14.2.1 Introduction

This chapter is prepared having regard to the standard guidelines for environmental assessment published by the EPA in 2002, 2003 and draft guidelines published in 2015 and 2017 and also uses the guidelines for arriving at significance of impact as discussed in the UK Highway Agency Design Manual for Roads and Bridges. The information sources referred to in **Section 14.2.3** below are standard for agricultural impact assessment for new road developments.

14.2.2 Guidelines

The following guidelines were referred to while preparing and writing this chapter:

- EPA (Environmental Protection Agency): Guidelines on the information to be contained in environmental impact assessment reports, (Draft May 2017)
- EPA: Revised Guidelines on the Information to be contained in Environmental Impact Statements, (2002 and Draft, September 2015)
- EPA: Advice Notes For Preparing Environmental Impact Statements, (2003 and Draft, September 2015)

14.2.3 Data Sources and Consultations

The information sources which support this impact appraisal are described in **Table 14.1** below.

Table 14.1: Data sources used for the Agricultural Assessment

Information	Data Source
Agricultural statistics	• Census of Agriculture 2010[1] from the Central Statistics Office (CSO) – used to provide background data on the average size and enterprise mix of farms in County Galway • CSO, Average crop yields from 2008 – 2016 and Teagasc data for grass production at Ballyhaise Agricultural College (2008 – 2016)
Soils	• EPA digital soils data • The 'General Soil Map of Ireland' (1980) • Windshield survey, orthophotography, and on-farm surveys
Land use & farm details	• Land registry mapping data • Farmer interviews • Windshield survey • Orthophotography - used as an aid in examining farm layout and land quality

A consultation letter was sent to the Department of Agriculture, Food and the Marine November 2016.

14.2.3.1 Technical Limitations

The author was able to engage directly with landowners in relation to 145 land parcels[2] (74%) of a total of 195 agricultural land holdings directly affected by the proposed road development. Where landowners could not be contacted directly the following information sources used were:

- Roadside vantage point surveys
- Examination of aerial photography
- Reference to other desk information sources such as Land Registry Mapping, CSO statistics for County Galway and Digital Soil Data

The available data was sufficient for the agricultural impact appraisal along the entire proposed road development.

[1] The Census of Agriculture 2010 is the most up to date survey providing data on farm and enterprise types and size on a per County basis.
[2] Where landowners could not be contacted directly the agricultural consultant wrote to the landowner.

14.2.4 Study Area and Baseline Data Collection

The study area comprises of 195 agricultural land parcels that are directly affected by the proposed road development, a total area of approximately 1,096 hectares. The locations of these land parcels is shown in **Figures 14.1.1** to **14.1.14** and extends from Na Foraí Maola in the west of the study area to Coolagh in the east. Proximity to an expanding city has resulted in many smaller, fragmented holdings and this combined with poor land quality (particularly west of the Corrib) means that the sensitivity of agriculture along the proposed road development is low (48% of land parcels are low or very low sensitivity). Landowner interviews and on-site surveys were conducted by the author in January 2016 – December 2017. Where possible landowners were interviewed and asked to describe their farming enterprise, how the land is being used, how access is provided and to identify sensitive features on their farms such as farm yards, wells/springs and access tracks and gates.

14.2.5 Impact Assessment Methodology

The assessment of agricultural impacts involves:

1. Evaluation of the baseline environment, the types of farms and the sensitivity of the individual farms along the route of the proposed road development
2. Evaluation of the nature and magnitude of the effects on each farm and the effects on farming collectively along the entire route of the proposed road development and within County Galway
3. Having considered the sensitivity of the baseline agricultural environment and the magnitude of effects, the impact significance is predicted for:
    a. each land parcel affected along the route of the proposed road development
    b. agriculture collectively along the proposed road development (i.e. locally within the study area)
    c. agriculture within County Galway (i.e. regionally)

These three elements of the methodology are described in **Sections 14.2.6.1**, **14.2.6.2** and **14.2.6.3**. It is important to note that this agricultural appraisal assesses the changes that will occur to the physical agricultural environment and assumes that, because landowners are compensated for attributable financial losses, their financial status will not change.

14.2.5.1 Evaluation of sensitivity of farms

Each land parcel is evaluated to determine its sensitivity based mainly on the criteria shown in **Table 14.2** below.

Table 14.2: Criteria for categorisation of sensitivity of farms

Farm Enterprise Type	Sensitivity
Stud farm, Equestrian centre	High - Very High
Dairy farm, Intensive equine enterprises	High
Non-dairy grazing livestock enterprises (including beef, sheep and non-intensive equine) and grass cropping enterprise	Medium
Tillage	Medium
Rough Grazing, Bog, Forestry, Woodland (where poor land quality restricts farming practices)	Low - Very low

Each appraisal of sensitivity is subject to professional judgement and evaluation of other site specific factors such as the land quality and importance of the enterprise.

14.2.5.2 Evaluation of impact magnitude

The magnitude of the potential impact is assessed by predicting the change on the affected farm or on agriculture along the route of the proposed road development. For example, if the proposed road development takes 10% of an affected grassland farm, and provided the farm enterprise can continue after the proposed road development is constructed, it is possible to predict that the yield of grass from the farm will be affected by approximately 10%. In order to quantify the magnitude of the impact, typical baseline trends[3] in the agricultural environment are examined and interpreted using the author's professional judgement. Therefore, impacts which result in a 2.5% to 5% variation in yield are considered to create a low magnitude impact on the farm and are similar to natural baseline trends in yield and is considered low magnitude. Between 5% and 10% the magnitude of yield loss is starting to exceed the natural baseline trends and is considered medium. Yield effects which exceed 10% are considered to be high magnitude. Other factors affect the magnitude of impact such as, severance or separation of land, the duration of impact, the quality of land affected and impact on farm yards and other facilities on the farm. **Table 14.3** shows the criteria which are used to indicate the magnitude of impact and each assessment is subjected to professional judgement.

[3] According to CSO data (2008 – 2016) the yield of spring barley and winter wheat will vary by approximately 7.5% from the average mean yield. Similarly, according to Teagasc data for grass production at Ballyhaise Agricultural College (2008 – 2016), the natural trend is for grass production to vary on average by 8% from year to year.

Table 14.3: Indicative criteria for assessment of impact magnitude

Indicative Criteria	Impact Magnitude
• A high proportion of the land permanently taken (e.g. >10%) • A high proportion of farm permanently separated (e.g. > 15 %) • Farm buildings or water sources may be affected permanently	High – Very High
• A medium proportion of the farm permanently taken (e.g. 5% - 10%) • A medium proportion of farm permanently separated (e.g. 7 % - 15%) • Farm buildings or water sources may be affected but can be replaced • Temporary (construction) impacts which have long term effects	Medium
• A small proportion of the farm permanently taken (e.g. 2.5% - 5%) • A small proportion of farm separated or no separation (e.g. 2.5% - 7%) • Farm buildings or water sources generally not affected but if affected can be replaced • Temporary (construction) impacts which have short – medium term effects	Low
• A very small proportion of the farm taken (e.g. <2.5%) • A very small proportion of farm separated or no separation (e.g. <2.5% of the farm) • Temporary (construction) impacts which do not have residual effects	Negligible – Very Low

Impacts that occur during the construction phase will generally have low or very low magnitude because of the short duration (e.g. construction noise and vibration). Medium magnitude impacts may arise during construction where for example there is a long term impact on land drainage as a result of the construction activity.

14.2.5.3 Evaluation of significance of impact

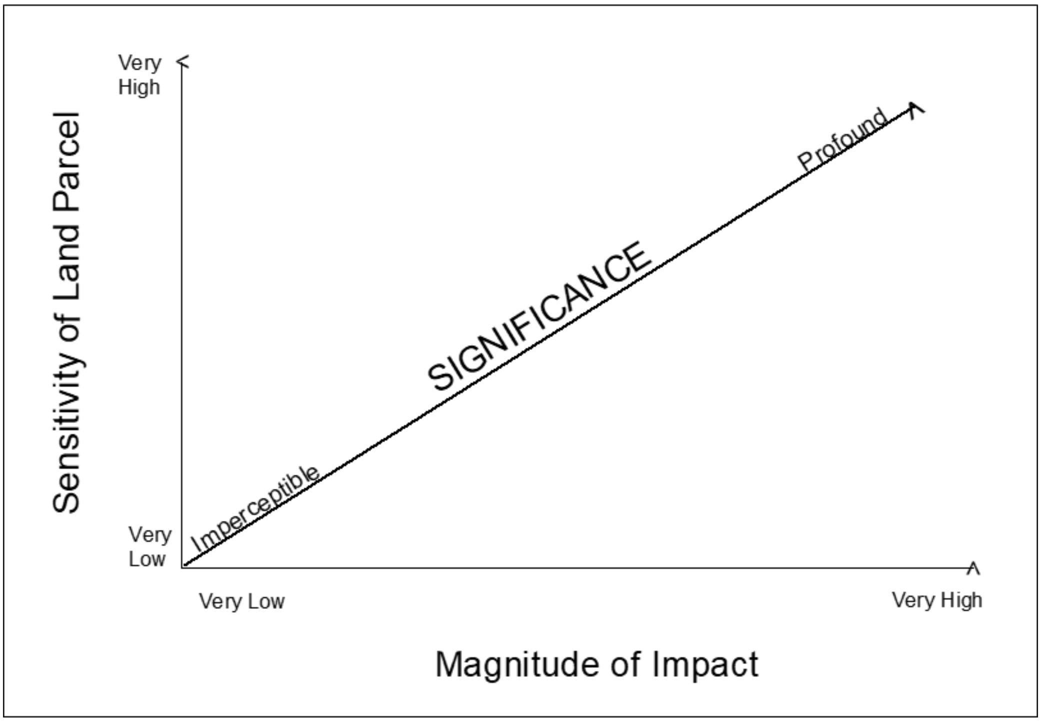
The significance of the impact is determined by evaluating both the magnitude of the impact and the sensitivity of the affected farm. Therefore, an impact which affects a farm with a low sensitivity will not be as significant as a similar magnitude of impact which affects a farm with a high sensitivity.

Section 3.7.3 of the EPA Guidelines on the information to be contained in environmental impact assessment reports (Draft, May 2017) contains guidelines for describing the significance of impacts. These guidelines have been adopted with minor adjustments that are appropriate for agricultural impact assessment. In general the impacts on agriculture are adverse in nature. The comparisons between the EPA guidelines and the criteria used in this appraisal are shown in **Table 14.4**.

Table 14.4: Comparison of significance of impact criteria used in this assessment with the EPA 2015 Guidance

Significance of impacts as per EPA 2017 Guidance	Significance of impacts used in this appraisal
Imperceptible Impact An effect capable of measurement but without significant consequences	**Not Significant Impact** An impact which may result in measurable effects and / or noticeable changes but the consequences are not significant.
Not Significant An effect which causes noticeable changes in the character of the environment without significant consequences	
Slight Impact An effect which causes noticeable changes in the character of the environment without affecting its sensitivities.	**Slight Adverse Impact** An impact which causes noticeable changes in the character and management of a farm in a minor way. The farm enterprise experiences inconvenience as a result of the proposed road development.
Moderate Impact An effect that alters the character of the environment in a manner that is consistent with existing emerging trends.	**Moderate Adverse Impact** An impact which alters the character of a farm in a manner that requires moderate changes in the management and operation of the farm. The farm enterprise can be continued as before but with increased management or operational difficulties.
Significant Impact An effect which by its character, magnitude, duration or intensity alters a sensitive aspect of the environment.	**Significant and Very Significant Adverse Impact** An impact which by its character, magnitude, duration or intensity alters a sensitive aspect of the farm. The farm enterprise can be continued, but will require major changes in management and operation of the farm. This would typically occur where the farm was split in two due to separation but where access between the separated portions and the farm buildings could still be achieved effectively. Assuming the enterprise can continue the degree of change in the management and operation of the farm will determine whether the impact is Significant or Very Significant.
Very Significant Impact An effect which by its character, magnitude, duration or intensity alters the majority of a sensitive aspect of the environment.	
Profound Impact An effect which obliterates sensitive characteristics.	**Profound Adverse Impact** An impact which obliterates sensitive characteristics of the farm. The farm enterprise cannot be continued as a result of the proposed road development. This would occur where landtake was of such a scale that the remaining land would not form a viable unit or where separation was of such a nature to make the holding unworkable or where important farm buildings and facilities were removed and could not be replaced. In some situations, the farm enterprise may continue but will require dramatic changes in the future management and operation of the farm, such that the scale and operation of the enterprise is changed dramatically.

Plate 14.1: Significance of Impact on Land Parcel Impacts



Significance of impact is determined by evaluating the magnitude of impacts and sensitivity of the farm. This assessment is subject to variation due to professional judgement on a case by case basis.

14.3 Receiving Environment

14.3.1 Agricultural Enterprise Types

195 land parcels are directly affected by the proposed road development. The locations of these land parcels are shown on **Figures 14.1.1** to **14.1.14**. **Table 14.5** below compares land use along the route of the proposed road development to the statistics for County Galway. The Census of Agricultural (2010) Statistics categorises land use into eight agricultural groups: specialist tillage, specialist dairy, specialist beef, specialist sheep, mixed grazing livestock, mixed crops and livestock, mixed field crops (mainly hay & silage) and other. For this appraisal the number of groups is reduced to five for comparison purposes as follows:

- Mainly Dairy - entirely a dairy farm or the dairy enterprise is the most significant target of the impact). Generally high sensitivity
- Non-dairy grazing livestock and mixed field crops– includes specialist beef cattle, specialist sheep, and mixed farms with cattle, sheep and horses. Generally medium sensitivity
- Mainly tillage - tillage cropping. Generally medium sensitivity
- Mixed crops and livestock - various crops and livestock. Medium sensitivity
- Other (e.g. pigs, poultry, horticultural cropping and equine as the main enterprises). Medium – very high sensitivity

The Census of Agriculture 2010 statistics show that the average size of farms in County Galway is 25.8 hectares. This compares to a national average size of 32.7 hectares. The average size of land parcels along the route of the proposed road development is approximately 6.0 hectares. The small size of land parcels along the proposed road development is a result of the close proximity to Galway City. Many holdings have been subdivided among family members and land has been sold for development. Approximately 21% of land parcels are less than 1 hectare in size and therefore have limited agricultural use. Beef farming is the main enterprise along the route of the proposed road development. Compared to the national average the number of small equine enterprises along the proposed road development is high; these horses are mainly kept for leisure purposes.

Table 14.5: Land Use Statistics along the Proposed Road Development compared to National and Regional Statistics

Farm/Enterprise Category	Total Nos. of affected land parcels within each category	% of farms within each category		
		Land parcels along proposed road development	Farms in Co. Galway	Farms nationally
Mainly Dairy	6	3	3	11
Beef and/or sheep and hay/silage	123 (4 with sheep)	63	95	82.5
Mainly Tillage	0	0	0.5	3.5
Mixed Crops & Livestock	0	0	1	2
Other (Equine)	34 (31 equine)	17.5	0.5	1
Not Farmed	32	16.5	0	0
Total	195	100	100	**100**

Table 14.5 shows that the main farm enterprise along the route of the proposed road development is beef (and sheep). The sensitivity of these land parcels range from very low to medium. There is one high sensitivity beef enterprise (cattle trader – PRO[4] 701) and two high[5] sensitivity dairy enterprises (PRO 239 & PRO 241). The Galway Racecourse (MO[6] 691) is classified as very high sensitivity due to the equine enterprise and regional importance. There are two very high sensitivity equine land parcels (MO 751 & MO 760) and the remaining equine enterprises are medium, low or very low sensitivity enterprises where horses and donkeys are kept mainly for leisure purposes. See **Appendix 14.1** for details of each individual land parcel.

[4] Protected Road Scheme Reference Number
[5] There are six dairy land parcels. Two dairy farmers rent four adjoining land parcels which are classified as medium sensitivity.
[6] Motorway Scheme Reference Number

14.3.2 Soil Types

Soil types along the route of proposed road development are described in detail in **Chapter 9, Soils and Geology** of this EIAR. In general, the soil quality is poorer west of the River Corrib. From the townland of An Baile Nua to Na hAille the dominant soil type is a peaty soil with rock out crops and interspersed with blanket bog. The drainage is poor and the land is wet. From Na hAille to the River Corrib the dominant soil type is a poorly drained mineral soil. East of the River Corrib the quality of land improves from an agricultural perspective; although the quality is variable. Adjoining the River Corrib there is low lying alluvium soils that are subject to flooding. Further east in Menlough and Ballindooley the topography is undulating and the dominant soil type is a mineral brown earth interspersed with a shallow soil with limestone out crop. From Ballindooley to Doughiska the dominant soil is a shallow free draining mineral soil. The topography is flat or gently undulating. This land is good quality grazing land and some of it is suitable for tillage. In general the soil types along the route of the proposed road development are suited to non-intensive grazing by beef cattle.

14.4 Characteristics of the Proposed Development

A detailed description of the proposed road development and construction activities are provided in **Chapter 5, Description of Proposed Road Development** and **Chapter 7, Construction Activities**. This section outlines the characteristics and activities of the proposed road development of relevance to material assets - agriculture.

The proposed road development will consist of a road carriageway, embankments, cut slopes, accommodation works, drainage features and planted/landscaped areas which will traverse agricultural lands. Approximately 219 hectares of land will be acquired from affected land parcels for the proposed road development.

14.4.1 Construction Phase

It is estimated that the construction period will last for approximately 36 months. At the beginning of the construction phase the land to be acquired will be fenced and access across it is restricted. In certain situations, temporary crossing points for livestock and machinery will be allowed until accommodation roads are constructed. Water and power supplies will be disrupted requiring alternative sources and ducting under the proposed road development. Watercourses will be diverted and the carriageway will be lower and higher than the adjoining farm land at different locations. This will disrupt land drainage requiring the construction of culverts and maintenance of the land drainage along the edge of the earthworks for the proposed road development.

Construction of the proposed road development will require activities such as excavation, tunnel work, pilling, rock breaking/blasting and movement of materials within the fenced off works area (ref. **Chapter 7, Construction Activities**). This will generate noise, dust and movement of machinery which will potentially impact on adjoining lands (ref. **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration**). The duration of these works will vary. In the worst case scenario (for example beside an in-situ crushing plant) this disturbance could last the entire construction period for that location, however, in general it is expected that construction activities such as rock breaking/blasting at any one location will last for a period of few days up to a few weeks.

14.4.2 Operational Phase

When the construction phase is complete and the mitigation measures implemented the residual effects of the proposed road development will be permanent. These effects will result in a change in the structure and layout of farms along the route of the proposed road development reducing the size and separating part of farms. A low level of disturbance will be experienced due to traffic. Landowners will be compensated to ensure they are not at a financial loss.

14.5 Evaluation of Impacts

14.5.1 Introduction

The potential impacts on each land parcel along the route of the proposed road development are evaluated and a summary presented in **Tables 14.6** and **14.7**. An assessment of the potential impacts on agriculture along the entire route (i.e. within the study area) is presented in **Sections 14.5.3** and **14.5.4**. The potential cumulative and regional impacts on agriculture are addressed in **Sections 14.5.5** and **14.5.6**.

14.5.2 Do Nothing Impact

Farmers as members of the local community regularly use the existing road network to access schools and shops and to purchase goods and sell produce. Tractors travel on the existing road network to access farms and herds of cattle. Lorries and goods vehicles deliver and collect goods from farms. In the “Do Nothing” scenario the existing traffic congestion will continue to have a small adverse impact on agriculture which is considered to be not significant.

14.5.3 Potential Construction Impacts

General construction noise and vibration and the generation of dust will have no significant or slight adverse impacts. Rock breaking/blasting and piling activities may result in a flight response in livestock but rarely causes a significant impact, particularly with mitigation, and will have no significant or slight adverse impacts. The landtake will result in the acquisition of farm buildings (mostly small sheds and outhouses) on 17 land parcels[7], which will result in temporary impacts because these facilities can be replaced with new buildings on the retained lands. There will be temporary disruption to power and water supplies but with mitigation the impact is not significant or slight adverse. Land drainage will be affected during the construction period where drainage outfalls from agricultural land is intercepted or blocked by the proposed road development. The proposed drainage design insures

[7] Ref Nos PRO/MO 117, 154, 229, 243, 259, 289, 495, 498, 572, 583, 625, 626, 632, 691, 689, 701 & 754

that all drainage outfalls are maintained or redirected to a suitable outfall and with mitigation the impacts are generally not significant.

Once the proposed development boundary fencing is erected the land inside it is no longer available to the landowner. The reduction in land area is a permanent impact and the range of impact due to loss of land ranges from not significant to profound. The proposed road development will cross 62 land parcels causing separation of part of the farm, separating approximately 163 hectares of land and creating 87 new land parcels. During construction temporary crossing points for livestock and machinery will be allowed until accommodation roads are constructed. Land separation is a permanent impact and the range of impact is not significant to significant adverse.

14.5.4 Potential Operational Impacts

The mitigation measures set out in **Section 14.6** will be constructed and implemented during the construction phase. Maintenance of the proposed road development will continue during the operational phase and in a very small number of cases remedial works may have to be carried out during the operational phase (e.g. maintenance of the fenceline along the mainline of the proposed road development). The land loss impact which commences with the fencing off of the acquired land during the construction period is a permanent residual impact that continues in the operational phase. The reduction in size will result in a reduction in farm output and the range of impact is not significant to profound. This impact cannot be mitigated except through compensation. In the longer term landowners may be able to replace the area of acquired land, but generally the replacement land will be separated from the original holding. Similarly, the separation of parts of farms (often referred to a severance) is a permanent impact that can be mitigated by providing access roads to the separated land parcel. This will result in additional travel distances and additional fixed costs on a farm and the range of impact is not significant to significant adverse. Impacts on drainage are generally not significant or slight adverse. The permanent disturbance impact caused by traffic, noise, air emissions and lighting is not significant.

14.5.5 Summary of Potential Impacts

The potential (pre-mitigation) impacts on land parcels along the route of the proposed road development are summarised in **Table 14.6**.

Table 14.6: Summary of Potential (Pre-Mitigation) Impacts

	Numbers of Land parcels				
Significance of Impact	**Mainly Dairy**	**Beef / sheep and hay / silage**	**Other (incl. Equine)**	**Not farmed**	**Totals**
Not significant	2	33	8	16	**59**
Slight	1	22	6	8	**37**
Moderate	-	19	6	6	**31**
Significant	-	35	11	2	**48**

	Numbers of Land parcels				
Significance of Impact	**Mainly Dairy**	**Beef / sheep and hay / silage**	**Other (incl. Equine)**	**Not farmed**	**Totals**
Very Significant	1	6	0	-	**7**
Profound	2	8	3	-	**13**
Total Nos. of Farms	**6**	**123**	**34**	**32**	**195**
	68 land parcels are predicted to have impacts which are significant adverse and greater (35% of all affected land parcels)				

The agricultural study area consists of 195 land parcels and 1,096 hectares of land of which approximately 219 hectares is within the proposed development boundary. Before mitigation, the potential impact on the study area is moderate adverse where in addition to 219 hectares of agricultural land which is acquired an additional, 172 hectares of land is separated without effective access (16% of the total agricultural area).

14.6 Mitigation Measures

14.6.1 Introduction

Mitigation of potential impacts takes place under two headings:

- General mitigation measures – described in **Sections 14.6.2 Construction Phase** and **14.6.3 Operational Phase** below
- Compensation under the Compulsory Purchase System – compensation to farmers for residual damage is part of the statutory process for compensation

14.6.2 Construction Phase

1. The landowner will be provided with access to all separated land parcels during the construction of the proposed road development. Where temporary disruptions to this access occur landowners will be notified in advance.
2. Where existing water and electricity supplies are disrupted during the construction phase an alternative water source or electricity supply will be made available e.g. water tanker or electric cable ducting. If access to surface drinking water sources are permanently restricted alternative groundwater supplies will be provided (or compensation to allow farmer drill his own well).
3. Suitable boundary fencing will be erected to delineate the line of the proposed development boundary and prevent disturbance to adjacent land.
4. A key contact person will be appointed during the construction phase to facilitate communications between affected landowners and to facilitate the re-organisation of farm enterprises by farmers during critical times.
5. Landowners with lands adjoining sites where either rock breaking, blasting or piling takes place will be notified in advance of these activities.

6. The impacts on water quality will be minimised by way of a programme of mitigation measures for surface and ground water sources as described in **Chapters 10, Hydrogeology** and **Chapter 11, Hydrology**.
7. The spread of dust onto adjoining lands will be minimised by way of mitigation measures set out in **Chapter 16, Air Quality and Climate**. Typically, the impact of dust on agricultural grazing livestock is not significant.
8. Where drainage outfalls are temporarily altered or land drains blocked or damaged an adequate drainage outfall will be maintained and land drains will be repaired.

14.6.3 Operational Phase

1. The loss of agricultural land due to the construction of the proposed road development is a permanent loss which cannot be mitigated except through financial compensation.
2. Landowners who lose buildings to the proposed road development will be compensated. Compensation payments will enable farmers to replace buildings.
3. All separated land parcels will be accessible either via the local road network, via accommodation access roads and access tracks.
4. Where existing water and electricity supplies to fields or farm yards are severed, the supply will be reinstated by provision of ducting where possible. Alternatively, where ducting is not feasible a permanent alternative water source or electricity supply will be made available. Compensation payments will enable farmers to replace power and water supplies.
5. Landowners may have to build additional farm facilities (e.g. cattle holding and testing pens) on their separated land. Field boundaries and paddock systems may have to be re-organised to take into account the altered shape of fields. These matters are addressed in the compensation settlements.
6. Water from the proposed road development will be diverted to attenuation ponds before discharging to watercourses or to ground. The drainage design of the proposed road development will intersect existing field drains and carry the drainage water to suitable outfalls.
7. Other injury impacts such as loss of shelter, removal of field boundaries, disruption of farm roads and field paddock systems and the increased potential for trespass on to private land due to the proposed road development are taken into account in this assessment. Statutory compensation will be used to compensate landowners for residual effects and to allow the landowners to execute mitigation measures and re-instatement works on their own land.
8. Landscaping along the proposed road development will minimise the visual impact on farms along the route of the proposed road development and will over time improve shelter in affected farms.

14.7 Residual Impacts

14.7.1 Introduction

Residual impacts are evaluated for each of the farms affected by the proposed road development. The impact on agriculture along the route of the proposed road development and within County Galway is evaluated and cumulative impacts are considered.

14.7.2 Construction Phase

The impacts resulting from the generation of noise, dust and construction traffic are temporary in nature and with mitigation are not significant. Prior to the construction of access roads or access tracks land will be separated by the proposed road development. In such situations points of temporary access will be provided to landowners to allow them to access their separated land parcels during the construction phase. Disturbance due to construction activity will be temporary and the impact is expected to be not significant or slight adverse. Land drainage impacts that are mitigated during the construction phase are not significant.

14.7.3 Operational Phase

The operational phase is considered to be in excess of 30 years and therefore residual effects that occur for this duration are permanent and therefore more significant than the temporary impacts that occur during the 36-month construction phase. Impacts such as loss of land and separation (severance) of land occur during the construction phase but are permanent residual impacts in the operational phase also. The design of the proposed road development will ensure that the land drainage of affected farms is not significantly affected and the significance of impact is not significant or slight adverse. The residual impacts on farms along the route of the proposed road development is summarised in **Table 14.7**.

Table 14.7: Summary of Residual Impacts

	Numbers of Land parcels				
Significance of Impact	**Mainly Dairy**	**Beef / sheep and hay / silage**	**Other (incl. Equine)**	**Not farmed**	**Totals**
Not significant	2	33	9	15	**59**
Slight	1	28	6	9	**44**
Moderate		25	8	8	**41**
Significant	1	28	10		**38**
Very Significant		8	0		**9**
Profound	2	1	1		**4**
Total Nos. of Land parcels	**6**	**123**	**34**	**32**	**195**
51 land parcels are predicted to have an impact which is significant adverse or greater (26% of all affected land parcels)					

The agricultural study area along the proposed road development consists of the area of all land parcels directly affected i.e. approximately 1,096 hectares. Approximately 219 hectares of land will be acquired which is approximately 20% of the study area. Land separation will affect 62 land parcels and 172 hectares of land will be separated – approximately 16% of the affected area. However, after mitigation effective access will be provided to the separated lands. The overall residual impact on agriculture along the proposed road development (i.e. within the study area) is moderately adverse.

14.7.4 Cumulative Impacts

The cumulative impact on regional agriculture is appraised by assessing the impact on agriculture in County Galway due to the landtake for the proposed road development in combination with other recently constructed and planned roads (M6, N17 / N18, N59 Maam Cross to Oughterard and Moycullen Bypass). The planned M6 (M17/M18) Motorway Service Area and the GTS measures (Eastern Galway City Park & Ride, Bearna Greenway, Galway to Oughterard Greenway and Galway City to Oranmore Cycleway) are also considered. These recently constructed and planned projects in combination with the proposed road development will require <1% of the agricultural area of County Galway (346,881 ha). When considered along with upward agricultural productivity trends[8] the cumulative impact on agriculture in County Galway is not significant.

There are cumulative impacts from the recently constructed M6 Scheme on four individual land parcels at the eastern end of the proposed road development. While there are significant cumulative impacts individually on these four[9] land parcels

[8] From 2010 – 2016 cattle numbers and sheep numbers increased 7% and 25% respectively – source CSO Table AAA08 and DAFM website.
[9] MO 751, MO 752, MO 754, and MO 758.

within the study area, the overall cumulative impacts on agriculture is not significant.

14.8 Summary

The proposed road development will traverse an area mainly consisting of small agricultural holdings. The land quality west of the River Corrib is generally poor and although mixed, the quality of land is better east of the River Corrib. The main farming enterprise is beef cattle. There is a relatively high proportion of very low – medium sensitivity equine enterprises along the route of the proposed road development.

The proposed road development will acquire approximately 219 hectares of land from 195 land parcels and will create separated land on 62 land parcels, resulting in the following residual impacts:

- 103 not significant and slight adverse (53% of land parcels along the route of the proposed road development)
- 41 moderate adverse (21% of land parcels along the route of the proposed road development)
- 38 significant adverse (19% of land parcels along the route of the proposed road development)
- 9 very significant adverse (5% of land parcels along the route of the proposed road development)
- 4 profound impacts (2.0% of land parcels along the route of the proposed road development)

The impact on agriculture within the study area is moderate adverse when cumulative effects from land loss due to other road developments are considered. The impact at a regional level (i.e. County Galway) is not significant.

15 Material Assets – Non-Agriculture

15.1 Introduction

This chapter of the EIAR consists of an appraisal of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, under the heading of material assets non-agriculture.

This chapter initially sets out the methodology followed (**Section 15.2**), describes the receiving environment (**Section 15.3**) and summarises the main characteristics of the proposed road development which are of relevance for material assets – non agriculture (**Section 15.4**). The evaluation of impacts of the proposed road development on material assets non-agriculture are described (**Section 15.5**), measures are proposed to mitigate these impacts (**Section 15.6**) and residual impacts are described (**Section 15.7**). The chapter concludes with a summary (**Section 15.8**) and reference section (**Section 15.9**).

This chapter has utilised the information gathered during the constraints and route selections studies for proposed road development to inform the material assets non-agriculture impact appraisal. **Sections 4.13**, **6.5.8** and **7.6.8** of the **Route Selection Report** considered the material assets non-agriculture constraints within the scheme study area and compared the potential of material assets non-agriculture impacts of the proposed route options respectively. These assessments and sections of the Route Selection Report contributed to the design of the proposed road development.

Material Assets are defined in the EPA Advice notes on current practice in the preparation of EIS (EPA 2003) as “resources that are valued and that are intrinsic to specific places, they may be either human or natural origin and the value may arise for either economic or cultural reasons”. The EPA revised Advice notes (2015) state that the “assessment shall be concerned primarily with ensuring equitable and sustainable use of resources”. Material assets of natural origin include renewable and non-renewable resources and assimilative capacities of such resources. Material assets of human origin include cultural heritage, cities/towns/settlements, transportation infrastructure, utilities/services infrastructure, land use, ownership and access, agronomy, property and tourism/recreational infrastructure. The EPA Guidelines on information to be contained in Environmental Impact Assessment Reports (2017), state that “Material assets can now be taken to mean built services and infrastructure” and includes roads and traffic and waste management.

Material assets are appraised in a number of chapters of this EIA Report as follows:

Natural resources are examined in **Chapter 9, Soils and Geology**, **Chapter 10, Hydrogeology** and **Chapter 11, Hydrology**. Cultural heritage is examined in **Chapter 13, Archaeological, Architectural and Cultural Heritage** whilst cities, towns, communities and settlements are examined in **Chapters 18, Human Beings, Population and Human Health** and **Chapter 2, Planning and Policy**. Tourism is also examined in **Chapter 18, Human Beings, Population and Human Health**. Agricultural assets (agronomy) are examined in **Chapter 14, Material Assets –**

Agriculture. The appraisal of waste management and associated infrastructure and proposed road closures are presented in **Chapter 7, Construction Activities**. The proposed road development and the associated traffic is presented in **Chapter 5, Description of Proposed Road Development** and **Chapter 6, Traffic Assessment and Route Cross Section**.

This chapter addresses the following aspects:

- Land use and ownership (non-agricultural properties including residential, commercial and industrial properties)
- Utilities (such as power, water supply, gas, sewerage, telecommunications)
- Land use zonings and planning permissions

15.2 Methodology

15.2.1 Introduction

This assessment is based on a desk study and on information gathered during consultations with landowners, utility and service providers and members of the public. The desk study included an inspection of land registry records, examination of aerial photography and inspection of planning records. A number of site walkovers and site visits with landowners and utility providers were also conducted to inform the findings of this assessment, see **Table 15.1** for further details.

15.2.2 Guidelines

This chapter is prepared in accordance with the following guidance documents:

- Environmental Protection Agency (EPA) - Advice Notes on Current Practice (2003)
- EPA - Guidelines on the Information to be contained in Environmental Impact Statements (2002)
- National Roads Authority (NRA) - Environmental Impact Assessment of National Road Schemes – A Practical Guide (2008)
- Environmental Protection Agency (EPA) Draft Revised Guidelines on Information to be contained in Environmental Impact Statements (EPA, 2015)
- Environmental Protection Agency (EPA) Draft Advice Notes for Preparing Environmental Impact Statements (EPA, 2015)
- Environmental Protection Agency (EPA) Draft Guidelines on Information to be contained in Environmental Impact Assessment Reports (EPA, 2017)

15.2.3 Data Sources and Consultations

The sources of the information gathered for this assessment are listed in **Table 15.1** below.

Table 15. 1: Sources of Data

Information	Data Sources
Landowner and land use details	Over 950 meetings with landowners have taken place since May 2014 A project office was set up in Ballybrit, Galway and facilitated ease of access for landowners and it became the central data collection point Public consultations in July 2014, January / February 2015 and May 2015 Public display November / December 2016 Design Update letters October 2016 and May 2017 Land registry to identify ownership of land and location of boundaries Aerial photography Galway City Development Plan 2017 – 2023 Galway County Development Plan 2015 – 2021 Bearn Local Area Plan 2007 – 2017 Gaeltacht Local Area Plan 2008 – 2018 (Amended 25 March 2013) Ardaun LAP 2018 – 2024 National University of Ireland, Galway, Strategic Plan 2015 – 2020
Location of properties	Windshield surveys Site visits to landowner properties Aerial photography Ordnance Survey (OS) Mapping
Planning applications	Galway County Council planning files Galway City Council planning files

15.2.4 Study area and Baseline Data Collection

The extents of the study area defined for the material assets non-agriculture assessment is the lands within the proposed development boundary, i.e. all lands to be acquired for the proposed road development and extends from An Baile Nua west of Bearna Village to Coolagh, Briarhill in the east. There are 313 non-agricultural properties including dwellings, industrial and commercial properties, NUIG Sporting Campus, Galway Racecourse and zoned lands that are directly affected by the proposed road development. A total area of 184 hectares including agricultural land zoned for future development but excluding agricultural lands which are not zoned, will be included within the proposed development boundary. The location of these land holdings is shown in **Figures 14.1.1** to **14.1.15**. All of the utilities within the proposed development boundary are also included in this assessment. The baseline data was collected from the sources outlined in **Table 15.1**.

15.2.5 Impact Assessment Methodology

Ten types of property were examined in the material assets non-agriculture assessment:

- Residential property
- Commercial property
- Industrial property
- Community property
- Amenity / Recreational areas – large wooded areas, sporting facilities, parks
- NUIG Sporting Campus
- Public Facilities – Churches, Community Centre etc.
- Lands zoned for residential, commercial or industrial development
- Other non-agricultural property
- Planning permissions for any of the above which have been granted

The potential impact on the infrastructure of public and private utilities / service providers and water supply is also assessed.

The potential impact of the proposed road development on non-agricultural properties and other material assets, listed above, was determined based on the following:

- Acquisition[1] or demolition[2] of buildings / facilities (including developments with live granted planning permission)

[1] Acquisition of a material asset results in the local authority being the property owner; it may be resold at a future time for reuse.
[2] Demolition of a material asset results in that property being razed to the ground and it is not available for reuse in its current form.

- Size of holding
- Size of land to be acquired
- Proximity of the landtake to the residence / business
- Loss of access
- Continued viability of the property / material asset

The level of impact of the proposed road development on non-agricultural properties is assessed according to the significance criteria detailed below in **Table 15.2**. These criteria were based on the EPA guidance documents listed above in **Section 15.2.2**. Each property is assessed on a case by case basis.

Table 15.2: Criteria for Assessing the Significance of Impact on Material Assets

Significance Level / Degree of Impact	Definition
Profound	An impact which obliterates sensitive characteristics. Occurs where a non-agricultural property or other material asset of national or regional importance is acquired and/or demolished
Very Significant	An impact which, by its character, magnitude, duration or intensity significantly alters most of a sensitive aspect of the environment. Occurs where part, or all, of a non-agricultural property or other material asset is acquired, which may result in demolition of the property or removal of more than one asset in the area, e.g. a cluster of properties in one area are proposed to be demolished or impact to a substantial community asset, or where acquisition results in loss of employment and total loss of the business
Significant	An impact which, by its character, magnitude, duration or intensity alters a sensitive aspect of the environment. Occurs where part, or all, of a non-agricultural property or other material asset is acquired, which may result in demolition of the property or removal of the asset, e.g. a single dwelling in one area is proposed to be demolished or removal of a business, or where acquisition results in partial loss of the business or total loss of the business without loss of employment
Moderate	An impact that alters the character of the environment in a manner which is consistent with existing and emerging baseline trends. Occurs where part, or all, of a non-agricultural property or other material asset is acquired, resulting in a major change to the environment of the property or material asset, e.g. the full acquisition of a property or a large portion of landtake from the property or the diversion of high voltage ESB network (110kV or 38kV) or gasman, or where acquisition results in partial loss of the business or potential business
Slight	An impact which causes noticeable changes in the character of the environment without affecting its sensitivities. Occurs where part of a non-agricultural property or other material asset is acquired, resulting in little change to the environment, e.g. a small portion of landtake from a property
Not significant	An impact which causes noticeable changes in the character of the environment but without noticeable consequences, e.g. the removal of a boundary wall or entrance to a property or the diversion of low and medium voltage ESB network, telecommunications or water supply and foul sewer services
Imperceptible	An impact capable of measurement but without noticeable consequences. Occurs where part of a non-agricultural property or other material asset is acquired, resulting in minimal changes to the environment of the property or

Significance Level / Degree of Impact	Definition
	material asset. This includes impacts on properties which are currently occupied by a public right-of-way. These lands are in the ownership of the adjacent property, however are occupied by existing roads.

15.3 Receiving Environment

The land along the proposed road development is a mixture of agricultural land (see **Chapter 14, Material Assets - Agriculture**) and non-agricultural lands which consist of residential clusters, villages, industrial and commercial properties as shown on **Figures 14.1.1** to **14.1.15** and described in the following sections. These figures show a plan of each landowners known holding from which lands will be acquired. The extents of the lands that are proposed to be acquired for the purposes of the proposed road development will be set out in the Protected Road Scheme[3] and Motorway Scheme Deposit Maps.

15.3.1 Material Assets Non-Agriculture excluding Services

15.3.1.1 R336 to Ballymoneen Road – Ch. 0+000 to Ch. 5+600

The proposed road development commences on the R336 in An Baile Nua approximately 2km west of Bearna Village and then proceeds north and east to the north of Bearna Village and onwards towards Letteragh passing through the townlands of Na Foraí Maola Thiar, Na Foraí Maola Thoir, Troscaigh Thiar, Troscaigh Thoir, Ballard West, Ballard East, and An Chloch Scoilte, An Cheapach and Ballymoneen.

This area is predominantly agricultural with sporadic one off rural housing and one commercial property within the area. The building pattern of existing homes is ribbon development like along the rural roads. There is planning for a dwelling in Na Foraí Maola Thiar. There is a crèche located on the Cappagh Road to the north of the proposed road development (see also **Chapter 18, Human Beings, Population and Health**).

The density of housing increases east of Cappagh Road as the proposed road development proceeds east towards Ballymoneen Road. There is a large residential development to the south east of the proposed road development on Ballymoneen Road in Ballyburke and an existing planning permission for a large residential development within this townland.

[3] A protected road, means a public road or proposed public road specified to be a protected road in a protected road scheme approved by An Bord Pleanála. A protected road scheme approved by An Bord Pleanála may provide for the prohibition, closure, stopping up, removal, alteration, diversion or restriction of any specified or all means of direct access to the protected road from specified land or from specified land used for a specified purpose or to such land from the protected road.

15.3.1.2 Ballymoneen Road to River Corrib – Ch. 5+600 to Ch. 9+300

Proceeding east through the townlands of Ballyburke, Rahoon, Mincloon and Letteragh toward Letteragh Road the lands to the north of the proposed road development are agricultural compared to the residential lands to the south. The lands between Ch. 5+850 and Ch. 6+060 are zoned as residential. There are also a number of residential zoned lands along the Rahoon Road and Letteragh Road. There is one valid planning permission for housing to the south of the proposed road development along Ballymoneen Road. Gateway Retail Park and Galway West Business Park are located at the southern end of Rahoon Road (see also **Chapter 18, Human Beings, Population and Health**). There is a fully granted planning permission for a primary school within the lands to the south of the Rahoon Road, however this is outside of the proposed development boundary.

As the proposed road development proceeds east through the townlands of Barnacranny, Bushypark and Dangan towards the River Corrib it enters a more urban and residential area. St. James' National School, Bushypark is located immediately to the south of the proposed road development but outside the proposed development boundary. Glenlo Abbey Hotel and Golf Course, Kelehans Pub and Bushypark Church are located to the north of the proposed road development and outside the proposed development boundary (see also **Chapter 18, Human Beings, Population and Health**).

There is housing located on both sides of the N59 Moycullen Road where the proposed road development traverses it at Dangan.

The NUIG Sporting Campus is also located at Dangan and is traversed by the proposed road development with the IDA Galway Business Park immediately south of these facilities and outside of the proposed development boundary. The sporting campus consists of a number of playing pitches including hockey and GAA and a sports pavilion. There is planning permission for flood lighting of the sports pitches to the south of the proposed road development on the western bank of the River Corrib. The sporting campus facility is also a public amenity as it is used by many other sports clubs within Galway (see also **Chapter 18, Human Beings, Population and Health**).

The banks of the River Corrib and the River Corrib itself are an important recreational area serving the population of Galway (see also **Chapter 18, Human Beings, Population and Health**).

15.3.1.3 River Corrib to N84 Headford Road – Ch. 9+300 to Ch. 12+150

Menlo Castle is situated on the eastern bank of the River Corrib in the townland of Menlough (see also **Chapter 13, Archaeological, Architectural and Cultural Heritage**). The proposed road development proceeds east from here on an embankment towards a viaduct in Coolough, Menlough before entering a tunnel immediately west of Lackagh Quarry (an inactive quarry in the townland of Coolough) and emerging in Lackagh Quarry (see also **Chapter 9, Soils and**

Geology). The lands east of the River Corrib in Menlough are rural with sporadic one off housing.

To the east of Lackagh Quarry the proposed road development traverses the N84 Headford Road and passes through the townlands of Ballinfoyle and Ballindooley. A number of individual dwellings in a small community are located either side of the N84 Headford Road. To the south of the proposed road development there is a scrapyard and plant hire business on the western side of N84 Headford Road and a company which source and bottle water and is a distribution centre on the eastern side of the N84 Headford Road (see also **Chapter 18, Human Beings, Population and Health**).

15.3.1.4 N84 Headford Road to N83 Tuam Road – Ch. 12+150 to Ch. 14+000

From the N84 Headford Road the proposed road development proceeds east crossing the townland of Castlegar before crossing the N83 Tuam Road[4]. The community of Castlegar is comprised of rural individual dwellings, along with a primary school and a newly constructed nursing home. Castlegar National School is located north of the proposed road development and the nursing home to the south. There is a mix of commercial, residential and zoned lands located on the N83 Tuam Road. The City North Business Park is located along the eastern side of N83 Tuam Road, which includes a car dealership and An Post parcel depot. On the western side of the N83 Tuam Road there is a builder’s supplier’s warehouse. See also **Chapter 18, Human Beings, Population and Health**.

15.3.1.5 N83 Tuam Road to existing N6, Coolagh – Ch. 14+000 to Ch. 17+450

East of the N83 Tuam Road the proposed road development traverses the townlands of Parkmore, Ballybrit, Briarhill and Coolagh. The proposed road development enters a tunnel as it traverses the Galway Racecourse in Ballybrit. Race meetings take place at this location four times a year with the main race meeting, the Galway Races, occurring annually in the last week of July. This is a major event for the city of Galway. There are a number of commercial and industrial areas including the Parkmore, Ballybrit and City East Business Parks. There are also individual dwellings in this area. See also **Chapter 18, Human Beings, Population and Health**.

The proposed Parkmore Link Road will make use of an existing cul-de-sac access road serving Hewlett Packard and Boston Scientific. Boston Scientific recently acquired lands to the east of the existing IDA road, the former APC site, a total area of 12.6 hectares. The alignment of the link road has been designed to take account of Boston Scientific’s plans to expand the existing facility and utilise the acquired APC site. This expansion involves the redevelopment of the existing buildings and the full integration of the existing buildings with the new facilities within the APC site. The first phase of the expansion plans includes the construction of a building immediately adjacent to and interlinked with the existing northern building. This

[4] Formally known as the N17 Tuam Road

will allow product and people to move throughout the expanded site without the need to move from a controlled sterile environment. It will be necessary for vehicles and workers to cross the link road to access other parts of the landholding that are included in future phases of the expansion plans.

The proposed road development ties into the existing N6 at Coolagh west of Coolagh Village. This is a rural community of ribbon development housing. The land is mainly used for agricultural purposes. The area outside of Coolagh village both north and south of the existing N6 has been zoned within the Galway City Development Plan 2017 - 2023 and included within the Ardaun Local Area Plan 2018 - 2024.

15.3.2 Material Assets Non-Agriculture – services

15.3.2.1 Electric Supply

A number of existing 110 kilovolt (kV) electricity transmission circuits (which are owned by ESB Networks and operated by EirGrid) traverse the corridor of the proposed road development and are widespread throughout the study area. These comprise both overhead power lines as well as an underground cable circuit. In addition, a significant number of existing low voltage (38kV) electricity distribution overhead circuits (which are owned and operated by ESB Networks) are located within or adjacent to the corridor of the proposed road development. A number of these existing electricity circuits cross the corridor of the proposed road development, and consequently require a local diversion and/or modification to facilitate the proposed road development. There is an existing ESB distribution substation located in Ballybrit.

The proposed road development traverses the existing 110kV lines at four areas (townlands) and existing 38kV lines at 12 areas as listed below in **Table 15.3** and shown on **Figures 15.1.1** to **15.1.15**.

Each of the proposed consequential local diversions associated with electrical services have been identified and planned in detailed engagement with ESB Networks and EirGrid in the preparation of this planning application and EIA Report. These consultations will continue prior to and during the construction phase of the proposed road development. A working group has been formed with ESB Networks, EirGrid, ESBI (the technical and environmental consultations to ESB Networks) and the design team so that all issues, concerns, plans etc. are identified and discussed in a coordinated manner.

Table 15.3: Locations where the proposed road development traverses existing 110kV and 38kV lines

Approx. Chainage	Townland	Description
Ch. 3+900	An Chloch Scoilte	ESB Networks 110kV Overhead Service
Ch. 6+200 (Gort Na Bró Roundabout)	Knocknacarra	ESB Networks 110kV Underground Service
Ch. 13+530	Castlegar	ESB Networks 110kV Overhead Service
Ch. 14+000 (City Business Park)	Ballybrit	ESB Networks 110kV Overhead Service

15.3.2.2 Telecommunications

Telecommunication services are provided throughout the study area by the following providers:

- Eir
- BT Ireland
- Virgin Media
- Three
- E-Net
- Vodafone

Eir operate a customer service network routed both overhead along local roads and underground along the verges of the existing road network which are traversed by the proposed road development and are widespread throughout the study area.

BT Ireland operate a network line along the existing N6, Bóthar na dTreabh and internal within the industrial estates and business parks on the east side of the city.

Virgin Media have a fibre optic cable along the existing Letteragh Road, within business parks and beneath the local roads in large residential housing estates.

Three Networks Ireland have a telecommunications mast located at Ch. 14+500 in Ballybrit which provides a mobile service to Galway City and County.

E-Net provide a fibre optic broadband network cable within Galway City and this is crossed multiple times by the proposed road development on the eastern side of the city.

There is a Vodafone telecommunications mast at Ch. 4+550 which provides a mobile service to Galway City and County.

15.3.2.3 Gas Supply

Gas Networks Ireland (GNI) manages the national natural gas transmission and distribution network in Ireland. The supply is via a small number of high pressure transmission mains. These transmission lines then branch off as distribution lines which serve the residential areas and follow housing estate patterns.

The proposed road development crosses the gas transmission and distribution lines at the following locations which are also shown in **Figures 15.2.1** to **15.2.5**:

- Ch. 6+200 (Western Distributor Road) – distribution network
- Ch. 6+550 (Rahoon Road Junction) – distribution network
- Ch. 6+900 (Bóthar Diarmuida Junction) – distribution network
- Ch. 13+150 (School Road, Castlegar) – this transmission network is the main gas supply for Galway City
- Ch. 15+500 (Parkmore Link Road) – distribution network

- Ch. 16+650 (Doughiska) – distribution network

15.3.2.4 Public Water Supply and Foul Water Supply

Galway City and County Councils in conjunction with Irish Water have potable water infrastructure serving the settlement areas within the study area. Properties located in the urban area around Galway City are generally connected to the public watermains. There are also dwellings within the proposed development boundary that have private wells. There are no private group water schemes within the proposed development boundary. The proposed road development traverses a number of watermains in both the rural and urban areas.

The local authorities and Irish Water also have surface water and foul water sewers in areas within the study area. The proposed road development traverses a number of foul and surface water sewers in the urban areas. There is one private sewer in Ballybrit that will also be traversed by the proposed road development. The majority of properties in the rural areas within the study area utilise septic tanks.

There are two reservoirs within the study area, in the vicinity of the proposed road development but outside of the proposed development boundary, one located in Letteragh and the second in Coolagh, Briarhill.

15.4 Characteristics of the Proposed Road Development

Galway City and its environs have critical transport issues that require urgent resolution as detailed in **Chapter 3, Need for the Proposed Road Development**. There are however significant constraints for developing new transport infrastructure for Galway given (i) the physical form of the city, (ii) the limited space available, (iii) the built environment and residential areas on both sides of the River Corrib, and (iv) the presence of designated sites.

The proposed road development is the optimum transport solution to resolve the transport issues in Galway and although its route has been designed to skirt the city and lands zoned for development, given the built environment, the linear development of the city with housing along every road radiating out of the city and the unavoidable proximity to residential areas, the proposed road development will unfortunately and unavoidably result in a number of property demolitions.

This must however, be viewed and balanced in the context of the overall benefit, described in **Chapter 3, Need for the Proposed Road Development**, that the proposed road development will deliver for the future of Galway and its environs and connectivity to the Western Region.

Numerous alternatives have been considered as detailed in **Chapter 4, Alternatives Considered**, however the conclusion of the consideration of the alternatives is that the proposed road development represents the optimum transport solution and has avoided the greatest number of known and immovable constraints and is the option that overall has a lesser environmental impact taking all other potential environmental impacts into account.

Further, once chosen, the design of the emerging preferred route has been refined in as much as possible to eliminate and reduce impacts on the human environment. As discussed in **Chapter 4, Alternatives Considered**, significant design measures such as steeper earthwork slopes, steepened green embankments and retaining walls are employed in the scheme design to minimise the impact on the human environment. Additional mitigation measures such as noise barriers, landscaping, planting, earth bunding are also utilised to minimise the overall impact on the receiving environment as discussed in **Chapter 12, Landscape and Visual** and **Chapter 17, Noise and Vibration**.

The proposed road development is consistent with proper planning and sustainable development and this view is supported / validated by the inclusion of policy support for both GTS and constituent measures, including the proposed road development, in the relevant Galway Development Plans.

A detailed description of the proposed road development, including the localised works to the existing electricity transmission and distribution networks, and construction activities are provided in **Chapter 5, Description of Proposed Road Development** and **Chapter 7, Construction Activities**. This section outlines the characteristics and activities of the proposed road development of relevance to material assets non-agriculture.

15.4.1 Construction Phase

The construction of the proposed road development will require the acquisition of approximately 184 hectares of non-agricultural land and the demolition and acquisition of residential, commercial and industrial properties as described in **Section 15.5**. All construction activities will be carried out within the proposed development boundary. The construction of the proposed road development will also require localised works to the existing electricity transmission and distribution networks (specifically comprising the diversion of the 110kV and 38kV as shown on **Figures 15.1.1** to **15.1.15**), gasmains, water supply and foul water services. Road closures and temporary traffic diversions are assessed in **Chapter 7, Construction Activities**.

At the beginning of the construction phase the land to be acquired will be fenced and access across it is restricted. In certain situations, temporary crossing points will be facilitated until accommodation roads are constructed. Properties will be acquired and demolished or secured for the duration of the works. Construction of the proposed road development will require activities such as excavation, tunnel work, piling, rock breaking and movement of materials within the fenced off works area (ref. **Chapter 7, Construction Activities**). This will generate noise, dust and movement of machinery which will potentially impact on adjoining lands in addition to visual impacts and these indirect impacts on material assets non-agriculture are assessed in **Chapter 12, Landscape and Visual**, **Chapter 16, Air Quality and Climate**, **Chapter 17, Noise and Vibration** and **Chapter 18, Human Beings, Population and Health**. There are no known indirect effects from the proposed road development on material assets non-agriculture as all potential impacts regardless of the scale, for example a right of way, are considered to be direct.

15.4.2 Operational Phase

Once the proposed road development is operational, all remaining properties will have access; all utilities and services will operate and function to a level of service as is the current situation with the exception of NUIG Sporting Campus which will require a full reconfiguration of its masterplan to facilitate the proposed road development. The proposed road development itself will become an additional material asset non-agriculture.

15.5 Evaluation of Impacts

15.5.1 Do Nothing Impact

In the event of the proposed road development not being constructed, the existing N6, Bóthar na dTreabh and the Quincentenary Bridge will remain the major route for traffic crossing the River Corrib and travelling from the east to west County Galway. The potential impacts, in terms of on material assets non-agriculture would essentially remain the same as the current situation. The proposed property acquisition and impacts on services will not be required.

15.5.2 Potential Construction Impacts

The proposed road development has been designed to avoid as many properties as possible but given the built environment and the linear development of the city with housing along every road radiating out of the city its construction will unfortunately and unavoidably result in a number of property acquisitions or demolitions.

In total there are 313 non-agriculture properties directly impacted by the proposed road development, i.e. full acquisition or partly acquisition of the property. The direct impacts on non-agricultural properties are detailed in the following sections:

- **Section 15.5.2.1** – Full acquisition or demolition of: residential, commercial or industrial properties; landholdings zoned for residential or commercial development; and lands with full planning permission which are to be fully acquired
- **Section 15.5.2.2** – Partial acquisition of lands from a residential property or landholding zoned for residential development
- **Section 15.5.2.3** – Partial acquisition of lands from a commercial or industrial enterprise or landholding zoned for commercial or industrial development
- **Section 15.5.2.4** – Partial acquisition of lands from other holdings not included above for example education facilities and Galway Racecourse
- **Section 15.5.2.5** – Planning permissions to be revoked or modified as a result of the proposed road development
- **Section 15.5.2.6** – Potential Impacts to utilities and services

Potential indirect impacts on material assets non-agriculture from factors such as landscape and visual, air, noise, human beings are assessed in **Chapter 12,**

Landscape and Visual, **Chapter 16, Air Quality and Climate**, **Chapter 17, Noise and Vibration** and **Chapter 18, Human Beings, Population and Health**.

In some cases, the proposed road development will require the acquisition of land over which there is a public right of way which entails the acquisition of road bed at the front of certain properties. The road bed comprises that portion of land outside a property's boundary wall to the centre of the public road which is in private ownership but in public use. These lands are occupied by existing roads but remain in the ownership of the adjacent property. These lands are outside the curtilage of the property therefore the impact is imperceptible as defined in **Table 15.2**. The proposed road development will also remove a number of existing private rights of way.

Where there is an impact on existing services during the construction phase an alternative supply will be made available. It will be necessary to maintain supply to existing services, as far as possible, during construction. Achieving this may entail temporary diversions of services and / or staging of the works. There may also be short periods where outages of the services are required to facilitate the construction. These outages will be kept to a minimum and people using these services will be given due notification in advance of any outage.

15.5.2.1 Residential, Commercial or Industrial Properties to be Fully Acquired or Demolished

From the outset of the design of the proposed road development every effort was made to avoid property demolitions where possible. However, there are still unfortunately and unavoidably a number of property demolitions that are necessary for the construction of the proposed road development and to secure the many benefits the proposed road development offers as follows:

- 44 residential properties
- 2 industrial properties (one property includes four buildings)
- 2 commercial properties

In addition to the demolition of 44 residential properties, an additional 10 residential properties, one commercial property and one landholding that has a full residential planning permission require full acquisition.

All 60 of these properties are listed below in **Table 15. 4** and shown in **Figures 14.1.1** to **14.1.15** and **Figures 15.3.01** to **15.3.15**.

Whilst this is a large number of property impacts with the associated impacts on families living in them, the overall context of the impacts is assessed against the potential benefits that can be accrued from the proposed road development, including the very significant and very much needed benefits to Galway City and its environs and connectivity to the Western Region and the European TEN-T network. A detailed analysis of the impact of the proposed road development on the community is presented in **Chapter 18, Human Beings, Population and Human Health**.

Table 15.4: Residential, Commercial or Industrial Properties to be Fully Acquired or Demolished

Protected Road Order / Motorway Order Number	Townland	Description	Area of Property (Ha)	Nature of Impact		Level of Impact

724 **	Doughiska / Coolagh	Two houses and garden and zoned lands	4.074	Demolition of 2 houses and garden and partial landtake	2.717	Significant

Note:

** this property is also dealt with in **Chapter 14, Material Assets Agriculture** as the property to be demolished is part of an agricultural property and areas quotes include agricultural lands*

*** this property also includes zoned lands (and are also included in **Tables 15.6** and **15.7** below and areas quotes include those lands.*

**** at the time of writing sites have valid planning permission*

15.5.2.2 Partial Land Acquisition of Residential Properties

The proposed road development will require the partial acquisition of lands such as gardens and paved areas, part of which may also include road bed in front of houses, from residential properties or land holdings zoned for residential development as follows:

- 76 residential properties

There are also a number of "road bed only acquisitions" where road bed owned by a private residential property or residential development over which there is a public right of way only is required to be acquired. These include the following:

- 58 residential properties

All of these 134 properties are listed below in **Table 15.5** and shown on **Figures 14.1** to **14.15**. Compensation for these impacts are to be agreed by a valuer at a later stage after appropriate liaison with the property owners affected.

There will also be road bed purchased adjacent to agricultural properties which is assessed in **Chapter 14, Material Assets Agriculture**, however this has not been quantified in this chapter.

Table 15.5: Partial Land Acquisition of Residential Properties

*Note: * this property is also dealt with in **Chapter 14, Material Assets Agriculture** as the property to be demolished is part of an agricultural property and areas quotes include agricultural lands*
*** this property also includes zoned lands (and are also included in **Tables 15.6** and **15.7** below and areas quotes include those lands.*
**** at the time of writing sites have valid planning permission*

15.5.2.3 Partial Land Acquisition of Commercial or Industrial Enterprises

The proposed road development will require the partial acquisition of lands such as (i) green open spaces, (ii) paved surfaces for car parking from 17 commercial or industrial enterprises or landholdings zoned for commercial or industrial development as follows:

- Partial landtake from 12 commercial or industrial enterprises including car sales facilities, business parks, a company which source and bottle water, nursing home and is a distribution centre and An Post depot.
- Partial landtake from 5 landholdings zoned for commercial or industrial development

There are also a number of "road bed only acquisitions" where road bed owned by a commercial or industrial enterprise over which there is a public right of way only is acquired without any acquisition form the actual property itself. These include the following:

- 2 commercial or industrial enterprises

All of these properties are listed below in **Table 15.6** and shown in **Figures 14.1** to **14.15**. Compensation for these impacts are to be agreed by a valuer at a later stage after appropriate liaison with the property owners affected.

720	Doughiska	Car Sales	0.200	Partial landtake (paved area)	0.008	Slight

Note: ** this property is also dealt with in* ***Chapter 14, Material Assets Agriculture*** *as the property to be demolished is part of an agricultural property and areas quotes include agricultural lands*

15.5.2.4 Land Acquisition of Other Non-Agricultural Properties

The remaining 107 land holdings are made up of (i) the acquisition of isolated roadbeds from 24 properties, (ii) the acquisition of river bed from two properties and (iii) and the partial acquisition of lands at the following properties:

- Galway County Council storage depot
- National University of Ireland (NUIG), Galway Sporting Campus facilities
- Castlegar National School
- Church at Bushypark
- Church at Coolagh
- Galway Racecourse
- Disused railway track

There is also acquisition of land 74 parcels of zoned lands.

These are listed below in **Table 15.7** and shown in **Figures 14.1.1** to **14.1.15**. Compensation for these impacts are to be agreed by a valuer at a later stage after appropriate liaison with the property owners affected.

The NUIG Sporting Campus facilities will be severely affected during the course of the construction works, as the central part of the sporting campus will become a construction site with restricted access for a period of approximately 18 months. Access to the bank of the River Corrib which is used as a local amenity and the river itself will also be restricted at times during construction. The existing sports pitches adjacent to the River Corrib will be unavailable for use for the duration of the construction of the new 3G sports pitches which is likely to be nine months. Once they are constructed they will be available for use within approximately one month.

Note:

** this property is also dealt with in **Chapter 14, Material Assets Agriculture** as the property is part of an agricultural property and areas quotes include agricultural lands*

*** property also included in **Table 15.4***

15.5.2.5 Planning Permissions affected by the proposed road development

The proposed road development will require the acquisition of lands from five properties upon which there is currently full planning permission for residential or commercial development. These acquisitions will result in either the revocation or the need for modification of the planning permission. These are listed below in **Table 15.8** and are shown in **Figures 14.1.1** to **14.1.14**.

Table 15.8: Planning Permissions affected by the proposed road development

PRO / MO No.	Townland	Description	Area of property (Ha)	Nature of Impact		Level of Impact	Revoke or modify
				Description of Landtake	Land to be acquired (Ha)		
124*	Na Foraí Maola Thiar	Full residential planning permission	0.470	Acquisition of whole site	0.470	Moderate	Revoke
149	Troscaigh Thiar	Planning permission for roadside boundary wall and existing access point as constructed with all associated works and ancillary services.	0.200	Boundary Wall relocation, Road Bed acquisition	0.0075	Imperceptible	Modify
229	Ballyburke	Planning permission granted for the demolition of two existing houses shed and outbuildings, construction of crèche, 3 no retail units, 3 no office units, bar/restaurant and 299 residential units in varying design and form, in two and three storey blocks, bin storage, ESB substation, surface and basement car parking and all associated external and site development works including 3 vehicular access points and road widening along Ballymoneen Rd. (1454) (Extension of time to 18/07/2019)	9.2	Severance of site	1.45	Moderate	Modify
528_543	Dangan Lower	Permission for new all-weather sports pitch on the site of existing training pitch (including floodlighting)(14104)	95.896	Partial acquisition of property	6.293	Very Significant	Revoke
528_543	Dangan Lower	Permission for flood lighting of existing GAA pitches adjacent to the river. (17159)	95.896	Partial acquisition of property	6.293	Very Significant	Revoke

*Note: * Lands also included in **Table 15.4**. above*

15.5.2.6 Potential impacts on Material Assets Non-Agricultural - Services

Electricity services, gas services, telecommunication services, water supply and foul water services will each be affected by the proposed road development as outlined below in this section.

Electrical Services

The proposed road development will require the localised diversion and/or modification of the existing 38kV and 110kV networks as follows:

- 110kV network to be diverted at 3 locations
- 38kV network to be diverted at 9 locations

Conflicts[5] with the existing 110kV network have been discussed ESB Networks, the Transmission System Owner, and EirGrid, the Transmission System Operator. The 110kV network comprises overhead conductors, supported on double-wood polesets along straights, with lattice steel structures (known as ‘‘angle towers’’) where the circuit alignment changes direction. Where resolution is necessary it is proposed by way of localised diversion, or by a generally modest raising of existing polesets/towers in immediate proximity to the proposed road development in order to ensure adequate separation distance between the overhead conductors and ground levels (known as ‘‘vertical clearance’’). At some locations the existing towers can be retained at their current location and the proposed road development will pass underneath. Where adequate vertical clearance is available no works will be required. In instances of inadequate vertical clearance the line will need to be raised between towers allowing for sag of the line due to ‘its loading” - the amount of power it carries – as well as for seasonal weather conditions, especially ice. Each diversion has been assessed from both a construction point of view, but also from an operational point of view to ensure the continued operation of the electrical grids while constructing the proposed road development. The alternative of localised undergrounding of all of the existing 110kV overhead lines as part of the diversion works was considered by this working group; however due to the conflict locations and the necessity to underground the line back to a substation and the proximity to such a substation it was agreed by ESB Networks and EirGrid not to be feasible, nor indeed necessary and/or appropriate, given that it would have a potentially significant adverse impact upon the safe, secure and reliable operation of the grid, by introducing significant complexity into the system.

The diversion locations are listed in **Table 15.9**, and shown in **Figures 15.1.1** to **15.1.15**. Once these diversions are complete the powerlines will operate in the same way as they currently do. However, there is a temporary impact to the service to complete these diversions. These impacts include a power outage of the line which can only be completed during the outage season (generally April-October when demand for electricity is generally lower in comparison with the winter period), and

[5] The technical term for the intrusion of a planned development with an existing circuit is a ‘conflict’. This simply means something that needs to be resolved, rather than in its more literal sense. ESB Networks have a dedicated Conflicts Section, and the resolution of ‘conflicts’ is an established practice, occurring by way of localised re-design or diversion.

switching of power onto other circuits during that time. All of this requires a phased and careful planned approach to the development of different circuits, the outage season, the phasing of the transmission development in advance of main construction, and protection of the circuits during the construction. This is undertaken exclusively by EirGrid and ESBN as Transmission System Operator (TSO) and Distribution System Operator (DSO)respectively, and is not within the power of the Applicant to control or undertake. As such these potential impacts are ranked as Moderate, albeit temporary, and strictly controlled to ensure no loss of supply to customers and the general public.

There will also be a requirement to protect in-situ[6] the 38kV and 110kV services as follows:

- 110kV service to be protected in-situ at 5 locations
- 38kV services to be protected in-situ at 14 locations

These potential impacts are ranked as Not Significant.

The lower voltage ESB powerlines will require diversion at 36 locations. These potential impacts are ranked as Slight.

There is also a requirement to protect in-situ the lower voltage ESB powerlines at 63 locations. These potential impacts are ranked as Not Significant as there will be no consequences to this service as a result of these measures.

The underground 110kV line is in conflict with the proposed road development in four locations however this service will be protected in-situ and no diversion works are required. These potential impacts are ranked as Not Significant as there will be no consequences to this service as a result of these measures.

Table 15.9: Electrical Services affected or in conflict with the Proposed Road Development

Approx. Chainage	Townland	Description	Affected Lengths (m)	Level of Impact	Proposed Mitigation
Ch. 6+300	Rahoon	ESB 38kV Underground Service	167m	Moderate	Divert as shown on **Figure 15.1.04** as agreed with ESB
Ch. 6+675	Rahoon	ESB 38kV Overhead Service	76m	Moderate	Divert as shown on **Figure 15.1.04** as agreed with ESB
Ch. 8+270 to 8+400	Barnacranny	ESB 38kV Overhead Service	127m	Moderate	Divert as shown on **Figure 15.4.05** as

[6] The existing infrastructure will be maintained in its current location and protected during construction by the use of 'goal posts' and fencing for the overhead powerlines and utilising a protection layer over the underground cable circuit. All works will be undertaken in accordance with the safe working guidelines as outline in ESB Networks "Safe Construction with Electricity").

Approx. Chainage	Townland	Description	Affected Lengths (m)	Level of Impact	Proposed Mitigation
					agreed with ESB

N59 Link Road South	Rahoon	ESB 38kV Underground Service	33m	Moderate	Divert as shown on **Figure 15.1.12** as agreed with ESB

Gas Services

The proposed road development will require the localised diversion and/or modification of the existing of Gas Networks Ireland (GNI) services at two locations as shown on **Figures 15.2.1** to **15.2.5** and listed in **Table 15.10** below. Once these diversions are complete the gas network will operate in the same way as they currently do. However, there is an impact to the service to complete these diversions. These impacts include an outage of the line which requires a phased and careful planned approach to the development in advance of main construction and protection of the network during the construction. As such these potential impacts are ranked as Moderate.

There is also a requirement to protect in-situ Gas Networks Ireland (GNI) services at nine locations. These potential impacts are ranked as Not Significant as there will be no consequences to this service as a result of these measures.

Table 15.10: GNI Services affected or in conflict with the Proposed Road Development

Approx. Chainage	Townland	Description	Affected Lengths (m)	Level of Impact	Proposed Mitigation
Ch. 6+520 (N59 Link Road South/Rahoon Road JNC)	Rahoon	Gas – Distribution network	95m	Moderate	Divert as shown on **Figure 15.2.01** as agreed with GNI
Ch. 13+150	Castlegar	Gas – Transmission network	115m	Moderate	Divert as shown on **Figure 15.2.03** as agreed with GNI

Telecommunications

There are a number of telecommunication services crossed by the proposed road development, including Eir, Virgin Media, E-Net, BT and Vodafone. New ducting will be provided in the verges of the proposed road development for future use resulting in a positive Moderate impact.

<u>Eir</u>

The proposed road development will require the localised diversion and/or modification of the existing of Eir services at 17 locations as follows:

- Ch. 0+000
- Ch. 2+840
- Ch. 2+845
- Ch. 3+325
- Ch. 3+550
- Ch. 5+620
- Ch. 6+300

- Ch. 6+300 to 6+450
- Ch. 7+250
- Ch. 8+550
- Ch. 10+100
- Ch. 12+120
- Ch. 13+170
- Ch. 15+045
- Ch. 15+700
- Ch. 15+870
- Ch. 16+250

These potential impacts are considered to be a Slight impact.

There is also a requirement to protect in-situ Eir services at 31 locations. These potential impacts are ranked as Not Significant.

<u>Virgin Media</u>

Virgin Media have a number of underground fibre optic cables running in ducting along existing roads crossed by the proposed road development. The proposed road development will require the localised diversion and/or modification of the existing of Virgin Media services at two locations as follows:

- Ch. 7+280
- Ch. 7+285

These potential impacts are considered to be a Slight impact.

There is also a requirement to protect in-situ Virgin Media services at six locations. These potential impacts are ranked as Not Significant.

<u>E-Net</u>

E-Net have a number of fibre optic cables running in ducting along existing roads crossed by the proposed road development.

The proposed road development will require the localised diversion and/or modification of the existing of E-Net fibre optic at five locations as follows:

- Ch. 13+700
- Ch. 15+050
- Ch. 15+730
- Ch. 15+880
- Ch. 16+350

These potential impacts are considered to be a Slight impact.

There is also a requirement to protect in-situ E-Net fibre optic at 14 locations. These potential impacts are ranked as Not Significant.

BT Ireland

BT Ireland have a number of underground fibre optic cables running in ducting along existing roads crossed by the proposed road development.

The proposed road development will require the localised diversion and/or modification of the existing of BT Ireland optic at one location as follows:

- Ch. 16+300

This potential impact is considered to be a Slight impact.

There is also a requirement to protect in-situ BT Ireland at five locations. These potential impacts are ranked as Not Significant.

Vodafone

The proposed road development will require the full acquisition of a telecommunications mast at Ch. 4+650 which is operated by Vodafone. This mast has planning permission until 2020 at which time planning permission maybe renewed or the mast decommissioned.

Three Networks Ireland

Three Networks Ireland operate a telecommunications mast at Ch. 14+500 which will be decommissioned for the construction of the proposed road development and relocated.

Water Supply and Foul Water Services

The proposed road development is in conflict with a number of water services (watermains, foul and surface water sewers) within the study area. The conflicts that require diversion works are listed in **Table 15.11** below along with the level of impact.

There are no waste facilities potentially impacted by the proposed road development.

Table 15.11: Water Services affected or in conflict with the Proposed Road Development

15.5.3 Potential Operational Impacts

Once the proposed road development will be operational, all properties with the exception of NUIG Sports Pavilion will have access and utilities will operate and function to a level of service as is the current situation. The NUIG Sports Pavilion will have restricted access to its western perimeter, due to the presence of the proposed road development.

Through traffic on the Parkmore Link Road will introduce a delay to the movement of product and people within the Boston Scientific campus. However, the proposed link road will be at-grade and, while assessed as a moderate impact, any delay to movement will not be long enough to amount to a significant impact.

Galway Racecourse will continue to operate and function to a level of service as is the current situation.

15.6 Mitigation Measures

15.6.1 Introduction

This section outlines the proposed mitigation measures for material assets non-agriculture.

15.6.2 Construction Phase

In the event of an approval of the Protected Road Scheme and Motorway Scheme and approval under Section 51 of the Roads Act 1993 (as amended), by An Bord Pleanála and subject to the availability of funding, Notice to Treat will be served firstly on owners, lessees and occupiers of the dwelling houses and commercial properties to be acquired, within six months of the scheme becoming operative, unless an application has been made for Judicial Review, in which case the Notice to Treat[7] will be served in accordance with the provisions of Section 217 (6A) of the Planning and Development Act 2000 as inserted by the Compulsory Purchase Orders (Extension of Time Limits) Act 2010. Compensation will be agreed or determined by the property arbitrator as soon as possible after service of Notice to Treat. After compensation has been agreed or determined and satisfactory title has been produced, part payment can be made while the claimant remains for an agreed period in the property to be acquired. This will facilitate the claimant in removing uncertainty and will facilitate arrangements being made, as early as possible, to secure a replacement property.

Where existing access to property is affected, this will be reinstated or an alternative access provided.

Where part of a property or land surrounding a property is to be acquired, appropriate accesses have been designed and appropriate boundary treatment will be constructed.

The proposed road development severs the NUIG Sporting Campus facilities. During construction, restricted access across the construction area at the NUIG Sporting Campus facilities will be maintained.

Alternative pitch facilities will be provided to replace the existing pitches directly impacted by the proposed road development. The facilities include a floodlit 3G GAA pitch and a floodlit 3G training area and associated site infrastructure for the drainage of these pitches and furniture such as ball-stop netting. The proposed road development also intercepts the existing sports pavilion resulting in direct impacts to its western end and the building will be modified as follows:

- the existing western plant room, 1 no. changing room, 1 no. storage area, 1 no. weights area and associated access hallways on both ground floor and upper levels will be demolished

[7] This notice requests landowners to submit their claim for compensation for lands being taken under the Protected Road Scheme or Motorway Scheme. This is the initial step in the acquisition of property and lands.

- the western plant room and its associated plant will be relocated
- Construction and reconfiguration of the internal and external walls, roof, windows and door locations

During the construction of the River Corrib Bridge, alternative access to that along the bank of the River Corrib will be provided.

Temporary stables will be provided for Galway Racecourse during the construction of the proposed road development until such time as the Galway Racecourse Tunnel is complete and the permanent stables are constructed.

Mitigation measures as detailed in individual accommodation works agreements, such as boundary treatment, domestic entrances, property condition surveys (as outlined in **Chapter 17, Noise and Vibration**), provision of ducting to facilitate services, maintenance of access during construction amongst other items will remove impacts related to the properties with partial landtake. Compensatory measures for the loss of land, buildings and other injurious affection will form part of the land acquisition process and will be agreed at a later date with a valuer. Compensation does not form part of the EIA process and is therefore not considered further.

Each of the utility diversions associated with the proposed road development have been planned with ongoing and detailed engagement with relevant utility providers during the preparation of this EIA Report. This engagement will continue prior to and during the construction phases. Each diversion has been assessed from both a construction point of view, but also from an operational point of view.

Where the infrastructure for service providers is impacted, this will be diverted or reinstated in accordance with service providers' requirements prior to construction. Service users will be notified in advance of any temporary disruption or outages necessitated by the construction works. The disruption to services or outages will be carefully planned so the duration is minimised.

Public water supply and foul water systems affected will be reconnected. All necessary diversions will be carried out in accordance with the local authority and Irish Water's requirements. Where private potable water supplies are impacted, a new well or alternative water supply or financial compensation for the loss of the well will be provided.

Mitigation for interference with septic tanks will be agreed by the valuer at a later stage.

15.6.3 Operational Phase

The proposed road development will result in a 20 per cent reduction of the NUIG Sporting Campus at Dangan, due to the encumbrance caused by the viaduct support structures. This will result in the removal of two grass based GAA sized playing pitches.

As a consequence, the NUIG Sporting Campus will require a new Sporting Campus Plan and Strategy. The provision of a viaduct structure at the NUIG Sporting Campus will provide access to the north and south of the Sporting Campus and the

River Corrib during the operational phase, maintaining connectivity and permeability beneath the proposed road development.

The current road which provides access to Hewlett Packard and Boston Scientific will become a through road at the operational phase of the proposed road development. The additional traffic will present new severance compared with the Do-Nothing scenario. However, a speed of 50kph will limit speeds and traffic will be generally for local access only.

The stable yard and associated facilities for Galway Racecourse will be relocated as shown on **Figure 15.4.1** and detailed in **Appendix A.15.2**, mitigating the operational impacts on the racecourse.

Noise barriers will be provided across the length of the proposed road development to mitigate potential increase in noise as detailed in **Chapter 17, Noise and Vibration** and shown on **Figures 17.1.1** to **17.1.15**.

15.7 Residual Impacts

The residual impacts from all of the very significant/significant impacts, 54 residential properties, eight commercial properties and one residential planning permission, which will be acquired and/or demolished to accommodate the proposed road development, remain as very significant/significant impacts as no mitigation is possible to reduce the impact. The residual impact post compensation cannot be assessed as the compensation to be agreed as part of the land acquisition are outside the scope of the EIA process. Mitigation measures as detailed in individual accommodation works agreements will remove the residual impacts related to the properties with partial landtake.

There are no residual impacts on dwellings from which part of the road bed will be acquired. The residual landscape and visual impacts of diverting existing overhead powerlines are considered in **Chapter 12, Landscape and Visual**. There will be no residual impacts on services or services infrastructure.

The residual impacts on NUIG Sporting Campus remain as very significant in the absence of a new University Sports Masterplan. The proposed road development will effectively divide the Sports Campus into two, removing the two centrally located grass based sand carpet full sized GAA pitches. In tandem with this the existing context of the existing sporting changing facilities setting and curtilage will be altered completely. With an appropriate level of masterplanning and implementation of the following in such a masterplan would reduce the residual impact to moderate:

1. The sporting campus at Dangan will require a new sporting campus plan and strategy to re-accommodate the removed pitches and ancillary sports pavilion. This must be in line with the University’s overall strategic sport’s vision
2. The removal of the existing sports fields will require replacement by similar or more likely improved facilities which allow for the more intensive use of the remaining reduced campus footprint
3. Utilities, roads and access and egress routes around the campus will require complete re-planning to re-integrate with the proposed road development

4. The remaining sports pitches will require remodelling to accommodate a more intensive use of the existing campus footprint
5. The landscape setting of the existing campus will need to be developed to screen the visual effects of the proposed River Corrib Bridge from the surrounding pitches
6. Ancillary supporting facilities such as car parking and changing facilities will require remodelling

The residual impact on NUIG Sporting Campus post compensation cannot be assessed as the compensation to be agreed as part of the land acquisition is outside the scope of the EIA process.

There will be a positive residual impact on Galway Racecourse once the mitigation measures have been constructed with the provision of enhanced access to the premises and a new stable yard.

The residual impacts on Material Assets Non-Agriculture identified for the construction phase also apply for the operational phase.

15.7.1 Cumulative Impacts

Cumulative impacts are defined as the combination of many minor impacts creating one, larger, more significant impact (NRA, 2009 and EPA 2017). Cumulative impacts consider existing stresses on the natural environment as well as developments that are underway and in planning.

The cumulative impacts of the proposed road development on material assets non-agriculture with the following projects and plans have been assessed:

- M17 Galway to Tuam Road Project
- N18 Oranmore to Gort Road Project
- N17 Tuam Bypass
- M6 Motorway
- N59 Maam Cross to Oughterard Road Project
- N59 Maigh Cuilinn (Moycullen) Bypass Road Project
- Galway Harbour Port Extension
- Galway Transport Strategy (GTS), which includes the following:
    - Investigate prospective sites to the east of the city for Park and Ride
    - Bearna Greenway
    - Galway to Oughterard (part of the Galway to Clifden) Greenway
    - Galway City to Oranmore (part of the Galway to Dublin) Cycleway
- Galway City Development Plan 2017 – 2023
- Galway County Development Plan 2015 – 2021

Although the proposed road development overlaps with other proposed projects such as the GTS measures which include the Tuam Road Bus Corridor and the

Galway to Oughterard Greenway, there are no cumulative impacts on Material Assets Non-Agriculture other than the potential impacts identified in **Section 15.5** above.

Similarly, the other proposed projects which have been identified will not result in any significant cumulative impact with the addition the proposed road development on Material Assets Non-Agriculture identified in the study area for the proposed road development.

15.8 Summary

The proposed road development will cross through lands populated by residential and commercial properties on the outskirts of Galway City and include both agriculture lands and lands zoned for development. The proposed road development has been designed to avoid as many properties as possible but given the built environment, and the linear type development of the city where housing is situated along every road radiating from the city, its construction will unfortunately and unavoidably result in a number of property demolitions.

Numerous alternatives have been considered as detailed in **Chapter 4, Alternatives Considered**, however the conclusion of the consideration of the alternatives is that the proposed road development represents the optimum solution and has avoided the greatest number of known and immovable constraints and is the option that overall has a lesser environmental impact taking all other potential environmental impacts into account.

Furthermore, the design of the emerging preferred route has been refined in as much as possible to eliminate and reduce impacts on the human environment. As discussed in **Chapter 4, Alternatives Considered**, significant design measures such as steeper earthwork slopes, steepened green embankments and retaining walls are employed in the scheme design to minimise the impact on the human environment. Additional mitigation measures such as noise barriers, landscaping, planting, earth bunding are also utilised to minimise the overall impact on the receiving environment as discussed in **Chapter 12, Landscape and Visual** and **Chapter 17, Noise and Vibration**.

The proposed road development is consistent with proper planning and sustainable development and this view is supported/validated by the inclusion of policy support for both GTS and constituent measures, including the proposed road development, in the relevant Galway Development Plans.

The proposed road development will acquire 184ha of land from 320 non-agricultural properties including residential, commercial, industrial properties and lands zoned for development, a sporting campus, racecourse, school lands and church lands. Included in this number is the acquisition of lands currently located within the public road in the registered ownership of private individuals. Road bed acquisition has an imperceptible impact on affected properties as works are entirely outside of the existing site boundary walls or fences.

It is proposed that there will be 54 residential properties fully acquired or demolished to facilitate the construction of the proposed road development. Of these 54 residential properties 10 require full acquisition while the remaining 44 will require demolition. Five commercial properties will be full acquired or demolished. Of these five commercial properties, one requires full acquisition and the remaining four will require demolition. One landholding that has a full residential planning permission will also require full acquisition.

Of the 320 non-agricultural properties, 31 of these properties will have very significant impacts, 28 significant impacts, 59 moderate, 103 slight, with the remaining 99 being imperceptible. There are no non-significant impacts resulting from the proposed road development.

The proposed road development will have very significant impacts on the NUIG Sporting Campus at Dangan in the absence of a new University Sports Masterplan.

The stable yard and associated facilities for Galway Racecourse will be relocated mitigating the potential operational impacts on the racecourse. There will be enhanced ingress and egress from the racecourse as a result of the proposed road development. Overall it is considered that the proposed road development will result in a slight positive residual impact on the racecourse.

The area is well serviced with utility networks including electricity, gas, telecommunications and water supplies. There are a number of conflicts with utility services and the proposed road development as follows:

- 8 conflicts with the 110kV ESB network
- 23 conflicts with the 38kV ESB network
- 99 conflicts with MV and LV ESB network
- 11 conflicts with Gas Networks Ireland services
- 48 conflicts with Eir services
- 8 conflicts with Virgin Media services
- 19 conflicts with E-Net services
- 6 conflicts with BT Ireland services
- 1 conflicts with Vodafone services
- 1 conflicts with Three Networks Ireland services
- 29 conflicts with watermain services
- 5 conflicts with foul sewer services
- 4 conflicts with surface water services

Of these conflicts, there are 14 moderate impacts on services which include the diversions associated with ESB (three 110kV diversions and nine 38kV diversions) and GNI services (two diversions).

Of the remaining conflicts, there are:

- 29 slight and 29 Not Significant impacts to ESB Low and Medium Voltage network

- 4 Not Significant impacts to ESB Networks (110kV underground line installed by SSE)
- 17 slight and 31 Not Significant impacts to EIR services
- 2 slight and 6 Not Significant impacts to Virgin Media services
- 5 slight and 14 Not Significant impacts to E-Net services
- 1 slight impact to Vodafone services
- 1 slight impact to Three Networks Ireland services
- 1 slight and 5 Not Significant impacts to BT services
- 29 slight impacts to Irish Water watermains
- 4 slight impacts to Irish Water public foul sewers
- 1 slight impact to an IDA private foul sewer
- 4 slight impacts to Galway City Council public surface water sewers

Where there is an impact on existing services during the construction phase an alternative supply will be made available. It will be necessary to maintain supply to existing services, as far as possible, during construction. There are no residual impacts on services.

There will be no cumulative impacts from the proposed road development on material assets non-agriculture with other projects and plans.

16 Air Quality and Climate

16.1 Introduction

This chapter of the EIAR consists of an appraisal of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development under the heading of air quality and climate.

This chapter initially sets out the methodology followed (**Section 16.2**), describes the receiving environment (**Section 16.3**), and summarises the main characteristics of the proposed road development which are of relevance for air quality and climate (**Section 16.4**). The evaluation of impacts of the proposed road development on air quality and climate impacts are described (**Section 16.5**). Measures are proposed to mitigate these impacts (**Section 16.6**) and residual impacts are described (**Section 16.7**). The chapter concludes with a summary (**Section 16.8**) and reference section (**Section 16.9**).

This chapter has utilised the information gathered during the pre-application stage of the proposed road development to inform the air quality and climate impact appraisal. **Sections 4.4**, **6.5.9** and **7.6.9 of the Route Selection Report** considered the air quality and climate constraints within the scheme study area and compared the potential of air quality impacts of the proposed route options respectively. These assessments and sections of the Route Selection Report contributed to the design of the proposed road development which this chapter appraises.

16.2 Methodology

16.2.1 Introduction

This chapter is prepared having regard to the requirements of the Transport Infrastructure Ireland (TII, formerly National Roads Authority (NRA)) document *'Guidelines for the Treatment of Air Quality during the Planning and Construction of National Road Schemes*', 2011.

The impact of the proposed road development on air quality is assessed for both the construction and operational phases by considering the pollutant background concentrations, emissions from road traffic, potential for construction dust and emissions from construction traffic. Predicted concentrations are compared to the relevant limit values.

Carbon emissions are considered in terms of Ireland's obligations to reduce its carbon emissions.

This chapter has also been prepared having regard to the following guidelines:

- Guidelines on the information to be contained in environmental impact assessment reports (EPA, Draft 2017)
- Revised Guidelines on the Information to be contained in Environmental Impact Statements (EPA, Draft 2015)

- Advice Notes for Preparing Environmental Impact Statements (EPA, draft 2015)
- Guidelines on the Information to be contained in Environmental Impact Statements (EPA 2002)
- Advice Notes on Current Practice in the Preparation of Environmental Impact Statements (EPA 2003)

16.2.2 Legislation and Guidelines

This section sets out the legislation and guidelines under the headings of:

- Air quality standards and limits
- Climate change obligations and policy
- Transport Infrastructure Ireland Guidance

16.2.2.1 Air Quality Standards and Limits

In order to reduce the risk of poor air quality, national and European statutory bodies have set limit values in ambient air for a range of air pollutants. These limit values are set for the protection of human health and ecosystems.

On 12 April 2011, the Air Quality Standards Regulations (AQS) 2011 (S.I. No. 180 of 2011) came into force and transposed EU Directive 2008/50/EC on ambient air quality and cleaner air for Europe (the Air Quality Directive) into Irish law. The purpose of the 2011 Regulations is to establish limit values and alert thresholds for concentrations of certain pollutants, to provide for the assessment of certain pollutants using methods and criteria common to other European Member States, to ensure that adequate information on certain pollutant concentrations is obtained and made publicly available and to provide for the maintenance and improvement of ambient air quality where necessary. These standards were introduced to avoid, prevent or reduce harmful effects on human health and the environment as a whole.

The limit values established under these regulations relevant to the assessment of road schemes are included in **Table 16.1**.

Table 16.1: Air Quality Standards (AQS) from Regulations 2011 (S.I No. 180 of 2011)

Pollutant	Limit value for the protection of:	Averaging period	Limit value ($\mu g/m^3$)	Basis of application of limit value	Limit value attainment date
NO_2	Human Health	1-hour	200	≤18 exceedances p.a. (99.79 % ie)	1 January 2010
		Calendar year	40	Annual mean	1 January 2010
NO_x	Vegetation	Calendar year	30	Annual mean	1 January 2010
PM_{10}	Human Health	24-hours	50	≤35 exceedances p.a. (98.1%ile)	1 January 2005
		Calendar year	40	Annual mean	1 January 2005
$PM_{2.5}$	Human Health	Calendar year	20	Annual mean	1 January 2020

Pollutant	Limit value for the protection of:	Averaging period	Limit value ($\mu g/m^3$)	Basis of application of limit value	Limit value attainment date
CO	Human Health	8-hour Annual Average	10,000	8-hour Average	1 January 2005
Benzene	Human Health	Calendar year	5	Annual mean	1 January 2010

According to the *UK Design Manual for Roads and Bridges (DMRB, Volume 11, Section 3, Annex F, 2007*) (hereafter referred to as DMRB) road transport represents a negligible source (less than 1%) of UK sulphur dioxide emissions. Concentrations may have been slightly elevated at heavily trafficked roadside locations in the past, but because the maximum permitted sulphur content of road fuels has periodically been reduced, the contribution is now much lower. On this basis, sulphur dioxide is not considered further.

The TII guidelines state that air quality and climate predictions should be carried out using the screening model method described in the DMRB.

The WHO *Air quality guidelines for particulate matter, ozone, nitrogen dioxide and sulphur dioxide, Global update 2005* provide limit values for those pollutants. **Table 16.2** outlines those guidelines for PM_{10}, (particles of 10 microns or more) $PM_{2.5}$ (particles of 2.5 microns or more) and nitrogen dioxide.

Table 16.2: WHO Air quality guidelines

Pollutant	Averaging period	Limit value ($\mu g/m^3$)
NO_2	Annual mean	40
	1-hour mean	200
PM_{10}	24-hour (99 percentile)	50
	Annual mean	20
$PM_{2.5}$	24-hour (99 percentile)	25
	Annual mean	10

The guidelines for NO_2 are the same as the air quality standards. Guidelines for PM_{10} and $PM_{2.5}$ are substantially lower than the standards. As the air quality standards are the statutory limits that apply in Ireland, baseline and predicted values are compared to these levels. However, an assessment of compliance with the WHO guideline values is also included for completeness.

Ultrafine particles (UFP) are the smallest constituents of airborne particulate matter at less than 0.1 micrometres. UFP can be inhaled more deeply into the lungs than larger particles, and are likely to have adverse health effects. However, as yet, no air quality standard has been set by the EU as further monitoring and assessment of potential effects is ongoing. The WHO concluded that while there is considerable toxicological evidence of potential detrimental effects of ultrafine particles on human health, the existing body of epidemiological evidence is insufficient to reach a conclusion on the exposure response relationship of ultrafine particles (WHO Air quality guidelines, 2005).

There are no national or EU limits for dust deposition. However, the *Technical Instructions on Air Quality Control* (TA Luft, 2002) provide a guideline for the rate of dust deposition of 350 mg/m^2/day averaged over one year.

The Environmental Protection Agency (EPA) concurs that this guideline may be applied, although applied as a 30-day average, in its document *Environmental Management in the Extractive* Industry (Non-Scheduled Minerals) (EPA, 2006).

Directive (EU) 2016/2284 on the reduction of national emissions of certain atmospheric pollutants, was published in December 2016. The directive specifies reductions for nitrogen oxides, particulate matter and non-methane Volatile Organic Compounds (NMVOC) for the period from 2020 to 2019 and from 2030 onward compared with 2005 levels. The limits that apply to Ireland are outlined in **Table 16.3**.

Table 16.3: Directive (EU) 2016/2284 emission limits

Pollutant	Reduction compared with 2005 in 2020-2029 (%)	Reduction compared with 2005 in 2020-2029 (kilotonnes)[1]	Reduction compared with 2005 in 2030 (%)	Reduction compared with 2005 in 2030 (kilotonnes) [1]
Nitrogen oxides	49	61.9	69	87.2
Particulate matter	18	n/a	41	n/a
NMVOC	25	14.7	32	18.8

[1] Based on the following 2005 values: nitrogen oxides-126.4kt, NMVOC- 58.8kt, no PM data available

The impact of nitrogen deposition is also considered in the assessment at ecologically sensitive areas. The TII Guidelines quotes the United Nations Economic Commission for Europe (UNECE) Critical Loads[1]for Nitrogen. As the Lough Corrib candidate, Special Area of Conservation (cSAC) is designated for the protection of a multitude of habitats including, hard water lakes, floating river vegetation, raised bogs, alkaline fens, bog woodland, a number of UNECE Critical Loads could be selected for assessment. The most stringent of these is for inland and surface water habitats (5-10kg(N)/ha/yr) and therefore, this is used in this assessment in **Section 16.5.4.2**. Critical levels[2] are also included in this assessment

1 Critical Loads are defined as: " a quantitative estimate of exposure to one or more pollutants below which significant harmful effects on specified sensitive elements of the environment do not occur according to present knowledge"

(Source: http://www.unece.org/env/lrtap/WorkingGroups/wge/definitions.htm)

2 Critical levels are defined as "concentrations of pollutants in the atmosphere above which direct adverse effects on receptors, such as human beings, plants, ecosystems or materials, may occur according to present knowledge".

(Source: http://www.unece.org/env/lrtap/WorkingGroups/wge/definitions.htm) for various relevant pollutants. These are not habitat specific, as in critical loads, but are set to cover broad vegetation types. They are defined as pollutant concentrations, as opposed to deposition values for critical loads.

16.2.2.2 Climate change obligations and policy

Ireland's climate obligations

In December 2008, the European Union (EU) Climate Change and Renewable Energy Package set out a number of commitments. This package commits to reduce the EU's Greenhouse Gas (GHG) emissions from non-Emission Trading Scheme (ETS) sectors (such as transport, agriculture, residential and waste) by 20% on 2005 levels by 2020 or by a more ambitious 30% in the event of a comprehensive global agreement.

As part of the effort-sharing proposal of this package, Ireland is one of the countries facing the highest target of a 20% reduction on 2005 levels for non-ETS sectors. This will result in a limit of approximately 38 million tonnes of carbon dioxide equivalent (Mt CO_2 eq) for Ireland's non-ETS emissions in 2020, together with annual binding limits for each year from 2013 to 2020.

In October 2014, EU leaders agreed a 2030 policy framework to reduce greenhouse gas emissions by at least 40% compared to a 1990 baseline. No agreement on the contribution of individual EU Member states has yet been reached.

National Policy on Climate Action

The Climate Action and Low-Carbon Development National Policy Position for Ireland was published in 2014. The Position provides a high-level policy direction for the adoption and implementation by Government of plans to enable the State to move to a low carbon economy by 2050.

The Climate Action and Low Carbon Development Act was published by government in January 2015. The Act sets out the national objective of transitioning to a low carbon, climate resilient and environmentally sustainable economy in the period up to 2050. The act provides for the preparation of National Mitigation Plans and Sectoral Plans which will specify policies to reduce greenhouse gas emissions for each sector, including transport. The first National Mitigation Plan was published in July 2017 by the Department of Communications, Climate Action and Environment. The Plan is designed to be a whole-of-Government approach to tackling greenhouse gas emissions, particularly, in the key sectors i.e. electricity generation, the built environment, transport and agriculture.

Climate Action and Transport Sector

In 2013, an Issues Paper for Consultation on the Preparation of Low-Carbon Roadmap for Transport was prepared by the Department of Transport, Tourism and

Sport. This paper proposed the following relevant policy measures to contribute to a low carbon future:

- Engines and fuels (efficiencies and alternatives)
- Travel demand
- Modal shift

The document Smarter Travel - A Sustainable Transport Future, A New Transport Policy for Ireland 2009 – 2020 includes a number of targets to reduce carbon emissions:

- Work-related commuting by car will be reduced from a current modal share of 65% to 45%, which will mean that between 500,000 and 600,000 commuters will be encouraged to take means of transport other than car driver (of these 200,000 would be existing car drivers)
- Car drivers will be accommodated on other modes such as walking, cycling, public transport and car sharing (to the extent that commuting by these modes will rise to 55% by 2020) or through other measures such as e-working
- The road freight sector will become more energy efficient, with a subsequent reduction in emissions
- Transport will make a meaningful contribution to Ireland’s commitment under the proposed EU effort-sharing arrangement in relation to climate change and real reductions on current levels of emissions will be achieved

Policies to reduce transport emissions include the reduction of travel demand, increase use of alternatives to the private car and improve the efficiency of motorised transport.

Ireland’s first National Climate Change Adaptation Framework (NCCAF), which was published in December 2012 by the Department of Environment, Community and Local Government, aims to ensure that adaptation actions are taken across key sectors and also at local level to reduce Ireland's vulnerability to climate change. This Framework is currently under review. Climate change adaptation measures have been considered through the provision of attenuation storage to accommodate the 100-year storm event with climate change, refer to **Chapter 11, Hydrology**.

16.2.2.3 Transport Infrastructure Ireland Guidelines

Operational Criteria

The TII Guidelines specifies that the changes in pollutant concentrations alongside roads with a significant change in traffic should be determined. It states that receptors should be considered at all road links where a greater than 5% change in Annual Average Daily Traffic (AADT) is predicted for the “Do-Something” option during the operational phase and during the construction phase where an increase of AADT greater than 10% is predicted.

Significance criteria have been adopted from the TII guidelines, these are presented in **Tables 16.4**, **16.5** and **16.6**.

Table 16.4: Definition of Impact Magnitude for Changes in Ambient Pollutant Concentrations

Magnitude of Change	Annual Mean NO2/PM10	No. days with PM10 concentration greater than 50 ug/m3	Annual Mean PM2.5
Large	Increase/decrease ≥ 4µg/m^3	Increase/decrease >4 days	Increase/decrease ≥2.5 µg/m^3
Medium	Increase/decrease 2-<4µg/m^3	Increase/decrease 3 or 4 days	Increase/decrease 1.25 -<2.5µg/m^3
Small	Increase/decrease 0.4-<2µg/m^3	Increase/decrease 1 or 2 days	Increase/decrease 0.25-<1.25µg/m^3
Imperceptible	Increase/decrease <0.4µg/m^3	Increase/decrease <1day	Increase/decrease <0.25µg/m^3

Table 16.5: Air Quality Impact Descriptors for Changes to Annual Mean Nitrogen Dioxide and PM_{10} and $PM_{2.5}$ Concentrations at a Receptor

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration[3]		
	Small	**Medium**	**Large**
Increase with Proposed Road Development			
Above Objective/Limit Value With Proposed Road Development (≥40 µg/m^3 of NO_2 or PM_{10}) (≥25µg/m^3 of $PM_{2.5}$)	Slight Adverse	Moderate Adverse	Substantial Adverse
Just Below Objective/Limit Value With Proposed Road Development (36≤40 µg/m^3 of NO_2 or PM_{10}) (22.5≤25µg/m^3 of $PM_{2.5}$)	Slight Adverse	Moderate Adverse	Moderate Adverse
Below Objective/Limit Value With Proposed Road Development (30≤36 µg/m^3 of NO_2 or PM_{10}) (18.75≤22.5 µg/m^3 of $PM_{2.5}$)	Negligible	Slight Adverse	Slight Adverse
Well Below Objective/Limit Value With Proposed Road Development (<30 µg/m^3 of NO_2 or PM_{10}) (<18.75µg/m^3 of $PM_{2.5}$)	Negligible	Negligible	Slight Adverse
Decrease with Proposed Road Development			
Above Objective/Limit Value Without Proposed Road Development (≥40 µg/m^3 of NO_2 or PM_{10}) (≥25µg/m^3 of $PM_{2.5}$)	Slight Beneficial	Moderate Beneficial	Substantial Beneficial
Just Below Objective/Limit Value Without Proposed Road Development (36-<40 µg/m^3 of NO_2 or PM_{10}) (22.5-<25µg/m^3 of $PM_{2.5}$)	Slight Beneficial	Moderate Beneficial	Moderate Beneficial
Below Objective/Limit Value Without Proposed Road Development (30-<36 µg/m^3 of NO_2 or PM_{10}) (18.75-<22.5 µg/m^3 of $PM_{2.5}$)	Negligible	Slight Beneficial	Slight Beneficial

[3] Where the impact magnitude is imperceptible, then the impact description is negligible.

Absolute Concentration in Relation to Objective/Limit Value	Change in Concentration[3]		
	Small	**Medium**	**Large**
Well Below Objective/Limit Value Without Proposed Road Development (<30 µg/m^3 of NO_2 or PM_{10}) (<18.75µg/m^3 of $PM_{2.5}$)	Negligible	Negligible	Slight Beneficial

Table 16.6: Air Quality Impact Descriptors for Changes to Number of Days with PM_{10} Concentration Greater than 50µg/m^3 at a Receptor

Absolute Concentration in Relation to Objective/Limit Value	Changes in Concentration[4]		
	Small	**Medium**	**Large**
Increase with Proposed Road Development			
Above Objective/Limit Value with Proposed Road Development (≥35 days)	Slight Adverse	Moderate Adverse	Substantial Adverse
Just Below Objective/Limit Value with Proposed Road Development (32-<35 days)	Slight Adverse	Moderate Adverse	Moderate Adverse
Below Objective/Limit Value with Proposed Road Development (26-<32 days)	Negligible	Slight Adverse	Slight Adverse
Well Below Objective/Limit Value with Proposed Road Development (<26 days)	Negligible	Negligible	Slight Adverse
Decrease with Proposed Road Development			
Above Objective/Limit Value Without Proposed Road Development (≥35 days)	Slight Beneficial	Moderate Beneficial	Substantial Beneficial
Just Below Objective/Limit Value Without Proposed Road Development (32-<35 days)	Slight Beneficial	Moderate Beneficial	Moderate Beneficial
Below Objective/Limit Value Without Proposed Road Development (26-<32 days)	Negligible	Slight Beneficial	Slight Beneficial
Well Below Objective/Limit Value Without Proposed Road Development (<26 days)	Negligible	Negligible	Slight Beneficial

The significance criteria outlined above varies slightly from that outlined in the EPA guidelines. A substantial impact is rated as a significant/profound impact from the EPA guidelines.

Due to the number of sensitive ecological sites in the vicinity of the proposed road development, a detailed assessment of the potential impacts upon sensitive ecosystems has been carried out. The significance criteria is applied to the assessment of NO_x impacts at the ecological sensitive sites as described in **Tables 16.4, 16.5** and **16.6**.

[4] Where the impact magnitude is imperceptible, then the impact description is negligible.

Construction criteria

As stated in the TII Guidance it is *"very difficult to accurately quantify dust emissions arising from construction activities". "A semi quantitative approach is recommended to determine the likelihood of a significant impact, which should be combined with an assessment of the proposed mitigation measures"*. The semi-quantitative assessment methodology outlined in **Table 16.7** is used to assess the impact of dust during the construction phase.

Table 16.7: Assessment Criteria for the Impact of Dust Emissions from Construction Activities with Standard Dust Control Measures Mitigation in Place

Source		**Potential distance for Significant Effects (Distance from Source)**		
Scale	**Description**	**Soiling**	**PM_{10}[a]**	**Vegetation Effects**
Major	Large construction sites, with high use of haul routes	100 m	25 m	25 m
Moderate	Moderate sized construction sites, with moderate use of haul routes	50 m	15 m	15 m
Minor	Minor construction sites, with limited use of haul routes	25 m	10 m	10 m

Note: [a] Significance based on the PM_{10} Limit Values specified in SI No. 180 of 2011, which allows 35 daily exceedances/year of 50 µg/m³

TII guidance states that dust emissions from construction sites can lead to elevated PM_{10} concentrations and can cause soiling of properties.

The potential impact of dust emissions during the construction phase is assessed by estimating the area over which there is a risk of significant impacts, in line with the TII guidance. The impact of construction dust on sensitive habitats is also considered, and additional mitigation measures proposed, as required. The TII Guidelines do not provide a definition of 'standard mitigation', however, the following is assumed:

- Spraying of exposed earthwork activities and site haul roads during dry weather
- Provision of wheel washes at exit points
- Control of vehicle speeds and speed restrictions. It is proposed that site traffic is restricted to 20km/hr. This will help to minimise the occurrence of dust re-suspension.
- Sweeping of hard surface roads

16.2.3 Data Sources and Consultations

The Environmental Protection Agency (EPA) is responsible for coordinating and managing air quality monitoring in accordance with relevant legislation. This includes a nationwide network of 33 monitoring stations which measures levels of air pollutants and delivers this information in real-time. This data along with on-site monitoring data is used to establish the baseline air quality in the study area.

Consultations were undertaken with stakeholders during the design development process, refer to **Chapter 1, Introduction**. Any comments that related to air quality and climate were considered during the preparation of this chapter.

16.2.4 Study area and Baseline Data Collection

The DMRB states *that only properties and designated sites within 200m of the roads affected by the project need be considered*. On this basis, properties located within 200m of the edge of the proposed road development are considered in the assessment and is the extent of the study area for the air quality and climate appraisal for this EIAR.

As described in **Section 16.2.3**, long-term baseline data provided by the EPA is used in the assessment. Since the commencement of the environmental studies for the proposed road development, the EPA has published air quality data for 2014 and 2015, this is included in the description of the receiving environment in **Section 16.3**.

16.2.5 Impact Assessment Methodology

16.2.5.1 Air Quality

Monitoring data conversion methodology

Three months of site specific air quality monitoring was carried out in the vicinity of the proposed road development. Appendix 2 of the TII *Guidelines for the Treatment of Air Quality during the Planning and Construction of National Road Schemes, 2011* provides a methodology to calculate the annual mean from short-term monitoring. This is based on long term published monitoring data from the EPA from appropriate monitoring stations. Using this approach, predicted annual mean concentrations of PM and NO_2 were made. **Table 16.8** outlines the calculation method for estimating annual mean averages of pollutant concentrations.

Table 16.8: Formula for calculating annual average concentration from short term data

Abbreviation	Unit	Description
M	µg/m^3	Measured average from monitoring carried out (06/02/17 to 01/05/17).
A	µg/m^3	Annual average from Zone C monitoring station. As taken from EPA published data for 2014, 2015 and 2016.
P	µg/m^3	Period mean from Zone C monitoring station (06/02/17 to 01/05/17). As taken from EPA published datasets.
R		Ratio of A/P.
E	µg/m^3	Estimated annual mean (M x R).

DMRB methodology

In accordance with the TII guidelines, the DMRB Screening Method (Version 1.03c) spreadsheet is used in this assessment. This spreadsheet calculates annual average concentrations of NOx (for the assessment of nitrogen deposition), NO_2, CO, benzene, PM_{10} and $PM_{2.5}$ and was used to assess the air quality impact of the proposed road development.

The DMRB spreadsheet method computes concentrations of pollutants at a local and regional level based on factors including:

- Location and distance of sensitive receptors to proposed road development
- Annual average daily traffic (AADT) flows, refer to **Chapter 6, Traffic Assessment and Route Cross-section**
- Average speed of traffic
- Traffic composition
- Road type and length
- Background pollutant concentrations

The spreadsheet was used to assess the potential local and regional air quality impacts and potential climate impacts.

The scenarios modelled for the purpose of the air quality assessment are described below:

- The 'Do-Minimum' (DM) Scenario assumes that the proposed road development is not constructed with traffic scenarios for 2024 (Opening Year) and 2039 (Design Year)
- The 'Do-Something' (DS) Scenario assumes that the proposed road development is constructed with traffic scenarios for 2024 and 2039

The air quality assessment utilises traffic predictions for 2024 and 2039 outlined in **Chapter 6, Traffic Assessment and Route Cross-section**.

The M17/M18 Junction with the M6 is a committed development in the area. Traffic associated with this development has been included in all the scenarios.

Potential air quality impacts at all sensitive receptors are considered. Sensitive receptors are described in the TII guidelines as residential housing, schools, hospitals, places of worship, sports centres and shopping areas as well as designated ecological areas.

ADMS-Roads model

The Environmental Protection Agency (EPA) State of the Environment Report, 2016 – An Assessment states that the *failure of real-world emissions of NOx Euro 5 class vehicles to meet the standards set for them has had a disproportionate impact on ambient air (EEA, 2015). Euro 5 class vehicles showed a reduction in NO_2 emissions in laboratory tests; however, these reductions were not observed in real world driving. As a result, projections of NO_2 emission reductions did not come true and an increase in vehicle numbers actually led to increasing NO_2 levels across*

Europe. In order to fully consider the potential air quality impacts associated with actual vehicle emissions compared to laboratory tests, the ADMS-Roads version 4 atmospheric dispersion model has been used.

The assessment follows the methodology set out in Defra's Local Air Quality Management Technical Guidance (LAQM.TG16) for aspects not covered by the TII Guidelines. The Defra guidance also states that exceedances of the NO_2 1-hour mean is unlikely to occur where the annual mean is below 60µg/m^3. Both the DMRB and ADMS-Roads models only predict annual means for NO_2.

The assessment scenarios are as prepared for the DMRB screening model.

ADMS-Roads has been used to predict NO_x, PM_{10} and $PM_{2.5}$ concentrations. Predicted NO_x concentrations have been processed to determine annual mean NO_2 concentrations for comparison with the annual mean NO_2 objectives.

Vehicle emissions and background air quality are predicted to improve over time due to the introduction of cleaner vehicles into the vehicle fleet. However, there is uncertainty as to how successful the implementation of stricter controls of vehicle emissions will be. To account for this uncertainty modelling has been carried out assuming no improvement in vehicle emissions nor background concentrations for the future scenarios. This represents a worst case scenario, as some improvements are likely during this period.

The traffic data used for this assessment consisted of 24-hour AADT flows, the percentage of heavy goods vehicles (HGVs) and free flow speeds, refer to **Chapter 6, Traffic Assessment and Route Cross-section** for traffic data. The speeds provided were based on the free flow speeds for each road link. As recommended in TII Guidelines, traffic speeds were slowed at junctions to 20kph, for a distance of 50m from the yield/stop line.

In accordance with TII guidelines, emission rates have been calculated using the Defra Emissions Factor Toolkit (EFT) v7[5]. Emission factors from 2015 have been used in all modelled scenarios as a worst-case.

Details of the locations and heights of the proposed noise barriers were also considered in this assessment. Noise barriers located close to the modelled sensitive air receptors have been included in the air modelling. Modelling has been carried out with and without the noise barriers, to determine their potential to change air quality at the receptor. Refer to **Chapter 17, Noise and Vibration** and **Figures 17.1.101** to **17.1.114** for details on these noise barriers.

Receptor Locations

Worst-case receptors, such as close to junctions and those close to the kerbside, were selected as part of the DMRB and ADMS assessments. Their locations are shown in **Figures 16.1.1** to **16.1.14**, except where the receptors are located away from the proposed road development. The location and height of the receptors are

[5] Defra Emission Factor Toolkit v7 (http://laqm.defra.gov.uk/review-and-assessment/tools/emissions-factors-toolkit.html) accessed September 2016

given in **Table 16.9**. A height of 1.5m corresponds to typical inhalation height at a ground floor property.

Table 16.9: Modelled Receptors

Receptor ID	Receptor type	OS Grid Ref.		Receptor height (m)
		X m	Y m

An air quality modelling assessment was undertaken using ADMS to consider potential additional impacts at the locations of the proposed tunnel portals. Details of the tunnels as modelled are given in **Table 16.10**.

Table 16.10: Tunnel locations

Tunnel		OS Grid Ref	Bore depth (m)	Outflow link	Outflow width (m)
Galway Racecourse eastbound	Entrance portal	533809, 728070	6	51_T_EB_W	13.45
	Exit portal	533973, 727894	6	51_T_EB_E	11.95
Galway Racecourse westbound	Entrance portal	533962, 727885	6	51_T_WB_E	13.0

	Exit portal	530108, 728387	8.1	53_T_WB_W	10.9

The proposed road development crosses the Lough Corrib cSAC. Concentrations of NO_x along four 200m transects from where the proposed road development crosses the Lough Corrib cSAC have been modelled. Transects 1 to 3 were selected due to their proximity to the Lackagh Tunnel portals. Transect 4 was selected as the location where the Lough Corrib cSAC is closest to the proposed road development. The ecological transects and their location in relation to the proposed road development, Lackagh Tunnel portals and Lough Corrib cSAC are shown in **Plate 16.1** and **16.2**.

Plate 16.1: Lough Corrib cSAC, Lackagh Tunnel portals and ecological transects 1 to 3

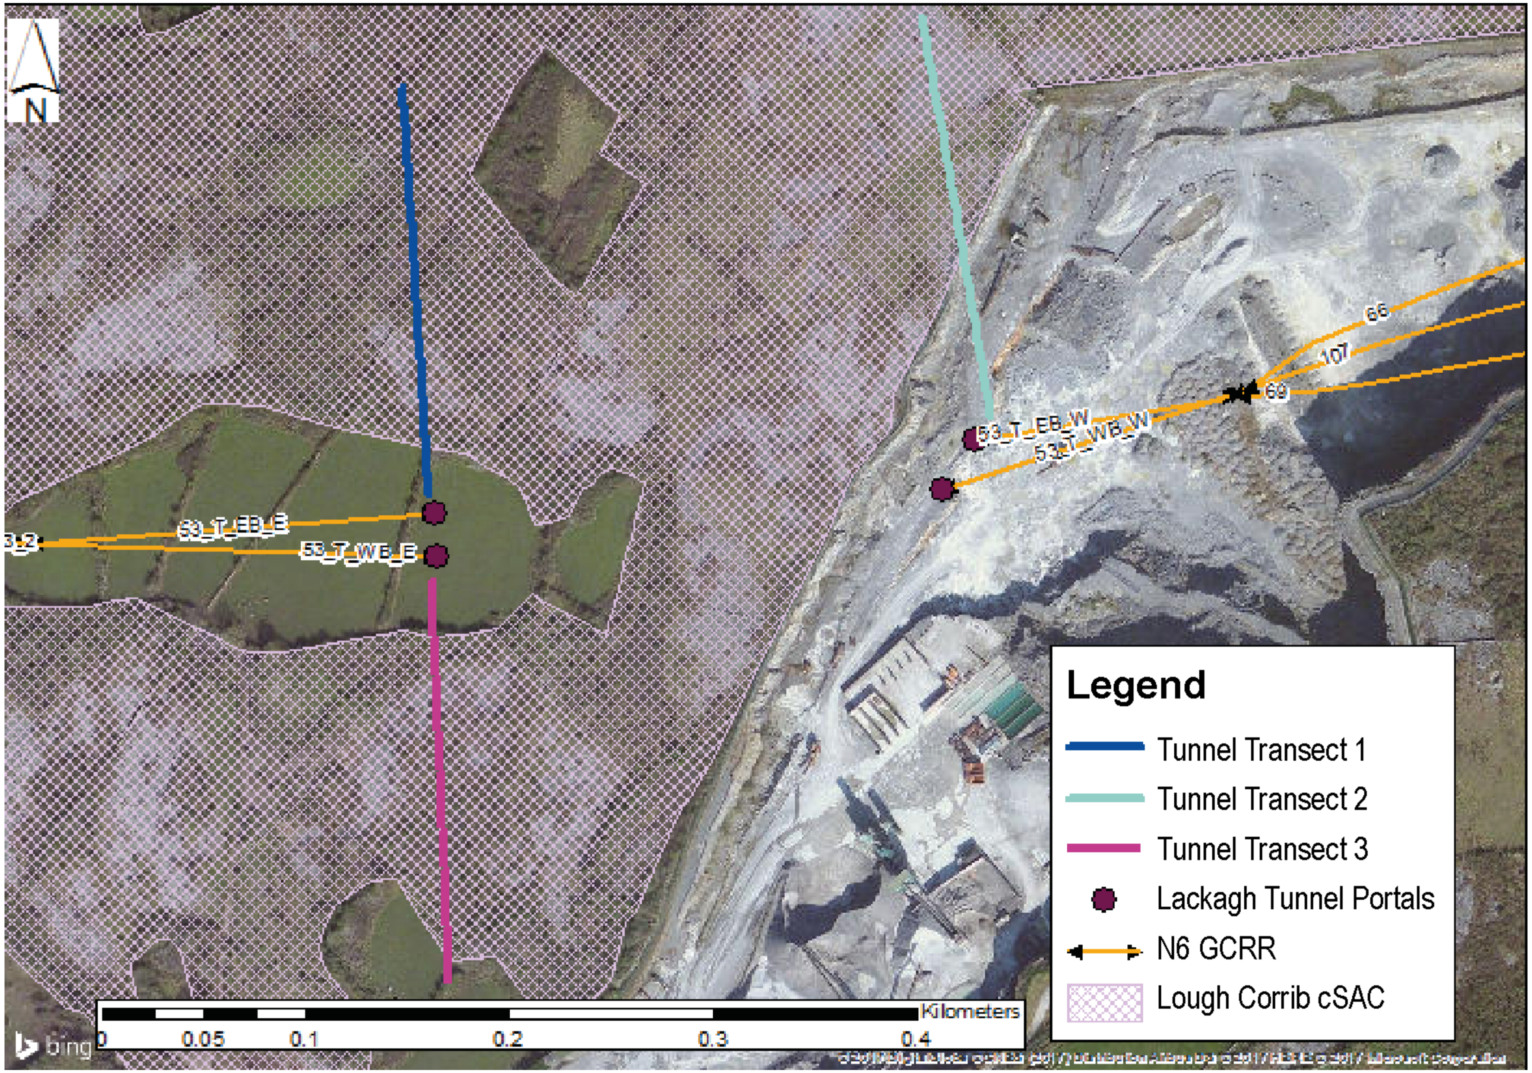

Plate 16.2: Lough Corrib cSAC and ecological transect 4

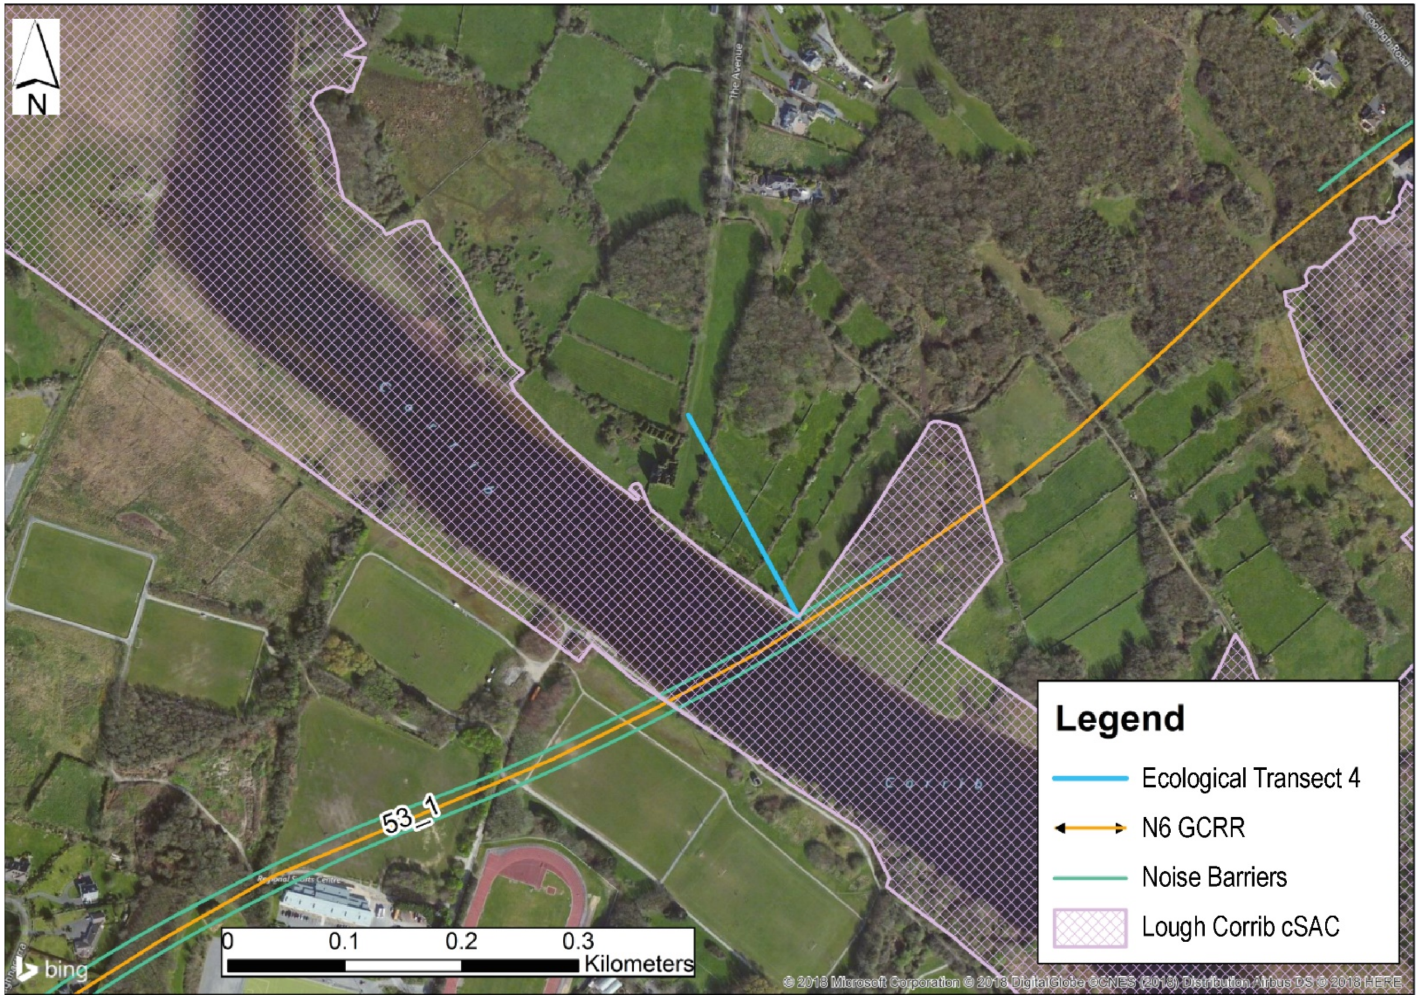

Ecological impact assessment

The UK DMRB states that some air pollutants can have an effect on vegetation. Concentrations of pollutants in air and deposition of particles can damage vegetation directly or affect plant health and productivity. It states that the pollutants of most concern for sensitive vegetation near roads, and perhaps the best understood, is NO_x. It refers to the EU limit set for NO_x for the protection of vegetation. This value was based on the work of UNECE and WHO and has been implemented into the Irish air quality standards. The report states that *'critical loads for the deposition of nitrogen represents the exposure below which there should be no significant harmful effects on sensitive elements of the ecosystem (according to current knowledge)'*. In relation to heavy metals, the manual states that *small quantities of heavy metals released during combustion and from vehicle wear and tear may accumulate in soils near the road. However, such emissions cannot be reliably quantified or the negative ecological effects determined*.

The manual describes the assessment procedure to be used to assess the impact of air pollution on ecologically sensitive sites. The procedure was developed in collaboration with the Joint Nature Conservation committee and Natural England and adopted by the TII in its guidelines.

The Natural England report 'the Ecological Effects of Air Pollution from Road Transport' published in 2004 and the 2016 update were reviewed in the context of this assessment. These reports were commissioned to assess the potential risk to biodiversity due to air pollution from roads.

The reports summarise studies carried out to determine the effect of traffic emissions on NOx and nitrogen deposition on various species. In general, the study concludes that a review of relevant studies *provides further evidence of the impacts on individual species from exposure to NO_x and NO_2 associated with vehicle emissions and that these are greatest within the first 50-100m from the roads but may be discernible at greater distances.*

In relation to Volatile Organic Compounds (VOCs), the report states that most studies testing the responses of plants exposure to VOCs have used high concentrations over short exposure periods (hours or days). Therefore, the effects of exposure to low concentrations of VOC is difficult to determine. Also, few of the studies tested the responses of vegetation to the species of VOCs emitted by vehicles. Studies have generally concentrated on the effects of ethylene which is emitted by motor vehicles and naturally occurring in plants. The report also states that *levels of ethylene likely to be found in the vicinity of roads may be high enough to adversely affect sensitive species*. Sensitive species include flowers, fruit, seed production and morphology. *The report concludes that the response of vegetation to other VOCs emitted by motor vehicles is unclear; although possible effects are degradation of leaf surface waxes, pigment bleaching and ultra-structural changes.*

In relation to metals, the report states:

The studies also evidence that traffic emissions are a significant source of metal contamination for vegetation close to roads, although the leaf concentrations recorded are unlikely to present a significant immediate toxic risk to plants.

Metals are likely to persist in soils and levels may therefore build up over time in the vicinity of roads. A number of laboratory studies have cultured a variety of plant species in soil containing elevated concentrations of heavy metals and have found a range of tolerances depending on the species tested.

There is the potential for elevated concentrations of metals in soils close to roads. However, the report also states that soil metal content is generally only substantially elevated within 20-30m from even the busiest of roads.

In relation to ammonia, the report states:

Ammonia is emitted in small amounts by vehicles with catalytic converters and roadside atmospheric concentrations are well below critical levels for this pollutant (UK Critical Levels Advisory Group, 1996). Gaseous ammonia is thus unlikely to be a key issue, and effects on vegetation are more likely to arise from enhanced deposition of nitrogen to the soil environment. This elevation in soil nitrogen will be limited to areas within tens of metres of roads due to the high rates of deposition of this gas.

In relation to particulates/dust, the following is stated:

Few attempts have been made to assess the impacts of particulates and dust from motor vehicles on vegetation under controlled conditions… The authors conclude that it is difficult to assess the significance of these results for roadside plants under realistic conditions.

16.2.5.2 Climate

The Construction Carbon Calculator was published by the UK Environment Agency in July 2012. The carbon calculator measures the greenhouse gas impacts of construction activities in terms of carbon dioxide equivalency (CO_2e). It does this by calculating the embodied CO_2e of materials plus the CO_2e associated with their transportation. It also considers personnel travel, site energy use and waste management.

The potential impact of the proposed road development on carbon emissions was assessed using the DMRB spreadsheet as described in **Section 16.2.8.1**.

The potential micro-climatic impacts of the proposed road development were assessed in relation to existing micro-climatic conditions, the size of the proposed road development and the nature of use of the surrounding environment.

16.3 Receiving Environment

16.3.1 Introduction

The receiving environment for this appraisal comprises of local air quality, national air quality and climate.

Road traffic on the national routes (including the existing N6, N83[6], N67, N59 and N84) and on the local road network is currently generating levels of pollution. Emissions are higher under congested traffic conditions, such as those experienced in certain areas of Galway City, particularly during peak times. The EPA carries out air quality monitoring at Bodkin Junction in Galway. PM_{10} and heavy metals levels are shown to comply with air quality standards in 2017 (www.epa.ie).

Heating for residential and commercial premises currently generates levels of pollution, particularly in the areas of higher density population in Galway City and suburbs. Agricultural activities also generate pollution due to farming plant and dust generating activities.

There are operational quarries located in proximity to the proposed road development. There is the potential for windblown dust to be generated from open faces and stockpiles.

Table 16.11 presents a list of industrial facilities licenced by the EPA within the study area, under Industrial Emissions (IE) or Integrated Pollution Licence (IPC).

Table 16.11: EPA IE/IPC Licence holders within the vicinity of the proposed road development

Licence No	Company	Address	IPC/IED

[6] Formally known as the N17 Tuam Road

Licence No	Company	Address	IPC/IED
P0264-02	Medtronic Vascular Galway	Parkmore Industrial Estate, Galway	IPC

In addition to the air emission sources outlined above, the effect of the emission sources presented in the above table are likely to be reflected in the baseline air monitoring data presented in **Table 16.12**.

Sensitive receptor locations within the scheme study area are defined in the guidelines as residential housing, schools, hospitals, places of worship, sports centres and shopping areas, i.e. locations where members of the public are likely to be regularly present. In addition, sensitive ecological sites are considered in the assessment.

16.3.2 Local Air Quality data from EPA long-term monitoring

The TII Guidelines advise that if sufficient data is available and pollutant concentrations are well below air quality standards then existing published data can be used as a baseline.

The Air Quality Standards (AQS) Regulations describe the air quality zoning adopted in Ireland as follows:

- Zone A (Dublin Conurbation)
- Zone B (Cork Conurbation)
- Zone C (16 Cities and Towns with population greater than 15,000, including Naas)
- Zone D (Rural Ireland: areas not in Zones A, B and C)

The proposed road development falls within the vicinity of Galway City and is therefore considered in Zone C.

Background levels from 2016, 2015 and 2014 air quality monitoring of NO_x, NO_2, CO, benzene, $PM_{2.5}$ and PM_{10} in Zone C provided by the EPA are presented in **Table 16.12**.

Concentrations of each pollutant recorded in Zone C are averaged to represent typical background levels. Average concentrations were obtained from all Zone C stations where 90% data capture was achieved. This is in accordance with the air quality standards which specifies that any site used for assessment purposes must comply with 90% data capture. For pollutants where the 90% capture rule was not achieved at any Zone C sites, the average of other sites was taken instead. Where no validated data exists for Zone C, Zone B data was used as it is expected to be similar or higher than Zone C data, resulting in a worst-case.

Table 16.12: Annual Mean Background Pollutant Concentrations for Zone C

Year	Pollutants	Time Period	Location	Measured concentrations µg/m³	Air Quality Standard µg/m³	% of Air Quality Standard
2016	NO_2	Annual average	Zone C	8.8	40	22
	NO_x	Annual average	Zone C	14.3	30	47.6
	CO	8-hour annual average	Zone C	400	10,000	4
	$PM_{2.5}$	Annual average	Zone B	7	25	28
	PM_{10}	Annual average	Zone C	15.3	40	38.2
	Benzene	Annual average	Zone A	1.01	5	20.2
2015	NO_2	Annual average	Zone C	7.5	40	18.8
	NO_x	Annual average	Zone C	11.5	30	38.3
	CO	8-hour annual average	Zone C	400	10,000	4
	$PM_{2.5}$	Annual Average	Zone C	9.5	25	38
	PM_{10}	Annual Average	Zone C	15	40	37.5
	Benzene	Annual Average	Zone C	0.1	5	2.6
2014	NO_2	Annual average	Zone C	5	40	12.5
	NO_x	Annual average	Zone C	8	30	26.7
	CO	8-hour annual average	Zone C	200	10,000	3
	$PM_{2.5}$	Annual average	Zone B	12	25	48
	PM_{10}	Annual average	Zone C	21	40	52.5
	Benzene	Annual average	Zone B	0.1	5	2.6

All current baseline concentrations are in compliance with AQS. Note that concentrations of PM_{10} slightly exceed the WHO guideline of 20µg/m³ in 2014. Concentrations of $PM_{2.5}$ slightly exceed the WHO guideline of 10µg/m³ in 2014.

The EPA State of the Environment Report, 2016 – An Assessment states that in recent years while *exhaust emission limits become stricter, this is offset by increases in the numbers of cars. New EU emissions standards for vehicles, cleaner technology, and a reduction in the number of vehicles using the roads as a result of the economic downturn led to a decrease in NO_2 in our urban centres. However, this is unlikely to continue into the future. Economic recovery will most likely lead to an increase in NO_2 levels. The failure of real-world emissions of NOx Euro 5 class vehicles to meet the standards set for them has had a disproportionate impact on ambient air (EEA, 2015). Euro 5 class vehicles showed a reduction in NO_2 emissions in laboratory tests; however, these reductions were not observed in real world driving. As a result, projections of NO_2 emission reductions did not come true and an increase in vehicle numbers actually led to increasing NO_2 levels across Europe.*

Average background concentrations are provided in **Table 16.13**. The TII Guidance provides correction factors to predict background levels for future assessment years to take into account concentration decreases in future years due to improved vehicle technology etc. However, in order to consider a worst-case scenario, no improvement is assumed and current values are used for future years. Although uncertainty regarding future year emission factors relates primarily to NO_x emissions, it should be noted that the same approach of holding vehicle emission factors and background pollutant concentrations has been taken for PM_{10} and $PM_{2.5}$ concentrations.

Table 16.13: Average background concentrations

Pollutant	Average concentration μg/m^3 (2014 to 2016)	Air Quality Standard μg/m^3
NO_2	7.1	40
NO_x	11.2	30
CO	333	10,000
$PM_{2.5}$	9.5	20
PM_{10}	17.1	40
Benzene	0.4	5

Average background concentrations are in compliance with Air Quality Standards.

Modelled background concentrations for 1990, 2000 and 2020 nitrogen deposition are provided in the EPA research document *'Development of Critical Loads for Ireland: Simulating Impacts on Systems (SIOS)*, Aherne, Henry and Wolniewicz. In the area of the proposed road development, background levels are in the range of 1 to 2.5kg(N)/ha/yr.

16.3.3 Site specific air quality monitoring

16.3.3.1 Monitoring results

Site specific monitoring of PM and NO_2 was carried out over a period of three months, refer to **Appendix 16.1** for full monitoring report. As outlined in **Section 16.2.5.1**, concentrations can be adjusted using TII methodology for comparison with annual mean limits outlined in the air quality standards.

This approach utilises data from each of the monitoring stations contained within the appropriate zone, in this case Zone C. Individual annual average concentrations for PM and NO_2 have been calculated using three years of monitoring data (2014-2016) from all Zone C stations where 90% data capture was achieved. This is in accordance with the air quality standards which specifies that any site used for assessment purposes must comply with 90% data capture. Where the 90% capture rule was not achieved at any Zone C sites, Zone B data was used as it is expected to be similar or higher than Zone C data, resulting in a worst-case.

It should be noted that only datasets with sufficient coverage over the three month period from 6 February to 2 May for each assessment year have been used, in accordance with air quality standards.

PM_{10} and $PM_{2.5}$

Schedule 11 of the Air Quality Standards Regulations states that PM_{10} concentrations should not exceed 50μg/m^3 more than 35 times in a calendar year over one day periods (24-hours) or exceed 40μg/m^3 over an annual period. For $PM_{2.5}$, concentrations should not exceed 25μg/m^3 over an annual period. There were no such exceedances during the monitoring period.

Table 16.14 outlines the monitoring data for PM_{10} and $PM_{2.5}$ from 6 February to 2 May 2017.

Table 16.14: Average PM_{10} and $PM_{2.5}$ concentration (μg/m^3) for 24-hour period from 6 February - 2 May 2017

Monitoring Period	Daily average (μg/m^3)	
	PM_{10}	$PM_{2.5}$
6 February to 2 May 2017	9.72	5.36

Table 16.15 outlines the calculated average concentrations of PM_{10} based on the method outlined in **Table 16.8**.

Table 16.15: Predicted annual average PM_{10} concentration (μg/m^3)

Zone C Monitoring station	Galway	Portlaoise	Ennis	Ennis
Year	**2016**	**2015**	**2015**	**2014**
Measured 3-month average (μg/m^3) - M	9.72			
Annual average (μg/m3) –A	15.3	12	18	21
Period average (3-month average) (μg/m^3) – P	16	15.9	22.4	21.3
Ratio of A/P - R	0.95	0.75	0.8	0.98
Estimated annual average (μg/m^3) - E	8.83	7.29	7.77	9.52
Average of estimated annual averages (μg/m^3)	8.35			

The predicted annual average PM_{10} concentration is in compliance with the annual air quality standard of 40μg/m^3 and the WHO guideline of 20μg/m^3.

Table 16.16 outlines the calculated average concentrations of $PM_{2.5}$ based on the method outlined in **Table 16.8**.

Table 16.16: Predicted annual average PM2.5 concentration (µg/m^3)

Zone C Monitoring station	Heatherton Park*	Bray	Ennis	Coleraine St**	Rathmines**	Finglas**	Marino**
Year	**2016**	**2015**	**2015**	**2014**	**2014**	**2014**	**2014**
Measured 3-month average (µg/m^3) - M	5.36						
Annual average (µg/m^3) –A	7	7	12	9	9	7	8
Period average (3-month average) (µg/m^3) – P	8.1	8	13	10.1	9.7	9.5	8.6
Ratio of A/P - R	0.86	0.87	0.92	0.89	0.92	0.73	0.93
Estimated annual average (µg/m^3) - E	4.6	4.6	4.93	4.77	4.93	3.91	4.98
Average of estimated annual averages (µg/m^3)	4.67						

* Data obtained from Zone B Monitoring Station as no data available from Zone C Stations where 90% data capture was achieved
** Data obtained from Zone A Monitoring Stations as no data available from Zone C or Zone B Stations where 90% data capture was achieved

The predicted annual average $PM_{2.5}$ concentration is in compliance with the annual air quality standard of 20µg/m^3 and the WHO guideline of 10µg/m^3.

NO_2

Table 16.17 outlines the monitoring data for NO_2 from the 6 February to 2 May 2017.

Table 16.17: Average NO_2 concentration (µg/m^3) for monthly period from 6 February - 2 May 2017

Time Period	Location 1 (µg/m^3)	Location 2 (µg/m^3)	Location 3 (µg/m^3)	Location 4 (µg/m^3)
6 February to 6 March 2017	8.2	9.09	11.06	20.45
6 March to 6 April 2017	5.58	6.29	9.29	8.66
3 April to 2 May 2017	8.75	4.22	7.02	10.82
Average (µg/m^3)	7.51	6.53	9.12	13.31
Average for all four locations (µg/m^3)	9.12			

Table 16.18 outlines the calculated average concentrations of NO_2 based on the method outlined in **Table 16.8**.

Table 16.18: Predicted annual average NO_2 concentration (µg/m^3)

Zone C Monitoring station	Kilkenny Seville Lodge	Portlaoise	Kilkenny Seville Lodge	Kilkenny Seville Lodge
Year	**2016**	**2016**	**2015**	**2014**
Measured 3-month average (µg/m^3) - M	9.12			
Annual average (µg/m^3) –A	6.6	11.1	5	5
Period average (3-month average) (µg/m^3) – P	6.9	10.1	5.03	4.7
Ratio of A/P - R	0.95	1.09	0.99	1.06
Estimated annual average (µg/m^3) - E	8.66	9.94	9.02	9.66
Average of estimated annual averages (µg/m^3)	9.32			

The predicted annual average NO_2 concentration is in compliance with the annual air quality standard of 40µg/m^3 and the WHO guideline of 40µg/m^3.

16.3.3.2 Selection of background data for modelling assessments

Table 16.19 presents background data from EPA published data and from the assessment presented in **Section 16.3.3.1**.

Table 16.19: Background pollutant concentrations

Pollutant	Average concentration 2014 to 2016 (μg/m^3)	Predicted average concentration from monitoring data (μg/m^3)	Background value selected for assessments (μg/m^3)	Air Quality Standard (μg/m^3)
NO_2	7.1	9.3	9.3	40
PM_{10}	17.1	8.4	17.1	40
$PM_{2.5}$	9.5	4.7	9.5	20
Benzene	0.4	n/a	0.4	5
NO_x	11.2	n/a	11.2	30
CO	333	n/a	333	10,000

As a worst case, the highest level background data has been selected for use in the modelling assessments.

16.3.4 National Air Quality

In 2015, the EPA in a press release reported that emissions of nitrogen oxides (NO_x) decreased by 45% between 1990 and 2013. Between 2010 and 2011 there was a 10% reduction, caused by reductions across all sectors and in particular power generation. Despite this reduction, Ireland is currently exceeding its 2010 NO_x ceiling of 65 kilotonnes by 11 kilotonnes in 2013.

The road transport sector represents the largest source of NO_x emissions, accounting for 53% of total NO_x emissions in 2013.

The national total emissions of VOC were 90 kilotonnes in 2013 which exceeds the ceiling of 55 kilotonnes. Transport emissions comprise approximately 8% of total VOC emissions. However, technological controls for VOCs in motor vehicles have led to a significant reduction in emissions from road transport in recent years.

16.3.5 Macro climate

In April 2017, the EPA produced the report 'Ireland's final greenhouse gas emissions in 2015'. This concluded that there was an increase of 4.2% or 0.48Mtonnes of CO_{2eq} from the transport sector in 2015. This is the third year of increases in transport emissions following five consecutive years of decreases since 2007. The increase primarily reflects higher usage of diesel with gasoline usage decreasing. It is noted that biofuels use increased in 2015 by 10.3%.

In March 2016, the EPA reported that Ireland is unlikely to meet 2020 EU greenhouse gas targets for all sectors including transport. Current projections indicate that Ireland will be 6-11% below 2005 levels by 2020. This falls well short of the target of 20% below 2005 levels by 2020. Transport is predicted to constitute 29% of Ireland's non-Emissions Trading Scheme (ETS) emissions in 2020.

16.3.6 Micro-climate

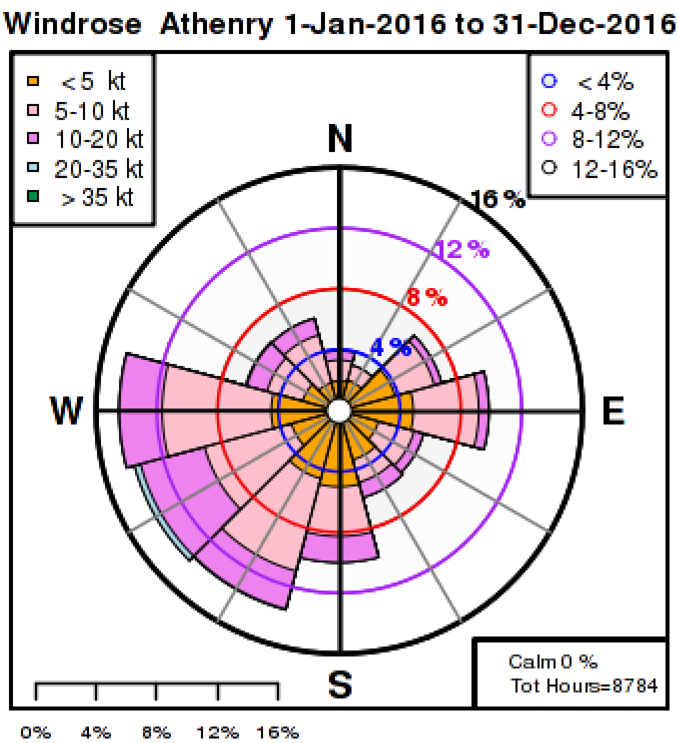
The nearest representative Met Éireann synoptic meteorological station is at Athenry which is located approximately 20km east of the proposed road development at 47m above mean sea level. Meteorological data is only available at this station from July 2011. All climate data cited below is taken from the 6 year averages reported for Athenry meteorological station (www.met.ie).

The annual mean temperature is 9.8ºC. The annual mean of daily maxima is 13.6ºC and of daily minima is 6ºC.

The mean annual rainfall is 1,004mm.

The annual mean wind speed is 3.9m/s (7.5 knots). A windrose for Athenry meteorological station is provided in **Plate 16.3** (www.met.ie).

Plate 16.3: Windrose for Athenry 2016



16.4 Characteristics of the Proposed Development

16.4.1 Construction Phase

The construction of the proposed road development will require earthworks, particularly during site clearance and excavation, refer to **Chapter 7, Construction Activities** for further details. Dust emissions are likely to arise from the following activities:

- Site earthworks
- Windblow from temporary stockpiles
- Handling of construction materials
- Landscaping
- Construction traffic movements
- Demolitions
- Concrete batching and crushing

In general, any additional airborne concentrations of particulate matter arising from construction would be small and very local to the construction activity (minimising human exposure). Particles generated by most construction activities tend to be larger than 10µm in diameter which are too large to enter the human lung.

Based on the assessment criteria outlined in **Table 16.7**, the potential dust impacts at locations where the main construction works will occur are assessed in **Section 16.5**.

A number of construction compounds are proposed, refer to **Figures 7.101** to 7.**123** for the locations of these compounds. The main construction compound will be located at Lackagh Quarry. It is assumed that concrete batching and rock crushing plant will be utilised at each compound.

It is also expected that a mobile crushing plant will be used in areas where extensive cut is required.

16.4.2 Operational Phase

The proposed road development comprises the construction of a single carriageway from the western side of Bearna as far as the Ballymoneen Road and a dual carriage from here to the eastern tie in with the existing N6 at Coolagh with associated link roads.

Predicted traffic volumes are outlined in **Chapter 6, Traffic Assessment and Route Cross-section**.

16.5 Evaluation of Impacts

16.5.1 Introduction

The following sections consider the potential impact of the proposed road development on air quality and climate during the construction and operational phases. The construction assessment considers potential impacts due to construction activities and traffic. The operational phase assesses the potential impact locally and regionally due to traffic emissions.

16.5.2 Do-Nothing Impact

The Do-nothing impact is considered and compared to the Do-Something scenarios in **Section 16.5.4**.

16.5.3 Potential Construction Impacts

16.5.3.1 Construction Activities

As outlined in **Section 16.4**, the construction of the proposed road development will require earthworks, particularly during site clearance and excavation.

Based on the assessment criteria outlined in **Table 16.7**, the potential dust impacts at locations where the main construction works will occur are assessed. The proposed road development has been split into six sections for the purpose of this assessment as outlined below. The sensitive receptors are shown on **Figures 16.01** to **16.14**.

Section 1: Ch. 0+000 to 5+600 (R336 to Ballymoneen Road Junction)

A single carriageway is proposed from Ch. 0+000 to Ch. 5+600 totalling 5.6km in length. This section of the proposed road development includes one new roundabout with a number of side road realignments, refer to **Table 5.2** of **Chapter 5, Description of proposed road development**. Works associated with Section 1 are considered to be of a major scale (refer to **Table 16.7**). There is potential for soiling effects at receptors located within 100m of the site works and PM_{10} and vegetation effects at receptors located less than 25m from the site works with standard dust control mitigation measures in place.

There are approximately 42 sensitive receptors located within 100m at which there is the potential for significant soiling effects with standard dust control mitigation measures in place. Approximately seven receptors are located less than 25m from the proposed site works at which there is the potential for significant PM_{10} and vegetation effects with standard dust control mitigation measures in place.

Section 2: Ch. 5+600 to 9+250 (Ballymoneen Road Junction to River Corrib Bridge)

A dual carriageway is proposed from Ch. 5+600 to Ch. 9+300 totalling 3.7km in length. This section of the proposed road development includes the N59 Letteragh Junction and approximately 2.2km of single carriageway for the N59 Link Road

North and South at Ch. 7+550. The scale of these works is considered to be of a major scale (refer to **Table 16.7**). There is potential for soiling effects at receptors located within 100 m of the site works and PM_{10} and vegetation effects at receptors located less than 25 m from the site works with standard mitigation in place.

There are approximately 39 sensitive receptors located within 100m of the works at which there is the potential for significant soiling effects with standard dust control mitigation measures in place. Approximately six receptors are located less than 25m from construction works at which there is the potential for PM_{10} and vegetation effects with standard dust control mitigation measures in place.

Section 3: Ch. 9+250 to 12+150 (River Corrib Bridge to N84 Headford Road Junction)

Section 3 of the proposed road development is also a dual carriageway and includes the construction of the River Corrib Bridge, 650m in length at Ch. 8+840, Menlough Viaduct, 30m in length at Ch. 10+090, Lackagh Tunnel, 270m in length at Ch. 11+140 and the N84 Headford Road Junction at Ch. 12+150. The scale of these works is considered to be of a major scale (refer to **Table 16.7**). There is potential for soiling effects at receptors located within 100m of the site works and PM_{10} and vegetation effects at receptors located less than 25m from the site works with standard mitigation in place.

There are approximately 13 sensitive receptors located within 100m at which there is the potential for significant soiling effects with standard dust control mitigation measures in place. Approximately three receptors are located less than 25m from construction works at which there is the potential for significant PM_{10} and vegetation effects with standard dust control mitigation measures in place.

Construction works will also take place in or adjacent to the Lough Corrib cSAC in Section 3. There is the potential for significant PM_{10}, soiling and vegetation effects at these locations with standard dust control mitigation measures in place.

Section 4: Ch. 12+150 to 14+300 (N84 Headford Road Junction to N83 Tuam Road Junction)

Section 4 of the proposed road development is also a dual carriageway and includes the N83 Tuam Road Junction. The construction works are considered to be of a major scale (refer to **Table 16.7**), including the construction of the N83 Tuam Road Junction.

The remainder of the works in Section 4 are considered to be of a major scale with the potential to result in soiling effects within 100m, PM_{10} and vegetation effects within 25m with standard mitigation in place.

There are approximately 29 sensitive receptors located within 100m of the works at which there is the potential for significant soiling effects with standard dust control mitigation measures in place. Approximately five receptors less than 25m from construction works at which there is the potential for significant PM_{10} and vegetation effects within 25m of the works and the potential for significant soiling effects within 100m of the works with standard dust control mitigation measures in place.

Section 5: Ch. 14+300 to 15+900 (N83 Tuam Road Junction to R339 Monivea Road) including Parkmore

Section 5 of the proposed road development is also a dual carriageway and includes the Galway Racecourse Tunnel at Ch. 14+950 to Ch. 15+200. This is considered to be of a major scale (refer to **Table 16.7**). There is potential for soiling effects at receptors located within 100m of the site works and PM_{10} and vegetation effects at receptors located less than 25m from the site works with standard mitigation in place.

There are approximately 14 sensitive receptors located within 100m at which there is the potential for significant soiling effects with standard dust control mitigation measures in place. Approximately two receptors are located less than 25 m from construction works at which there is the potential for significant PM_{10} and vegetation effects with standard dust control mitigation measures in place.

Section 6: Ch. 15+900 to 17+450 (R339 Monivea Road to Coolagh Junction)

Section 6 of the proposed road development is also a dual carriageway and includes the Coolagh Junction. This section is considered to be of a major scale (refer to **Table 16.7**). There is potential for soiling effects at receptors located within 100m of the site works and PM_{10} and vegetation effects at receptors located less than 25m from the site works with standard mitigation in place.

There are a number sensitive receptors located within 100m of the works at which there is the potential for significant soiling effects with standard dust control mitigation measures in place.

16.5.3.2 Construction Compounds

There are twelve sites identified as potential site compounds across the proposed road development. They have been identified at strategic locations across the proposed road development to minimise the distance for site construction traffic and personnel to travel. Sites identified have been chosen taking cognisance of proximity to major structures, excavations and embankments, proximity to residential properties, environmental constraints and current land use and ownership. Larger area compounds have the potential for material stockpiling, crushing, regrading and delivery in tandem with site offices. Refer to **Table 7.9** in **Chapter 7, Construction Activities** and **Figures 7.1.101** to **7.1.123**, for potential site compound locations.

One of the construction compounds (SC08/01) will be for the storage of materials only and therefore its impact on dust emissions has been categorised as minor scale. All other construction compounds have been categorised as moderate scale, see **Table 16.7**.

In total, approximately 16 sensitive receptors are located with 50m of the potential construction compounds at which there is the potential for significant soiling effects with standard dust control mitigation measures in place. Approximately, two receptors are located less than 15m of the construction compounds at which there is the potential for significant PM_{10} and vegetation effects with standard dust control mitigation measures in place.

16.5.3.3 Construction traffic

As stated in **Section 16.2.5**, construction traffic impacts are assessed when traffic generated (AADT) of greater than 10% are predicted to occur due to the proposed road development. Only three links are predicted to generate traffic volumes greater than 10% during the construction phase, i.e. R336 Bearna Moycullen Road, Cappagh Road and Menlough Road. **Table 16.20** provides the predicted concentrations at the worst-case receptor (5m from the centre of the road) for each road link. All predicted concentrations are in compliance with AQS.

Table 16:20: Predicted Pollutant Concentrations Including Background Concentrations – Construction Phase

Receptor	Scenario	NO_2 (µg/m³)	PM_{10} (µg/m³)	$PM_{2.5}$ (µg/m³)	PM_{10} (Days > 50 µg/m³)	CO (µg/m³)	Benzene (µg/m³)
	Limit Values	**40**	**40**	**25**	**35**	**10,000**	**5**
R336 Bearna Moycullen Road	DN	9.82	17.24	9.57	<1	343	0.5
	DS	9.92	17.26	9.58	<1	343	0.5
	DS – DN	0.1	0.02	0.01	0	0	0
	Impact Rating	Negligible	Negligible	Negligible	n/a	Negligible	Negligible
Cappagh Road	DN	9.49	20.59	9.5	<1	334.8	0.5
	DS	9.6	20.6	9.51	<1	336.4	0.5
	DS – DN	0.11	0.01	0.01	0	1.6	0
	Impact Rating	Negligible	Negligible	Negligible	n/a	Negligible	Negligible
Menlough Road	DN	10.22	17.34	9.66	<1	345	0.5
	DS	10.3	17.36	9.67	<1	347	0.5
	DS – DN	0.08	0.02	0.01	0	2	0
	Impact Rating	Negligible	Negligible	Negligible	n/a	Negligible	Negligible

The impact ratings for NO_2, PM_{10} and $PM_{2.5}$ are negligible. No impact rating is provided for benzene or CO in the TII Guidance. However, due to the small changes in concentrations and the easy compliance with limit values, a rating of negligible would be expected for all pollutants.

16.5.4 Potential Operational Impacts

16.5.4.1 Local air quality impacts based on DMRB screening model

The potential impact on air quality is assessed for the Opening Year (2024) and Design Year (2039) under the 'Do-Minimum' (DM) and 'Do-Something' (DS) scenarios respectively. Pollutant concentrations are provided at the worst-case receptors, i.e. those properties that are closest to the affected links.

The results provided are based on the use of the DMRB model (refer to **Section 16.2.5.1** for methodology).

Opening Year (2024)

Predicted concentrations (including background concentrations) for the DM, and DS scenarios for the Opening Year 2024 are presented in **Table 16.21**.

The receptor where the highest concentration of pollutants are predicted (including the background concentrations) as a result of the DS scenario is Receptor 17 for NO_2, PM_{10}, $PM_{2.5}$, CO and Benzene (refer to **Figure 16.1.06**).

At this receptor, annual average concentrations of NO_2 are predicted to be 14.42µg/m³, which complies with the AQS of 40µg/m³; annual average concentrations of $PM_{2.5}$ are predicted to be 11.3µg/m³, which complies with the proposed limit value of 20µg/m³ and the annual average concentrations of PM_{10} are predicted to be 19.2µg/m³ which complies with the limit value of 40µg/m³. The number of annual days which PM_{10} levels is predicted to exceed the limit of 50µg/m³ is <3 days. This complies with the limit of 35 days. Annual average concentrations of benzene are predicted to be 0.48µg/m³, which complies with the AQS of 5µg/m³ and 8 hour concentrations of CO are predicted to be 387.2µg/m³, which complies with the AQS of 10,000µg/m³.

From **Tables 16.4**, **16.5** and **16.6**, the predicted changes in concentration of all pollutants are rated as negligible or imperceptible impacts at all receptors except at receptors, R16 and R17 where an impact of slight adverse is predicted for NO_2. No impact rating is provided for benzene or CO in the TII Guidance. However, due to the small changes in concentrations and the easy compliance with limit values, a rating of negligible would be expected for all pollutants.

Under the 2024 DS scenario, all predicted pollutant concentrations comply with the relevant limit values at all worst-case receptors selected. Following guidance provided in LAQM.TG16 [7], as all modelled results predict annual mean concentrations less than 60µg/m³, it is unlikely that this area would exceed the hourly mean NO_2 objective.

---

[7] Defra (2016) Local Air Quality Management Technical Guidance TG16

It should also be noted that predicted concentrations comply with the PM_{10} WHO guideline values at all locations.

The WHO $PM_{2.5}$ annual mean limit of 10µg/m^3 is exceeded for the DM and DS scenarios with the background level in excess of this guideline level.

Table 16.21: Predicted Pollutant Concentrations Including Background Concentrations 2024

Receptor	Scenario	NO_2 (µg/m³)	PM_{10} (µg/m³)	$PM_{2.5}$ (µg/m³)	PM_{10} (Days > 50 µg/m³)	CO (µg/m³)	Benzene (µg/m³)

Design Year (2039)

Predicted concentrations (including background concentrations) for the 'DM', and 'DS' scenarios for the Opening Year 2039 are presented in **Table 16.22**. The receptor where the highest concentration of pollutants are predicted (including the background concentrations) as a result of the 'DS' scenario is Receptor 17 for NO_2, PM_{10}, $PM_{2.5}$, CO and Benzene (refer to **Figure 16.1.1**).

For this receptor, annual average concentrations of NO_2 are predicted to be 14.72µg/m³, which complies with the AQS of 40µg/m³; annual average concentrations of $PM_{2.5}$ are predicted to be 11.4µg/m³, which complies with the proposed limit value of 25µg/m³ and the annual average concentrations of PM_{10} are predicted to be 19.3µg/m³ which complies with the limit value of 40µg/m³. The number of annual days which PM_{10} levels is predicted to exceed the limit of 50µg/m³ is <3 days. This complies with the limit of 35 days. Annual average concentrations of Benzene are predicted to be 0.5µg/m³, which complies with the AQS of 5µg/m³ and 8 hour concentrations of CO are predicted to be 390.9µg/m³, which complies with the AQS of 10,000µg/m³.

From **Tables 16.4**, **16.5** and **16.6**, the predicted changes in concentration of all pollutants are rated as negligible or imperceptible impacts at all receptors except at receptors, R17 and R16 where an impact of slight adverse is predicted for NO_2. No impact rating is provided for benzene or CO in the TII Guidance. However, due to the small changes in concentrations and the easy compliance with limit values, a rating of negligible would be expected for all pollutants. The increase in magnitude of change in PM_{10} daily values is also considered negligible.

Under the 2039 DS scenario, all predicted pollutant concentrations comply with the relevant limit values at all receptors selected. Following guidance provided in LAQM.TG16[8], as all modelled results predict annual mean concentrations less than 60µg/m³, it is unlikely that this area would exceed the hourly mean NO_2 objective.

[8] Defra (2016) Local Air Quality Management Technical Guidance TG16

It should also be noted that predicted concentrations comply with the PM_{10} WHO guideline values at all locations.

The WHO $PM_{2.5}$ annual mean limit of 10µg/m^3 is exceeded for the DM and DS scenarios at some of the receptors with the background level of 9.5µg/m^3 close to this guideline level.

At the entrance and exit to the Lackagh Tunnel at Ch. 11+150, the closest residential receptors are approximately 470m from the eastern entrance and 480m from the western entrance. No significant air quality impacts are envisaged at these locations due to the separation from the tunnel openings to the nearest receptors.

At the entrance and exit to the tunnel at the Galway Racecourse, the closest sensitive receptors are approximately 80m from the eastern entrance and 350m from the western entrance. No significant air quality impacts are envisaged at these locations due to the separation from the tunnel openings to the nearest receptors.

Ecologically Sensitive Areas

Lough Corrib cSAC

The following sections assess the potential for pollution due to the proposed road development under the headings of nitrogen compounds, VOC, metals/dust and ammonia at the Lough Corrib cSAC, at the River Corrib Bridge between Ch. 9+250 and Ch. 9+600, between Ch. 9+800 and Ch. 10+100 at Menlough, and Lackagh Tunnel between Ch. 10+450 and Ch. 11+450 during the operational phase, refer to **Figures 8.15.7** and **8.15.8**.

NOx

Table 16.23 presents the results from the air quality modelling using DMRB methodology based on traffic volumes for 2024 (Year of Opening) and 2039 (Design Year) for the Do-Minimum (without the proposed road development) and Do-Something (with the proposed road development) scenarios at the section of road at the Lough Corrib cSAC. The potential impact of NO_x concentration and deposition was assessed at various distances from the edge of the proposed road. The assessment was carried out in accordance with TII Guidelines using the DMRB Screening Model. Background concentrations are as outlined in **Table 16.19**.

Ambient NO_x concentrations predicted for the Opening and Design Years along a transect of up to 200m from the centre of the proposed road development are given in **Table 16.23** in accordance with TII guidance. The contribution of the proposed road development to NO_x deposition is also given and was calculated using the TII guidance methodology.

The annual average NO_x concentration at various distances from the centre of the road complies with the limit value of 30 µg/m³ for the Do-Minimum scenario in 2024 and 2039, with NO_x concentrations reaching 37% of this limit in 2024 and 2039. For the Do-Something scenario, the limit values are complied with in 2024 at 80% of the limit value and complied with in 2039 with the predicted concentration at 83% of the limit value, including background concentrations at 10m from the edge of the proposed road.

The potential impact of the proposed road development results in a maximum increase in NO_x concentrations of a maximum of 13.64μg/m^3 at 10m from the proposed road edge. All predicted concentrations are in compliance with the Air Quality Standard for the protection of vegetation.

The proposed road development contribution to the NO_2 dry deposition rate along the 200m transect from the proposed road edge is also detailed in **Table 16.23**. The maximum increase in the NO_2 dry deposition rate is 1.03kg(N)/ha/yr in 2024 and 1.06kg(N)/ha/yr in 2039 for the Do-Something scenario. This is approximately 20% of the critical load for the lower boundary limit of inland and surface water habitats of 5-10kg(N)/ha/yr (TII 2011).

As outlined in **Section 16.3.2**, background nitrogen deposition levels are likely in the range of 1 to 2.5kg(N)/ha/yr. The addition of these background levels results in continued compliance with the critical load.

Table 16.23: Predicted Nitrogen Concentration including Background and Deposition at the Lough Corrib cSAC for 2024 and 2039

VOC

No critical load limits exist for VOCs for the protection of vegetation.

An assessment of emissions of benzene was carried out for the proposed road development, in accordance with TII methodology using the DMRB modelling spreadsheet. Predicted concentrations were compared to the air quality standard of 5µg/m^3 for the protection of human health. The maximum predicted concentration for the Do-Something scenario was 10.2% of the standard including background concentrations of 5µg/m^3. As stated previously, these limits have been developed to protect the environment as a whole.

Benzene concentrations predicted for the Opening and Design Years along a transect of up to 200m from the proposed road development are given in **Table 16.24**.

As outlined in **Section 16.2.5**, the Natural England report states that *levels of ethylene likely to be found in the vicinity of roads may be high enough to adversely affect sensitive species*. On this basis, comparisons of emission factors of VOCs (mg/vehicle/km) have been examined in order to estimate an appropriate ratio of ethylene to benzene. The five studies examined[9]; various types of vehicles, over a ten year period, across three countries. The highest ratio of ethylene to benzene determined was 3:1, for vehicles which were primarily diesel emissions. Increases in ethylene from the proposed road development have been predicted using this ratio and results presented in **Table 16.25**. No background data or relevant limit values are available for ethylene. At 10m from the proposed road edge a 0.28µg/m³ increase is predicted in 2024 and a 0.33µg/m³ increase in 2039.

Table 16.25: Predicted ethylene concentrations at the Lough Corrib cSAC for 2024 and 2039

Metals/Dust

No critical load limits exist for metals or dust for the protection of vegetation.

As outlined in the Environmental Protection Agency Air Quality in Ireland report 2015, high levels of heavy metals are usually observed in areas with a lot of heavy industry such as smelting and mining. Ireland as a country which has few heavy industries such as these, and as a consequence, the concentration of heavy metals is likely to remain low in the future. No reference is made to high levels of metals due to traffic emissions.

Heavy metals are continually monitored by the EPA for Zone C, at the heavily trafficked Bodkin Junction, Galway. Since 2015 measured heavy metals (Lead, Arsenic, Cadmium and Nickel) are all well below target values i.e. Lead 0.7%, Arsenic 15%, Cadmium 6%, Nickel 3% of the target values (Directive 2004/107/EC). These limits were developed to protect the environment as a whole.

PM_{10} concentrations predicted for the Opening and Design Years along a transect of up to 200m from the proposed road development are given in **Table 16.26**. Values include background concentrations of 17.1μg/m^3. All predicted concentrations are in compliance with the air quality standard for PM_{10} of 40μg/m^3. A maximum increase of 1.89μg/m^3 is predicted to occur in 2039 at 10m from the proposed road edge.

Table 16.26: Predicted PM_{10} concentrations at the Lough Corrib cSAC including Background Concentrations for 2024 and 2039

Ammonia

As outlined earlier, ammonia is emitted in small amounts by vehicles with catalytic converters and *roadside atmospheric concentrations are well below critical levels* for this pollutant. The Natural England report states that it is *unlikely to be a key issue, and effects on vegetation are more likely to arise from enhanced deposition of nitrogen to the soil environment*. The potential impact of nitrogen deposition on ecological sites has been assessed earlier in this Section.

River Corrib Bridge Crossing

The proposed road development crosses the River Corrib which is within the Lough Corrib cSAC on a bridge and embankment (between Ch. 9+500 and Ch. 9+600).

Noise barriers are proposed on both sides of the bridge structure. These will contain the majority of pollutants generated by traffic accessing the proposed road development. The elevated position of the proposed road development at this location will also result in good dispersion of pollution generated from traffic. This will have the effect of significantly lowering ground level concentrations. In addition, predicted concentrations of NO_x and nitrogen deposition levels are below relevant limits at this location even within 10m from the proposed road edge, refer to **Table 16.23**.

Predicted concentrations of VOCs and dust are in compliance with air quality standards for the protection of the environment as a whole.

Menlough – Ch. 9+800 to 10+100

To the east of the River Corrib the proposed road development continues east on embankment toward the Menlough Viaduct and traverses outside of the boundary of the Lough Corrib cSAC, overlapping it in places. The ecologically sensitive area where the qualifying interests of the Lough Corrib cSAC are located is to the southeast of this section of the proposed road development and comprises of an area of semi-natural Oak-Ash-Hazel woodlands, scrub, wet grassland and calcareous grassland; some of which correspond to Qualifying Interest (QI) Annex I habitats.

The elevated position of the proposed road development at this location will result in good dispersion of pollution generated from traffic. In addition, predicted concentrations of NO_x and nitrogen deposition levels are predicted to be below relevant limits at this location even within 10m of the proposed road edge.

Predicted concentrations of VOCs and dust are in compliance with air quality standards for the protection of the environment as a whole.

A windrose for Athenry meteorological station is provided in **Plate 16.3** (www.met.ie). This demonstrates that the prevailing wind in the area is from the south-west and west. The wind directions required to direct pollution towards this sensitive area are from the northwest and west. According to the windrose, wind from the northwest in 2016 was recorded for approximately 7% of the time in 2016. Therefore, the likelihood of pollution generated by road traffic interacting with the sensitive area is low due to northwest winds. Westerly winds were recorded for approximately 15% of the time in 2016. However, for approximately 10% of this time the wind speeds recorded are greater than 5 knots. This results in high dispersion of potential pollutants during this time, greatly reducing pollutant concentrations.

The separation between the edge of the proposed road development and the ecologically sensitive area is approximately 15m. As outlined in **Table 16.23**, the nitrogen deposition levels due to the proposed road development at such distances is predicted to be less than relevant limits.

Lackagh Tunnel

East of the Menlough Viaduct, the proposed road development enters a section of cut preceding Lackagh Tunnel immediately west of Lackagh Quarry and exits the tunnel in the disused quarry. The Lackagh Tunnel passes underneath Lough Corrib cSAC. The overlying habitats within the Lough Corrib cSAC at this location comprise a mosaic of Limestone pavement, and Calcareous grassland. All of these habitat types are Qualifying Interest (QI) habitats of the Lough Corrib cSAC.

As the proposed road development is in tunnel beneath the Lough Corrib cSAC at this location and the eastern approach is within Lackagh Quarry surrounded by quarry walls up to 40m in height, emissions generated here will not be physically able to interact with the designated areas. At the portals and at the western approach to the tunnel which runs adjacent (approximately 10m) to the Lough Corrib cSAC, there is the potential for air quality impacts. However, as outlined in **Table 16.23**, the nitrogen deposition levels due to the proposed road development at such distances is predicted to be less than relevant limits.

In addition, the dispersal of pollution at the eastern and western approach to the tunnel will be contained due to the effective barrier caused by the cutting along the Lough Corrib cSAC at this location.

Between Ch. 10+450 and Ch. 10+600 and between Ch. 10+750 and Ch. 10+900 there are short sections of embankment adjacent to the Lough Corrib cSAC. QI habitats are located c.75m from the first location (north of the proposed road development) and at the second location, c.45m from the northern edge of the proposed road development and c.15m from the southern edge of the proposed road development. At these distances of between 10 and 75m from the edge of the proposed road, NOx concentrations are predicted to be in compliance with the air quality standards for the protection of vegetation and the critical load for nitrogen deposition, refer to **Table 16.23**.

Predicted concentrations of VOCs and metals/dust are in compliance with air quality standards for the protection of the environment as a whole, refer to **Tables 16.24** and **16.25**.

Other ecological sensitive sites

Table 16.26 presents the results from the air quality modelling using DMRB methodology based on traffic volumes for 2024 (Opening Year) and 2039 (Design Year) for the Do-Minimum (without the proposed road development) and Do-Something (with the proposed road development) scenarios at the section of the proposed road development between N83 Tuam Road and N84 Headford (highest predicted traffic volumes). Lesser concentration and deposition values would be expected at all other sections of the proposed road development where lesser traffic volumes are predicted. The potential impact of NO_x concentration and deposition was assessed at various distances from the edge of the proposed road. The assessment was carried out in accordance with TII Guidelines using the DMRB Screening Model. Background concentrations are as outlined in **Table 16.19**.

The annual average NO_x concentration at various distances from the proposed road edge complies with the limit value of 30μg/m^3 for the Do-Minimum scenario in 2024 and 2039, with NO_x concentrations reaching 37% of this limit in 2024 and 2039. In the 2024 Do-Something scenario, the limit values are complied with at 86% of the limit value, this equates to a slight adverse impact. In the 2039 Do-Something scenario, the limit values are complied with at 92% of the limit value, this equates to a slight adverse impact.

Further away from the proposed road edge, all predicted concentrations comply.

The potential impact of the proposed road development results in a maximum increase in NO_x concentrations of a maximum of 16.53μg/m^3 at 10m from the proposed road edge.

The proposed road development contribution to the NO_2 dry deposition rate along the 200m transect from the proposed road edge is also detailed in **Table 16.27**. The maximum increase in the NO_2 dry deposition rate is predicted to be 1.22kg(N)/ha/yr in 2024 and 1.27kg(N)/ha/yr in 2039 for the Do-Something scenario. This is approximately 24.4% and 25.4% respectively of the critical load for the lower boundary limit of inland and surface water habitats of 5-10kg(N)/ha/yr (TII 2011).

Air Quality Improvements

Table 16.28 outlines locations where air quality will improve as a result of decreases in AADT. Light green areas represent scenarios where AADT flow values will decrease by 10%, the darkest green represents up to an 80% decrease.

The reduction in traffic will result in a localised improvement of air quality in these regions, which will be particularly evident where sensitive receptors are adjacent to roadways and traffic reductions are substantial.

Table 16.28: Locations of Improved Air Quality as a result of reduced AADT flows (refer to Figure 6.9 for location of link numbers)

16.5.4.2 Local air quality impacts based on ADMS model

NO_2

Annual mean NO_2 concentrations were predicted at the receptor locations for the future year when the proposed road development Opens (2024) and the Design Year (2039). It should be noted that this has been undertaken retaining vehicle emission factors and background pollutant concentrations at baseline levels (**Table 16.19**) to represent a worst case scenario.

Predicted annual mean NO_2 concentrations for the Do-Minimum (without the proposed road development) and Do-Something (with the proposed road development), the change in concentrations as a result of the proposed road development and the impact descriptor at each receptor are shown in **Table 16.29** and **Table 16.30** for the Opening Year (2024) and Design Year (2039), respectively. Results of modelling with the noise barriers in place area also included for the receptors, where relevant.

Table 16.29: Predicted concentrations of NO_2 ($\mu g/m^3$), 2024

R28	10.7	10.8	0.1	Negligible	-	-	-

Predicted annual mean concentrations are all well below the limit value (40µg/m^3). The maximum concentration was predicted at R16 (16.4µg/m^3 in 2024), where the maximum change in concentration (7.4µg/m^3) was predicted. The predicted impact at R16 can be therefore described as slight adverse, refer to **Tables 16.4**, **16.5** and **16.6**. A slight adverse impact was also predicted at R17. A negligible impact was predicted at all other locations.

With the proposed noise barriers in place, lower concentrations are predicted at all of the nearby receptors, excluding R04, R06, R12, R15, R21 and R23, where the difference in predicted concentrations is <0.01µg/m^3. The trend for lower concentrations near to the proposed road development with the noise barrier in place is expected, but the impact will depend on the orientation of the noise barrier with respect to the wind direction. At all locations, the lower predicted change in concentrations with the noise barriers in place does not change the impact descriptor.

Following guidance provided in LAQM.TG16[10], as all modelled results predict annual mean concentrations less than 60µg/m^3, it is unlikely that this area would exceed the hourly mean NO_2 objective.

Table 16.30: Predicted concentrations of NO_2 (µg/m^3), 2039

R28	12.1	12.4	0.3	Negligible	-	-	-

Predicted annual mean concentrations are all well below the limit value (40µg/m³). The maximum concentration was predicted at R16 (18.2µg/m³ in 2039), where the maximum change in concentration (8.5µg/m³) was predicted. The predicted impact at R16 can be therefore described as slight adverse, refer to **Tables 16.4**, **16.5** and **16.6**. A slight adverse impact was also predicted at R17 and R20. A negligible impact was predicted at all other locations.

With the proposed noise barriers in place, lower concentrations are predicted at all of the nearby receptors, excluding R04, R06, R12, R15 and R23, where the difference in predicted concentrations is <0.01µg/m³. The trend for lower concentrations near to the road with the noise barrier in place is expected, but the impact will depend on the orientation of the noise barrier with respect to the wind direction. At all locations, the lower predicted change in concentrations with the noise barriers in place does not change the impact descriptor.

Following guidance provided in LAQM.TG16[11], as all modelled results predict annual mean concentrations less than 60µg/m^3, it is unlikely that this area would exceed the hourly mean NO_2 objective.

PM_{10}

Annual mean PM_{10} concentrations were predicted at the assessed receptor locations for the future year when the proposed road development opens (2024) and the Design Year (2039). Although uncertainty regarding future year emission factors relates primarily to NOx emissions, it should be noted that the same approach of holding vehicle emission factors and background pollutant concentrations (**Table 16.19**) has been taken for PM_{10} and $PM_{2.5}$ concentrations.

Predicted annual mean PM_{10} concentrations for the do minimum and do something scenarios, the change in concentrations as a result of the proposed road development and the impact descriptor at each receptor are shown in **Table 16.31** and **Table 16.32**, for the Opening Year (2024) and Design Year (2039), respectively. Results of modelling with the noise barriers in place area also included for the receptors, where relevant.

Predicted annual mean concentrations are all well below the limit value (40μg/m^3) at all locations in 2024 and 2039. The maximum concentration was predicted at R16 (19.2μg/m^3 in 2039), where the maximum change in concentration (1.6μg/m^3) was predicted. These levels were reduced following the inclusion of noise barriers. A negligible impact was predicted at all locations, refer to **Tables 16.4**, **16.5** and **16.6**.

The WHO guideline level is complied with at all receptor points.

$PM_{2.5}$

Annual mean $PM_{2.5}$ concentrations were predicted at the assessed receptor locations for the future year when the proposed road development opens (2024) and the Design Year (2039).

Predicted annual mean $PM_{2.5}$ concentrations for the Do-Minimum and Do-Something scenarios, the change in concentrations as a result of the proposed road development and the impact descriptor at each receptor are shown in **Table 16.33** and **Table 16.34**, for the Opening Year (2024) and Design Year (2039), respectively. Results of modelling with the noise barriers in place area also included for the receptors, where relevant.

Table 16.33: Predicted concentrations of $PM_{2.5}$ ($\mu g/m^3$), 2024

R27	10.4	10.4	0	Negligible	-	-	-
R28	10.1	10.2	0.1	Negligible	-	-	-

Predicted annual mean concentrations are all well below the limit value (20µg/m³) at all locations in 2024 and 2039. The maximum concentration was predicted at R16 (9µg/m³ in 2024), where the maximum change in concentration (0.9µg/m³) was predicted. A negligible impact was predicted at all locations, refer to **Tables 16.4**, **16.5** and **16.6**.

The WHO guideline level is exceeded at all receptor points, excluding R05 and R26 in 2024 and R05 in 2039. The exceedances are due to the contribution of background concentrations.

NOx

The proposed road development crosses the Lough Corrib cSAC. The concentration of NOx along four transects 200m from where the proposed road development crosses the Lough Corrib cSAC have been predicted. The background NOx concentration listed in **Table 16.19** (11.2µg/m^3) has been added to the modelled results. Noise barriers are located alongside part of this section of the route and the results of modelling with the noise barriers in place have therefore also been included. The results and the change in concentrations for 2024 and 2039 are listed in **Table 16.35** and **Table 16.36** respectively for each of the four transects described in **Section 16.2.5.1**.

Table 16.35: Predicted NO_x concentrations (µg/m^3) at Lough Corrib cSAC, 2024

Distance from proposed road (m)	Do-Minimum (µg/m^3)	Without noise barriers			With noise barriers

190	11.6	13.2	1.6	Negligible	13.2	1.6	Negligible

Distance from propose d road (m)	Do-Minimum ($\mu g/m^3$)	Without noise barriers			With noise barriers		
		Do-Something ($\mu g/m^3$)	Change in NO_x ($\mu g/m^3$)	Impact	Do-Something ($\mu g/m^3$)	Change in NO_x ($\mu g/m^3$)	Impact
200	11.6	13.2	1.6	Negligible	13.2	1.6	Negligible

Predicted annual mean NO_x concentrations are all below the limit value (30µg/m^3). A maximum concentration of 23.2µg/m^3 was predicted at 10m from the proposed road development in 2039 (transect 4). A lower concentration of 19.8µg/m^3 was predicted with the noise barrier in place. In 2039, without the noise barriers in place, a slight adverse impact was predicted at distances from 10m to 50m with a negligible impact at further distances. With the noise barriers in place, the impact rating remains the same.

16.5.4.3 Regional air quality impacts

The DMRB regional approach was used to estimate total emissions from the existing road network. The assessment focuses on the change in emissions of nitrogen oxides, total hydrocarbons (THC) and particulate matter in the Opening and Design Years. **Table 16.37** presents the predicted pollutant emissions at regional level.

Table 16.37: Predicted NO_x, THC and PM_{10} Emissions at Regional Level for 2024 and 2039 (Tonnes per Annum)

	Scenario	NOx (t/a)	THC (t/a)	PM_{10} (t/a)
2024	DM	135	32	5.6
	DS	186	40	7.8
	DS - DM	51	8	2.2
2039	DM	171	38	7.0
	DS	242	50	9.9
	DS - DM	72	12	2.9
	% of change (2039) relative to Directive Limits	0.11%	0.02%*	n/a

*Note: * limit for VOC*

Nitrogen oxides are predicted to increase by 0.1% of the Directive 2016/2284 limit for NO_x in 2039. THC are predicted to increase by 0.02% of the Directive limit for VOC in 2030, refer to **Section 16.2.2.1**.

As there is no national reporting of particulate matter levels and no Directive limits exist, no comparison of annual particulate matter emissions can be made.

16.5.4.4 Potential Construction Impacts on Climate

Based on expected construction activities and methods, CO_2 values have been estimated during the construction phase, refer to **Table 16.38**.

Table 16.38: Total Estimated CO_2 Produced as a result of the Construction of the Proposed Road Development

	tonnes/year
Ireland's non-ETS CO_2 Commitment for 2020	38,000,000
Total CO_2 during construction phase Year 1 (maximum emissions)	150,000
Increase relative to CO_2 commitment per year	0.39%
Total CO_2 during construction phase	275,000

During the construction phase of the proposed road development, 150,000 tonnes per year of CO_2 are estimated to be generated, assuming a 36-month construction programme. Ireland has committed to achieve a 20% reduction in non-ETS greenhouse gas emissions by 2020 (relative to 2005 levels). The emissions predicted to be produced during the construction phase of the proposed road development constitutes 0.39% of Ireland's 2020 CO_2 limit under the EU Climate Change and Renewable Energy Package. These emissions will occur for the duration of the construction phase. Measures to mitigate these potential impacts are outlined in **Section 16.6**.

16.5.4.5 Potential Operational Impacts on Climate

Macro Climate

Table 16.39 describes the predicted CO_2 produced as a result of the proposed road development. The results include CO_2 levels based on Do-Minimum and Do-Something for both 2024 and 2039. Results are based on traffic data for the proposed road development and include the design speed for each existing and proposed road, refer to **Chapter 6, Traffic Assessment and Route Cross-section**. Ireland has committed to achieve a 20% reduction in non-ETS greenhouse gas emissions by 2020 (relative to 2005 levels). Predicted changes in levels of CO_2 due to the proposed road development are compared to Ireland's non-ETS commitments under the EU Climate Change and Renewable Energy Package. The projected increase of CO_2 in 2039 is 0.094% of Ireland's non-ETS commitment.

Table 16.39: Total Estimated CO_2 Produced as a result of the Operation of the Proposed Road Development

Scenario	**Tonnes/year**
Ireland's non-ETS CO_2 Commitment for 2020	38,000,000
Total CO_2 as a result of scheme 2024 (DM-DS) [1]	26,059
Change relative to CO_2 commitment	0.069%
Total CO_2 as a result of scheme 2039 (DM-DS) [1]	35,776
Change relative to CO_2 commitment	0.094%

Note:[1] Total C converted to total CO_2 using a factor of 44/12

It should be noted that the calculations include for a worst-case scenario which considers traffic within the city centre travelling at speed limits. In reality, these speeds are likely to be significantly slower particularly during peak times.

In order to replicate the existing congestion in Galway City, an assessment of the Do-Minimum scenarios for both 2024 and 2039 were undertaken using slower speeds than the design speeds for city centre link roads.

Traffic speeds were reduced by 50% and 75% for internal City link roads for the Do-Minimum scenarios in order to determine the potential change in CO_2 emissions.

- For a 50% reduction in traffic speeds for the Do-Minimum scenario, CO_2 emissions (DS-DM) for 2024 decrease from 26,059 tonnes per year to 17,233 tonnes per year; a 34% decrease compared to emissions at the speed limits. For 2039, CO_2 emissions for 2039 decrease from 35,776 tonnes per year to 26,129 tonnes per year; a 27% decrease compared to emissions at speed limits
- For a 75% reduction in traffic speeds for the Do-Minimum scenario, CO_2 emissions (DS-DM) for 2024 decrease from 26,059 tonnes per year to 8,686 tonnes per year; a 67% decrease compared to emissions at speed limits. For 2039, CO_2 emissions for 2039 decrease from 35,776 tonnes per year to 16,672 tonnes per year; a 53% decrease compared to emissions at speed limits
- When a congested (75% of design speed) Do-Minimum scenario is assessed against the Do-Something scenario, this predicted to result in a change of 0.023% of the EU Ireland's non-ETS CO2 Commitment for 2020 and 0.044% in 2039

Micro-Climate

The proposed road development will result in changes to the shape of the existing terrain. Such changes may modify airflow and temperature profiles in the area. These modifications will not be significant from a climatic perspective and are unlikely to result in any adverse impact on local flora and fauna and residential populations.

16.6 Mitigation Measures

16.6.1 Introduction

A description of the proposed air quality and climate mitigation measures to be implemented during the construction and operational phases are described below.

16.6.2 Construction Phase

16.6.2.1 Air quality

Emissions to air during earthmoving and construction will occur, although the prevailing weather, the size of the site and its distance from sensitive receptors will assist in facilitating the management of any effects. The focus of the control procedures will therefore be to reduce the generation of airborne material.

The assessment of potential construction impacts contained in **Section 16.5.3** includes the implementation of 'standard mitigation', as stated in the TII Guidelines. This shall include the following measures:

- Spraying of exposed earthwork activities and site haul roads during dry weather
- Provision of wheel washes at exit points
- Control of vehicle speeds and speed restrictions. It is proposed that site traffic is restricted to 20km/hr. This will help to minimise the occurrence of dust re-suspension
- Sweeping of hard surface roads

In addition, the following measures will be implemented. These measures are based on best practice as outlined in the British Research Establishment (BRE) document 'Controlling particles, vapour and noise pollution from construction sites' and the Institute of Air Quality Management (IAQM) 'Guidance on the assessment of dust from demolition and construction', 2016.

- A public communication strategy will be implemented by the Contractor which will outline procedures to inform members of the community on activities that may be disruptive, further details are contained in **Appendix A.7.5 Construction Environmental Management Plan**. This appendix also includes details of a complaints register which will be implemented during the construction phase
- Exhaust emissions from vehicles operating within the site, including trucks, excavators, diesel generators or other plant equipment, will be controlled by the contractor through regular servicing of machinery
- During dry periods when dust generation is likely or during windy periods, construction areas and vehicles delivering material with dust forming potential will also be sprayed with water, as appropriate
- Areas where materials will be handled and stockpiled will be positioned away from main site access roads. These areas will also be designed to minimise their exposure to wind – all stockpiles shall be kept to the minimum practicable height with gentle slopes
- There shall be no long-term stockpiling on site and storage time will be minimised
- Material drop heights from plant to plant or from plant to stockpile will be minimised
- Water suppression will be used during the demolition of buildings
- Crushing and concrete batching plant will be located as far from sensitive receptors as is reasonably practicable. All storage bins and transfer points will be covered. Silos will be fitted with reverse jet air filters

Dust screens will be implemented at locations where there is the potential for air quality impacts during the construction phase as outlined in **Section 16.5.3**, i.e. at locations where sensitive receptors are located within 100m of the works. In addition, a 2m dust screen will be provided at the locations at the locations in the areas of the overlap of the proposed road development and the Lough Corrib cSAC and the area of the proposed road development adjacent to Moycullen Bogs NHA.

Employee awareness is also a most important way that dust may be controlled on any site. Staff training and the vigilant management of operations ensure that all dust suppression methods are implemented and continuously inspected. Further details on employee training are provided in the Construction Environmental Management Plan (CEMP) in **Appendix A.7.5**.

Dust deposition monitoring will be conducted at a number of locations in the vicinity of the proposed road development. At a minimum, monitoring will be carried out at the two nearest sensitive receptors at locations where works of a ‘major’ scale is proposed while works are taking place in proximity, refer to **Section 16.5.3.1**. Monitoring will be carried out using the Bergerhoff method, i.e. analysis of dust collecting jars left on-site (German Standard VDI 2119, 1972). Results will be compared to the TA Luft guidelines. Should an exceedance of the TA Luft limit occur during the construction phase or a complaint be received in relation to dust levels, additional mitigation measures, for example more regular spraying of water, will be implemented. At least one month of dust deposition monitoring will be carried out in advance of the commencement of works to determine a baseline.

In addition, it is proposed to carry out particulate monitoring (PM_{10} and $PM_{2.5}$) at the nearest sensitive receptors upwind and downwind of the construction works where sensitive receptors have been identified within 25m of the works, refer to **Section 16.5.3.1**. This monitoring programme will take place when works likely to generate dust are being carried out. The monitoring will allow direct comparison with the PM_{10} and $PM_{2.5}$ air quality standards on a daily basis.

The particulate and dust deposition limits will be used to determine potential occurrences of dust nuisance associated with the proposed construction works. Should the limit values be approaching an exceedance during the construction works, the levels will be recorded by the contractor. An investigation will subsequently be carried out to determine potential causes and the options available to reduce the level of dust.

All potential causes for the high levels will be analysed. These will include the construction works taking place, potential off site sources and meteorological conditions. Should the construction works taking place be identified as the primary cause of the high level, the contractor will ensure that the mitigation measures listed above are improved upon. Should high dust levels continue to occur following these improvements, the contractor will provide alternative mitigation measures and/or will modify the construction works taking place.

16.6.2.2 Climate

The following mitigation measures will be implemented during the construction phase of the development so as to minimise CO_2 emissions:

- Materials required for the construction works will be sourced locally where possible. There are operational quarries located in proximity to the proposed road development. Rock crushing will be undertaken on site where possible, to reduce the requirement to import crushed stone to site
- The Construction Traffic Management Plan outlined in the CEMP in **Appendix A.7.5** will be implemented in full. This will minimise congestion and encourage car sharing and the use of public transport
- Materials will be handled efficiently on site to minimise the waiting time for loading and unloading, thereby reducing potential emissions
- Engines will be turned off when machinery is not in use
- The regular maintenance of plant and equipment will be carried out
- Materials with a reduced environmental impact will be used where available, such as:
    - Ground Granulated Blast Furnace Slag (GGBS) and Pulverished Fly Ash (PFA) will be used as replacements for Portland cements
    - Recycled steel

The Contractor will be required to implement an Energy Management System for the duration of the works. This will include the following at a minimum:

- Use of thermostatic controls on all heating systems in site buildings
- The use of insulated temporary building structures
- The use of low energy equipment and power saving functions on all computer systems
- The use of low flow tap fittings and showers

The use of solar/thermal power to heat water for the on-site welfare facilities including sinks and showers.

16.6.3 Operational Phase

16.6.3.1 Air Quality

As it is predicted that all air quality standards for the protection of human health and vegetation will be complied with, no specific mitigation measures are required.

At a National / European level, improvements in air quality are likely over the next few years as a result of the on-going comprehensive vehicle inspection and maintenance program, fiscal measures to encourage the use of alternatively fuelled vehicles and the introduction of cleaner fuels.

16.6.3.2 Climate

The *Transport Infrastructure Ireland Environmental Impact Assessment of National Road Schemes – A Practical Guide* notes that climate change issues are largely outside the scope of an EIAR for individual road schemes as the issues and mitigation measures are the subject of specific policies and strategies set out by government.

However, it is anticipated that the proposed road development will assist with the removal of traffic congestion from within Galway City and its environs by transferring existing and future traffic from the existing road network to the new road infrastructure. Therefore, journey times will reduce and journey time certainty will increase for both public transport and private vehicle users. The reduction in traffic congestion will reallocate the space for cyclists, pedestrians and reconfigure the public transport network. This will result in reducing the number of short commuter journeys by car by facilitating journeys by bicycle/on foot. The positive impact of this modal shift is difficult to quantify in terms of carbon emissions however, it will help to reduce emissions.

Improvements to the Galway bus network have been identified as necessary to better cater for existing and future travel patterns in Galway City. The reallocation of road space for public transport will assist with the delivery of an improved bus network resulting in carbon emission reductions.

In addition, the provision of improved public transport, traffic management measures, cycling and walking facilities and the introduction of the ‘Cross-city Link’ by the GTS will encourage a modal shift in line with Smarter Travel - A Sustainable Transport Future, A New Transport Policy for Ireland 2009 – 2020. This shift has the potential to reduce greenhouse gas emissions associated with the proposed road development in the future.

CO_2 emissions for the average new car fleet were reduced to 120g/km by 2012 through EU legislation on improvements in vehicle motor technology and by an increased use of biofuels.

The National Mitigation Plan outlines a number of existing mitigation measures and future possible mitigation measures under consideration relating to road transport, as follows:

Existing:

- Taxation system where a lesser road tax is paid where CO_2 emissions are within lower bands
- Grants provided by Sustainable Energy Authority Ireland (SEAI) to incentivise the purchase of electric vehicles
- Deploy natural gas refuelling stations and gas injection facilities
- Using intelligent transport systems (ITS) to enhance the efficiency of infrastructure and fuel use in a transport network

Under consideration:

- Further measures to accelerate the take-up of low carbon technologies
- Increase in carbon tax on transport fuel
- The motor tax and VRT system could be further amended in line with improvements to energy efficiency and emissions reductions in cars and vans

to additionally incentivise or maintain the advantages of purchasing of the lowest emitting vehicles

- encourage the take-up of alternatively fuelled vehicles, removing or reducing supports or preferential treatment for petrol and diesel fuelled vehicles
- Reduce maximum speed limits on motorways to 110km/hr in order to reduce emissions. It is noted that the design speed for the proposed road development at 100km/hr is less than the 120km/hr that usually applies to motorway schemes

16.7 Residual Impacts

16.7.1 Introduction

Residual impacts are assessed for the construction and operational phases of the proposed road development.

16.7.2 Construction Phase

The residual impact on air quality as a result of the proposed road development will not be significant following the implementation of mitigation measures outlined above. Dust deposition and PM_{10}/$PM_{2.5}$ monitoring shall be carried out to confirm the effectiveness of the mitigation measures.

16.7.3 Operational Phase

As it is predicted that all air quality standards for the protection of human health and vegetation will be complied with, no residual impacts are envisaged. See **Chapter 18, Human Beings, Population and Human Health** for an appraisal of potential health impacts.

It is expected that potential carbon emissions generated by the proposed road development can be offset by measures outlined in the Galway Transport Strategy, removing congestion in Galway City and measures outlined in the National Mitigation Plan.

16.7.4 Cumulative Impacts

The traffic data used in the assessment for future years, considers development proposed for the Galway area listed below, and incorporates the cumulative impacts of these projects into the 'Do-Minimum' traffic data used in this EIAR.

- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- M6 Motorway (operational)
- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)

- N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction)
- Galway Transport Strategy (GTS), which includes the following:
  - Investigation of prospective sites to the east of the city for Park and Ride
  - Bearna Greenway
  - Galway to Oughterard (part of the Galway to Clifden) Greenway
  - Galway City to Oranmore (part of the Galway to Dublin) Cycleway

No major construction works are envisaged to take place in such proximity to the proposed road development which would significantly impact on dust levels.

The cumulative impacts are considered by incorporating background concentrations into predicted values and existing traffic volumes and are described in the impact assessment sections above.

The main aim of the Galway Transport Strategy is to address the current and future transport requirements of Galway City and its environs.

This includes the provision of new transport infrastructure, as follows:

- Public transport: the introduction of a 'Cross City Link' to increase the amount of people able to access the heart of the city by public transport
- Walking and cycling: ensuring that a network of cycle and walking routes is developed across the city and its environs
- Road network: Providing improved access and movement across and within Galway City and its environs

The proposed road development has been assessed with reference to the objectives of the Galway Transport Strategy. Negative significant cumulative impacts on air quality will not arise.

16.8 Summary

The potential air quality and climate impact of the proposed road development has been assessed during the construction and operational phases. During the operational phase, all air quality standards are predicted to be complied with and a worst-case impact of slight adverse is expected. Following the implementation of mitigation measures, no significant residual air quality and climate impacts are envisaged. During the construction phase, particulate monitoring and dust deposition monitoring will be carried out to ensure the effectiveness of the mitigation measures and compliance with air quality standards.

17 Noise and Vibration

17.1 Introduction

This chapter of the EIAR consists of an appraisal of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, under the heading of noise and vibration.

The chapter sets out the methodology (**Section 17.2**), describes the receiving environment (**Section 17.3**) and summarises the main characteristics of the proposed road development which are of relevance for noise and vibration (**Section 17.4**). The evaluation of impacts of the proposed road development on noise and vibration are described (**Section 17.5**). Measures are proposed to mitigate these impacts (**Section 17.6**) and residual impacts are described (**Section 17.7**). The chapter concludes with a summary (**Section 17.8**) and reference section (**Section 17.9**).

This chapter has utilised the information gathered during the constraints and route selection studies for the proposed road development to inform the noise and vibration impact appraisal. **Sections 4.15**, **6.5.10** and **7.6.10** of the **Route Selection Report** considered the noise and vibration constraints within the scheme study area and compared the potential noise and vibration impacts of the proposed route options respectively. These sections of the Route Selection Report contributed to the design of the proposed road development which this chapter appraises.

The key guidance documents referred to in this chapter are the TII 2004 *Guidelines for the Treatment of Noise and Vibration in National Road Schemes* and the TII 2014 Document *Good Practice Guidelines for the Treatment of Noise during the Planning of National Road Schemes*, referred to as the TII 2004 Noise Guidelines and the TII 2014 Noise Guidelines respectively within this chapter.

17.2 Methodology

17.2.1 Introduction

In order to assess the noise impact of any proposed road development, the following methodology has been adopted:

- The first stage is to assess and quantify the existing noise environment in the vicinity of sensitive receptors that may be affected by the proposed road development. Noise sensitive receptors include residential properties, education buildings, hospitals and areas of high amenity value in existing low noise settings. In the case of a road scheme, the selected noise-sensitive locations are those in closest proximity to the proposed road development and along sections of existing roads where changes in traffic volumes are expected.
- The noise levels resulting from both the construction and operational phases for the future years are then calculated using established prediction techniques.

- The results of the predicted assessment are compared against the most appropriate criteria for both construction and operational phases. Where predicted noise levels are in excess of the adopted criteria, mitigation measures are proposed.

Further details of each phase of the assessment are set out in the individual sections of this chapter.

17.2.2 Relevant Guidelines

The assessment has been undertaken with reference to the most appropriate guidance documents relating to environmental noise and vibration from road traffic which are set out within the relevant sections of this chapter and included in the references section. Specifically, as noted in **Section 17.1**, the key guidance documents relating to this chapter are:

- TII 2004 Guidelines for the Treatment of Noise and Vibration in National Road Schemes
- TII 2014 Document Good Practice Guidelines for the Treatment of Noise during the Planning of National Road Schemes, (TII 2014)

In addition to specific noise guidance documents, the following guidelines were considered and consulted for the purposes of the proposed road development:

- Guidelines on the Information to be contained in Environmental Impact Statements', (EPA, 2002)
- 'EPA Advice Notes on Current Practice (in the preparation of Environmental Impact Statements), (EPA, 2003)
- 'EPA Advice Notes for Preparing Environmental Impact Statements, (Draft, September 2015)
- EPA Guidelines on the information to be contained in environmental impact assessment reports (Draft August 2017)

17.2.2.1 Construction Phase

Guidelines relating to construction noise and vibration limits are set out within the TII guidance documents and other relevant national and international documentation for the control of noise and vibration from construction sites. These are discussed in the following sections.

Construction Noise

The TII noise guidance documents specify noise levels that are deemed acceptable in terms of construction noise for new national roads. These limits are set out in **Table 17.1**.

Table 17.1: Maximum Permissible Noise Levels at the Facade of Dwellings during Construction Phase

Days and Times	Noise Levels (dB re. $2x10^{-5}$ Pa)	
	$L_{Aeq,1hr}$	L_{ASmax}
Monday to Friday 07:00 to 19:00hrs	70	80
Monday to Friday 19:00 to 22:00hrs	60*	65*
Saturdays 08:00 to 16:30hrs	65	75
Sundays & Bank Holidays 08:00 to 16:30hrs	60*	65*

Note * Construction activity at these times, other than that required for emergency works, will normally require the explicit permission of the local authority.

The TII guidelines do not include specific night-time construction noise limit values. In order to determine appropriate limits for any scheduled night-time works, best practice guidelines are taken from the British Standard BS5228 – 1: 2009 +A1 2014: *Code of practice for noise and vibration control on construction and open sites – Noise*. The standard provides guidance on setting appropriate limit values for construction based on exiting ambient noise levels in the absence of construction noise. The guidance levels for night-time periods are summarised in **Table.17.2**.

Table 17.2: Example Threshold of Significant Effect at Dwellings

Days and Times	Threshold Values (dB)		
	Category A [A]	Category B [B]	Category C [C]
Night-time 23:00 to 07:00hrs	45	50	55

- Note A: Category A: threshold values to use when ambient noise levels (when rounded to the nearest 5dB) are less than these values.
- Note B: Category B: threshold values to use when ambient noise levels (when rounded to the nearest 5dB) are the same as category A values.
- Note C: Category C: threshold values to use when ambient noise levels (when rounded to the nearest 5dB) are higher than category A values.

Construction Vibration

With regards to construction vibration, the TII guidelines outline the following limits in respect of ensuring that no cosmetic damage occurs to buildings in the vicinity of construction works.

Table 17.3: Allowable vibration during road construction in order to minimise the risk of building damage

Allowable vibration velocity (Peak Particle Velocity) at the closest part of any sensitive property to the source of vibration, at a frequency of		
Less than 10Hz	10 to 50Hz	50 to 100Hz (and above)
8mm/s	12.5mm/s	20mm/s

Blasting

When assessing the potential impact of blasting, the relevant parameters used are both air overpressure and Peak Particle Velocity (PPV) mm/s. The TII guidelines recommends a PPV limit value of 12mm/s for blasting control. The Irish EPA Guidance *Environmental Management in the extraction industry* (2006) also recommend a PPV limit of 12mm/s in addition to an acceptable limit for air overpressure of 125dB (Lin) Peak Value. In addition, the EPA recommends blasting is only carried out between 09:00 – 18:00 Monday to Friday.

BS 6472 -2 2008: *Guide to Evaluation of Human Exposure to vibration in buildings. Part 2: Blast Induced Vibration* suggests satisfactory vibration magnitudes from blasting relating to human response. The document notes that for up to three blasts per day, a PPV limit value between 6 and 10mm/s is deemed reasonable, however it states these limit values relate to long term blasting operations from surface mineral extraction sites. The standard notes that *for civil engineering projects, such as tunnel and foundation excavations, it should be recognised that the application of human response criteria, rather than conservative damage criteria, could significantly prolong project durations. In turn this could lead to increased complaint levels.*

The standard notes higher levels may be more appropriate for short term projects, where good public relations, property surveys etc. are undertaken.

The frequency of blasting for the proposed road development will be no greater than one blast per day in any one site. Taking the blasting frequency into account, the nature of this engineering project and to expedite works as far as practical in excavation areas to avoid prolonged impacts, the limit values relating to structural damage are considered the most appropriate for this project, i.e. 12mm/s.

Disturbance of Particularly Vibration-Sensitive Equipment and Processes

There are no standard criteria for assessing the potential impact of vibration on sensitive equipment or processes. British Standard BS 5228 *Code of Practice for Noise and Vibration Control on Construction and Open Sites* – Part 2: *Vibration* (2009 +A1 2014) provides a guide of vibration sensitivities of differing types of sensitive equipment from microscopes to microelectronic manufacturing equipment, however these ranges are generic and relate to the sensitivity of the equipment as installed, not the external façade of the building. The most advisable approach for the control of potential vibration impacts at areas of vibration sensitive equipment or processes, is to review each location on its own merit in order to determine the site specific vibration limits taking into account any building or machinery isolation already in place. In this instance, where a receptor has been identified or made known within the study area that is potentially sensitive to vibration through questionnaires and consultations, this area is highlighted as one for consideration and consultation. In these instances, it is not possible to set specific vibration limits at this stage of the EIAR due to complexities in both the level of detail available at this stage and knowledge of the receptor. Further discussion on particularly sensitive equipment/processes are set out in **Section 17.6.1**.

17.2.2.2 Operational Phase

TII Noise Guidance Documents

There are no statutory guidelines relating to noise from road schemes in Ireland. In the absence of statutory guidance, the most commonly applied standard is that issued by the TII within their 2004 and 2014 noise guidance documents. Both documents specify that the following absolute noise design criterion for new national road schemes in Ireland is appropriate:

Day-evening-night value of: **60dB L_{den}.**

This is a free field façade criterion, i.e. does not take account of reflections from building facades.

L_{den} is the 24hour noise rating level determined by the averaging of the L_{day} with the $L_{evening}$ (plus a 5dB penalty) and the L_{night} (plus a 10dB penalty). L_{den} is calculated using the following formula:

$$L_{den} = 10log\left(\frac{1}{24}\right)\left(12 * \left(10^{\frac{Lday}{10}}\right) + 4 * \left(10^{\frac{Levening+5}{10}}\right) + 8 * \left(10^{\frac{Lnight+10}{10}}\right)\right)$$

Where:

- L_{day} is the A-weighted long-term average sound level as defined in ISO 1996-2, determined over all the day periods of a year
- $L_{evening}$ is the A-weighted long-term average sound level as defined in ISO 1996-2, determined over all the evening periods of a year
- L_{night} is the A-weighted long-term average sound level as defined in ISO 1996-2, determined over all the night periods of a year

This criterion applies to new national roads. The following three conditions must be satisfied under the TII guidelines in order for noise mitigation to be provided:

a) The combined expected maximum traffic noise level, i.e. the relevant noise level, from the proposed road development together with other traffic in the vicinity is greater than the design goal of 60dB L_{den}

b) The relevant noise level is at least 1dB more than the expected traffic noise level without the proposed road development in place

c) The contribution to the increase in the relevant noise level from the proposed road development is at least 1dB

The proposed road development under consideration here is a new national road and hence the design goal and assessment methodology set out in the TII guidelines for the assessment of potential noise impacts from national road schemes are deemed directly applicable.

It should be noted that the design goal is applicable to new road schemes only. In addition, the design goal is applied to existing receptors in respect of both the year of opening and the Design Year, typically 15 years after projected year of opening. In the case of this proposed road development a commencement year of 2024 and a future Design Year of 2039 have been assessed.

Galway City and County Council Noise Action Plans 2013 - 2018

The Galway City Council and the County Galway Local Authorities Noise Action Plans (NAP) relates to the management of environmental noise in accordance with the Environmental Noise Directive (END) (202/49/EC). The purpose of the Action Plan is to manage and reduce, where necessary, environmental noise through the adoption of the action plans.

In the case of Galway City Council, noise due to road traffic sources from sections of roads with a traffic flow threshold above 3 million vehicle trips per annum were mapped in accordance with the second round of noise mapping studies within Europe. This applied to certain sections of the R336, R337, R338, R339, R446, R863, R864, R865, R866, R921, N6, N83, N59 and N84, which lie within the city boundaries.

Both NAPs have proposed the onset levels for assessment of noise management measures as follows.

- 70dB, L_{den}
- 57dB, L_{night}

The onset levels for noise management in addition to a decision matrix is used to identify those areas which may require noise intervention or management.

An implementation plan outlines a proposed programme of works for the period 2013 – 2018. The programme is largely dependent on traffic management and construction projects with the aim to reduce vehicle numbers and to re-distribute traffic on the road network of the city.

One of the management procedures referred to within both plans is mitigation through traffic planning. These specifically refers to a ring road for Galway City as a management procedure for reducing traffic volumes along existing routes across the city.

17.2.3 Data Sources and Consultations

Information relating to the proposed road development have been obtained primarily from the design team. Any comments that related to noise and vibration from consultations undertaken by the design team with stakeholders during the design development process were considered during the preparation of this chapter.

The following items of information were supplied by the design team which formed the main basis for the impact assessment:

- Background OS Mapping of the study area
- 3D ground contour mapping
- 3D road alignment drawings for the proposed road development
- Traffic flow forecasts for future opening and design years for study area
- Ongoing consultation feedback relevant to noise and vibration issues from interested and affected parties

- Landscaping proposals
- Construction plan information (compound locations, expected areas of blasting, construction traffic information etc.)

17.2.4 Study area and Baseline Data Collection

The study area for the noise and vibration impact assessment is focused on the areas likely to be affected by the operation of the proposed road development. This includes the closest noise/vibration sensitive locations along the route of the proposed road development in addition to those in proximity to existing roads in the vicinity of the proposed road development. Noise sensitive locations within a study area of approximately 300m from the centreline of the proposed road development was focused on for the baseline noise studies which is considered to capture the baseline noise environment at locations likely to be impacted by the proposed road development.

A comprehensive baseline noise study has been undertaken within the study area in order to provide a context of the typical noise environment and to determine the main contributors to the existing environment.

The surveying was completed in accordance with relevant guidance and standards including:

- Guidelines for the Treatment of Noise and Vibration in National Road Schemes (NRA, 2004)
- Good Practice Guidance for the Treatment of Noise during the Planning of National Road Schemes (NRA, 2014)
- Calculation of Road Traffic Noise Shortened Measurement Procedure (CRTN 1988)
- ISO 1996-2007 Acoustics – Description, Measurement and Assessment of Environmental Noise – Part 2 Determination of environmental noise levels. 1:2016

The survey locations were selected to represent the environments through which the proposed road development will pass which is predominately residential. Survey locations were therefore focused on residential areas set back from existing roads along the route of the proposed road development, residential estates, and residential properties located along local, regional and national roads. Additional surveys were undertaken at recreational facilities, schools and crèches, a church, a hospital, and commercial facilities. These were surveyed to gain information specific to these locations in addition to representing general ambient noise levels in the areas which they are located. Further details are set out in **Section 17.3**.

Unattended 24-hour monitoring stations were selected to represent specific noise environments (including those listed above) and a range of satellite attended measurement locations were monitored in the vicinity of these locations to characterise the noise environment within each area.

Given the extent of the baseline study area, it was not possible to gain access to all locations requested as part of the baseline study. In these instances, attended noise measurements were made at proxy locations to the nearest sensitive properties and unattended noise measurements were conducted, as far as practicable, at adjacent properties, depending on access being granted to private lands.

The surveying programme encompassed attended surveys at 73 locations and unattended surveys at 33 locations. A summary of results is presented and discussed in **Section 17.3**.

A survey of vibration levels along the corridor of the proposed road development was not undertaken, as levels associated with existing roads would not be expected to be of a magnitude sufficient to cause disturbance to people or structural damage to property. Furthermore, vibration was not perceptible at any of the noise survey locations. Comment on vibration sensitive equipment is set out in **Section 17.6.2.3**.

17.2.4.1 Unattended Measurements

The continuous measurements were conducted using a Brüel & Kjær UA 1404 Environmental Outdoor Kit, with either Brüel & Kjær Type 2238 or 2250 Sound Level Meters.

The measurement apparatus was check calibrated before and after each survey using a Brüel & Kjær Type 4231 Sound Level Calibrator. The results were saved to the instrument memory for later analysis.

Unmanned continuous measurements were conducted over at least 24-hour periods at thirty-three locations. L_{den} values are derived directly from the measured $L_{Aeq,1\,hour}$ measured data using the formula included in **Section 17.2.1**.

17.2.4.2 Attended Measurements

The short-term measurements were performed using Brüel & Kjær Type 2250 or 2260 Sound Level Meters. Short-term measurements were conducted at survey locations on a cyclical basis. Sample periods were 15 minutes. The results were noted onto a Survey Record Sheet immediately following each sample, and were also saved to the instrument memory for later analysis where appropriate. Survey personnel noted all primary noise sources contributing to noise build-up.

The survey work was conducted in accordance with the short-term measurement procedure as specified in the TII noise guidance documents.

When surveying traffic noise, the acoustical parameters of interest are $L_{A10(1hour)}$ and $L_{A10(18hour)}$, expressed in terms of decibels (dB) relative to 2x10-5Pa.

The value of $L_{A10(1hour)}$ is the noise level exceeded for just 10% of the time over the period of one hour. $L_{A10(18hour)}$ is the arithmetic average of the values of $L_{A10(1hour)}$ for each of the one-hour periods between 06:00 and 24:00hrs. $L_{A10(18hour)}$ is the parameter typically used in for the purposes of assessing traffic noise, where relevant.

The shortened measurement procedure involves a method whereby $L_{A10(18hour)}$ and L_{den} values are obtained through a combination of measurement and calculation as follows:

- Noise level measurements are undertaken at the chosen location over three consecutive hours between 10:00 and 17:00hrs
- The duration of the sample period during each hour is selected to encompass sufficient traffic flows to ensure reliable results
- The $L_{A10(18hour)}$ for the location is derived by subtracting 1dB from the arithmetic average of the three hourly sample values, i.e.

  $L_{A10(18hour)} = ((\sum L_{A10(15\ minutes)})\div 3) - 1$ dB
- The derived L_{den} value is calculated from the $L_{A10(18hour)}$ value, i.e.

  $L_{den} = 0.86 \times L_{A10(18hr)} + 9.86$ dB

The L_{den} is a long-term average indicator and represented the annual daily noise level.

The guidelines note that *where traffic is not the dominant noise source, then the normal correction cannot be applied to convert the 15 minute samples to an 18-hour value. However, it may be possible to derive a site specific correction from a nearby long-term site affected by the same noise sources. If there is not comparator site, a short-term measurement is inappropriate and a 24-hour measurement will be required.*

The baseline survey locations were selected in order to ensure that where traffic was not the dominant source at monitoring positions that an unattended 24-hour survey was conducted in order to directly derive a L_{den} from the measured data and satellite attended measurements were conducted in the vicinity of this location.

17.2.4.3 Monitoring Locations

The location of the surveyed baseline monitoring positions are presented in **Figure 17.1.01** to **17.1.14**. The majority of monitoring locations were positioned within gardens of residential properties or at proxy locations to residential locations in public areas where access to private lands were not possible. Additional surveys were undertaken at the Sporting Campus of NUIG (10b), Dangan House Commercial/Recreational (10c), St. James' Church, Bushypark (9g), Castlegar School (11i/11g), Ballybrit Industrial Estate (13a), Galway Clinic (14b) and Galway Racecourse (13h).

The location of the monitoring positions and the calculated L_{den} for each position is included in **Table 17.8** in **Section 17.3**. Baseline monitoring which are grouped in attended and unattended satellite locations are presented together. Full survey results for all locations are included in **Appendix A.17.1**.

17.2.4.4 Survey Periods

The baseline survey was undertaken over the course of the following dates:

- 10 February 2016
- 11 February 2016
- 23 February 2016
- 24 February 2016
- 25 February 2016
- 14 March 2016
- 15 March 2016
- 16 March 2016
- 22 March 2016
- 19 April 2016
- 20 April 2016
- 22 April 2016
- 31 May 2016
- 01 June 2016

17.2.4.5 Personnel and Instrumentation

The baseline surveys were undertaken by Enfonic and AWN Consulting Ltd. This involved installing all noise monitoring equipment at the monitoring locations and conducting the attended surveys.

17.2.5 Impact Assessment Methodology

17.2.5.1 Operational Phase Impact Assessment Process

The impact assessment methodology used for this chapter is based on the guidance contained within the 2004 and 2014 TII noise guidance documents and the EPA Draft Guidelines on the information to be contained in environmental impact assessment reports (Draft August 2017). The following methodology has been undertaken in accordance with the relevant guidelines:

- Characterise the existing baseline noise environment through environmental noise surveys
- Develop a 3D noise model of the study area and calculate noise levels for a baseline model to calibrate the model output

- Calculate the traffic noise levels at the nearest noise sensitive locations which are affected by the operation of the proposed road development for the following scenarios:
    - Do-Minimum – Opening Year (i.e. proposed road development is not built)
    - Do-Something – Opening Year (i.e. the proposed road development is built)
    - Do-Minimum – Design Year
    - Do-Something – Design Year
- In the case of this proposed road development, the Opening Year assessed is 2024 and the Design Year is 2039
- Assess the calculated noise levels for each scenario at the assessment locations to determine if the three conditions for noise mitigation have been met (Refer to **Section 17.2.2**). The cumulative impact assessment is incorporated into the modelling scenarios for the various scenarios defined above
- Where the three conditions for noise mitigation have been met, a review of potential noise mitigation measures is conducted for each assessment location to reduce noise levels to within the design goal, where practicable
- Determine the residual noise impacts taking into account the proposed mitigation measures at the sensitive locations along the route of the proposed road development
- Characterise the residual noise impacts of the proposed road development through reference to relevant criteria
- Assess the likely potential construction noise and vibration impacts associated with the short-term construction phase

17.2.5.2 Construction Phase Impact Assessment

Assessment of potential impacts during the construction phase is limited to information available at EIAR stage. Whilst the phasing of works and location of activities and work sites have been progressed to detailed stages as part of the EIAR, the specifics in terms of plant items, plant numbers, their locations and operational duration will be subject to site conditions, work scheduling and contractor proposals. In this instance, it is not possible to perform detailed calculations or detailed impact assessment for any one area given the variations in the items above on a week to week or day to day basis. It is however possbile to determine noise levels from typical construction activities associated with the various phases.

The TII Guidelines spefically note that there is limited information available on specific construction methods, numbers and types of plant before the appointment of a Contractor, which will normally happen after a scheme has been approved. The guidelines note that it is more appropriate to address the way in which potential construction impacts will be assessed and how they will be managed, including forms of mitigation and codes of practices that will be applied.

The guidelines do note, however, that areas of major earthworks or blasting should be noted and locations where particularly noisy activities such as piling (depending on the method used), rock breaking, and or night-works are identified.

The TII guidelines note that in the absence of an Irish or international standard relevant to construction noise, reference can be made to BS 5228 *-:2009+A1:2014 Code of Practice for Noise and Vibration Control on Construction and Open Sites Part 1 Noise* and Part 2 *Vibration.* This standard includes recommended methodologies for calculating construction noise levels and includes a range of best practice mitigation and management measures for the control of noise and vibration from construction sites.

In terms of calculation, this standard sets out sound power levels for a wide range of plant items normally encountered on construction sites, which in turn enables the prediction of indicative noise levels at distances from the works. The standard also includes empirical data on vibration levels measured at set distances from specific vibration generating activities in different ground and site conditions.

17.2.5.3 Operational Phase Impact Assessment

Noise Modelling

A computer-based prediction model has been prepared in order to quantify the traffic noise level associated with the operational phase of the proposed road development and associated road traffic changes on the surrounding network. This section discusses the methodology behind the noise modelling process.

Brüel & Kjær Type 7810 Predictor

Proprietary noise calculation software was used for the purposes of this impact assessment. The selected software, Brüel & Kjær Type 7810 Predictor, calculates traffic noise levels in accordance with the UK's Department of Transport, Calculation of Road Traffic Noise (CRTN) 1988 and relevant TRL correction procedures for calculating L_{den}.

Predictor calculates noise levels in different ways depending on the selected prediction standard. In general, however, the resultant noise level is calculated taking into account a range of factors affecting the propagation of sound, including:

- The magnitude of the noise source in terms of sound power or traffic flow and average speed
- The distance between the source and receiver
- The presence of obstacles such as screens or barriers in the propagation path
- The presence of reflecting surfaces
- The hardness of the ground between the source and receiver

Prediction of Traffic Noise

Noise emissions during the operational phase of the proposed road development have been modelled using Predictor using the CRTN methodology and the TRL 'Method 1' calculation procedure to calculate L_{den} values, using hourly traffic flows. The CRTN method of predicting noise from a road development consists of the following five elements:

- Divide the proposed road development into segments so that the variation of noise within this segment is small
- Calculate the basic noise level at a reference distance of 10 metres from the nearside carriageway edge for each segment
- Assess for each segment the noise level at the reception point taking into account distance attenuation and screening of the source line
- Correct the noise level at the reception point to take account of site layout features including reflections from buildings and facades, and the size of source segment
- Combine the contributions from all segments to give the predicted noise level at the receiver location for the whole proposed road development

Note that all calculations are performed to one decimal place. For the purposes of comparison with the design goal of 60dB L_{den}, the relevant noise level is to be rounded to the nearest whole number in accordance with TII guidance.

Model Inputs

The noise model was prepared using the following data:

- 3D road alignment drawings of the proposed road development supplied by the design team
- 3D topographical contour data for the surrounding study area incorporating the noise sensitive assessment locations
- background ordnance survey mapping
- the Annual Average Daily Traffic (AADT), % Heavy Goods Vehicles (HGV's) and traffic speeds

Modelled traffic data for the 'Medium Growth' scenario has been used for the noise impact assessment. Where noise mitigation was identified as a requirement for specific locations, however, the effectiveness of the mitigation was also tested against the 'High Growth' traffic scenarios to ensure a robust analysis.

Traffic flow data was provided for the Do-Nothing and Do-Something scenarios for the Opening Year of 2024 and Design Year of 2039. (Refer to **Chapter 6, Traffic Assessment and Route Cross Section**, for traffic figures used in the modelling exercise).

A standard road surface type, such as hot rolled asphalt (HRA), has been assumed for all roads as part of the base model development.

Model Calibration and Validation

The purpose of noise model validation is to ensure that the software is correctly interpreting the input data and providing results that are valid for the scenario under consideration. It should be noted that the purpose of the model validation is not to validate the prediction methodology in use as the CRTN prediction methodology has itself been previously validated.

Given the nature of the scale of the proposed road development in question, it was decided that the most appropriate mechanism for calibration would be to compare the output of a Predictor model scenario, using the AADT traffic flows for the existing road network in 2016, with the measured L_{den} values at the unattended survey locations in the vicinity of the existing national road network. The reason for choosing those survey locations along the existing national road network for the purposes of calibration, is to ensure that the noise environment was dominated by road traffic noise during the survey period. Noise levels calculated at 9 unattended locations in proximity to existing roads are presented in **Table 17.4** and compared against those measured during the baseline noise surveys. The variation in calculated noise levels is between 0 and ±1dB L_{den} at the assessment locations and hence is considered a strong correlation. It should be noted that the model results reflect road traffic noise only whereby the baseline noise environment has other contributing sources from other local roads, environmental conditions (leaf rustle, bird song etc.) industrial, commercial and or residential type sources, where relevant.

The results of the calibration are presented in **Table 17.4**.

Table 17.4: Model Calibration

Survey Location	Incident to road	Measured L_{den}, dB	Model Predicted L_{den}, dB	Variation (dB)
R1c	R336 Bearna	65	64	1
R3a	Na Foraí Maola	45	44	1
R9c	N59 Moycullen Road	62	61	1
R11g	School Road	52	52	0
R12e	N83 Tuam Road	72	72	0
R13d	Monivea Road R339 East	62	62	0
R14a	N6 Bóthar na dTreabh	57	56	1
R14b	R446	64	65	-1
R17b	N84 Headford Road	56	56	0

Receiver Locations

Free-field traffic noise levels have been predicted at a number of properties in the vicinity of proposed and existing roads. For single storey properties, noise levels are calculated to a height of 1.5m above ground. For multiple storey properties, the calculated noise level is made at the height of the most exposed window (e.g. first, second or third floor).

A total of 270 noise sensitive buildings have been considered in this assessment. For certain properties, receiver locations have been positioned at two or more locations around the building to assess noise levels associated with different facades facing different noise sources thus resulting in a total of 299 modelled receiver locations. The properties were selected on the basis of proximity to the existing and proposed roads. The modelled locations represent the closest noise sensitive locations to the proposed road development and along sections of the existing road network where traffic volumes are modelled to change as a result of the proposed road development. Receptor locations were positioned at locations representing clusters or rows of properties where a number of noise sensitive buildings are in close proximity to each other.

The locations of all receptors are shown on **Figure 17.1.001** to **17.1.114**.

<u>Model Output</u>

The output of the model is a calculated traffic noise levels in terms of the L_{den} parameter at specific modelled receiver locations.

Four scenarios have been considered as follows:

- Year 2024 – Do-Minimum (i.e. proposed road development is not built)
- Year 2024 – Do-Something (i.e. proposed road development in place)
- Year 2039 – Do-Minimum
- Year 2039 – Do-Something

<u>Criteria for Noise Mitigation</u>

The calculated noise levels at each modelled location are reviewed and compared against the three criteria for noise mitigation set out in the TII noise guidance documents as included in **Section 17.2.2.2**.

Where modelled locations are determined to meet the three criteria, the use of noise mitigation has been recommended to reduce noise levels to within the relevant design criterion.

Evaluation of Potential Noise Impacts

There are no guidelines in Ireland for assigning significance criteria for new road developments. The TII Guidance for noise does not prescribe a methodology for evaluating the magnitude or significance of road traffic noise from a new road development. The use of an absolute criterion is used as a threshold value above which noise mitigation measures are to be provided, assuming the 3 conditions for noise mitigation are met. The 60dB L_{den} design goal takes into consideration the alignment of the majority of new national roads in Ireland across a range of different environments including rural, semi-rural, suburban and urban locations.

In order, therefore, to evaluate the potential significance of the noise levels associated with the operation of the proposed road development, consideration needs to be given to issues such as the absolute level of noise under consideration, the magnitude of change in noise levels at a given location and the receptor sensitivity. Comment on potential night-time noise exposure should also be considered.

Magnitude of Change

In the absence of any Irish guidelines or standards relating to describing the effects associated with changes in road traffic noise levels, reference has been made to the UK's Design Manual for Roads and Bridges. Volume 11 Section 3 Part 7 (2011). This document provides suggested magnitude rating tables relating to changes in noise levels associated with road traffic noise. The document suggests that during the year of opening, the magnitude of impacts between the Do-Minimum and the Do-Something scenarios are likely to be greater compared to the longer term period when people become more habitualised to the source.

This document suggests that changes in noise levels between the Do-Minimum and Do-Something scenarios for the year of opening are compared and categorised in line with the 'short term' table reproduced in **Table 17.5**. Longer term impacts are assessed by comparing the Do Minimum noise level calculated for the opening year against the Do Something scenario for the design year (typically 15 years after opening) as reproduced in **Table 17.6**.

It should be noted the tables below relates to the $L_{A10,18hr}$[1] parameter as opposed to the L_{den} which is the assessment parameter for road traffic noise in Ireland.

Table 17.5: Classification of Magnitude of Noise Impacts in the Short Term

Noise Change, dB(A)	Magnitude of Impact
0	No Change
0.1-0.9	Negligible
1 – 2.9	Minor
3 – 4.9	Moderate
5+	Major

Table 17.6: Classification of Magnitude of Noise Impacts in the Long Term

Noise Change, dB(A)	Magnitude of Impact
0	No Change
0.1 – 2.9	Negligible
3 – 4.9	Minor
5 – 9.9	Moderate
10+	Major

Whilst the DMRB magnitude of change tables are a means of assigning an objective rating against a change in noise levels, it is important to note the following limitations of this approach:

[1] This parameter refers to the $L_{A10,18hr}$ parameter which is typically equivalent to L_{den} when free field conditions are considered. The $L_{A10,18hr}$ includes a façade correction which broadly equivalent to L_{den} (free field) plus 2.5dB.

- The DMRB notes the method used to assess magnitude of change significance is based on surveys conducted at sites where road traffic was the dominant noise source with noise exposure levels in the range of 65 to 78dB $L_{A10,18h}$, with the changes in traffic noise being up to 10dB $L_{A10,18h}$ at dwellings up to 18m from the roadside kerb. The document states that on this basis this method should be used with caution.
- Reliance on calculated ‘Do Minimum’ noise levels to represent noise levels in the absence of the proposed road development will result in artificially low base levels at some receptors, particularly in rural settings set back from modelled roads.
- Reference to the baseline measured noise levels is required to verify the pre-existing noise environment.
- Whilst a significance rating is applied to a change in noise level based on the above information, the absolute noise level is an important consideration when determining the response to noise levels from the population at large. This is particularly valid for locations where ‘major’ ratings are applied against comparably low absolute noise levels.

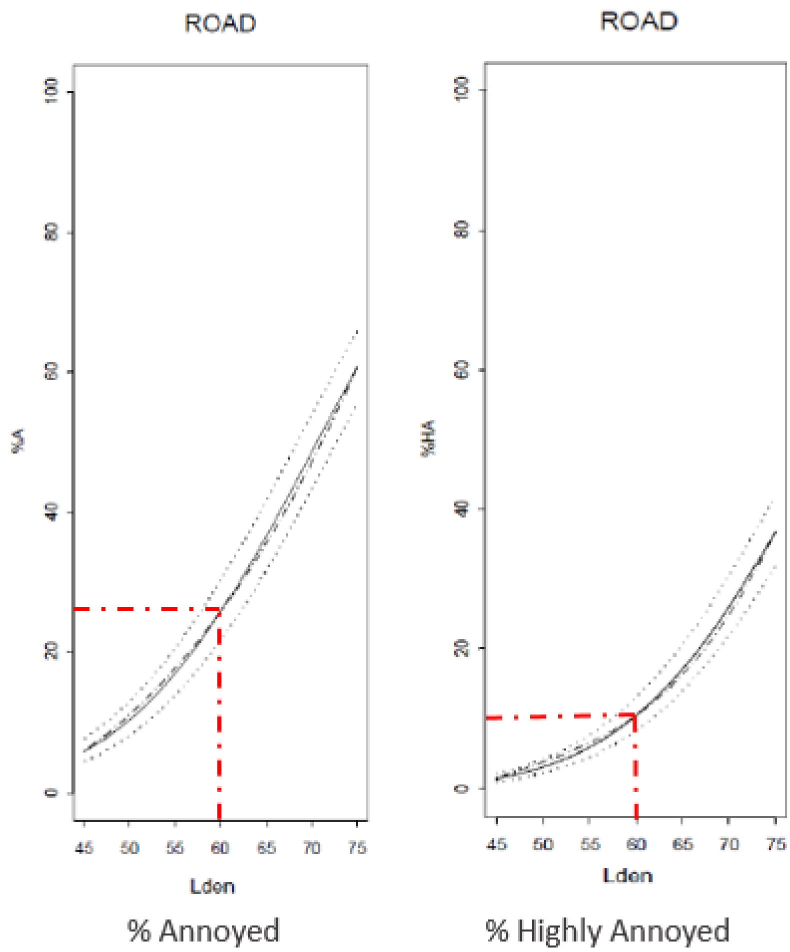
Commentary on Absolute Noise Level

The absolute noise level associated with the proposed road project is another important consideration when evaluating the impacts of the proposed road development. In instances where an increase of noise levels of +5dB(A) are calculated during the year of opening, resulting in a ‘major’ significance rating, for example, the actual level of traffic noise at the property may still be below a level considered to cause any significant effect.

In order to provide some context on the potential level of annoyance associated with road traffic noise, reference is made to the European Environmental Agency (EEA) publication ‘Good Practice Guide on Noise Exposure and Potential Health Effects’ (EEA Technical Report 11/2010). This document provides exposure-response relationships relating to different noise source types. Figure 3.1 of the document presents the percentage of the population defined as being ‘annoyed’ and ‘highly annoyed’ by road traffic noise based on European wide studies. The parameter referred to in the study is L_{den} which is directly comparable to the parameter assessed as part of this proposed road development.

The annoyance figure is reproduced in **Plate 17.1** with the 60dB L_{den} value illustrated against which the proposed road development has been assessed.

Plate 17.1: Percentage of People Annoyed by Road Traffic Noise



The figure indicates that at a road traffic noise level of 60dB L_{den}, 26% of the population have the potential to be 'annoyed' and 10% 'highly annoyed'. The report notes that for roads with quiet road surfaces, there is a decrease in reported annoyance response compared to those in the response curves.

<u>Night-time Noise Levels</u>

Noise levels relating to the proposed road development are assessed in terms of the L_{den} parameter which includes day, evening and night-time noise levels with the relevant penalties included for evening and night-time periods. The TII noise documents do not specify a separate design goal for night-time periods, however it is important to note that night-time noise levels are encompassed within the overall 60dB L_{den} deign goal.

The following relevant documents provide guidance on night-time noise levels:

- The Galway City and Galway Council Noise Action plans (2013 – 2018) sets night-time onset levels of 57dB L_{night} as a threshold for consideration for noise management.
- The WHO Night Noise Guidelines for Europe (NNG 2009) sets an Interim Target of 55dB L_{night}, outside.

- The DMRB notes that night-time road traffic noise levels below 55dB are not included in a relative change assessment as they fall below the WHO Night Noise Guidelines for Europe (NNG 2009) Interim Target of 55dB L_{night}, outside.
- The DMRB recommends that changes in noise levels are assessed for locations with a road traffic noise level in excess of 55dB L_{night}. At these locations, the magnitude of noise change is determined using the 'Long term' classification tables.

Receptor Sensitivity

Other considerations relating to the evaluation of impacts is the sensitivity of the receptor under consideration. The following sensitivity is proposed for the property types along the route of the proposed road development.

Table 17.7: Classification of Receptor Sensitivity to Noise

Sensitivity of Receptor	Description
High	Residential properties, hospitals, nursing homes, educational buildings (daytime)
Medium	Places of worship, community facilities, amenity areas
Low	Commercial and industrial premises

The noise sensitive receptors assessed along route of the proposed road development are predominately residential properties. There are two schools (St. James' National School, Bushypark and Castlegar School, on School Road) a nursing home on School Road and Galway Clinic along R446 Road, all of which are categorised as High Sensitive receptors.

One church (St. James' Church, Bushypark) is included in the assessment which is defined as a medium sensitive receptor. The community facilities and amenity areas of the NUIG Sporting Campus and Galway Racecourse are also included in the assessment and are considered to be of medium sensitivity. A small number of commercial premises are assessed along the N83 Tuam Road and Parkmore and Ballybrit area and are defined as being of low noise sensitivity. Vibration sensitive locations are addressed separately.

The above information will be used as a basis for evaluating potential noise impacts from the proposed road development.

17.3 Receiving Environment

The receiving environment for the proposed road development is a mixture of semi-rural and suburban lands on the fringes of Galway City. In the case of a road development, the selected noise-sensitive locations are those in closest proximity to the proposed road development and those along existing roads which are being traversed by the proposed road development. Both the construction and operational phases of the proposed road development are reviewed when selecting appropriate measurement locations.

17.3.1 Summary of Survey Results

A summary of the measured and derived L_{den} values for each monitoring location is presented in **Table 17.8** below. The baseline monitoring which are grouped in attended and unattended satellite locations are presented together for each area.

Full survey results for all attended and unattended survey locations, along with the derived L_{den} values, are presented in **Tables A.17.1.1** to **A.17.34** in **Appendix 17.1**.

17.3.2 Discussion of Baseline Environment

The results of the baseline surveys indicate the range of noise levels measured across the extent of the study area.

17.3.2.1 R336 Coast Road to Cappagh Road (Ch. 0+000 – 4+450)

At the western end of the proposed road development at properties along the R336 Coast Road, noise levels are dominated by traffic flows along this road. Noise levels were measured in the range of 60 to 67dB L_{den}, the main difference in the measured levels being the proximity to and line of sight from the road of the monitoring position.

Within Na Foraí Maola, residential properties are set back from heavily trafficked roads such as the R336 Bearna Road at distances of approximately 200m to 1km and are influenced predominately by local passing traffic, local activities within the residential areas and environmental sources including bird song, leaf rustle etc. Noise levels were measured in the range of 42 to 52dB L_{den} at the surveyed locations. The higher noise levels measured in this area were typically associated with intermittent local sources during the surveys, e.g. local deliveries to properties (post-delivery, oil deliveries, garden activities etc.).

Surveyed locations in the vicinity of Troscaigh and Ballard West were measured in the range of 43 to 50dB L_{den}.. Noise levels at the surveyed locations were noted to be influenced by passing traffic along the local roads in proximity to the monitoring positions in addition to local activities within gardens and bird song.

17.3.2.2 Cappagh Road to Rahoon Road (Ch. 4+450 – 6+650)

Noise monitoring locations within the gardens of properties in the vicinity of Cappagh Road, Ballymoneen Road and Árd Na Gaoithe in Ballymoneen set back from passing traffic were measured in the range of 43 to 45dB L_{den}. Noise levels at property facades located along the Cappagh and Ballymoneen Roads, were of the order of 52 and 53dB L_{den}. The highest noise level measured in this area was at monitoring location 6c which was measured at the front gate of a property along the footpath which was dominated by passing traffic, an L_{den} noise level of 64dB was measured at this location.

Surveyed properties along the Rahoon Road were measured in the range of 46 to 64dB L_{den}. At survey locations set back from the existing road and screened from passing road traffic by the property buildings, noise levels were measured in the range of 46 to 51dB L_{den}. At locations located in closer proximity to the existing road, noise levels were in the range of 57 to 64dB L_{den}, the higher noise level being recorded at location 7f which was noted to be influenced by passing road traffic.

17.3.2.3 Rahoon Road to N59 Moycullen Road (Ch. 6+650 – 8+550)

Noise levels at two areas in the vicinity of Rosán Glas within Letteragh were surveyed. At survey location 8a an L_{den} value of 45dB(A) was derived. Noise levels at this location were influenced mainly by intermittent passing vehicles entering the estate along Bóthar Diarmuida and bird song. At location 8b passing traffic was noted to be significantly more frequent and the monitoring location closer to the road side. In addition, a greater level of local estate activities was noted resulting in noise levels of 63dB L_{den} being measured at this location.

Noise levels measured in the vicinity of Letteragh Road and Knocknabrona were measured 47 to 56dB L_{den} (survey locations 8c to 8g). Similar to the above areas, at survey locations set back from passing road traffic, lower noise levels were measured, typically in the range of 47 to 51dB L_{den} which were noted to be influenced by distant and intermittent passing traffic and bird song. The highest noise level of 56dB L_{den} was measured at location 8f due to the proximity and line of sight to passing road traffic.

In the vicinity of the proposed N59 Letteragh Junction and proposed River Corrib Bridge, noise levels varied at the surveyed locations depending on their distance to existing road traffic. At monitoring locations within The Heath and Knockadoney within Upper Dangan (9a, 9b & 9e), noise levels were measured in the range of 47 to 58dB L_{den}. At all locations road traffic from the N59 Moycullen Road and birdsong was noted to be the main noise sources noted. Higher noise levels were recorded at properties located closer to the N59 Moycullen Road (i.e. location 9d & 9c) measuring noise levels in the range of 58 to 62dB L_{den}.

Properties directly accessing the N59 Moycullen Road (9g, 9f, 18b, 18c, 18e and 18f) measured highest noise levels in this area, ranging between 63 to 71dB L_{den} depending on the proximity of the measurement position to the existing road.

17.3.2.4 N59 Moycullen Road to Menlough (Ch. 8+550 – 11+000)

In the vicinity of NUIG Sporting Campus and Aughnacurra (10a, 10b, 10c and 10h), measured noise levels were recorded in the range of 49 to 53dB L_{den} which were noted to be influenced predominately by distant road traffic, grounds works, birdsong and plant noise from an adjacent business campus. Similar noise levels were recorded in the vicinity of Menlough and Coolough (locations 10d, 10d and 10f) in were the range of 47 to 54dB L_{den} which were noted to be influenced by intermittent traffic, bird song, dog barking and leaf rustle. Higher noise levels were recorded at Location 10g (63dB L_{den}) due to the proximity of the monitoring location to the road.

17.3.2.5 Menlough to N83 Tuam Road (Ch. 11+000 – 14+450)

To the east of Coolough the proposed development passes through a more built up environment crossing a number of main routes into Galway City, namely the N84 Headford Road, N83 Tuam Road and existing N6.

In the vicinity of the N84 Headford Road and proposed new junction, noise levels were measured in the range of 54 to 77dB L_{den}. Noise levels of 54 and 56dB L_{den} were recorded at the unattended monitoring positions located to the rear and side of properties set back from the N84 Headford Road (locations 11a and 17b). Higher noise levels were measured to the front of properties facing directly into the existing road with survey locations 17a and 11c recording highest levels due to their close proximity to the existing road.

Within the area of Castlegar, noise levels were measured in the range of 45 to 54dB L_{den} which were noted to be influenced by road traffic from School Road, the N84 Headford Road and from passing local traffic. Properties located off School Road measured noise levels in the vicinity of 63 to 67dB L_{den} when measured at the property boundaries in close proximity to the existing road. At monitoring locations set back from the road edge, noise levels measured 56dB L_{den} (11g) and were lower again at the rear of properties along this road shielded by road traffic noise (11g), measuring 52dB L_{den}.

Noise surveys undertaken at properties in the vicinity of the proposed N83 Tuam Road Junction were predominately influenced by traffic along the N83 Tuam Road. Monitoring locations fronting properties along this existing road were in the range of 61 to 77dB L_{den} (locations 12a, 12e, 16a, 16b and 16c). Lowest noise levels in this area were recorded at location 12d (48dB L_{den}) which is set back from the N83 Tuam Road and was shielded from the road traffic by local topography.

17.3.2.6 N83 Tuam Road to Coolagh Junction (Ch. 14+450 - 17+500)

Noise surveys conducted in the area of Ballybrit and Briarhill ranged between 50 and 57dB L_{den} (locations 13a, 13b, and 13c). Higher noise levels were recorded at locations 13b and 13c due to their proximity to road traffic from Ballybrit Crescent and local passing traffic.

At surveyed locations along the R339 Monivea Road and the existing N6 in the vicinity of the Ballybrit and Doughiska (locations 13d, 13e, 13f, 13g, 14b), noise levels were measured in the range of 61 to 66dB L_{den} which were all influenced by passing road traffic.

Within Galway Racecourse, noise levels presented represent those when no race activity was taking place. This represents lowest noise levels in this area when the facility is typically not in use. Noise levels were measured in the range of 53 to 63dB L_{den} over a 5 day monitoring period.

To the east of the proposed Coolagh Junction within Coolagh (locations 14a, 14c and 14e), noise levels were measured in the range of 48 to 56dB L_{den}. The dominant sources at these locations were noted to be road traffic and birdsong.

At survey locations along the R339 Monivea Road to the south of the existing N6 (locations 15a, 15b and 15c) noise levels were measured in the range of 54 to 72dB L_{den}. Lowest noise levels were measured at location 15a which was positioned within a green area fronting houses within The Meadows Estate which was shielded from road traffic. Highest noise levels were recorded at locations 15b due high volumes of traffic passing along the R339 Monivea Road in addition to the existing N6.

17.3.3 Summary of Noise Survey Results

The results of the baseline noise survey indicate that the noise environment varies across the proposed road development depending on the surrounding noise sources. In general, properties facing directly onto existing roads are dominated by road traffic and experience noise levels in excess of 60dB L_{den}. Properties in more rural settings set back from road traffic experience noise levels typically in the range of 42 to 50dB L_{den} depending on local sources in the vicinity.

The range of noise levels measured during the baseline surveys are an accurate representation of the baseline noise environment at properties likely to be affected by the proposed road development.

17.4 Characteristics of the Proposed Road Development

17.4.1 Construction Phase

The construction phase of the proposed road development will involve predominately ground breaking, earthworks and earthworks haulage, drainage works, construction of drainage ponds and surfacing works, construction of tunnels, bridges and overpasses, as well as the movement of machinery and materials within and to and from the construction compounds and along local roads.

A variety of items of plant will be in use during these construction works all of which have the potential to generate high levels of noise and potential levels of perceptible vibration. These will include breakers, rock drills, excavators, dump trucks, and generators in addition to general road surfacing and levelling equipment.

Blasting of bedrock will also be required on certain sections of the proposed road development depending on the ground conditions and the required depth of excavations. **Chapter 7, Construction Activities** provides a full description of the proposed construction phasing and works for the proposed road development.

It is envisaged that an east to west build will be adopted and construction may be completed in two concurrent phases or a single overall contract:

- Phase 1 – N6 Coolagh to N59 Letteragh Junction – 9.9km (Including the N59 Link Road North and South.)
- Phase 2 – N59 Letteragh Junction to R336 Coast Road west of Bearna -7.5km

In general, road building works by their nature are transient in nature as the works progress along the length of the route of the proposed road development. This includes excavation and fill works, structures, and road completion works. Site compounds in phases 1 and 2 will be set up typically at the commencement of the works and remain in place until all construction in the area is completed.

Within each phase, it is likely that the main construction work for the proposed road development will be split up into different sections along the route of the proposed road development. For the purposes of the EIAR, 15 individual construction sections are set out. Sections may be completed simultaneously and combined in certain areas. **Table 7.1** in **Chapter 7, Construction Activities** includes a summary of each section with the estimated time for the completion of works in these areas.

Typical working hours during the construction phase will be:

- 0700 1900 Monday – Friday
- 0700 1600 Saturday

It will be necessary to work overtime (including weekends) and night shifts at certain critical stages during the project. There may be some periods where 24hr work and supervision is required. Over the expected 36 month construction phase there will be up to 10 weeks of night time working along different sections of the proposed road development primarily to facilitate bridge works over existing roads.

The potential noise and vibration impacts associated with this phase are set out within **Section 17.5.3**.

17.4.2 Operational Phase

The operational phase will involve a new road alignment, junctions, overpasses, tunnels and bridges as part of the proposed road development. The proposed road development will introduce traffic noise to areas which are not currently exposed to any significant level of road traffic, particularly at properties set back from existing local roads in rural settings. The character of the noise environment will be altered at properties where intermittent traffic forms part of the noise environment to a more continual source of noise as a result of the operational phase. In addition to the above, the proposed road development will divert traffic flows from sections of existing roads across the city and hence, will result in a reduction in traffic noise along sections of these roads once operational.

The operational phase will be of long term duration and will alter the existing noise environment at properties in proximity to the proposed road development and along existing roads to different extents.

The potential impacts associated with this phase are set out within **Section 17.5.4**.

17.5 Evaluation of Impacts

17.5.1 Introduction

The potential impacts of noise and vibration as a result of the proposed road development will vary depending on the proximity of sensitive locations to the proposed road development, the pre-existing noise levels in the area and the duration of the impacts considered. It is estimated that the overall construction period will last for approximately 36 months. During the construction phase, potential noise and vibration impacts will be more significant compared to the operational phase but the duration will be short-term in nature. The operational phase will result in long-term effects but the significance of which will vary depending on the sensitivity of the existing environment and the magnitude of change against the Do-Minimum scenario, and the absolute noise levels under consideration.

17.5.2 Do-Nothing Impact

The Do-Nothing impact of the proposed road development assumes the proposed road development is not built and traffic management plans within the Galway city area are not in place. In line with traffic growth factors, traffic volumes will continue to increase along the existing routes accessing Galway City as part of the Do-Nothing Scenario. From a noise point of view, this will result in increased noise levels over and above the current scenario at properties located along the main national and regional roads. At properties set back from trafficked roads, noise levels measured as part of the baseline survey are expected to remain broadly similar. Noise levels at properties identified as 'hot spots' and areas for noise management within the Galway City Noise Action Plan (2013 – 2018) will remain above the threshold noise levels for noise management and are likely to be further increased as a result of increased traffic volumes.

17.5.3 Potential Construction Impacts

17.5.3.1 Noise

As per TII guidance, indicative ranges of noise levels associated with construction may be calculated in accordance with the methodology set out in *BS 5228-1:2009+A1:2014 Code of Practice for Noise and Vibration Control on Construction and Open Sites - Noise*. This standard sets out sound power levels for plant items normally encountered on construction sites, which in turn enables the prediction of noise levels. However, it is not possible to conduct detailed accurate prediction calculations for the construction phase of a project in support of the EIAR due to the limitations previously discussed in **Section 17.2.5**. The following section discusses typical noise levels associated with road construction activities and comments on potential noise impacts across the proposed road development.

Intrusive Works and High Noise Activities

Reference to BS 5288:2009+A1 2014: Part 1 indicates that highest noise levels are associated with activities associated with rock breaking, rock drilling, rock crushing and some impact piling works. Noise levels from these activity types are typically in the range of 85 to 95dB L_{Aeq} at 10m. All of the above activities will be required as part of the construction of the proposed road development.

For construction activities associated with rock extraction and processing a total construction noise level of 93dB L_{Aeq}, at 10m has been used for the purposes of indicative calculations. This would involve for example, 1 item of plant at 90dB L_{Aeq} and 3 items of plant at 85dB L_{Aeq} operating simultaneously within one work area which is considered a worst-case scenario.

Utilities, Bulk Excavation, Bridge Works & Road Works

For construction works associated with activities such as site clearance, excavation and fill, bridge works etc. including excavators, loaders, dozers, cranes, generators, concreting works etc. noise levels are typically in the range of 70 to 80dB L_{Aeq} at 10m.

For ongoing construction activity associated with the above activities, a total construction noise level of 85dB L_{Aeq} at 10m has been used for the purposes of indicative calculations. This would include, for example two items of plant at 80dB L_{Aeq} and three items of plant at 75dB L_{Aeq} operating simultaneously within one work area.

Compounds and Lower Noise Activities

For construction work areas with lower noise levels such as site compounds (for storage, offices and material handling, generators etc.), smaller items of mobile plant (excavators, cranes, dozers), landscaping and concreting works with lower noise emissions, a total construction noise level of 78dB L_{Aeq} at 10m has been used for the purposes of indicative calculations. This would include, for example one item of plant at 75dB L_{Aeq} and three items of plant at 70dB L_{Aeq} operating simultaneously within a work area.

Given the variations of on-site activities and noise levels over any one day and considering that all activities will not operate simultaneously, the values noted above are considered robust for the purposes of assessing potential construction impacts.

The closest properties to the proposed road development which are not being acquired or demolished are at distances of approximately 20m. Remaining properties are located at distances of 50 to >300m from different work phases.

Table 17.9 presents the calculated noise levels at distances between 20 and 250m representing the closest noise sensitive properties to the construction works. The calculations assume that plant items are operating for 66%[2] of the time and do not

2 This estimate that assumes that the plant will operate a full 8-hour shift over the proposed 12 hour working period which equates to a 66% on time over a daytime period or 40 minutes over a 1-hour period. The dynamic nature of construction sites is such that this is deemed to be a conservative estimate, particularly for breaking and drilling work.

include any attenuation from screening of site hoarding, road cuttings, buildings or structures, hence relate only to distance attenuation over hard ground.

Table 17.9: Indicative construction noise calculations at varying distances

Construction Activities	Combined LAeq at 10m	Calculated Noise Level at Increasing Distances					
		20m	50m	80m	100m	150m	250m
Rock Breaking / Drilling / Rock Crushing / Impact Piling	93	85	77	73	71	68	63
Site Clearance Utilities Excavation & fill Structures Road Works	85	77	69	65	63	60	55
General site work	77	69	62	57	55	52	48

The reference values outlined in **Table 17.9** indicate that for construction activities with highest noise levels (L_{Aeq} up to 93dB at 10m), the daytime construction noise limit value of 70dB L_{Aeq} Monday through Friday (07:00 to 19:00hrs) is likely to be exceeded at distances of up to 100m from the works boundary in the absence of any noise mitigation. Evening and weekend construction noise limits would be exceeded at distances up to 250m in the absence of noise mitigation. Noise mitigation will therefore be required to reduce construction noise levels from this type of activity during all periods at the closest properties.

During normal road construction works including site clearance, bulk excavation, structures etc. with site works up to 85dB L_{Aeq} at 10m, the daytime construction noise limit value of 70dB L_{Aeq} Monday through Friday (07:00 to 19:00hrs) is likely to be exceeded at distances of up to 50m from the works boundary in the absence of any noise mitigation. Evening and weekend construction noise limits would be exceeded at distances up to 150m in the absence of any mitigation. Noise mitigation will therefore be required to reduce construction noise levels from this type of activity, particularly during any scheduled evening and weekend works.

During general site work with lower noise emissions (L_{Aeq} up to 77dB at 10m) the daytime construction noise limit value of 70dB L_{Aeq} Monday through Friday (07:00 to 19:00hrs) can be complied with at distances of 20m and beyond. Evening and weekend construction noise limits would be exceeded at distances up to 80m in the absence of any mitigation. Noise mitigation will therefore be required to reduce construction noise levels from this type of activity, specifically during any scheduled evening and weekend works.

It should be noted that the calculations set out in the above tables are indicative and are used for the purposes of comparison only with the adopted criteria. Where exceedance of the recommended criteria is expected, the use of noise mitigation measures will be used as part of the construction works. Further details are set out in **Section 17.6.1**.

In line with the TII Guidelines on assessment of construction noise impacts, areas of major earthworks, blasting and piling (depending on the method to be used) should be identified. In addition, given two tunnel sections form part of the proposed road development, discussion of these areas should be included also. These are discussed in turn below.

Major Earthworks

Areas of major earthworks are associated with large cuttings and embankment constructions involving activities including excavation works, drill and blast techniques, rock crushing and fill works.

Moving west to east, construction of the mainline of the proposed road development below the Aille Road L5384 (Construction Section S2) will require a substantial amount of material excavation most likely using drill and blast techniques. Given the extent of the work in this area, it is likely that excavated material will be segregated, graded and crushed using mobile plant items within the excavated area. The closest properties to these works are some 120m from the earthworks boundary. During the early stages of construction in this area, there is potential for construction noise levels to exceed the noise criteria in the absence of any noise mitigation assuming rock drilling, crushing and a number of mobile plant items are operating at existing ground level. As the excavation works progress, the lowered ground level and screening from the cutting will significantly reduce noise levels at the closest properties.

Construction of the Letteragh Junction and approach roads (Construction Section S3 and S4) will require a substantial volume of engineering fill and an element of cutting for slip roads. Closest noise sensitive locations are between 50m and 60m from these junction works. In the absence of specific noise mitigation measures, there is potential for evening and weekend construction noise criteria to be marginally exceeded, should works occur during these time periods.

Construction of the N59 Link Road North (Construction Section S5) involves deep excavation towards the N59 Moycullen Road tie in, therefore a substantial volume of soil and rock excavation will be required which will likely require drill and blasting excavation. Closest noise sensitive locations are approximately 50 from the excavation works. In the absence of specific noise mitigation measures, it is likely that construction noise limits during, day, evening and weekend periods will be exceeded, specifically during the intermittent use of high noise activities (rock drilling, crushing and breaking, if required). The use of specific noise mitigation measures will be applied in this area therefore including scheduling of works, choice of plant, screening etc. Further discussion on mitigation measures are discussed in **Section 17.6.1**.

Construction of the N59 Letteragh Junction (Construction Section S6) involves an extensive area of cuttings which will likely require drill and blast excavation. Closest noise sensitive locations are approximately 25m from the excavation works. Whilst excavation works will take place within the cutting area, it is likely that crushing and regrading works will take place within a specific site compound located along the N59 link Road North, set back from noise sensitive properties. Notwithstanding the above, given the close distances of excavation works to noise sensitive properties, the use of controlled noise mitigation measures will be required in this area to reduce construction noise levels at the nearest noise sensitive locations.

Construction Section S10 involves construction of a large embankment connecting to the Menlough Viaduct. Moving east, construction of the dual carriageway will involve a deep cutting as it approaches the Lackagh Tunnel. The closest noise sensitive properties in this area are approximately 40m from the embankment works but are over 300m from the excavation works for the cutting. In the absence of specific noise mitigation measures, there is potential for evening and weekend construction noise criteria to be marginally exceeded, should works occur during these time periods.

Construction of the Lackagh Tunnel (Construction Section S11) will be undertaken in an east to west direction using drill and blast techniques. The tunnel portal and main works area will be within the Lackagh Quarry site compound. The closest noise sensitive properties to the tunnel are over 500m and hence are well set back from the main excavation works in this area. Further comment on Lackagh Quarry site compound is discussed separately in the following Section.

Construction of the N84 Headford Road Junction and the cutting on the eastern side of Lackagh Quarry (Construction Section S12) will involve substantial earthworks for both cutting and embankment construction. There will be a large cutting into the eastern face of Lackagh Quarry within the eastern end of this Section which is located some 300m from the nearest noise sensitive locations. Construction of the N84 Headford Road Junction will involve extensive engineered fill works to cross the existing N84 Headford Road with an element of cutting required for slip roads. The closest noise sensitive locations are within 40 to 50m from these works and hence there is potential for construction noise levels to exceed daytime, evening and weekend construction noise criteria in the absence of noise mitigation measures.

Construction Section S13 between School Road to Galway Racecourse Tunnel will involve a large number of major earthworks including a large cutting east of School Road and a grade separated junction at the N83 Tuam Road involving engineered embankments to cross the existing N83 Tuam Road. Moving east, the mainline will cut into a hill as far as the portal of the proposed Galway Racecourse Tunnel, thus requiring extensive excavation in this area. Drill and blast will be required for the main excavated sections in these areas. The closest noise sensitive locations to the excavation works west of School Road are between 30 and 50m thus the construction noise criteria for day, evening and weekend periods are likely to be exceeded in the absence of mitigation measures during specific excavation works. Further discussion on mitigation measures are discussed in **Section 17.6.1**.

Construction Section S14 involves the construction of the Galway Racecourse Tunnel using cut and cover techniques. Excavation will likely involve drill and blast to remove the shallow rock head in this area. The works will be scheduled in consultation with Galway Racecourse to minimise the disruption to the commercial practice of the business throughout the year. The construction works will be phased and will cease for the racing period. The closest noise sensitive locations to the tunnel works are typically 90 to 100m at commercial premises to the north and residential properties to the southeast. During short term periods of high noise activities (drill and blast, rock crushing etc.) there is potential for the construction noise criteria to be exceeded in the absence of mitigation. During the main construction of the tunnel structure and ancillary elements, construction noise levels will be further reduced.

The construction Section S15 between Galway Racecourse Tunnel and Coolagh Junction will involve excavation works to the east of the tunnel portal and the connection with the existing N6/M6 at Coolagh. Drill and blast excavation is possible at these locations due to the presence of shallow rock. There is a large amount of engineering fill required in this section due to the proposed overbridges and raised junction at Coolagh which will require a large amount of earthworks mobile plant and machinery. The closest noise sensitive locations to large excavation works are at distances of approximately 90m. There is potential for exceedance of the construction noise criteria during day, evening or weekend periods in the absence of noise mitigation at these properties. The closest noise sensitive locations to the Coolagh Junction are between 80 and 100m. It is possible to work within the construction noise criteria at these distances from the main engineering fill works, depending on the activities involved.

Structures

Construction of various bridge structures over and under existing roads, the Menlo Viaduct, River Corrib Bridge Crossing, Lackagh and Galway Racecourse Tunnel Structures will involve standard construction techniques which will likely involve piling (type and method dependent on ground conditions), engineered fill structures, lifting equipment etc. Daytime construction noise limits can typically be complied with at distances of 50m and beyond from these works.

Temporary night-time closure of existing roads will be required where overbridges are to be constructed at locations such as the Rahoon Road, Letteragh Road, N59 Moycullen Road, Menlo Castle Bóthrín, Bóthar Nua, An Seanbóthar, N84 Headford Road, N83 Tuam Road, Briarhill Business Park Road and R339 Monivea Road. This is required to avoid road closure during day time periods to facilitate lifting beams into place and other key works. Heavy or noisy construction activities will be avoided outside normal hours and the amount of work outside normal hours will be strictly controlled.

Noise levels associated with night-time works will tyically involve lifting equipment for beam construction. There is potential for the use of generators to power temporary lighting and other small items of mobile plant. Noise levels will be strictly controlled during these phases to ensure noisy items of plant are sited away from noise sensitive properties (e.g. generators), are enclosed or screened. Specific noise limits for night-time works will be set taking into account the pre-existing noise environment as per **Table 17.2**. These limits are site specific, hence will be fully reviewed prior to commencement of any night works and specific noise control measures put in palce. Best practice control meaures that will form part of the noise mitigation are included in **Section 17.6.1**.

Site Compounds

There are twelve sites identified as potential site compounds across the proposed road development. The siting of compounds has been chosen based on proximity to major works, proximity to residential properties and other environmental constraints. The site compounds are listed in **Table 17.10** with approximate distance to nearest noise sensitive locations and general comments on potential noise impacts included.

Table 17.10: Site Compound Potential Noise Impacts

Site No.	Location	Main Construction Activities	Closest Noise Sensitive Locations (m)	Potential Impacts
SC 00/01	R336 Baile Nua	Western tie-in for proposed road development	10	Potential exceedance of construction noise criteria to east of compound. Boundary screening, working hours, site layout planning to be undertaken prior to commencement of works
SC 04/01	Aille	Aille Cutting, Rock Crushing Plant	320	No significant impacts expected due to distances to NSL's. Assessment of rock crushing noise impacts required prior to commencement
SC 05/01	Ballymoneen	Aille Cutting, Letteragh and Rahoon Road Overbridge	50 – 100	Potential exceedance of construction noise criteria to southeast of compound, depending on siting of on-site activities. Boundary screening to south/ south east and site layout planning will be undertaken
SC 07/01	Letteragh	Major cut at Letteragh for GSJ and River Corrib Bridge (western section) Rock Crushing & Regrading Plant	400	Impacts can be well controlled through siting high noise activities away from noise sensitive boundaries
SC 08/01	Dangan (Aughnacurra)	River Corrib Bridge (western section). Used for storage only.	10 – 20	Storage only. No significant activities on site. No significant impacts expected
SC 09/01	Menlough (East of River Corrib)	River Corrib Bridge (eastern section) & Menlough Viaduct	400	No significant impacts expected due to distances to noise sensitive locations
SC 11/01	Lackagh Quarry	Lackagh Tunnel and potential for concrete batching plant, crushing and regrading of material.	100 – 200	Impacts can be well controlled through siting high noise activities away from noise sensitive boundaries, site orientation and use of quarry face for noise screening

Site No.	Location	Main Construction Activities	Closest Noise Sensitive Locations (m)	Potential Impacts
SC 14/01	Twomileditch (N83 Tuam Road Junction)	N83 Tuam Road Junction and Parkmore Link Road - Rock Crushing Plant	40 – 50	Potential exceedance of construction noise criteria at closet boundaries. Boundary screening to west and site layout planning will be undertaken
SC 14/02	Twomileditch (N83 Tuam Road Junction)	N83 Tuam Road Junction and Parkmore Link Road	200	No significant impacts. Boundary screening and site layout where necessary following assessment prior to commencement
SC 14/03	Twomileditch (N83 Tuam Road Junction)	N83 Tuam Road Junction and Parkmore Link Road	250	No significant impacts. Boundary screening and site layout where necessary following assessment prior to commencement
SC 14/04	Galway Racecourse Tunnel Western Portal	Galway Racecourse Tunnel (western section)	240	No significant impacts. Boundary screening and site layout where necessary following assessment prior to commencement
SC 15/01	Coolagh/Briarhill	Galway Racecourse Tunnel (eastern section)	30	Potential exceedance of construction noise criteria at closet boundaries. Boundary screening to north and east and siting of noisy activities away from noise sensitive boundaries will be undertaken
SC 16/01	Coolagh	Coolagh Junction	90	Potential exceedance of construction noise criteria at closet boundaries Boundary screening to north and east and site layout where necessary following assessment prior to commencement

The site compounds across the site are largely set back from noise sensitive properties and the noise emissions from these areas can be largely controlled through the use of boundary screening and site layout planning, as required. The largest site compound will be located at Lackagh Quarry which will be in use for the full extent of the construction of the proposed road development. This compound will be the main portal for the Lackagh Tunnel and will likely include a concrete batching plant, mobile rock crushing and rock grading equipment. All of the above have the potential to generate high levels of noise, however, given the large extent of the compound (9ha approximately), there is ample opportunity to sufficiently locate activities with high noise levels away from noise sensitive boundaries. In addition, the existing quarry profile will provide substantial screening to noise sensitive properties beyond.

Other site compounds where rock crushing activities are likely are well set back from noise sensitive locations and noise levels from this activity is not expected to generate noise levels in exceedance of the construction noise criteria. There is potential for rock crushing plant to be positioned within Site Compound SC 14/01 at the N83 Tuam Road Junction where noise sensitive properties are at distances of approximately 40m across the N83 Tuam Road. The location of rock processing equipment can be sited at distances further into the compound to reduce noise emission from this activity.

Overall, the potential impacts during the construction phase will be moderate to very significant and short term in the absence of noise mitigation. A range of control measures will be required at specific working areas to suitably reduce noise impacts at noise sensitive locations.

Emergency Work

Emergency work may include the replacement of warning lights, signs and other safety items on public roads, the repair of damaged fences, repair of water supplies and other services which have been interrupted, repair to any damaged temporary works and all repairs associated with working on public roads.

17.5.3.2 Construction Traffic

In addition to direct impacts from the construction works including site compounds, there is also the potential for noise impacts from construction traffic along public roads.

A detailed analysis of construction traffic volumes has been conducted to determine the expected lorry movements required to transport the materials extracted and delivered to site. A total of 16 public roads has been identified as required haul routes where construction traffic will be permitted to travel along. Whilst the overall construction period is forecast as three years, construction traffic movements are split over a 12 month period along haul roads accessing specific work zones and a two-year period for national and regional roads serving multiple work zones to allow for a robust assessment to be made.

Traffic volumes for the base scenario are based on the 2024 Do Minimum flows projected along the local road network. These are AADT flows with percentage HGV’s. The additional HGV and LGV flows per day associated with construction traffic along each road including construction staff vehicles, deliveries and earthworks material haulage are added to the base traffic volumes. The estimated construction traffic volumes incorporate a series of worst case assumptions including concentrated construction periods at working areas and assumes that no delivery of materials will occur along the corridor of the proposed road development which is highly worst case. In reality the proposed road development will be constructed in phases and the corridor of the proposed road development will be used for a large bulk of construction delivery vehicles along its route.

In order to determine the potential noise impacts associated with additional construction traffic on the identified haul routes, a comparison between traffic noise levels during for the base (Do Minimum) scenario and the Do Something (base plus construction) scenario were determined.

Noise levels associated with passing event such as road traffic may be expressed in terms of its Sound Exposure Level (L_{AX}). The Sound Exposure Level can be used to calculate the contribution of an event or series of events to the overall noise level in a given period using the following formulae:

$L_{Aeq,T} = L_{AX} + 10\log10(N) - 10\log10(T)$ dB

where:
$L_{Aeq,T}$ is the equivalent continuous sound level over the time period T (in seconds)
L_{AX} is the "A-weighted" Sound Exposure Level of the event considered (dB)
N is the number of events over the course of time period T

The mean value of Sound Exposure Level for truck moving at low to moderate speeds is in the order of 82dB L_{AX} at a distance of 10 metres from the vehicle. The mean value of Sound Exposure Level for car or light good vehicle passing at low to moderate speeds is in the order of 68dB L_{AX} at a distance of 10 metres from the vehicle.

Noise levels associated with additional construction traffic volumes are calculated over a 12hr period, relating to the typical construction working day (i.e. 07:00 to 19:00hrs). The combined value represents the total noise level over a daily (24hr) period.

Table 17.11 presents a summary of the construction traffic noise assessment. Traffic noise levels at a distance of 10m from the haul roads is calculated for the base (Do-Minimum) scenario and the Do-Something (base plus construction) scenario. The increase in noise levels between both scenarios is also presented.

Reference to **Table 17.11** overleaf confirms the increase in noise level along the majority of the haul routes is negligible (<1dB) due to the existing volume of traffic along these roads and the relatively low additional HGV and LGV traffic per day forecast. The greatest increase in noise levels is calculated along the Bearna to Moycullen Road (L1321) in Zone 1, the Cappagh Road in Zone 2 and along Bóthar Nua in Zone 4.

Along the Bearna to Moycullen Road (L1321), existing traffic volumes are moderate with an associated low number of HGV's. Noise levels are calculated to increase by the order of 3dB over a concentrated worst case 12-month period assuming an additional 20 HGV and 374 LGV movements per day along this road. Reference to **Table 17.5** (classifications of Magnitude of Noise Impacts in the Short Term) defines an increase of this magnitude to be 'moderate'. Whilst a perceptible change in noise level is calculated, the overall noise level along this road is of low to moderate level, calculated at 56dB $L_{Aeq,T}$ at 10m from the road edge. Considering the above, the overall impact is deemed to be moderate, short-term.

Along the Cappagh Road, existing traffic volumes are low with an associated low number of HGV's. Noise levels are calculated to increase by the order of 8dB over a concentrated worst case 12-month period assuming an additional 29 HGV and 370 LGV movements per day along this road. Reference to **Table 17.5** (classifications of Magnitude of Noise Impacts in the Short Term) defines an increase of this magnitude to be 'major'. Whilst a perceptible change in noise level is calculated, the overall noise level along this road will remain low to moderate, at

55dB $L_{Aeq, T}$ at 10m from the road edge. Considering the above, the overall impact is deemed to be moderate, short-term.

Along Bóthar Nua, existing traffic volumes are moderate and baseline noise levels are calculated as 55dB $L_{Aeq, T}$ at 10m from the existing road edge. Noise levels are calculated to increase by the order of 7dB over a concentrated worst case 12-month period assuming an additional 154 HGV and 177 LGV movements per day along this road. Reference to **Table 17.5** defines an increase of this magnitude to be 'major'. Whilst a perceptible change in noise level is calculated, the overall noise level along this road are calculated as 62dB $L_{Aeq,T}$ at 10m from the existing road edge. Considering the above, the overall impact is deemed to be major, short-term.

Table 17.11: Construction Traffic Noise Assessment

Section	Road Link	Do Minimum		Do Something (Construction)		Calculated Change in Noise Levels, dB

17.5.3.3 Vibration

The potential for elevated levels of vibration at sensitive locations during construction is typically associated with excavation works, rock-breaking and blasting operations. Depending on the method and equipment used, there is potential for some vibration relating to piling operations, demolition works and lorry movements on uneven road surfaces. The more significant of these relates to vibration from excavation and rock-breaking operations.

In terms of piling, low vibration methods involving bored or augured piles will be selected over and above percussive type piling, where ground conditions permit. This piling method significantly minimises the levels of both noise and vibration generated as it is a non-percussive piling technique.

For the purposes of this assessment, however, vibration levels associated with driven piles are assessed in order to determine potential worst case impacts. British Standard BS 5228 *2 :2009+A1:2014: Vibration*, includes measured magnitude of vibration associated with different piling types. **Table 17.12** reproduces those associated with steel sheet piling.

Table 17.12: Vibration Magnitudes associated with Sheet Steel Piling

Soil Conditions	Pile Dimensions	Distance, m	PPV, mm/s
Very soft to soft (0 – 10m), soft to medium clay (10 – 20m)	U-shaped LX 16 sheet piles	4.8 – 24	4.3 – 0.5
(not provided)	U-shaped piles	7.1	0.3 – 0.7
Made ground 0 – 3m, loose and very dense sand and silt 3 – 17m, firm to stiff clay 17 – 25m	244mm diameter driven tubular steel piles	5 – 20	13.9 – 4.3
Made ground 0 – 3m, loose and very dense sand and silt 3 – 17m, firm to stiff clay 17 – 25m	275mm driven square piles	5 – 20	11.4 – 4.3

The vibration magnitudes outlined in **Table 17.12** indicate that at distances beyond 20m, vibration magnitudes are significantly reduced to well below those associated with any form of cosmetic damage to buildings.

During rock breaking, there is also potential for vibration to be generated through the ground. Empirical data for this activity is not provided in the BS 5228-*2:2009+A1:2014* standard, however the likely levels of vibration from this activity is expected to be significantly below the vibration criteria for building damage on experience from other sites. AWN Consulting have previously conducted vibration measurements under controlled conditions, during trial construction works, on a sample site where concrete slab breaking was carried out. The trial construction works consisted of the use of the following plant and equipment when measured at various distances:

- 3 tonne hydraulic breaker on small CAT tracked excavator
- 6 tonne hydraulic breaker on large Liebherr tracked excavator

Vibration measurements were conducted during various staged activities and at various distances.

Peak vibration levels during staged activities using the 3 Tonne Breaker ranged from 0.48 to 0.25 PPV (mm/s) at distances of 10 to 50m respectively from the breaking activities. Using a 6 Tonne Breaker, measured vibration levels ranged between 1.49 to 0.24 PPV (mm/s) at distances of 10 to 50m respectively.

Whilst these measurements relate to a solid concrete slab, the range of values recorded provides some context in relation typical ranges of vibration generated by construction breaking activity.

Demolition of existing structures will involve careful deconstruction using controlled techniques. There may be a requirement for breaking ground as part of specific demolition procedures, depending on the structure. Vibration levels associated with this activity will be of similar or lower magnitude to rock breaking discussed above.

Referring to the vibration magnitudes above, vibration impacts due to ongoing construction works will be not significant and short term.

Notwithstanding the above, any construction activities undertaken on the site will be required to operate below the recommended vibration criteria set out in **Table 17.3**.

17.5.3.4 Blasting

Ground investigations have indicated that blasting will be required at a number of locations along the route of the proposed road development, in proximity to access roads, stream diversions and attenuation ponds, ref **Figures 7.3.1** and **7.3.2**. The extent of blasting will depend on the rock type and depth in the area and the depth of the cutting involved. For the majority of identified locations, a relatively shallow blast depth is required. There are a number of locations along the route of the proposed road development where a cut depth of greater than 10m will be required as part of the construction of the proposed road development.

Whilst drill and blast methods generate intermittent high noise levels when taking place, the time period over which impacts are experienced are significantly shorter compared to other extraction methods. For the proposed road development where a significant portion of hard rock is required to be excavated, the use of drill and blast will enable extraction works to be undertaken at a significantly faster rate compared to traditional rock breaking techniques.

Blasting impacts relate to both ground vibration and air overpressure, the magnitude of which depends on a variety of factors.

Air Overpressure (AOP)

Air overpressure is energy transmitted from the blast site within the atmosphere in the form of pressure waves. As such a wave passes a given position, the pressure of the air at this point rises very rapidly to a value above the ambient pressure, and then falls more slowly to a value below, before returning to the ambient value after a series of oscillations. The maximum excess pressure in this wave is known as the peak air overpressure. This value is typically measured in terms of dB (L_{in}).

These pressure waves will consist of energy over a wide range of frequencies, some of which are audible and known as sound waves or noise, but most of the energy is inaudible at frequencies of less than 20Hz which is not heard by the human ear but is sensed as pressure.

The main sources of air overpressure from blasting relate to blast design and set up (e.g. detonating cord, stemming release and gas venting) and physical properties of the site (movement of rock and reflection of stress waves). The intensity of air overpressure levels at a receiver location is highly dependent on meteorological conditions which affect ambient air pressure including temperature, cloud cover, humidity, wind speed and direction etc. Due to the large variability in these conditions, it is not possible to reliably calculate AOP. The control of its intensity is therefore undertaken at source through careful blast design.

It is important to note that routine open-pit blasting operations regularly generate air overpressures up to a magnitude of 120dB (Lin), with levels in excess of 125dB (Lin) being relatively rare. Damage levels are rarely approached let alone exceeded. BS 5228-2 notes that there is no known evidence of structural damage to structures from excessive air overpressure levels from quarry blasting in the UK.

Ground Vibration

The level of vibration at a receiver location from a blast depends predominately on the distance from the blast, the maximum instantaneous charge (MIC), sequencing of charges and ground conditions between the blast area and the receiver location. Whilst it is possible to undertake indicative predictive calculations for ground vibrations from a blast site using information on the MIC, distance and ground factors, the most accurate methodology for determining vibration levels is through controlled trial blasts at specific sites and undertaking scaled distance regression analysis to determine maximum charge values in order to comply with set criteria. This is therefore undertaken by experienced contractors as part of the blast design (refer to **Chapter 9, Soils and Geology**).

In the case of the proposed road development, blast events will be clearly perceptible at the nearest sensitive receptors due to ground vibration and air overpressure levels, however the duration of the effects are intermittent. The overall impacts are therefore considered to be significant, momentary and localised. The closest sensitive properties to the identified likely blast sites are at distances of 30 to 50m. It is expected that these potential impacts can be appropriately mitigated through the implementation of best practice blasting control measures which are outlined in **Section 17.6.1**. Specific assessment of potential impacts of blasting on birds and other sensitive species are included in **Chapter 8, Biodiversity**.

17.5.4 Potential Operational Impacts

17.5.4.1 Operational Noise Levels

Traffic noise levels have been calculated at the 299 receiver locations along the length of the proposed road development in accordance with the methodologies outlined in **Section 17.2.5**.

The calculated noise levels in **Table 17.13** are presented for the Opening Year (2024) and Design Year (2039) of the proposed road development and compares the calculated results against the three TII conditions (referenced in **Section 17.2.2.2**) for noise mitigation.

When considering the requirement for noise mitigation under Condition C, traffic noise levels must be attributed to the physical proposed road development under consideration in order for noise mitigation to be provided. In certain instances, traffic flows along the local road network are higher during the Do-Something scenario compared to the Do-Nothing scenario due to traffic volumes along these road links. In these instances, Condition C is not triggered and hence noise mitigation is not included as part of this proposed road development.

The calculated "Do Minimum" noise levels presented in Table 17.13 relate to traffic noise levels associated with modelled roads only. These are presented predominately to assess the requirement for noise mitigation against Condition b, particularly for locations along existing roads where traffic noise levels exceed 60dB L_{den} in the absence of the proposed road development.

The modelled calculated noise level at each assessment location is included within **Table 17.13**.

Table 17.13: Calculated Traffic Noise Levels

Model Results - Year 2024

On review of the modelled results and subsequent analysis, a total of 92 of the modelled locations satisfy the requirements for noise mitigation i.e. the predicted road traffic noise level is above 60dB L_{den} and noise levels are increased by 1dB or more as a direct result of the proposed road development. Noise mitigation is therefore deemed necessary at these locations based on the TII criteria. The number of properties determined to require noise mitigation excludes properties which will be demolished as part of the proposed road development but includes those that are to be acquired.

Model Results – Year 2039

On review of the modelled results and subsequent analysis, a total of 106 of the modelled locations satisfy the requirements for noise mitigation i.e. the predicted road traffic noise level is above 60dB L_{den} and noise levels are increased by 1dB or more as a direct result of the proposed road development. Noise mitigation is therefore deemed necessary at these locations based on the TII criteria. The number of properties determined to require noise mitigation excludes properties which will be demolished as part of the proposed road development but includes those that are to be acquired.

Summary of Receptors Requiring Mitigation

Analysis of the modelled results indicates that during the Design Year of 2039, 106 properties meet the three criteria for noise mitigation. These are distributed across the length of the proposed road development including the mainline, link roads and along existing roads which will be upgraded as part of the proposed road development.

Whilst the 106 properties identified satisfy the requirement for noise mitigation, the suitability and or practicality of noise mitigation for each location may not be possible at all locations. Further discussion on the recommended mitigation measures for the operational phase are included in **Section 17.6.3**.

17.5.4.2 Operational Vibration

As a vehicle travels along a road, vibration can be generated in the road and subsequently propagate towards nearby buildings. Such vibration is generated by the interaction of a vehicle’s wheels and the road surface and by direct transmission through the air of energy waves. Some of these waves arise as a function of the size, shape and speed of the vehicle, and others from pressure fluctuations due to engine, exhaust and other noises generated by the vehicle.

It has been found that ground vibrations produced by road traffic are unlikely to cause perceptible structural vibration in properties located near to well-maintained and smooth road surfaces. Perceptible road traffic vibration can therefore be largely avoided by maintenance of the road surface.

17.6 Mitigation Measures

17.6.1 Introduction

Mitigation measures for the construction and operational phases are set out below in order to reduce potential impacts as far as practicable to within the adopted design goals for noise and vibration.

17.6.2 Construction Phase

17.6.2.1 Noise

The contract documents will clearly specify the construction noise criteria included in this chapter which the construction works must operate within. The Contractor undertaking the construction of the works will be obliged to take specific noise abatement measures and comply with the recommendations of *BS 5228-1:2009+A1:2014 Code of Practice for Noise and Vibration Control on Construction and Open Sites - Noise* and the European Communities (Noise Emission by Equipment for Use Outdoors) Regulations, 2001. These measures will ensure that:

- No plant used on site will be permitted to cause an ongoing public nuisance due to noise
- The best means practicable, including proper maintenance of plant, will be employed to minimise the noise produced by on site operations
- All vehicles and mechanical plant will be fitted with effective exhaust silencers and maintained in good working order for the duration of the contract
- Compressors will be attenuated models fitted with properly lined and sealed acoustic covers which will be kept closed whenever the machines are in use and all ancillary pneumatic tools shall be fitted with suitable silencers
- Machinery that is used intermittently will be shut down or throttled back to a minimum during periods when not in use
- Any plant, such as generators or pumps that is required to operate before 07:00hrs or after 19:00hrs will be surrounded by an acoustic enclosure or portable screen
- During the course of the construction programme, the contractor will be required to manage the works to comply with the limits detailed in **Table 17.1** using methods outlined in *BS 5228-1:2009+A1 2014. Part 1 - Noise*

BS 5228 *-1:2009+A1 2014* includes guidance on several aspects of construction site practices, which include, but are not limited to:

- Selection of quiet plant
- Control of noise sources
- Screening

- Hours of work
- Liaison with the public
- Monitoring

Further comment is offered on these items in the following paragraphs and in **Appendix A.17.2**, however specific control measures relating to construction activities undertaken by the contractor will be set out within the construction noise and vibration management plan. Noise control measures that will be considered include the selection of quiet plant, enclosures and screens around noise sources, limiting the hours of work and noise monitoring. The contractor will be required to conduct construction noise predictions prior to works taking place and put in place the most appropriate noise control measures depending on the level of noise reduction required at any one location.

Selection of Quiet Plant

The potential for any item of plant to generate noise will be assessed prior to the item being brought onto the site. The least noisy item of plant will be selected wherever possible. Should a particular item of plant already on the site be found to generate high noise levels, the first action will be to identify whether or not said item can be replaced with a quieter alternative.

For static plant such as compressors and generators used at work areas such as construction compounds etc., the units will be supplied with manufacturers' proprietary acoustic enclosures where possible.

The contractor will evaluate the choice of piling, excavation, breaking or other working method taking into account various ground conditions and site constraints. Where possible, where alternative lower noise generating equipment that would economically achieve, in the given ground conditions, equivalent structural / excavation / breaking results, these will be selected to minimise potential disturbance.

The decision regarding the type of pile, excavation technique, rock breaking, crushing etc. to be used on a site will normally be governed by other engineering, environmental constraints. In these instances, it may not be possible for technical reasons to replace a noisy process by a quieter alternative (e.g. rotary bored piling over driven piles). Even if it is possible, the adoption of a quieter method may prolong the overall process (e.g. manual rock breaking versus blasting); the net result being that the overall disturbance to the community will not necessarily be reduced.

General Comments on Noise Control at Source

If replacing a noisy item of plant is not a viable or practical option, consideration will be given to noise control "at source". This refers to the modification of an item of plant, or the application of improved sound reduction methods in consultation with the supplier or the best practice use of equipment and materials handling to reduce noise.

In practice, a balance may need to be struck between the use of all available techniques and the resulting costs of doing so. It is therefore proposed to adopt the concept of "*Best Available Techniques"*. as defined in EC Directive 96/61. In this context *"best"* means *"the most effective in achieving a high general level of protection of the environment as a whole"*.

The expression *"available techniques"* means *"those techniques developed on a scale which allows implementation…., under economically and technically viable conditions, taking into consideration the costs and advantages, whether or not the techniques are used or produced within the State, as long as they are reasonably accessible to the operator carrying on the activity"*.

The term *"techniques"* includes *"both the technology used and the way in which the installation is designed, built, managed, maintained, operated and decommissioned"*.

Thus, the concept of Best Available Techniques requires a degree of balance between the attainment of environmental benefits and the likely cost implications. In the identification of Best Available Techniques, regard will be had to a wide range of factors, however, emphasis will be given to *"practical suitability"* and the need *"to reduce an emission and its impact on the environment as a whole"*.

Proposed techniques will also be evaluated in light of their potential effect on occupational health and safety. The following outline guidance relates to practical noise control at source techniques which relate to specific site considerations:

- For mobile plant items such as cranes, dump trucks, excavators and loaders, the installation of an acoustic exhaust and/or maintaining enclosure panels closed during operation can reduce noise levels by up to 10dB. Mobile plant will be switched off when not in use and not left idling
- For piling plant, noise reduction can be achieved by enclosing the driving system in an acoustic shroud. For steady continuous noise, such as that generated by diesel engines, it is possible to reduce the noise emitted by fitting a more effective exhaust silencer system or utilising an acoustic canopy to replace the normal engine cover
- For percussive tools such as pneumatic concrete breakers, rock drills and tools a number of noise control measures include fitting muffler or sound reducing equipment to the breaker 'tool' and ensuring any leaks in the air lines are sealed. Erection of localised screens around breaker or drill bit when in operation in close proximity to noise sensitive boundaries are other suitable forms of noise reduction
- For concrete mixers, control measures will be employed during cleaning to ensure no impulsive hammering is undertaken at the mixer drum
- For all materials handling, the contractor will ensure that best practice site noise control measures are implemented including ensuring that materials are not dropped from excessive heights and drop chutes/dump trucks are lined with resilient materials. This is an important consideration for site compounds where materials are loaded and unloaded. Site compounds in close proximity to noise sensitive areas (refer to **Table 17.10**) will incorporate a strict noise control policy relating to materials handling

- Where compressors, generators and pumps are located in areas in close proximity to noise sensitive properties/ areas and have potential to exceed noise criterion, these will be surrounded by acoustic lagging or enclosed within acoustic enclosures providing air ventilation
- Resonance effects in panel work or cover plates can be reduced through stiffening or application of damping compounds; rattling and grinding noises can be controlled by fixing resilient materials in between the surfaces in contact
- Demountable enclosures can also be used to screen operatives using hand tools and may be moved around site as necessary
- All items of plant will be subject to regular maintenance. Such maintenance can prevent unnecessary increases in plant noise and can serve to prolong the effectiveness of noise control measures

Screening

Typically screening is an effective method of reducing the noise level at a receiver location and can be used successfully as an additional measure to other forms of noise control. The effectiveness of a noise screen will depend on the height and length of the screen, its mass, and its position relative to both the source and receiver.

The length of the screen should in practice be at least five times the height, however, if shorter sections are necessary then the ends of the screen will be wrapped around the source.

BS 5228 *-1:2009+A1 201* states that on level sites the screen should be placed as close as possible to either the source or the receiver. The construction of the barrier will be such that there are no gaps or openings at joints in the screen material. In most practical situations the effectiveness of the screen is limited by the sound transmission over the top of the barrier rather than the transmission through the barrier itself. In practice, screens constructed of materials with a mass per unit of surface area greater than 10kg/m^2 will give adequate sound insulation performance. As an example, the use of a standard 2.4m high construction site hoarding will provide a sufficient level of noise screening once it is installed at a suitable position between the source and receiver. Annex B of *BS 5228-1:2009+A1:2014* (Figures B1, B2 and B3) provide typical details for temporary and mobile acoustic screens, sheds and enclosures that can be constructed on site from standard materials.

In addition, careful planning of the site layout will also be considered. Within site compounds, the placement of site buildings such as offices and stores between the site and sensitive locations can provide a good level of noise screening. Similarly, in some instances materials such as topsoil or aggregate along the route of the proposed road development can provide a degree of noise screening if placed between the source and the receiver.

Hours of Work

Construction activity will mostly take place during daytime hours Monday to Friday and Saturdays (ref **Section 17.2.2.1**). Depending on the noise emission levels experienced and associated noise impact, the contractor will be flexible and able to conduct certain works at hours which reflect periods when the neighbouring properties have lower sensitivities to noise.

It will be necessary to work overtime (including weekends) and night shifts at certain critical stages during the project. Over the expected 36-month construction phase there will be up to 10 weeks of night time working along different sections of the proposed road development primarily to facilitate bridge works over existing roads.

Consideration will be given to the scheduling of activities in a manner that reflects the location of the site and the nature of neighbouring properties. Each potentially noisy event/activity will be considered on its individual merits and scheduled according to its noise level, proximity to sensitive locations and possible options for noise control. In situations where a particularly noisy activity is scheduled e.g. activities identified in **Table 17.9** (rock breaking/crushing/impact piling etc.) or other activities of similar noise level, the use of other on-site activities will be scheduled to ensure control cumulative noise levels.

Liaison with the Public

On typical road construction sites, the major sources of noise are essentially mobile and the noise received at any control points will therefore vary from day to day as work proceeds. The duration of piling, excavation, breaking and other high noise or vibration activities works is usually short in relation to the length of construction work as a whole, and the amount of time spent working near to sensitive areas can represent only a part of the overall period. It is important, therefore, that clear forms of communication are established between the contractor and noise sensitive areas in proximity so that residents or building occupants are aware of the likely duration of activities likely to generate higher noise or vibration.

A designated noise liaison officer will be appointed to site during construction works. All noise complaints will be logged and followed up in a prompt fashion by the liaison officer.

Monitoring

During the construction phase noise monitoring will be undertaken at the nearest sensitive locations to ensure construction noise limits outlined in **Table 17.1** are not exceeded. Noise monitoring will be conducted in accordance with the International Standard ISO 1996: *Acoustics – Description, measurement and assessment of environmental noise* Part 1 (2016) and Part 2 (2017). The selection of monitoring locations will be based on the nearest sensitive buildings to the working area which will progress along the length of the road construction.

It is recommended that noise control audits are conducted at regular intervals throughout the construction programme in conjunction with noise monitoring. The purpose of the audits will be to ensure that all appropriate steps are being taken to control construction noise emissions and to identify opportunities for improvement, where required.

17.6.2.2 Blasting and Air Overpressure

Air overpressure from a blast is difficult to control because of its variability, however, much can be done to reduce the effect and the control of the blast design at source.

In terms of blast design control, specific guidance will be obtained from the recommendations contained within *BS 5228-2:2009+A1:2014 Code of Practice for Noise and Vibration Control on Construction and Open Sites – Vibration* in relation to blasting operations in addition to experienced blast control techniques used by the contractor. These will include some or all of the following:

- All blasting will be undertaken by professionally trained blast contractors
- Restriction of hours within which blasting can be conducted (09:00 – 18:00hrs)
- Trial blasts will be tested in less sensitive areas to assist in blast designs and identify potential zones of influence
- Explosive charges will be properly confined by a sufficient amount of stemming
- Blasting contractors will ensure that the minimum amount of primer cord is used, and that no primer cord is located above ground
- Profiling will be carried out after each blast in order to ensure the geometry of the rock face can be established, enabling the optimum burden and spacing to be applied for subsequent blasts
- The design, execution and completion of any blasting within 150metres of any existing structure shall require special considerations. This will include the use of pre and post condition structural surveys by a competent structural engineer
- Ground vibration and air over pressure (AOP) will be recorded simultaneously for each blast at the most sensitive locations, depending on the works area being blasted
- When blasting moves into a new area, an initial low level blast will be carried out (i.e. a low Maximum Instantaneous Charge (MIC)) and monitoring will be carried out simultaneously at a number of sensitive properties in different directions in order to generate specific scaled distance graphs
- The scaled distance graphs will be used to determine the optimum MIC for subsequent blasts area in order control vibration and AOP limits below the relevant limit values (as set out in **Section 17.2.1**) at the nearest sensitive buildings

In line with best practice mitigation measures from vibration sources, good communication and public relations are a key factor in reducing any startle effects to residents. In this instance, a Public Communications Strategy will be implemented by the contractor prior to the commencement of any blast works. In such cases, the following recommended mitigation measures are proposed:

- Relevant nearby residents will be notified before any work and blasting starts (e.g. a minimum of 24-hour written notification)

- The firing of blasts will be undertaken, where possible, at similar times to reduce the 'startle' effect
- Ongoing circulars will be issued informing people of the progress of the blasting works
- The implementation of an onsite documented complaints procedure will be maintained by the contractor
- The use of independent monitoring will be undertaken by external bodies for verification of results

17.6.2.3 *Vibration*

The TII Guidelines recommend that in order to ensure that there is no potential for vibration damage during construction, vibration from construction activities should be limited to the values set out in **Table 17.3**.

On review of the likely vibration levels associated with construction activities, it may be concluded that the construction of the proposed road development is not expected to give rise to vibration that is either significantly intrusive or capable of giving rise to structural or cosmetic damage to buildings.

In the case of vibration levels giving rise to human discomfort, in order to minimise such impacts, the following measures shall be implemented during the construction period:

- A clear communication programme will be established to inform adjacent building occupants in advance of any potential intrusive works which may give rise to vibration levels likely to exceed perceptible levels. The nature and duration of the works will be clearly set out in all communication circulars
- Alternative less intensive working methods and/or plant items shall be employed, where feasible
- Appropriate vibration isolation shall be applied to plant, where feasible
- Cut off trenches to isolate the vibration transmission path shall be installed where required
- In the case of impact piling or demolition works for instance, a reduction in the input energy per blow shall be considered where required
- Monitoring will be undertaken at identified sensitive buildings, where proposed works have the potential to be at or exceed the vibration limit values

Property Condition Surveys

Property condition surveys will be offered for all buildings within 50m of the proposed development boundary and those within 150m of proposed blasting works along the proposed road development. Property condition surveys will also be carried out at buildings and structures considered appropriate relative to their proximity to the works. Such property condition surveys shall be carried out by a Chartered Surveyor or Chartered Structural Engineer. Such property condition surveys, subject to the written agreement of relevant property owners, shall be carried out in two stages as the follows:

- the first stage shall consist of pre-construction condition surveys including photographic records which shall be carried out prior to the commencement of construction
- the second stage shall consist of post-construction condition surveys which shall include photographic records

Disturbance of Particularly Vibration-Sensitive Equipment and Processes

The location of potentially vibration sensitive activities have been identified for manufacturing facilities within the Parkmore and Racecourse Business Parks. This location is in proximity to an area where blasting will take place as part of the proposed tunnel at Ballybrit. The most effective form of mitigation for this type of sensitive process is through on-going consultation with the property owners as the design and construction of the proposed road development progresses. This will involve baseline vibration monitoring and the use of trial blasts using an initial low level charge with simultaneously vibration measurements undertaken at the building. This information will be used to determine acceptable vibration levels for the facility relating to the sensitivity of the operating equipment. The results of this trial assessment will then set appropriate agreed limits values at the facility in question which will be monitored during subsequent blasts or other excavation methodologies. Where no safe limit is determined, the timing and scheduling of blasts will be undertaken in consultation with the facility when no sensitive operations are taking place. Given the short time period over which an individual blast takes place (i.e. a number of seconds), this approach is deemed to be feasible.

17.6.3 Operational Phase

The following section details the mitigation measures deemed practicable to achieve the design goals previously defined in **Section 17.2**.

The mitigation measures required to reduce traffic noise levels are specified based on the predicted noise levels for the Design Year of 2039. The results of the modelling exercise show that noise mitigation is required for 106 properties along the proposed route of the proposed road development for this Design Year.

Options to reduce operational noise levels along the proposed road development include the use of a Low Noise Road Surface (LNRS) to reduce noise generated at source and the use of noise barriers to reduce noise levels along the propagation path between the source (proposed road development) and the specific receivers (houses, schools, churches etc.). These screens may be constructed as earth bunds, proprietary noise barriers or a combination of both.

As part of the assessment, therefore, the use of a low noise road surface (LNRS) providing a mean reduction in traffic noise level of -2.5dB compared to Hot Rolled Asphalt (HRA) has been modelled along the length of the mainline of the proposed road development and the main junction slip roads accessing the N59 Moycullen Road, N84 Headford Road, N83 Tuam Road and existing N6 in addition to the N59 Link Road North and South as part of the proposed road development. **Table 17.14** summarises the noise barrier requirements for the proposed road development required in addition to the use of a low noise road surface.

Table 17.14: Likely Extent of Noise Screening

Receiver No.	Structure Name	Start Chainage	End Chainage	Height (m)	Location	Lateral Siting / Type

The proposed noise mitigation set out above have been designed to sufficiently reduce traffic noise levels at or below the traffic noise design goal of 60dB L_{den}, where relevant.

The combined mitigation measures associated with the use of a LNRS surface in addition to physical noise screening has been assessed to provide the most suitable available noise mitigation at the nearest sensitive locations. Discussion on the residual impacts taking account of the proposed mitigation measures are outlined in **Section 17.7.2**.

17.7 Residual Impacts

17.7.1 Introduction

The residual impacts associated with the construction and operational phase are considered taking account of the proposed mitigation measures. These are discussed in the following sections.

17.7.2 Construction Phase

During the construction phase of the proposed road development noise levels at properties closest to working areas will be temporarily increased. The assessment has indicated that construction activities can, for the majority of activities operate within the adopted noise limits for daytime periods at the nearest properties to the works. Given the linear nature of the works, noise emissions related to construction works will be of short term impact at any one area as the works progress along the length of the proposed road development. The most appropriate noise mitigation measures for each work area will be determined taking account of the various control measures included within **Section 17.6.2**, **Appendix A.17.3** and the CEMP in **Appendix A.7.5**. The various mitigation measures will be selected in order to control construction noise levels to within the limit values included in **Table 17.1**.

Once the various mitigation measures are put in place and the limit values complied with, noise impacts associated with the construction phase will be of moderate to major, short term impact. Highest noise impacts will occur during periods of excavation, particularly in areas where sections of hard rock are to be excavated. As noted within the earlier section, the use of drill and blast methods will likely be chosen in these areas. Whilst high noise levels are associated with an individual blast, the effects are momentary and the blast designs will be strictly controlled to ensure the AOP and PPV levels are within the specified limit values. The use of this form of rock breaking will expedite the level of rock extraction in any one any and hence reducing overall exposure times and overall impacts. Mechanical breaking, crushing and excavation of rock and materials will be strictly controlled through the use of control of noise at source, screening, scheduling of works to ensure noise limit values at the closest sensitive properties are not exceeded.

The assessment has indicated that the use of standard construction activities can operate comfortably within the recommended vibration limits for standard residential and other light-framed buildings. With the adoption of best practice methodologies for the control of vibration from blasting, potential vibration impacts at the most sensitive premises can be adequately mitigated to within acceptable levels.

17.7.3 Operational Phase

The residual impacts associated with the proposed road development have been assessed for each modelled location. A full set of calculated residual noise levels for the 299 receiver locations are included in **Table A.17. 2.1** in **Appendix A.17.3**.

Table 17.15 overleaf presents the calculated residual noise levels for those locations where the conditions for mitigation were identified.

17.7.3.1 Residual Noise Level

The results of the assessment have indicated that along the length of the proposed road development, traffic noise levels at or below 60dB L_{den} can be achieved, and/or the Do-Something noise levels can be reduced to the equivalent Do-Nothing traffic noise levels at the majority of locations with the recommended mitigation measures in place.

There are a small number of instances where a residual noise level of 1 to 2dB above the design goal remains. These locations primarily relate to properties which are to be acquired (R195, 198a), remain dominated by traffic along the local road network which falls outside the proposed development boundary (R79, R206), or where access onto the local road restricts physical additional mitigation (R63a, R80a). There are a small number of properties along the proposed road development where a residual noise level of 61 to 62dB L_{den} is calculated (R140, 151a, 155, 170, 173, 208 and 212). Whist these exceedances are strictly above the design goal, reducing traffic noise levels to at or below 60dB L_{den} at these properties will require substantial additional barrier lengths and heights over and above those in place in order to achieve an insignificant change to the overall noise level at a property.

The 2004 TII noise guidance document notes the following with respect to achievement of the noise design goal:

> *"The Authority accepts that it may not always be sustainable to provide adequate mitigation in order to achieve the design goal. Therefore, a structured approach should be taken in order to ameliorate as far as practicable."*

The 2014 noise guidance document notes that:

> *"in some cases the attainment of the design goal may not be possible by sustainable means".*

This guidance document also notes that caution should be exercised specifying substantial screening where small benefits (<3dB) are only achieved, given a change of 3dB(A) is the smallest change that would give a reliable difference in public response. Specifically, the TII 2014 document goes on to note that:

> *"It may be unsustainable to increase barrier dimensions significantly where the result would be a reduction of 1dB or less, as such a reduction would be close to imperceptible in a laboratory situation, and would not result in a difference in public response in the real world environment."*

In this instance, the extent of screening deemed feasible to achieve the target design goal at the relevant properties has been assessed, taking into account a level of proportionality with respect to changes in noise levels.

17.7.3.2 Evaluation of Residual Impacts

Section 17.7.3.1 presents the residual noise levels once noise mitigation has been included along the length of the proposed road development including a low noise road surface and an extensive number of acoustic barriers. As noted in the previous section, with the inclusion of the noise mitigation measures, noise levels are at or below the TII operational noise design goal of 60dB L_{den} at the majority of assessment locations (properties, schools, churches etc.) or have been reduced to within or below the pre-existing noise level.

In line with the methodology outlined in **Section 17.2.5.3**, in order to evaluate the significance of noise impacts, the following approach has been undertaken.

- Baseline noise levels (or Calculated Do-Minimum noise levels where road traffic dominates) are compared against the calculated Do-Something noise levels to determine the increase in noise levels
- The significance of change is assigned to each location based on the magnitude of change ratings from the DMRB short term table (Year of Opening) and long-term table (Design Year)
- Comment on the absolute noise levels against annoyance levels from population response studies

Table 17.16 summarises the number of properties categorised within each rating band for the year of opening and the Design Year based on the DMRB assessment tables only.

Table 17.16: Change in Noise Levels

Short-Term Impacts – Year of Opening			**Long-Term Impacts - Design Year**		
Noise Change, dB	**Magnitude**	**No of assessed properties**	**Noise Change, dB**	**Magnitude**	**No of assessed properties**
0	No Change/Reduction	99	0	No Change/Reduction	83
0.1 - 0.9	Negligible	18	0.1 – 2.9	Negligible	45
1 – 2.9	Minor	17	3 – 4.9	Minor	28
3 – 4.9	Moderate	31	5 – 9.9	Moderate	90
5+	Major	134	10+	Major	53
Total		299			299

During the Year of Opening (2024), the assessment has concluded that, 134 of the modelled receptors will experience a ‘Major’ short-term noise impact, which relates to any noise increase above 5dB. A total of 31 locations will experience a ‘Moderate’ noise impact as a result of the change in the noise environment. At the remaining locations, the impacts are categorised as ‘No Change’ to ‘Minor’.

During the Design Year of 2039, the assessment has concluded that 53 of the modelled receptors will experience a ‘Major’ long-term noise impact in accordance with the DMRB, which relates to any noise increase above 10dB. A total of 90 locations will experience a 'Moderate' noise impact as a result of the change in the noise environment. At the remaining locations, the impacts are categorised as 'No Change/Reduction' to 'Minor'. Assessment locations where a reduction in noise levels are calculated relate to properties along the existing road network where traffic volumes will be reduced as a result of the proposed road development.

Further analysis of the absolute noise levels for properties assigned a Moderate and Major change in noise levels for the two assessment years is presented in **Tables 17.17** and **17.20**, in order to provide context on the likely level of annoyance response relating to road traffic noise level exposure based on the EEA exposure-response studies, as discussed **in Section 17.2.5.3**.

Table 17.17: Assessment of Absolute Noise Level Annoyance Levels relating to Moderate Change in Noise Levels – 2024

Locations with Moderate Change in Noise Levels - Opening Year – 2024					
Change in Noise Level, Impact Rating	**Calculated Noise Levels**	**No properties**	**% Population 'Annoyed'**	**% Population 'Highly Annoyed'**	**Receptor Type, Comments**
Moderate	48	1	9	3	Residential
	49	1	10	3	Residential
	50	3	11	4	Residential
	51	1	12	4	Residential
	52	1	13	5	Residential
	53	1	15	5	Residential
	54	4	16	6	Residential
	55	3	18	6	Residential
	56	4	19	7	Residential
	57	2	21	8	Residential. 1 Amenity & Community facility (Moderate sensitivity)
	58	1	22	9	Residential
	59	4	24	9	Residential. 1 property to be acquired
	60	3	26	10	Residential
	61	1	27	11	Residential property to be demolished
	62	1	29	12	Residential property to be acquired

Reference to **Table 17.17** above indicates that where a 'Moderate' change in noise levels has been determined in accordance with the DMRB short-term assessment table, absolute noise levels are calculated in the range of 49 to 60dB L_{den} (excluding properties being acquired or demolished as part of the proposed road development).

The majority of assessment locations are residential properties (high sensitivity) and all residential properties in this category are below the TII design goal of 60dB L_{den}.

There is one amenity/community area at NUIG Sporting Campus categorised as moderate sensitivity. The calculated noise level in this area is 57dB L_{den} which is considered an acceptable noise level for outdoor amenity use.

Table 17.18: Assessment of Absolute Noise Level Annoyance Levels relating to Major Change in Noise Levels – 2024

Locations with Major Change in Noise Levels - Opening Year – 2024					
Change in Noise Level, Impact Rating	**Calculated Noise Levels**	**No properties**	**% Population Annoyed**	**% Population Highly annoyed**	**Receptor Type, Comments**

	62	1	29	12	Commercial, building to be demolished

Locations with Major Change in Noise Levels - Opening Year – 2024					
Change in Noise Level, Impact Rating	**Calculated Noise Levels**	**No properties**	**% Population Annoyed**	**% Population Highly annoyed**	**Receptor Type, Comments**
	63	1	31	14	Residential, building not habitable

During the Opening Year, where a 'Major' change in noise levels has been determined in accordance with the DMRB short-term assessment table, absolute noise levels are calculated in the range of 49 to 61dB L_{den} (excluding properties being acquired or demolished as part of the proposed road development).

The majority of assessment locations are residential properties (high sensitivity) and all residential properties not being demolished in this category are below the TII design goal of 60dB L_{den} with the exception of 4 properties, 1 of which remains unoccupied and 3 of which are dominated by traffic along local roads.

There is one nursing home in this impact category (high sensitivity) with an absolute noise level calculated at 53dB L_{den} which is below a level whereby noise levels are considered intrusive or at a level that would cause any significant annoyance to the general population. There are two amenity areas of moderate sensitivity i.e. Menlo Castle and NUIG Sporting Campus with a calculated level of 55dB L_{den} and 59dB L_{den} respectively. The NUIG location is immediately adjacent to the alignment of the proposed road development. There is 1 commercial property (Dangan House) with a low sensitivity with a calculated noise level of 55dB $L_{den.}$

Table 17.19: Assessment of Absolute Noise Level Annoyance Levels relating to Moderate Change in Noise Levels – 2039

Locations with Moderate Change in Noise Levels - Opening Year – 2039					
Change in Noise Level, Impact Rating	Calculated Noise Levels	No properties	% Population Annoyed	% Population Highly annoyed	Receptor Type, Comments

	56	11	19	7	Residential (1 property to be acquired, 1 to be demolished) 1

Locations with Moderate Change in Noise Levels - Opening Year – 2039					
Change in Noise Level, Impact Rating	Calculated Noise Levels	No properties	% Population Annoyed	% Population Highly annoyed	Receptor Type, Comments
					amenity area, 1 commercial
	57	9	21	8	Residential, 1 property to be acquired
	58	8	22	9	Residential, 1 amenity area
	59	13	24	9	Residential
	60	8	26	10	Residential, 1 amenity area
	61	7	27	11	Residential, 1 to be acquired
	62	3	29	12	Residential
	64	1	33	15	Building not habitable

Reference to **Tables 17.19** above indicates that where a 'Moderate' change in noise levels has been determined in accordance with the DMRB long-term assessment table for the design year, absolute noise levels are calculated in the range of 49 to 62dB L_{den} (excluding properties being acquired or demolished as part of the proposed road development).

The property types are predominately residential and hence are high sensitivity receptors. There are 10 residential properties with a residual noise level in the range of 61 to 62dB L_{den} (Refer to **Table 17.17** for specific receiver details). For all other residential properties where a moderate change in noise level is determined, the absolute noise level is below the 60dB L_{den} design goal.

There is one nursing home in this impact category (high sensitivity) with an absolute noise level calculated at 53dB L_{den}. There is one amenity area (Menlo Castle) of moderate sensitivity and 1 commercial property (Dangan House) with a low sensitivity, with a calculated level of 56dB $L_{den.}$ There are two assessment locations within the NUIG Sporting Campus (moderate sensitivity) with calculated noise levels in the range of 58 to 60dB $L_{den.}$ It should be noted, these locations are calculated in close proximity to the road alignment. Noise levels in this area reduce at the playing areas and amenity walking areas located further north and south of the proposed road alignment.

Table 17.20: Assessment of Absolute Noise Level Annoyance Levels relating to Major Change in Noise Levels – 2039

Locations with Major Change in Noise Levels - Opening Year – 2039					
Change in Noise Level, Impact Rating	**Calculated Noise Levels**	**No properties**	**% Population Annoyed**	**% Population Highly annoyed**	**Receptor Type, Comments**
Major	54	4	16	6	Residential
	55	6	18	6	Residential
	56	7	19	7	Residential
	57	8	21	8	Residential
	58	11	22	9	Residential, 1 property to be acquired
	59	10	24	9	Residential, 1 property to be acquired
	60	5	26	10	Residential, 1 property to be acquired
	61	1	27	11	Residential. Property to be demolished
	63	1	31	14	Commercial. Property to be demolished

During the design year, where a ‘Major’ change in noise levels has been determined in accordance with the DMRB long-term assessment table, absolute noise levels are calculated in the range of 54 to 60dB L_{den} (excluding properties being acquired or demolished as part of the proposed road development). All properties in this category which are not being acquired or demolished are residential and are all below the TII design goal of 60dB L_{den}.

Summary of Residual Impacts

Taking into account the proposed noise mitigation measures, the calculated residual noise levels, the increase in noise levels, and the absolute noise level under consideration, the impact of the residual noise impacts associated are determined as follows:

- Operational noise levels have been designed to not exceed the TII design goal of 60dB L_{den} at the majority of the noise sensitive locations along the proposed road development
- Absolute noise levels associated with both ‘Moderate’ and ‘Major’ changes in noise levels are in the range of 48 to 62dB L_{den}. The percentage of the population typically highly annoyed by road traffic noise in this range is 3 to 12% respectively. This represents a low percentage of the population likely to

experience high levels of annoyance when exposed to the range of noise levels under consideration

- Whilst a higher number of locations are determined to experience a ‘Major’ change in noise levels during the opening year, the absolute noise level under consideration are below a level that would pose high levels of annoyance to the typical population in accordance with published data
- During the design year, the number of properties determined to experience a ‘Major’ change in noise levels is significantly reduced compared to the opening year due to the threshold values for impact ratings in the long-term period
- Taking account of the factors above, it is considered that residual noise impacts across the full extent of the proposed road development are determined to be imperceptible to significant, with the majority of properties overall, experiencing an imperceptible to moderate impact

Comment on Schools Along the Proposed Road Development

There are two schools located in proximity to the proposed road development, St. James’ National School in Bushypark and Castlegar School off School Road. Both schools have been assessed in terms of their noise impacts. Calculated noise levels at St James’ National School are 56dB L_{den} taking account of noise mitigation in this area. This represents a minor increase above the pre-existing noise environment and is an acceptable external noise levels for school buildings.

Calculated noise levels at Castlegar school are made along the southern façade and rear facades facing the proposed road development. Taking account of the screening provided by the extensive cutting in this area, the proposed low noise road surface and noise barrier, residual noise levels are calculated in the range of 56 to 58dB L_{den}. Taking account of baseline noise levels measured at the school and adjacent properties along School Road, this represents a minor change in the noise environment and is an acceptable external noise levels for school buildings.

Reduction in Traffic Along Existing Road Network

The proposed road development will result in a reduction in traffic volumes along the existing road network, particularly along routes traversing Galway City Centre.

It is possible to determine the approximate change in noise levels between the Do Minimum and Do Something scenarios using the traffic volumes calculated for the wider road network within Galway City. Using the same formulae described in **Section 17.5.3.2**, the reduction in traffic noise levels along the existing road network across Galway City is calculated and presented in **Table 17.21**.

Table 17.21: Calculated Reduction in Traffic Noise Levels along Existing Road Network - 2039

Road Link	Do Minimum		Do Something		Estimated Reduction in Traffic Noise Level, dB
	AADT	% HGV	AADT	% HGV

Eglington Street	5,420	3%	4,728	2%	-2

Road Link	Do Minimum		Do Something		Estimated Reduction in Traffic Noise Level, dB
	AADT	% HGV	AADT	% HGV	
Cappagh Road - North of GCRR	548	0%	257	0%	-3
N6 East of Ballybrit	26,992	7%	17,179	4%	-3
N59 South of Link to Interchange	18,050	2%	14,687	0%	-4
Gort Na Bró South of Rahoon Road	2,927	0%	2,110	0%	-1
Western Distributor Road - East of Gort Na Bró	11,779	2%	8,065	1%	-3

Referring to **Table 17.21** the estimated reduction in traffic noise levels along the existing road network across Galway City is in the range of 1 to 10dB. The greatest reduction in noise levels will be experienced along sections of the R336, R337, R338 and the N59 Roads with estimated traffic noise reductions ranging between 4 and 10dB. There are extensive areas of high sensitive locations along and in proximity to these routes including high numbers of residential areas, educational buildings and hospitals which will therefore experience a moderate to major positive impact as a result of the proposed road development.

Referring the Galway City Noise Action Plan (2013 – 2018), sections of the N6, R336, R338, N84 and N59 which are identified as areas qualifying for noise management due to high traffic noise levels (>70dB L_{den} and > 57dB L_{night}) will experience a reduction in noise levels as a result of the proposed road development and hence will achieve part of the Noise Action Plan objectives.

The reduction in high volumes of traffic traversing the city centre will result in a positive moderate to major noise impact to an extensive number of noise sensitive properties along a large portion of the existing road network.

Night-Time Noise Levels

The TII guidelines do not prescribe any night-time noise limit values within its guidance document. The L_{den} parameter by its nature, however is a composite parameter relating to noise levels over day, evening and night-time periods. The 60dB L_{den} deign goal included in the TII documents for road projects therefore includes noise levels over all three periods.

The DMRB Volume 11 Section 3 Part 7 (2011), notes that night-time noise levels at or below 55dB L_{night} are not considered for impact rating. This is based on information contained in the WHO Night Noise Guidelines (2009) which sets an interim target level of 55dB L_{night} across Europe. The assessment notes that where locations exceed a night-time noise level of 55dB L_{night}, the impact rating relating to changes in the noise environment are assessed using the DMRB long-term assessment table.

The Galway City and Galway County Noise Action Plans both set an onset noise level of 57dB L_{night} for areas where noise management should be put forward for consideration.

Night-time noise levels are calculated as part of the L_{den} calculation procedure and are presented separately in **Appendix A.17.3** for each assessment location. There are a total of 33 properties included as part of this assessment which exceed a night-time noise level of 55dB L_{night}. All of these properties are along existing national and regional routes namely the N6, N83, N84 and N59 and R446. At 19 of these properties, night-time noise levels will be reduced as a result of the proposed road development and hence will experience a positive impact. At the remaining 14 properties, night-time noise levels are increased by 0.2 to 2.8dB L_{night} with an impact rating of negligible.

Specific comment in relation to night-time noise levels and associated health impacts are discussed in **Chapter 18, Human Beings, Health and Population**.

17.7.4 Cumulative Impacts

The traffic data used as part of the noise impact assessment is based on future modelled scenarios taking account of other committed and proposed road developments below which have the potential to generate traffic volumes within the study area:

- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- M6 Motorway (operational)
- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)
- N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction)
- Galway Transport Strategy (GTS), which includes the following:
    - Investigation of prospective sites to the east of the city for Park and Ride
    - Bearna Greenway
    - Galway to Oughterard (part of the Galway to Clifden) Greenway
    - Galway City to Oranmore (part of the Galway to Dublin) Cycleway

Further details on the traffic modelling forecasts are set out in **Chapter 6, Traffic Assessment and Route Cross Section**.

The cumulative traffic noise impacts have been assessed at each of the receptor locations considered as part of this assessment. During the Do-Nothing scenario, road traffic flows along the existing road network have been modelled and the cumulative traffic noise level calculated. For the modelled Do-Something scenarios, road traffic along the existing road network coupled with traffic along the proposed road development are combined to obtain a cumulative traffic noise level. The assessment takes account of any alignment alterations to the existing roads and junction and the re-distribution of traffic along the existing road network as a result of the proposed road development.

In this regard the cumulative road traffic noise impacts are incorporated into the calculated operational noise levels set out in **Table 17.13** and **Table 17.15**.

In relation to cumulative construction impacts, other committed or proposed construction projects have been reviewed in the vicinity of Galway City and County including the N59 Maam Cross to Oughterard Road Project (consented and pre-construction), N59 Moycullen Bypass (consented and pre-construction), M6(M17/M18) Motorway Service Area (pre-planning. All of these projects are set back at considerably distances from the proposed road development such that if under construction at the same time, no cumulative noise and vibration impacts would occur.

Whilst there is the potential to be other small local construction activities across the study area during the construction phase, for the purposes of this assessment it has been assumed that works associated with the proposed road development will be the dominant noise and vibration source at any one location.

17.8 Summary

An assessment relating to the potential noise and vibration impacts of the proposed road development has been determined for both the construction phase and the operational phase.

During the construction phase, the assessment has determined that noise impacts will be negative moderate short-term and in some instances negative significant and momentary depending on the activities involved. The use of best practice noise control measures, hours of operation, scheduling of works within appropriate time periods, strict construction noise limits and noise monitoring during this phase will ensure impacts are controlled to within the adopted criteria. Similarly, vibration impacts during the construction phase will be well controlled through the use of low impact equipment and adherence to strict limit values which will be subject to monitoring at the nearest sensitive buildings.

During the operational phase, noise levels will be increased at the majority of noise sensitive locations along the length of the proposed road development. Whilst noise levels of varying increases and impact magnitudes are calculated at the assessment locations, the incorporation of a low noise road surface and the use of noise barriers along the proposed roadside boundary will reduce noise levels to within the design goal of 60dB L_{den} or to the pre-existing Do Minimum noise levels at the majority of noise sensitive locations. Residual noise levels at a small number of locations will remain above the 60dB L_{den} design goal by 1 to 2dB. The assessment has concluded that changes in road traffic noise levels will be negligible to major in accordance with DMRB guidance. The overall noise impact at the assessment locations taking account of the change in the noise environment, the absolute noise levels under consideration and the typical population response to the absolute noise levels under consideration across the study area is determined to be imperceptible to significant, with the majority of properties overall experiencing a slight to moderate impact

Overall, noise levels will be increased at properties along the route of the proposed road development once operational and a change in the noise environment will occur. The proposed road development, however, has been designed to reduce operational noise levels to within national design guidelines through the incorporation of detailed noise mitigation measures. The number of properties along its route is relatively low compared to those within the city centre which are currently exposed to significantly higher noise levels from passing road traffic. The reduction in high volumes of traffic traversing the city centre will result in a moderate to major positive noise impact to an extensive number of noise sensitive properties along the existing road network.

18 Human Beings, Population and Human Health

18.1 Introduction

This chapter of the EIAR consists of an impact appraisal of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, under the heading of Human Beings, Population and Human Health. This is a broad ranging topic which *"covers the existence, activities and health of people, usually considering people as groups or 'populations'"* (EPA 2015)[1].

Aspects examined in this chapter primarily relate to impacts from the proposed road development on socio-economic activities and on local community health.

Aspects related to socio-economic activities include journey patterns, amenity and community severance, business, tourism and employment, and use of the Irish language. The Irish language is addressed separately in various sections of this chapter. Other aspects relevant to human beings such as natural amenity, built and natural heritage, ecosystem services, material assets and nuisance are dealt with in the following chapters:

- Chapter 7, Construction Activities
- Chapter 8, Biodiversity
- Chapter 9, Soils and Geology
- Chapter 10, Hydrogeology
- Chapter 11, Hydrology
- Chapter 12, Landscape and Visual
- Chapter 13, Archaeological, Architectural and Cultural Heritage
- Chapter 14, Material Assets Agriculture
- Chapter 15, Material Assets Non-Agriculture
- Chapter 16, Air Quality and Climate
- Chapter 17, Noise and Vibration

Human health impacts are primarily considered through an assessment of the environmental pathways by which health can be affected such as air, noise, water or soil. Therefore, the health assessment relies on the assessments in the following chapters and draws on the findings as necessary to examine whether the effects arising from any identified impacts may have a health impact and to ensure that the effects which may have a health impact are fully considered:

---

[1] Extracted from the Advice Notes for Preparing Environmental Impact Statements (EPA draft September 2015) which have not been updated since

- **Chapter 9, Soils and Geology** to identify if there are any areas of contaminated soils
- **Chapter 10, Hydrogeology** to identify areas with any potential impacts on groundwater
- **Chapter 11, Hydrology** and **Appendix A.11.1** to identify areas with any potential impacts on surface water and areas of flood risk
- **Chapter 16, Air Quality and Climate** to identify the predicted air quality values adjacent to the proposed road development
- **Chapter 17, Noise and Vibration** to identify the predicted noise levels at properties adjacent to the proposed road development

The health assessment also considers psychological effects, health improvement and improvement to services. Other aspects, such as changes in traffic flows which are dealt with in **Chapter 6, Traffic Assessment and Route Cross-Section**, have also been considered in this chapter in relation to the assessment of Socio-economic and Health impacts to ensure that the effects of these issues on human beings, population and human health have been addressed.

This chapter initially sets out the methodology (**Section 18.2**), describes the receiving environment (**Section 18.3**) and summarises the main characteristics of the proposed road development which are of relevance for human beings, population and human health (**Section 18.4**). The evaluation of impacts of the proposed road development on human beings, population and human health are described (**Section 18.5**). Measures are proposed to mitigate these impacts (**Section 18.6**) and residual impacts are described (**Section 18.7**). The chapter concludes with a summary (**Section 18.8**) and reference section (**Section 18.9**).

To inform the human beings, population and human health impact appraisal, this chapter has utilised the information gathered during the constraints and route selection studies for the proposed road development. Submissions received as part of the extensive public consultation carried out in respect of the project were assessed and design changes made to minimise the potential impacts on human beings and properties as part of the design phase. These submissions also informed the assessment undertaken for this chapter. **Sections 4.17, 6.5.11** and **7.6.11** of the **Route Selection Report** considered the human beings and population constraints within the scheme study area and compared the potential impacts on human beings and population of the proposed route options. These sections of the Route Selection Report contributed to the design of the proposed road development.

This chapter should be read in conjunction with **Figures 18.1.001**, **18.1.002** and **18.1.101** to **18.1.114** which illustrate the location of community facilities such as schools, hospitals, hotels relative to the proposed road development.

18.2 Methodology

18.2.1 Introduction

This assessment has been prepared in accordance with the relevant guidelines listed in **Section 18.2.2.1** below. Data has been collected primarily through a review of relevant documents listed in **Section 18.2.2.1** below and information gathered through the extensive public consultation detailed in **Chapter 1, Introduction** and mapping provided by the design team. This data was supported by site visits and local discussions with residents, businesses, schools and representatives of other community facilities. Furthermore, a Language Impact Assessment (LIA) for the proposed road development has been undertaken, the results of which are included in **Section 18.5.6**. A literature review on the potential impacts of roads on human health has also been carried out and is detailed in **Section 18.2.5.7** of this EIAR.

Aspects examined in this chapter primarily relate to impacts from the proposed road development on socio-economic activities and on local community health. These two themes are discussed together in some sections of this chapter but separately in other sections where appropriate.

18.2.2 Relevant Guidelines, Data Sources and Consultations

18.2.2.1 Relevant Guidelines

This assessment has been prepared having regard to the following guidelines:

- Guidelines on the Information to be contained in Environmental Impact Statements (EPA 2002)
- Advice Notes on Current Practice in the Preparation of Environmental Impact Statements (EPA 2003)
- Advice Notes for Preparing Environmental Impact Statements (EPA draft September 2015)
- Revised Guidelines on the Information to be Contained in Environmental Impact Statements (EPA, draft September 2015)
- Draft Guidelines on the Information to be Contained in Environmental Impact Assessment Reports (EPA, draft August 2017)
- Guidelines for treatment of tourism in an Environmental Impact Statement (Fáilte Ireland, 2011)
- European Commission Guidance (2003) Implementation of Directive 2001/42 on the assessment of the effects of certain plans and programmes on the environment
- Environmental Impact Assessment of Projects – Guidance on the preparation of the Environmental Impact Assessment Report (European Commission 2017)
- The World Health Organisation (WHO) Night time Noise Guidelines for Europe

- Health Impact Assessment Resource and Tool Compilation (US EPA 2016)
- World Health Organisation Guidelines for Community Noise (1999)
- Health in Environmental Impact Assessment - A Primer for a Proportionate Approach (IEMA 2017)
- Health Impact Assessment (Institute of Public Health Ireland 2009)

18.2.2.2 Data Sources and Consultations

An assessment of the potential impacts on human beings, population and human health requires an understanding of the community which is built up through background research, site visits, and discussions with members of the local community and the findings of the assessment of the environmental factors (pathways) through which health could be affected such as air, noise, water, soils, property acquisition or demolition and traffic volumes. The potential impacts of the proposed road development on human beings, population and human health is then assessed against this background data.

Background data has been collected for the proposed road development by means of:

- Primary data sources (e.g. demographic data from Census 2016, Census 2011 and Census 2006 as produced by the Central Statistics Office)
- Maps of the surrounding area, including Ordnance Survey 1:50,000 maps and aerial mapping
- A review of the design of the proposed road development and its potential impacts on material assets non-agriculture
- A review of secondary sources including the Galway County Development Plan 2015-2021 as varied and the proposed Variation No. 2 to the Galway County Development Plan, the Galway City Development Plan 2017-2023 as varied, the Bearna Local Area Plan as amended, the Gaeltacht Local Area Plan 2008-2014 as extended, the Ardaun Local Area Plan 2018-2024 and reports Galway City Council or Galway County Council such as the Socio Economic Statement of County Galway (2015), the Galway City Local Economic and Community Plan 2015-2021, and the various websites relating to economic developments, tourism, amenity and recreation e.g. www.galwaychamber.com and www.galwaytourism.ie
- Observation of local settlement and travel patterns and identification of community facilities
- Public consultation process which included discussions with local organisations and residents and with relevant statutory bodies. Over 950 individual property owner meetings, including many home visits, took place between the design team and property owners and the concerns expressed during these meetings were taken on board and fully informed the human beings, population and health assessment. The full details of this public consultation process are set out in **Chapter 1, Introduction**

- A literature review on the potential impacts of roads on human health. This review has focused on reviewing scientific evidence of the potential impacts of roads on human health and is detailed in the relevant sections below
- Collating the results of the assessment of the environmental factors (pathways) through which health could be affected such as air, noise, water, soils and traffic volumes, which are based upon reference to accepted standards/guidelines/limits for the protection of human health
- In this chapter, an assessment is performed by considering health in its broader aspects. As well as considering the protection of health, this chapter also considers opportunities for health improvements and access to services. The data used to assess opportunities for health improvements and access to services included information gathering during the extensive public consultations including a meeting with University Hospital Galway and data extracted from the traffic model to identify accessibility to services
- The traffic model was also used to quantify the health impacts in terms of difference in people walking or cycling and the level of accessibility and social inclusion with the proposed road development and the full set of measures identified by the GTS complete
- For the Irish Language assessment, consultation with Údarás na Gaeltachta and feedback from the public consultation was utilised
- A ‘human beings, population and health’ workshop also took place on the 8 June 2017 with the design team, noise, air, socio-economic, landscape and visual and health experts in attendance. The purpose of this workshop was to discuss any significant effects of the construction and operation of the proposed road development on human beings, population and health and the findings of this workshop informed this chapter

18.2.2.3 Study Area

The study area for the socio-economic appraisal covers the lands within and adjacent to the proposed development boundary in addition to areas where changes in traffic volumes are predicted. The study area extends from Na Foraí Maola, west of Bearna Village to the existing N6 to the east at Coolagh and includes a rural/semi suburban landscape populated with individual dwelling and community facilities.

The study area for the Irish language appraisal covers the lands within and adjacent to the proposed development boundary as for the socio-economic appraisal but also includes the Galway Gaeltacht.

The study area in relation to the protection of human health appraisal varies depending on the emission type and its extent, for example, impacts arising from noise, air, water and soil vary with the precise distance depending on the particular emission, its concentration and other dispersion factors. Refer to the **Chapter 9, Soils and Geology**, **Chapter 10, Hydrogeology**, **Chapter 11, Hydrology**, **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration** for details of the study areas of the particular emission types (soil, water, air and noise).

18.2.3 Impact Assessment Methodology - Socio-Economics

This section presents the methodology and criteria used in the socio-economic assessment of impacts on human beings and population, and is followed by the impact assessment methodology used in the Irish language assessment in **Section 18.2.4** and health assessment in **Section 18.2.5**.

The purpose of the socio-economic appraisal is to identify the potential significant impacts as they can affect local people and users of the proposed road development during both the construction and operational phases, along with the likely economic impacts at both local and regional level. Socio-economic impacts on human being's due to a development of this type fall into four key categories, namely:

1. <u>Journey characteristics:</u> accessibility and connectivity, including potential impacts on journey time, journey time reliability and travel patterns
2. <u>Amenity:</u>
    a. Journey amenity: Impacts on journey amenity arising from pedestrian/cyclist proximity to traffic, volume of traffic, frequency of congestion, pedestrian and cycle facilities, noise, air quality and changes in the visual environment (as discussed in respective chapters of this EIAR) as they relate to the pleasantness of the environment for walking, cycling or driving
    b. General amenity: Impacts due to any effect that the proposed road development may have on residential quality of life, amenity or recreation facilities due to the same factors together with changes in environmental quality or facilities for amenity
3. <u>Community severance:</u> with regard to the use of community facilities, particularly those used by older people, children or other vulnerable groups
4. <u>Economic</u>: an evaluation of the proposed road development in the context of economic development, tourism and employment

In addition, relative to many other road developments, the proposed road development will involve a high number of residential, and some commercial, demolitions and acquisitions, due to the dispersed pattern of development within the study area. These potential impacts are addressed specifically under the category of general amenity.

Impacts are compared between the Do-Nothing and the Do-Something scenarios and arise from direct, indirect, secondary and cumulative effects on environmental conditions. Impacts can be positive, neutral or negative. The significance of an impact/effect is described as *Imperceptible*, *Not Significant*, *Slight*, *Moderate*, *Significant*, *Very Significant* or *Profound*. It usually follows that the significance of an impact depends, among other considerations, on:

- The location and character of the local environment
- The sensitivity of the local population and its capacity to absorb change
- The nature of the environmental effect
- The timing and duration of an effect

- The scale or extent of the effect in terms of area or population affected
- The magnitude (duration and frequency) of an effect
- The probability of an effect's occurrence

The impacts may be short term, medium term or long term. Construction impacts relevant to the socio-economic assessment are, by their nature, temporary in nature, although the impact of demolitions can have a prolonged effect on communities that remain.

In line with best practice the socio-economic assessment generally addresses effects at a community level rather than for individuals or identifiable properties, although impacts for small communities are assessed where these may consist of a handful of houses or families, impacts on individual businesses are discussed where these are especially significant. The rationale for applying a particular level of significance to an impact as it would affect the worst hit subset of the population is summarised in **Tables 18.13** and **18.14**. The tables include:

1. The nature of an effect
2. Location and the population subgroup affected
3. The current situation
4. The potential impact due to the proposed road development
5. Impact significance
6. Impact duration (i.e. temporary, short, medium or long term)
7. Receptor extent
8. Proposed mitigation
9. The residual impact

Receptor extent qualifies the preceding assessment of significance by identifying the number of receptor types, i.e. people or businesses, likely to be affected as an approximate proportion of the local population or the total number of businesses. Receptor extent is assessed qualitatively as: few; medium; many; or very many. For instance, an impact may be significant for a particular population subset, but the number of people impacted could be few in number. The table also describes the mitigation proposed and the residual significance of the impact.

18.2.3.1 Journey Characteristics

The assessment of journey times and patterns is inevitably dependent on precisely where an individual journey originates and ends, when it is undertaken (e.g. within or outside peak hours) and by whom it is undertaken, i.e. by drivers, cyclists, users of public transport or pedestrians, including individuals whose transport options may be restricted. The impact varies for each journey, but typical journeys to popular destinations can often be identified. Potential impacts have been assessed in accordance with the significance criteria outlined in **Table 18.1** with positive impacts resulting from a decrease in journey length or time and negative impacts resulting from an increase in journey length or time.

Table 18.1: Criteria used in the assessment of changes in Journey Length or Duration

Impact level	Significance criteria
Imperceptible	No noticeable change to present journeys length or duration
Not significant	An effect which can cause noticeable change, but without significantly extending (or shortening) journey length or duration, or changing journey habits
Slight	Slight improvement to journeys length or duration where impact is positive. Some inconvenience where impact is negative. Some likelihood of changes in journey habits
Moderate	Moderate reduction in journey length or durations where impact is positive, moderate increase where impact is negative. Greater likelihood of changes in journey habits
Significant	Much shorter journey length or duration where impact is positive, much longer increase where impact is negative. High likelihood of changes in journey habits
Very significant	Considerably shorter journey length or duration where impact is positive, considerably longer increase where impact is negative. High likelihood of changes in journey habits
Profound	An approximate doubling (or halving) in typical journey length or duration sufficient to cause marked change in behaviour of a sizeable proportion of population

Journey length refers to the distance associated with a particular journey, whilst duration is the time taken to make the journey. The average walking speed for pedestrians is taken to be 5km/hr (3km/hr for vulnerable groups). International studies suggest that the average urban cycle speed is between 12-20km/hr. Impacts on journey amenity and community severance are addressed separately in the sections below, although there are obvious interactions between each of these categories and with economic impacts. In addition, new transport facilities can improve accessibility of places which were formerly awkward to reach or improve connectivity between home and workplaces, community facilities and between parts of a city or region. Improved connectivity can have implications for choice of transport mode, for land use and economic development.

18.2.3.2 Amenity

Journey amenity

The assessment of journey amenity uses the same significance categories as before and is supported by cross-reference where necessary with chapters on traffic, noise or visual impacts. The level of traffic on a road, the proximity and separation of footpaths and cycle-paths, the nature of any crossings/junctions to be negotiated, the legibility of a journey (including signage), visual intrusions (including sightlines) and perceived and actual safety, are amongst the factors relevant to the assessment of journey amenity, as are the number and types of people affected. The principal concern is with pedestrians or cyclists, but journey amenity impacts also apply to drivers, for example due to safety anxiety associated with the crossings of major roads. Such journeys could involve sensitive population subgroups such as older drivers or school children as passengers. There are interactions too with the assessment of journey characteristics and community severance.

General amenity

The key criterion in relation to general amenity is community wellbeing, including social sustainability. Direct effects on communities due, for example, to loss of community facilities such as amenity space, natural areas or opportunities to interact with others, can impact on community wellbeing or community interaction. Indirect effects may result from changes in environmental quality, for instance, from noise or visual intrusion and are cross-referenced where applicable with relevant chapters of the EIAR. Impact levels are defined in **Table 18.2** below.

Table 18.2: Criteria used in the assessment of amenity impacts

Impact Level	Significance Criteria
Imperceptible	No noticeable change in the character of the environment
Not significant	An effect which can cause noticeable changes in the character of the environment, but without significant consequences for the community's well-being, amenity or health
Slight	A small impact on community wellbeing can be attributed to the proposed road development
Moderate	A moderate impact on the community wellbeing can be attributed to the proposed road development
Significant	An effect which has the potential to impact on community wellbeing such as to affect people's behaviour and quality of life
Very significant	An effect which has the potential to substantially impact on community wellbeing such as to affect most people's behaviour and quality of life
Profound	Effects of a scale to significantly impact on community wellbeing to an extent that people's behaviour or quality of life is substantially changed, for example where significant health issues arise or where people may wish to relocate

Demolitions and acquisitions

Demolitions or acquisitions of residential properties are subject to financial compensation, but can have a significant impact on the householders involved. In addition, there can be significant impacts on communities or neighbours left behind, especially where the number of demolitions or acquisitions represents a high proportion of the total number of households. The impact definitions applied to the category of general amenity have been applied to the subject of demolitions and acquisitions in this chapter. The potential health impacts as a result of demolitions or acquisitions is assessed in **Section 18.5.5**.

18.2.3.3 Community Severance

Severance is a typical impact of a road. Its effect is to discourage community interaction and occurs where access to community facilities or between neighbourhoods is impeded by a lengthening of journey time or by the physical barrier of a road (for example, high traffic volumes or perimeter fencing). Social severance can occur due to restrictions on people's accessibility, but also where communities become identified by their containment within road boundaries. This can include the psychological effect of traffic or safety concerns as barriers to social interaction. Social severance can also occur for busy roads such as motorways even where access is available. On the other hand, relief from existing severance may be provided by a new road where traffic volumes or speed are moderated, by the inclusion of crossing facilities in the design, or through the presence of overbridges or underpasses.

The definition of severance is not precise. It depends on the location of community facilities, the level of use of facilities, the time of day or duration when traffic conditions are experienced, the sensitivity of the population affected and the geographical spread of the community. Children, the elderly, the mobility impaired and people without access to a private car would be amongst those most affected by community severance and any corresponding loss of neighbourhood interaction.

Sensitive receptors are identified specifically where they comprise a high proportion of pedestrian journeys or where specific amenities are associated with these groups. Sensitive groups can include young and older population cohorts, the mobility impaired and people at risk of social isolation. Relevant community facilities include schools, surgeries, hospitals, churches, post offices, shops, sports facilities and centres of social activity.

New Severance

New severance is a negative impact generated and occurs whenever a barrier is created between people and community facilities. The barrier could take the form of a new road, fencing, additional traffic or the need to detour from a current traveling route. **Table 18.3** below provides examples of how new severance can be defined. The criteria are specific to pedestrians, although severance will apply also to cyclists and potentially to local vehicle journeys too, particularly for some sensitive population sub-groups. Quantitative criteria have not been included in the table as impact definitions may vary depending on the nature of road trips and crossings (i.e. by car or pedestrian). Similarly, the introduction of crossing facilities could reduce severance even where traffic levels are increased.

Table 18.3: Criteria used in the assessment of New/Increased Severance

Impact level	Significance criteria
Imperceptible	Journey patterns maintained
Not significant	Noticeable effects on connectivity, but without significant consequences for journey patterns
Slight	Present journey patterns likely to be maintained, albeit with some hindrance to movement
Moderate	Some residents, including children and elderly people, are likely to encounter severance. For others, journeys will be longer or less attractive
Significant	Many residents, including children and elderly people, are likely to encounter significant severance which could discourage them from making particular journeys

Impact level	Significance criteria
Very significant	Most residents, including children and elderly people, are likely to encounter significant severance which will be sufficient to induce a reorganisation of their activities or cause them to make less frequent trips to nearby neighbourhoods or to make less use of particular community facilities
Profound	People are likely to be deterred from making trips to an extent that includes permanent loss of access or a change in the location of centres of activity

Relief from Severance

Relief from severance is a positive impact which is defined in relation to existing severance. Relief from severance could follow from a transference of traffic from an existing road, including heavy goods vehicles (HGVs), from improvements in road design or sightlines, or from the introduction of crossing facilities. The Annual Average Daily Traffic (AADT) data was taken from the traffic model for the proposed road development. However, the degree of relief from severance depends on the context in which this change occurs including the existing absolute volume of road traffic, but also the speed of traffic and number of crossings by pedestrians, cyclists or others. **Table 18.4** provides a guide to criteria used in the assessment of relief from severance. It should be noted that a relief from severance is a positive impact and therefore the table reflects the positive impact levels, increasing from imperceptible to profoundly positive. Where the assessment varies from these definitions due to the context in which the relief occurs, the reasons for the variance are discussed. There is also the potential for interactions with Journey Amenity, in that there are implications for real and perceived safety.

Table 18.4: Criteria used in the assessment of Relief from Severance

Impact level	Significance criteria
Imperceptible	No noticeable consequences for journey patterns
Not significant	Noticeable effects on connectivity, i.e. <10% reduction in daily traffic levels (AADT), but without significant consequences for journey patterns
Slight	10-30% reduction in traffic levels (AADT) or some reduction in severance
Moderate	31-50% reduction in traffic levels (AADT) or a reduction in severance sufficient to encourage some new journeys by foot or bicycle
Significant	51-70% reduction in traffic levels (AADT) or a reduction in severance sufficient to allow residents to make more frequent journeys to community facilities by foot or bicycle
Very significant	71-90% reduction in traffic levels (AADT) or a very significant reduction in severance sufficient to allow most residents to make more frequent journeys to particular community facilities by foot or bicycle
Profound	More than 90% reduction in traffic levels (AADT) or reductions in severance such as to provide new access to community facilities or to cause a very significant increase in pedestrian or cycle journeys

18.2.3.4 Economic

General

Economic and employment impacts occur at both the local and regional scale and can be either positive or negative. A development can have positive effects for ancillary businesses or for employment or, alternatively, have negative effects for other businesses. Changes in access or connectivity, as discussed under the category of journey characteristics, can have significant effects on business or investment. Impacts include changes in turnover or in access to business opportunities. Effects could impact on individual companies or the wider community, for example where a number of businesses are affected or where the retail or business environment of a town is impacted. Impact levels are defined in **Table 18.5** below.

Tourism

Tourism makes a significant contribution to the Irish economy, to local economies and to regional development. It provides opportunities for business development, growth and innovation with Small and Medium Sized Enterprises (SMEs) being well-represented in the sector. Consequently, it is also important for employment and is relatively labour intensive compared with other industrial sectors. Interactions between journey characteristics, journey amenity or the nature of destinations used for amenity, can have an impact on tourism and businesses and employment in this sector. Tourist numbers can be affected by either a lengthening or shortening of journeys and reduced or improved connectivity with tourism destinations. Changes in both journey characteristics and amenity can impact on the decision to stop or overnight at particular locations. Changes to sites of cultural or natural heritage value can either discourage or encourage tourists to stop or to continue with their journey or, in extreme cases, to travel at all. Tourists include international visitors as well as visitors from other regions of Ireland.

Table 18.5: Criteria used in the assessment of Economic Impacts

Impact level	Significance criteria
Imperceptible	No noticeable economic impacts
Not significant	An effect which causes noticeable changes in the character of the environment, but without noticeable consequences for the local economy, businesses or employment
Slight	A small effect (positive or negative) on the business environment can be attributed to the proposed road development
Moderate	A moderate effect (positive of negative) on the business environment can be identified
Significant	An effect (positive or negative) that has the potential to impact on business performance or to influence the location decisions of new business
Very significant	An effect (positive or negative) that has the potential to substantially impact on business performance or to influence the location decisions of new business
Profound	Effects of a scale to significantly impact (positively or negatively) on the performance of a major business or several businesses. Where these businesses are important local employers there is the possibility of major impacts for the general prosperity of the local area or region

18.2.4 Impact Assessment Methodology – Irish Language

The purpose of the Irish Language appraisal is to identify the potential significant impacts, if any, of the proposed road development during both the construction and operational phases on the Irish Language.

The Irish Language appraisal is based on:

- inspection of the associated environmental studies and project documentation
- consideration of national legislation and policy documents and the Galway County and City Gaeltacht Development Plans and local area plans (LAPs) including the Gaeltacht LAP as extended and Bearna LAP as amended
- review of relevant submissions made during the public consultations and consultation with Údarás na Gaeltachta
- consideration of previous case work experience

This assessment has been prepared with due regard to the guidelines on the preparation of environmental impact assessment report published by the EPA in 2017 and the preparation of environmental impact statements published by the EPA in 2002, 2003 and 2015.

18.2.5 Impact Assessment Methodology – Human Health

This section sets out the methodology that was used in order to assess the impact of the proposed road development on health.

18.2.5.1 Guidance on the methodology for assessing human health in EIA

The recitals to the 1985 and 2011 EIA Directives refer to "human health" and include "Human Beings" as the corresponding environmental factor. The 2014 EIA Directive (2014/52/EU) changes this factor to "Population and Human Health". However, no specific guidance on the meaning of the term Human Health has been issued in the context of Directive 2014/52/EU. In addition, no specific guidance on the assessment of human health in the context of EIA has been issued to date.

The 2017 draft EPA guidelines on the information to be contained in Environmental Impact Assessment Reports note that "*while no specific guidance on the meaning of the term Human Health has been issued in the context of Directive 2014/52/EU, the same term was used in the SEA Directive (2001/42/EC)*". The Commission's SEA Implementation Guidance (section 5.26) states "*The notion of human health should be considered in the context of the other issues mentioned in paragraph (f) and thus environmentally related health issues such as exposure to traffic noise or air pollutants are obvious aspects to study*". (Paragraph (f) (of Annex I of the SEA Directive) lists the environmental factors including soils, water, landscape, air etc.).

The 2017 draft EPA guidelines note that the above health assessment approach is consistent with the approach set out in the 2002 EPA Guidelines where health was considered through assessment of the environmental pathways through which it could be affected, such as air, water or soil:

"*The evaluation of effects on these pathways is carried out by reference to accepted standards (usually international) of safety in dose, exposure or risk. These standards are in turn based upon medical and scientific investigation of the direct effects on health of the individual substance, effect or risk. This practice of reliance upon limits, doses and thresholds for environmental pathways, such as air, water or soil, provides robust and reliable health protectors [protection criteria] for analysis relating to the environment*".

The 2017 draft EPA guidelines also note that in an EIAR, "*the assessment of impacts on population & human health should refer to the assessments of those factors under which human health effects might occur, as addressed elsewhere in the EIAR e.g. under the environmental factors of air, water, soil etc. and that "assessment of other health & safety issues are carried out under other EU Directives, as relevant. These may include reports prepared under the Integrated Pollution Prevention and Control, Industrial Emissions, Waste Framework, Landfill, Strategic Environmental Assessment, Seveso III, Floods or Nuclear Safety Directives. In keeping with the requirement of the amended Directive, an EIAR should take account of the results of such assessments without duplicating them*".

The Institute for Environmental Management and Assessment (IEMA) in the UK issued a discussion document in 2017 *Health in Environmental Impact Assessment*

- *A Primer for a Proportionate Approach*, which it describes as a primer for discussion on what a proportionate assessment of the impacts on health should be in EIA and is a useful document when considering what can and should be assessed in the context of EIA. Regard has been had to the general approach advocated in this document when compiling this chapter.

One of the messages in the IEMA document in terms of assessing health in EIA, is that there should be a greater emphasis on health outcomes, (that is the potential effects on human health), rather than simply the health determinants, (that is the agents or emissions which could have the potential to have health effects). The IEMA document noted that in EIA, there has previously been a strong focus on just the agents or emission levels (e.g. dust) rather than focussing on the effects of these agents/emission levels on human health. This change in emphasis does not mean a complete change in practice. For example, measurement and modelling of dust levels continues to be an essential part of the health assessment.

The IEMA document notes that "*public health is defined as the science and art of promoting and protecting health and well-being, preventing ill-health and prolonging life through the organised efforts of society and has three domains of practice: health protection, health improvement and improving services*". The IEMA document suggests that these three domains should be considered in the assessment of health in EIA. Examples of health protection issues to be considered could include issues such as chemicals, radiation, health hazards, emergency response and infectious diseases whilst health improvement issues could include lifestyles, inequalities, housing, community and employment. Examples of improving services issues could include service planning, equity and efficiencies.

The World Health Organization (WHO) defined health in its broader sense in its 1948 constitution as "*a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity"*. Therefore, whilst the EPA guidance is useful in terms of health protection, for a more holistic assessment as per the IEMA document, it is also worthwhile to look at broader health effects in terms of opportunities for improvement of health and for improvement of access to services. While it is important to do this, it is also important not to attribute every conceivable event as being a health effect. To further rely on the WHO definition, a health effect would be something that would have a material impact on somebody's physical mental and social well-being be that positive or negative.

Health Impact Assessment versus Environmental Impact Assessment

The IEMA document notes that Health Impact Assessment (HIA) and EIA are separate processes and that whilst a HIA can inform EIA practice in relation to human health, a HIA alone will not necessarily meet the EIA human health requirement. HIA is not routinely carried out for major infrastructure schemes in Ireland.

Guidance for performing Health Impact Assessment (HIA)'s was issued by the Institute of Public Health in Ireland in 2009. There are however considerable difficulties in performing a HIA as outlined by the Institute of Public Health for a project such as a road development. Not least of these is the difficulty of getting baseline health data. It is quite difficult due to patient confidentiality and other reasons to accurately determine levels of even relatively common medical conditions in a relatively defined population that might be affected by a road project. Qualitative and quantitative baseline health data is a vitally important part of the appraisal section of the HIA. In the absence of an accurate baseline it is very difficult to assess qualitative and quantitative changes that might occur. One could use more generalised data that might exist for larger areas such as a city or county but these would be at most an estimate of the local baseline and not accurate enough to allow for meaningful interpretation. Therefore, a standalone HIA is not considered the most appropriate for this assessment.

The IEMA document notes that the WHO provides an overview of health in different types of impact assessment[2] and presents the WHO perspective on the relationship of HIA to other types of impact assessment as follows:

"The health sector, by crafting and promoting HIA, can be regarded as contributing to fragmentation among impact assessments. Given the value of impact assessments from a societal perspective, this is a risk not to be taken lightly ... The need … and justification for separate HIA cannot automatically be derived from the universally accepted significance of health; rather, it should be demonstrated whether and how HIA offers a comparative advantage in terms of societal benefits …

Health issues can, and need to, be included [in impact assessment] irrespective of levels of integration. At the same time, from a civic society perspective, it would be unacceptable for HIA to weaken other impact assessments. A prudent attitude suggests optimizing the coverage of health along all three avenues:

- *better consideration of health in existing impact assessments other than HIA;*
- *dedicated HIA; and*
- *integrated forms of impact assessment*

It is clear therefore that even the WHO does not support a stand-alone HIA unless it could be demonstrated to be of advantage over the EIAR. It is for these reasons that this health assessment is part of the EIAR and there is no stand-alone HIA.

It is therefore important to note that this assessment on human health is part of an overall EIAR rather than a stand-alone HIA. The HIA is defined as a combination of procedures, methods and tools that systematically judges the potential, and sometimes unintended, effects of a policy, plan, programme or project on both the health of a population and the distribution of those effects within the population, whilst the health assessment in the context of EIA focuses the attention of the assessment on likely significant effects, i.e. on effects that are deemed likely to occur and, if they were to occur, would be expected to be significant (as per the requirements of the EIA Directive). Conducting an HIA will not necessarily meet the EIA population and human health requirement.

Therefore, *health protection, health improvement and improving services* are all considered in this chapter of the EIAR. The methodology for assessing health

2 World Health Organization Regional Office for Europe. Health in impact assessments: opportunities not to be missed. 2014

protection, health improvement and improving access to services is considered further in **Sections 18.2.5.3**, **18.2.5.4** and **18.2.5.5** respectively of this EIAR.

18.2.5.2 Literature Review

A literature review on the potential impacts of roads on human health has been carried out. This section presents the results of that literature review which informed the methodology used for human health assessment.

One of the first areas in the literature review to consider is the health determinants relevant to the proposed road development – that is the agents or emissions which could have the potential to have health effects. Health outcomes – that is the potential effects on human health arising from those health determinants are then considered.

The environmental factors (pathways) through which health could be affected by a road development both during construction and operational phases include:

- Noise and Vibration – for example potential exposure of people to noise emissions from vehicles and construction activities
- Air - for example potential exposure of people to dust and air emissions from vehicles and construction activities
- Water – for example potential exposure of people to changes in water quality (surface and ground water) or changes in water flows – flood risk
- Soils – for example potential exposure of people to contaminated land

The health outcomes arising from such emissions are discussed further below.

In addition, the impacts of the proposed road development on psychological health and also health improvements and improvements to services have been included in the literature review below. These topics also fall under the area of "Wellness".

The last fifteen years in Ireland has seen the development of the modern motorway network between the major urban centres as well as relief roads in urban areas. The literature review included a review of any published data of reported health effects from either the construction or operation of these roads. Using a "PubMed[3]" search, key words such as "Health Effects Roads Ireland" found that there were no published studies in peer reviewed literature. There was however a significant tranche of literature from outside Ireland and in particular in relation to emissions to air and noise. The vast majority of the studies deal with potential emissions from operational roads with a particular emphasis on Noise, Particulate Matter (including PM_{10} and $PM_{2.5}$) as well as other air pollutants such as NO_2 and SO_2 amongst others. The literature is clear that these are the major hazards with the potential for human health effects. The literature is also strongly consistent with a Dose response effect as presented in **Table 18.6** below with regard to noise and air emissions - the lower the dose the lower the effect. Health based standards[4] such as WHO and EU

[3] PubMed is a search engine accessing primarily the MEDLINE database of references and abstracts on life sciences and biomedical topics.

[4] The term standards in this instance covers guidelines for example noise guidelines as such standard are not currently available.

standards incorporate literature evidence in the setting of these standards. In essence there is little evidence of significant health effects from air and noise emissions when these standards are not exceeded. It is important to note that these standards are set to protect vulnerable subsections of the population including its most vulnerable members which include children and persons with disabilities and, accordingly, will necessarily protect the more robust subsections. Other emissions such as water and soil can be an issue if there is potential contamination to water or soil or an enhanced flood risk. Again, there is little evidence of significant health effects from water and soil emissions when these standards are not exceeded.

The health assessment in this EIAR considers the results of technical assessments for environmental factors listed above which are detailed in **Chapter 9, Soils and Geology**, **Chapter 10, Hydrogeology**, **Chapter 11, Hydrology**, **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration** and their proposed mitigation measures to establish any potential health hazard directly attributed to what is proposed.

These assessments use standards (such as air quality standards) in order to identify whether significant impacts will arise or not. Again, as noted above, the health standards such as those set by the WHO are primarily intended to protect the vulnerable subsections of the population and, accordingly, will necessarily protect the more robust subsections. The standards are set at levels for which there will be no significant health effects, but do not exclude each and every effect, i.e. slight or moderate health effects are possible even below the levels at which health based standards would apply.

These health based standards are discussed further below in relation to the various environmental pathways but it is also appropriate to understand the principle behind the setting of such standards.

Noise

Noise is measured using the standard decibel scale (dBA). The “A” represents a weighting that mimics human hearing. It is important to note that because the decibel is a logarithmic scale i.e. a non-linear scale, the figure can be somewhat confusing. Essentially, an increase by 3dB means a doubling of the sound intensity in energy terms.

The human ear however does not perceive this degree of increase in volume. Normally a 10dB increase in noise level equates to a subjective doubling in audible sound. Very few noise sources are constant. A series of noise events can be averaged over any given period of time using the equivalent continuous sound level (Leq). Leq is the method of averaging recommended in industry and environmental assessments and in guidelines issued by, for example, the World Health Organization.

It is normally assumed that noise inside a building with the windows open, will be at least an estimated 15dB less than that outside. With windows closed, noise levels are reduced further inside, up to in excess of 35dB, depending on the building fabric. The actual attenuation varies depending on the type of building, size of the windows and other factors.

It should be noted that the assessment for this EIA Report relates to environmental exposure to noise. Undoubtedly those with the highest noise exposure will be those working on the construction of the proposed road development. Legislation is in place for control of work place noise and is policed by the Health and Safety Authority.

A Europe-wide study by Fritschi, 2011[5]) and another paper by Hellmuth, 2012[6], published by WHO demonstrate a significant burden of adverse health impacts associated with environmental noise exposure, drawing from earlier WHO publications summarising health evidence and recommending guidelines for community noise exposure. A review of noise exposure across Europe in 2014 by the European Environment Agency (EEA) likewise recommends and applies metrics for various health outcomes. In general terms, increasing noise in communities is associated with adverse health outcomes and vice versa. The nature and the severity of these outcomes is further discussed below.

The potential health impacts due to noise include:

- Noise-Induced Hearing Impairment
- Interference with Speech Communication
- Disturbance at schools
- Sleep Disturbance
- Hypertension and Cardiovascular Disease

Noise-Induced Hearing Impairment

Hearing impairment is typically defined as an increase in the threshold of hearing. It is assessed by threshold audiometry. It only occurs however above a certain noise level. Data from the International Standards Organisation (ISO) and WHO states that Noise Induced Hearing Loss will not occur at noise levels below 70dB no matter how long the exposure continues.

Interference with Speech Communication

Noise interference can interfere with speech comprehension. These may include problems with concentration, fatigue, uncertainty and lack of self-confidence, irritation, misunderstandings, decreased working capacity, problems in human relations, and a number of stress reactions.

Particularly vulnerable to these types of effects are the hearing impaired, the elderly, children in the process of learning, and individuals who are not familiar with the spoken language. Sensitive communication takes place indoors for the majority of the time and as noted above, the average noise attenuation of being inside a building with the windows open is conservatively estimated to be 15dB.

[5] Fritschi, L. et al., 2011. Burden of disease from environmental noise, Copenhagen: WHO Regional Office for Europe

6 Hellmuth, T., Classen, T., Kim, R. & Kephalopolous, S., 2012. Methodological guidance for estimating the burden of disease from environmental noise, Copenhagen: WHO Regional Office for Europe

Disturbance at schools

There are several studies on the effect of environmental noise on education. However most of these relate to airport noise and to a lesser extent traffic noise. From the literature review undertaken, school learning may be the factor most affected by environmental noise.

The RANCH study was one of the largest studies performed on this matter in Europe and was published in the Lancet in 2005. While showing little new data, it suggests a small effect on reading comprehension in 9 to 10 year old primary school children. It also stated "Neither aircraft noise nor traffic noise affected sustained attention, self-reported health, or overall mental health." It was surprising that the study suggested significantly improved memory function in children exposed to high levels of traffic noise. This appears intuitively difficult to understand, but certainly does not suggest that there is the opposite effect. Based on this literature review, disturbance at schools will not be a significant issue.

Sleep Disturbance

Sleep disturbance is considered to be a major environmental noise effect on human health. It is however estimated that 80-90% of the reported cases of sleep disturbance in noisy environments are for reasons other than noise originating outdoors. Understanding of the impact of noise exposure on sleep stems mainly from experimental research in controlled environments.

Field studies conducted with people in their normal living situations are scarce. However most of the more recent field research on sleep disturbance has been conducted for aircraft noise.

Sensitive groups include the elderly, shift workers, persons especially vulnerable to physical or mental disorders and other individuals with sleeping difficulties.

There is evidence that habituation to night-time noise events occurs, and that noise-induced awakening decreases with increasing number of sound exposures per night. Studies have also shown that the frequency of noise-induced awakenings decreases for at least the first eight consecutive nights with people becoming accustomed to the noise thereafter (Journal Behavioural Sleep Medicine, 2007). In summary people get used to the noise and the potential for interference with sleep diminishes.

As stated above most of the published research is related to aircraft noise but in a published study (Babish, 2006) which studied some 23,000 people, the authors concluded that at the same average night time noise-exposure level, aircraft noise is associated with more self-reported sleep disturbance than road traffic, and road traffic noise is associated with more sleep disturbance than railways.

People also sleep during the daytime, for example shift workers, and instances where ambient noise levels are much greater during the day it is therefore less likely that an additional noise source will have a significant effect to those who try to sleep during day time.

Hypertension and Cardiovascular Disease

A number of studies have postulated a link between environmental noise and hypertension and also cardiovascular disease. There is somewhat more evidence in relation to airport noise rather than noise due to road traffic. Some of the studies, particularly in relation to noise due to road traffic, have problems due to potential confounders[7]. One of the issues was trying to differentiate whether effects may be due to air pollution rather than noise. Some more recent studies have suggested that noise may have an independent effect. The extent of the effect is difficult to determine but it is clear that it is only at higher levels of environmental noise that any measurable effect is likely to occur.

Regarding road noise specifically, several meta-analyses of cardiovascular disease have been published by W. Babisch. These date from 2006 to 2014 and show evidence to provide a risk ratio for all ischaemic heart disease (IHD), also known as coronary heart disease (CHD) risk. A meta-analysis published by Vienneau in 2015, used many of the same studies to establish an IHD risk ratio that was used in the 2014 European Environment Agency quantification of noise health impacts across Europe. A limited number of studies of stroke risk associated with environmental noise exposure have also been published by Houthuijis.

These postulated links have been considered by expert bodies such as the WHO when they set their noise guidelines and in particular the night time noise guidelines.

In 2009 the WHO issued Night Noise Guidelines for Europe which explore the effects of night time noise. It stated that in the two European countries studied (Switzerland and The Netherlands) that almost 50% of the population are exposed to night time noise in excess of 45dB L_{night}.

These guidelines quote some health effects at quite low night time levels and proposed an ideal noise level of 40dB L_{night} as measured outside residences. They do however accept that this is essentially unachievable in the foreseeable future and therefore proposes an interim value of 55dB L_{night} outside instead.

It should also be stated that the effects detected at lower night time levels (below 55dB L_{night}) are relatively benign in terms of health effects such as increased mobility (tossing and turning) while asleep. More significant health effects are only linked to much higher noise levels, usually in excess of 70dB L_{night}.

The WHO night noise guidelines refer to L_{night} parameter which relates specifically to noise levels over the night-time period. The NRA Guidelines on the Treatment of Noise and Vibration and quoted in **Chapter 17, Noise and Vibration** sets a design goal in terms of a composite 24 hour parameter, the L_{den}. Whilst the L_{den} includes for night-time noise, direct comparison of the two parameters is not possible as they relate to different averaging time periods. The results of the noise assessment were discussed by the author of this chapter and an understanding of the difference in units and its implications for the results was obtained.

[7] In statistics, a confounder (also confounding variable or confounding factor) is a variable that influences both the dependent variable and independent variable causing a spurious association.

In most urban environs one would expect many areas to have noise levels at or above 55dB L_{night} and Galway is no different. In this context any assessment of potential impacts must take into account the baseline or existing noise levels.

It is important to note that whilst the WHO Guidelines are used in assessing potential health impacts, they can at times be misinterpreted. They are not, and were never intended to be, considered as a threshold. For example, the difference between a property experiencing a night time noise level of 54dB and another property experiencing a night time noise level of 55.1dB would be imperceptible for individuals living there and differences in health status would also be imperceptible.

The WHO Guidelines are guidelines for protection of health in communities. In terms of potential impacts on health, night time noise is far less important and does not merit being considered in the same way as other factors such as diet, exercise, cigarette smoking and genetics. The slight increase or decrease in night-time noise that might occur on individual residences would be so small as to be unmeasurable in terms of health effects. Therefore, in assessing night time noise in the context of the WHO Guidelines, it should only be in the context of overall noise levels in the community rather than the increase or decrease at an individual residence or clusters of residences. Whilst noise levels are often quoted with respect to potential effects on health and they are used in the significance assessment, it should be noted that the differences in significance between the different levels are relative rather than absolute.

Summary Noise

In terms of the health effects of environmental noise there is some limited evidence of effects on blood pressure, cardiovascular risk, school performance and in relation to sleep disturbance. Any effects demonstrated are more likely at higher noise levels. Many effects are only demonstrated with ambient noise in excess of 70dB.

Vibration

Vibration has the potential to have health effects when perceptible. These could include for example sleep disturbance. Another issue which is sometimes described is infrasound. The latter is sound but at a frequency so low that it is not audible to the human ear. If at high levels it may be perceived as vibration. These effects, in relation to vibration and infrasound, however only occur when the levels are high and perceptible to human beings for example an underground train.

Air Quality

Vehicles with internal combustion engines emit air pollutions, including particular matter, carbon monoxide, nitrogen oxides and a variety of hydrocarbons. Previously, lead compounds were added to petrol and lead emissions were a major issue but the sale of leaded petrol has been banned for many years. In the last few years in Ireland, partly because of tax driven reasons, there has been a switch in the type of internal combustion engines in cars from primarily petrol to primarily diesel cars in newer vehicles. Emissions would be broadly similar. However, there are some differences and in particular there is a higher level of particulate emissions from diesel cars. Nitrogen oxides and hydrocarbons can oxidise oxygen in the air to ozone if exposed to high levels of sunlight. While this is problematic in some countries, it is less likely to be an issue in the Galway area for reasons outlined further below.

The following components of air emissions of motor vehicles were considered for the health assessment:

- carbon monoxide
- other products of combustion
- fine particulates

Carbon Monoxide

Carbon monoxide is formed by incomplete combustion of fuels such as petrol and diesel. It can be absorbed into the blood stream and reduce the oxygen carrying capacity of blood. It is present in all forms of combustion. High levels of carbon monoxide exposure are associated with increased hospital admissions, cardiovascular disease and mortality.

Products of combustion

Nitrogen dioxide, and oxides of Nitrogen in general, directly affects the lungs. It is also gas produced during fuel combustion and impairs the lungs immune defence mechanism. When contacted with water which would line the lungs, it forms an acid to essentially burn the airways. There can be an increased severity of asthmatic attacks, etc. due to high levels of exposure to nitrogen dioxide.

Fine particles

Fine particles include PM_{10}, i.e. particulate matter less than 10 micrograms in diameter but also in more recent time, more emphasis has been made on smaller particles, again including $PM_{2.5}$, i.e. less than 2.5 microns, PM_1 and even nanoparticles which are smaller particles again. These have been known to exacerbate respiratory conditions such as bronchitis and pneumonia and there is increased mortality with higher levels.

Particulate emissions have received attention in recent years given increasing evidence of their health effects. Indeed, there have been calls to ban diesel vehicles in larger cities because of potential adverse effects. However, when assessing the human health impacts of the proposed road development, one must consider the Do-Nothing scenario would lead to those vehicles continuing to go through congested city centre routes with slow average speeds giving the potential for greater emissions. Overall therefore the proposed road development may have potential benefits regarding particles compared to the Do-Nothing scenario. This is discussed further in **Section 18.6** of this EIA Report.

Appropriate Standards

The starting point in selecting the appropriate standard to apply is EU directives which had been set down. In Ireland, these are monitored by the EPA. The current applicable directive is the Clean Air for Europe (CAFÉ) Directive.

The following table shows the limit or target values specified by the directive that set down limits for specific air pollutants. The directive covers:

- Sulphur dioxide, nitrogen dioxide and oxides of nitrogen, particulate matter (PM_{10} and $PM_{2.5}$) and lead
- Carbon monoxide and benzene
- Ozone
- Arsenic, Cadmium, Nickel and Benzo(a)pyrene

Table 18.6: Limit values of CAFE Directive 2008/50/EC

Pollutant	Limit Value Objective	Averaging Period	Limit Value ug/m3	Limit Value ppb	Basis of Application of the Limit Value	Limit Value Attainment Date
SO_2	Protection of human health	1 hour	350	132	Not to be exceeded more than 24 times in a calendar year	1 Jan 2005
SO_2	Protection of human health	24 hours	125	47	Not to be exceeded more than 3 times in a calendar year	1 Jan 2005
NO_2	Protection of human health	1 hour	200	105	Not to be exceeded more than 18 times in a calendar year	1 Jan 2010
NO_2	Protection of human health	calendar year	40	21	Annual mean	1 Jan 2010
PM_{10}	Protection of human health	24 hours	50		Not to be exceeded more than 35 times in a calendar year	1 Jan 2005
PM_{10}	Protection of human health	calendar year	40		Annual mean	1 Jan 2005
$PM_{2.5}$ - Stage 1	Protection of human health	calendar year	25		Annual mean	1 Jan 2015
$PM_{2.5}$ - Stage 2	Protection of human health	calendar year	20		Annual mean	1 Jan 2020
Lead	Protection of human health	calendar year	0.5		Annual mean	1 Jan 2005

Pollutant	Limit Value Objective	Averaging Period	Limit Value ug/m3	Limit Value ppb	Basis of Application of the Limit Value	Limit Value Attainment Date
Carbon Monoxide	Protection of human health	8 hours	10,000	8620	Not to be exceeded	1 Jan 2005
Benzene	Protection of human health	calendar year	5	1.5	Annual mean	1 Jan 2010

As discussed previously, air quality standards are set to protect the vulnerable such as those with respiratory illnesses, the old and infirm. Slightly higher levels of oxides of nitrogen above the standards may have no effect on the vast majority of the population but may be significant for the vulnerable. Hence the human health impact assessment has relied on compliance with the Air Quality Standards to determine whether significant impacts will arise on human health or not. The standards used in **Chapter 16, Air Quality and Climate** include the *Air Quality Standards Regulations 2011*, which incorporate *European Commission Directive 2008/50/EC* which has set limit values for the pollutants SO_2, NO_2, PM_{10}, benzene and CO. The C*ouncil Directive 2008/50/EC* combines the previous *Air Quality Framework Directive (96/62/EC)* and its subsequent daughter directives (including *1999/30/EC* and *2000/69/EC*). Provisions were also made for the inclusion of new ambient limit values relating to $PM_{2.5}$. These are clearly appropriate and robust standards. The table above shows that the levels are set primarily for the protection of human health. Therefore, provided these levels are not exceeded one can be confident that there will be no adverse effect on human health due to air emissions.

Potential Health Impacts from Air

In 2010, the Health Effect Institute (HEI) Panel in the US, in a study partially funded by the US EPA on the Effects of Traffic-Related Air Pollution, concluded that exposure to air pollutants specifically from roads is likely to be associated with all-cause mortality[8], cardiovascular disease incidence and mortality, and reduced lung function, albeit with weaker evidence (due to fewer and smaller studies) than the wider air pollution health evidence base.

The WHO published a review in 2005 of the health effects of transport-related air pollution which concluded that health effects include increased cardiopulmonary mortality risk and respiratory morbidity risk.

Since 2013, the International Agency for Research on Cancer (IARC) defines diesel engine exhaust as carcinogenic to humans. Petrol engine exhaust is classified by IARC as possibly carcinogenic, as there is inadequate evidence to form a firmer conclusion.

A relatively recent article by Chen et Al published in the Lancet in early 2017 showed a small (7%) increase in the incidence of dementia in those living less than 50 meters from major roads but no increase in the incidence of Multiple Sclerosis or Parkinsons disease. The authors postulated that increased levels of $PM_{2.5}$ and

[8] This is mortality from all causes e.g. cancer, heart, lung etc.

NO_2 may be associated factors. However, there were important limitations on the study as the study was based in Ontaria, Canada where major roads would include very busy highways and trunk roads. Perhaps the most significant criticism of the study was that the authors could not account for socio-economic effects. Socio-economic effects are related to the incidence of dementia. Therefore, if the individuals living within 50 metres of major roads in Ontario were of lower socio-economic status than those living further away this might explain the relatively small increase in the occurrence of dementia in this study. Overall while further studies are recommended one can draw relatively little from this one study.

While there are some difficulties making comparisons between the impact of road building in say China, far more relevant information can be gleaned with similar projects within Ireland while being conscious of international published data. This is due to the fact that the baseline environment in densely populated counties such as China, which currently includes polluted air quality in its baseline, is not comparable to that of Ireland and in particular Galway.

The 2014 publication from the OECD The Cost of Air Pollution, The Health Impacts of Road Transports points out that while the health impacts of air pollution in western countries is decreasing, that it is increasing in countries like China and India. It is more important for us in Ireland to consider the data from this country and similar countries.

While it is now 13 years old, an important document in Ireland was the Health Impacts of Transport, a Review published in March 2005 by the Institute of Public Health in Ireland. This remains the most recent publication from this body on this subject.

The document reviews the elements of health impacts of transport. It originated as part of the transport HIA in Ballyfermot organised by the Eastern Regional Health Authority and proceeds from the Institute's strategic objective to strengthen the capacity of those working for public health.

In the Executive Summary they stated:

"the effect of air quality on human health has been extensively researched and expert opinion is available in this area. Currently, evidence is strongest for air pollution as a cause for short-term health problems in certain groups such as the elderly and those with underlying health problems such as heart or lung disease. Longer term health impacts are suspected to result from certain components of air pollution. However, it has been difficult to ascribe a cause and effect with certainty. Traffic is a leading source of air pollution and any issues which would reduce traffic volume can have potential benefits to health by improving air quality. Vehicle speeds is also a factor warranting consideration. Low average speeds such as those on congested routes are less efficient in the use of fuel and result in greater pollution emissions."

It can be concluded that the principal of moving traffic to a road with higher average speeds has actually a potential benefit on health.

It is important in these areas to consider the baseline environment. The EPA Air Quality Index shows that the air quality in both Galway City and County is very good. There are multiple reasons for this. One is Galway's geographical location on the edge of the Atlantic Ocean exposed to prevailing winds which predominantly blow air pollutions away from the centres population. There have also been very good controls with regard to potential sources of pollution in the Galway area. This was further supported by the site specific air quality monitoring undertaken for the proposed road development. Refer to **Chapter 16, Air Quality and Climate**.

There is no history of heavy industry emitting high levels of pollutions for example. The major sources of industry currently operating in Galway include medical device companies with very low emissions. It is against this background air quality that any emission would occur. These are detailed further in **Chapter 16, Air Quality and Climate**.

Water

Accessibility to high quality clean water is obviously very important contributor to human health. In Ireland these are regulated by the European Union (drinking water) Regulations 2014. These regulations impose duties on Irish Water and local authorities in relation to the sampling and recording of water quality. There are strict standards in relation to the quality of water in relation to its chemical content as well as microbiological aspects. Provided the standards are observed one can be confident that there will be no adverse effect on human health due to effects on water quality.

Flooding also has potential for human health effects. Apart from the economic impacts of flooding, particularly of repeated flooding in certain areas, individuals who have their homes and residences flooded can be subject to very significant psychological impacts. Financial loss can occur particularly in areas which previously experienced flooding and were no longer insured. This loss can relate to the actual damage to the properties caused by the flooding but also the potential loss in value of the property. These can be associated with increased levels of anxiety and even depression. Flooding can also be a potential source for the spread of disease. This made the spread by vermin or alternatively flooding the sewers and septic tanks. When considering the potential health effects of the proposed road development in relation to flooding, it is important to consider if the risk of flooding is increased or decreased or indeed unaffected by the proposed road development.

Soils

<u>Contamination of Land</u>

If a project has the capacity to contaminate land this also has the potential for human health effects. This contamination could for example arise if previously buried contaminated material is unearthed during the construction process. Examples of this might include an unidentified landfill, previous industrial contamination or indeed naturally occurring sources of contamination. Contaminated land could in turn affect health either by direct contact, either people living and working on the land itself or for example children playing on the land. Some contaminants may be concentrated in food grown in the land and this is another manner in which contaminated land could have a health effect.

Radon

Radon is a naturally occurring radioactive gas that originates from the decay of uranium in rocks and soils. It is colourless, odourless and tasteless and can only be measured using special equipment. When radon surfaces in the open air, it is quickly diluted to harmless concentrations, but when it enters an enclosed space, such as a house or other building, it can sometimes accumulate to unacceptably high concentrations. Radon decays to form tiny radioactive particles, some of which remain suspended in the air. When inhaled into the lungs these particles give a radiation dose that may damage cells in the lung and eventually lead to lung cancer.

It is only when radon has potential to build up in buildings that are inhabited by human beings that the health risk occurs. Indeed, these buildings due to heating or otherwise can in certain areas draw in radon from the ground as warm air rises within the buildings. If radon is found at high levels in buildings one of the most effective remedies is to create a sump which creates its own negative pressure and draws the radon away from entering the building. More information on this can be found on the EPA website[9].

Psychological

In the planning process, potential adverse effects on psychological health are often mentioned, for example, anxiety and stress experienced by those whose homes are to be unfortunately compulsory acquired or those whom will experience a change in the environment in which they live.

The community will also experience annoyance from the temporary impacts of traffic management and other effects during the construction phase. As against this there is the potential reduction in annoyance amongst road users in the operational phase where there are reduced journey times. Annoyance however, is not in itself a health effect.

For virtually every proposal for any road development there are concerns about potential adverse effects on a person’s overall psychological well-being. This is somewhat a more difficult matter to assess as there are no direct measurements one can use. While one can give great detail in predicting for example noise emissions one cannot use the same scientific certainty in predicting psychological impacts. It is not possible to use a standards-based approach for example.

There are various degrees of psychological impact and these can be both positive and negative. There can be a positive impact, whereby people may look forward to better transport. There can also be adverse effects of varying degrees. At the lower end of this impact might be annoyance where somebody is annoyed by for example, outside noise, dust depositing or temporary traffic delays associated with construction of the roads. This is not a medical impact as such. If someone develops a psychological illness such as anxiety or depression this would be a medical impact.

Construction by its very nature is transient but it is expected that construction activities will cause some annoyance such as from road diversions and temporary

[9] http://www.epa.ie/radon/getinformed/

road closures. The potential effects are minimised by use of appropriate traffic management and avoidance of extended night time closures. There has been a considerable amount of road construction in Ireland over the last few decades. However, there is no documented evidence from these projects to link adverse outcomes with psychological health in Ireland.

Health Improvements

The proposed road development has the potential to provide opportunities for health improvements.

Employment and income are among the most significant determinants of long-term health, influencing a range of factors including the quality of housing, education, diet, lifestyle, coping skills, access to services and social networks. Many epidemiological studies consistently show better health outcomes are associated with higher socio-economic status.

Consequently, poor economic circumstances can influence health throughout life, where communities subject to socio-economic deprivation are more likely to suffer from morbidity, injury, mental anxiety, depression and tend to suffer from higher rates of premature death than those less deprived. One of the most reliable methods to improve health within a community is to raise it socio-economic status.

Projects that have the potential to support regeneration, reduce unemployment and improve socio-economic circumstance, could contribute to improving the health and wellbeing of socio-economically deprived communities.

In social health terms, economic development also brings the opportunity for reducing inequities in society. Long-term unemployment for example is detrimental to the individual, family and society. It has potential to transfer across generations so that families where the head of household is long term unemployed are themselves far more likely to become or stay unemployed. This has potential to create and sustain social inequities. The economic development opportunities provided by the proposed road development have the potential to create more employment and reduce the risk of long-term unemployment. This in turn can lead to greater opportunities for equity in society.

Improvement of Access to Services

Studies show that recreational activities can have a positive impact on a person’s wellbeing and their health.

A study by Lyon et Al[10] from 2004 showed a much improved survival rate from out-of-hospital cardiac arrests was strongly influenced by reduced response times for emergency services. The ability for emergency services such as ambulances to rapidly access emergency situations therefore has the ability to save lives.

Improving access to cinemas, parks, retail and other recreational activities will therefore make it easier for people to undertake recreational activities. Improved

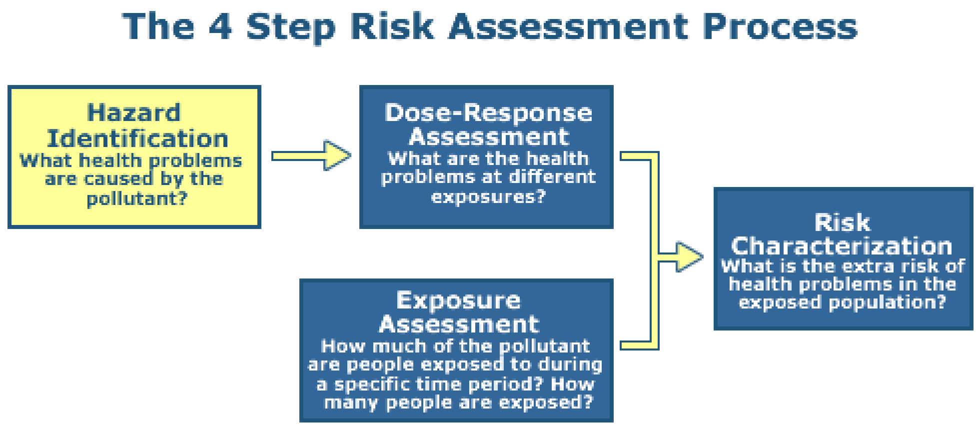
[10] Emerg Med J. 2004 Sep;21(5):619-24| Lyon RM1, Cobbe SM, Bradley JM, Grubb NR.

access to medical services will also have added benefits to a person's health as will access to education facilities as outlined above in the Health Improvement section.

18.2.5.3 Health Protection

The assessment of human health for the proposed road development, in terms of health protection, follows the approach set out in the EPA guidelines and in the European Commission's SEA Implementation Guidance. It is also similar in nature to the US EPA guidance. Human Health protection is considered through the assessment of the environmental factors (pathways) through which health could be affected such as air, noise, water and soils. The US EPA guidance includes a four step approach which is represented graphically in **Plate 18.1** below.

Plate 18.1: Human Risk Assessment



The potential noise, air, soils and water impacts which could affect human health were identified (Hazard Identification), the scale of these potential impacts (Dose-Response Assessment) and their duration (Exposure Assessment) were assessed and the significance of the potential impact on human health determined (Risk Characterisation).

When using a recognised Health Based Standard, the dose-response assessment is actually included in the standard. In other words, the authorities or expert committees which recommended the level of the standard will have taken into account the health problems at the different exposure levels and set the level within the standard to prevent these problems from occurring.

18.2.5.4 Health Improvement

Projects that have the potential to support regeneration, reduce unemployment and improve socio-economic circumstance, could contribute to improving the health and wellbeing of socio-economically deprived communities.

The assessment of human health for the proposed road development, in terms of health improvement, includes an assessment on how the proposed road development would impact on the socio-economics of the community.

18.2.5.5 Improvement of access to services

Improving access to services such as hospitals or recreational facilities will have an impact on the health of a community. Therefore, the assessment of human health for the proposed road development includes an assessment on whether or not the proposed road development will improve accesses to these services.

18.2.5.6 Significance of Health Impacts

There is a difficulty in assigning levels of significance to human health impacts. In medicine, as in all science, the concept of statistical significance is used. This involves attaching a value to significance, often expressed as a percentage level of confidence in the data. Confidence measures of 95% or even 99% are often used to measure levels of certainty or changes that are not due to chance alone.

This is a valid approach for the study of the impacts on a *population*, but does not absolutely exclude a response on an *individual*. However, it is difficult to assign levels of significance to individual human health impacts without detailed information about that individual. Thus, the significance of health effects are assessed on a group or community basis rather than on an individual basis. There is such a variability in human response that one could never identify all possible individual effects and so, in accordance with the guidance referred to above, it is considered to be more appropriate to assess the significance of health effects at a population level. The significance criteria for the assessment of the health of communities are therefore as outlined in **Table 18.7** below.

Table 18.7: Criteria Used in the Assessment of Community Health Protection Impacts

Impact Level	Significance Criteria
Imperceptible	No significant human health impacts are apparent
Slight	A small impact on reported symptoms but no change in health status can be attributed to the proposed road development
Moderate	A moderate impact on health status but no change in morbidity or mortality can be attributed to the proposed road development
Significant	The proposed road development has the potential to impact on health status with an associated change in morbidity
Very Significant	The proposed road development has the potential to impact on the health status of groups of people
Profound	The proposed road development has the potential to impact on the health status of communities

Asthma can be used as an example when using these criteria:

- An Imperceptible impact would be one with no measurable effect on asthma
- A Slight impact might be a temporary increase in symptoms but no change in the severity of the underlying condition or treatment required

- A Moderate impact might be an increasing use of inhalers attributable to the proposed road development but no change in underlying condition and no effect on the vast majority of asthmatics
- A Significant effect might be an individual becoming asthmatic or an individual's asthma becoming measurably more severe as a result of the proposed road development
- A Very significant effect might be a group of individuals becoming asthmatic or their asthma becoming measurably more severe as a result of the proposed road development
- A Profound effect might be a measurable increase in the incidence or severity of asthma in a community as a result of the proposed road development

18.3 Receiving Environment

18.3.1 Context

Galway City and its environs sits within the 4.5km[11] distance between the Lough Corrib and Galway Bay and is divided by the River Corrib with the built and natural environment and residential areas located on both sides of the river. The proposed road development skirts the city and majority of lands zoned for development. The baseline environment is represented by the semi-rural/urban fringe of Galway City and for the most part the landscape is dominated by low intensity grazing and uncultivated, undulating lands and bog and areas zoned for and built residential, commercial, and industrial and amenity development. However, given the built environmental, the linear development of the city with housing along every road radiating out of the city and the unavoidable proximity to residential areas, the proposed road development will unfortunately and unavoidably result in a number of property demolitions and community impacts.

Preliminary demographic data is available from Census 2016 (July 2016) on the population of Galway City and its environs. The Galway City Development Plan 2017-2023 draws on the population projections prepared for the Regional Planning Guidelines 2010-2022. In line with the National Spatial Strategy 2002-2020, it aims to concentrate population in the city with sufficient zoned land capacity to meet the needs of a population of 98,700 (36,286 households) by 2022. As of 2016, the Central Statistics Office (CSO) Census recorded a population of 78,668 for Galway City, an increase of 4.2% on the preceding figure for 2011 and 8.6% on 2006. The number of households also grew by around 4.1%. The figures demonstrate that the population has increased significantly in recent years despite the effect of the economic recession of 2008-2011. The population is, however, unlikely to grow at a rapid enough rate to meet the original projections of the Regional Planning Guidelines. Similarly, population projections in the Galway County Development Plan 2015-2021 also rely on the existing Regional Planning Guidelines. The County Development Plan proposes concentrating development in the hub town of Tuam, the Galway Gateway and the Strategic Economic Corridor to the east of Galway City between Oranmore and Attymon. Population growth will involve demand for

[11] Distance measured from south shore of Lough Corrib to Spanish Arch at Galway Docks

residential development and an increased pressure on the existing transport infrastructure.

Residential development has tended to occur on a largely west-east spine. Both the Galway City Development Plan and the Galway County Development Plan envisage an eastward extension of the city towards the area covered by the Ardaun LAP 2018-2024 to the east of Doughiska between the R339 Monivea Road and the R446 Doughiska Road. The development plans acknowledge the potential pressure that this new growth will place on existing transport infrastructure into the city and the need to integrate land use and transportation. A need for consolidation or regeneration within selected neighbourhoods is identified in the plans.

Residential development is more scattered within the urban fringe, often along minor roads and especially north of Bearna. There are distinct and established communities in addition to those listed in the data from the CSO below. Amongst others, these include Bearna, Na Foraí Maola, Troscaigh, An Chloch Scoilte, Cappagh, Ballymoneen, Keeraun, Mincloon, Dangan, Menlough, Ballindooley, Ballinfoyle, Castlegar, Parkmore, Doughiska and Coolagh.

Table 18.8: Population Galway City and County

	2016	2011	2006	2002
Galway City	78,668	75,529	72,414	65,832
Rest of County Galway	179,390	175124	159,256	143,245
Total County Galway	258,058	250,653	231,670	209,077

Table 18.9 indicates the population of each Electoral Division (ED) in the wider Galway area as recorded at the time of the 2016 Census. The table reveals modest percentage increases in population with some of the larger increases having been experienced in the suburban area of Ballybaan and the village of Bearna. Some more established areas such as Dangan have experienced an increase in population as compared to a reduction in the last Census period.

The extents of the Galway Gaeltacht area can be seen in **Figures 18.1.01** and **18.1.02**. Population figures for the Galway Gaeltacht to the west and north of the city are included in **Table 18.9** as these areas will be better connected by the proposed road development. Relative to several of the suburban and urban/rural fringe EDs, these figures reveal rather small population increases for the areas west of the city along the R336 as far as Rossaveel (Ros an Mhil) with the exception of Na Forbacha closer to the city where the population grew by 7.9%. The Gaeltacht is an area that is currently rather difficult to access from the east side of Galway City and the rest of the country, although growth potential here is somewhat restricted by the confinement to a narrow strip between the sea and blanket bog to the immediate north. The population growth has been greater in the Gaeltacht area along the N59 Moycullen Road between the city and Oughterard.

Table 18.9: Population Electoral Divisions

Electoral Division	Population 2016	Population 2011	Percent change	Population Density (persons per km²)
Galway Gaeltacht				
27054 Cil Chuimin (Kilcummin)	1314	1315	-0.1%	23.9
27061 Saileama	1453	1448	0.3%	21.2
27055 Cill Aithnin	1044	1000	4.4%	14.3
27063 An Spidéal	1443	1450	-0.5%	40.9
27051 Na Forbacha	1415	1312	7.9%	47.5
27159 Oughterard	2636	2604	1.2%	21.8
27162 Wormhole	2376	2315	2.6%	38.2
27062 Sliabh an Aonaigh	763	763	0%	13.2
27065 Tulaigh Mhic Aodhain	2075	1985	4.5%	68.4
27059 Maigh Cuillinn	2142	2008	6.7%	74.0
Galway Urban Rural fringe				
27044 Bearna (Barna Rural)	3727	3630	2.7%	156.4
27052 Galway Rural (part)[12]	149	126	18.3%	63.5
Galway suburbs				
26003 Bearna (Barna)	15185	14384	5.6%	2131.0
26015 Rahoon	3076	3009	2.2%	615.3
26006 Dangan	4132	3608	14.5%	2193
26013 Newcastle	1900	1820	4.4%	2500
26010 Menlough (Mionlach)	5118	4990	2.6%	610.8
26004 Castlegar (An Caisleán Gearr)	4053	4135	-2.0%	1079.6
26002 Ballybrit (Baile an Bhriotaigh)	949	898	5.7%	366.5
26001 Ballybaan	13019	12298	6.9%	1710.4
26011 Mervue	1831	1796	1.9%	1510

Based on the more detailed results from the 2016 Census, **Table 18.10** illustrates the expansion in the number of households in Galway over time in the study area and in the suburbs despite the current high levels of traffic on the existing N6. The table reveals how population trends over time have been reflected in the number of

[12] Galway Rural (part) is a small ED (#27052) on the south-west shore of Lough Corrib

private households. The table shows that expansion into the rural areas of Bearna (Rural) has been well-established and continuous over the years, albeit from a small base. By comparison, expansion into the main village of Bearna and the townlands of Rahoon and Castlegar has been more recent, mainly from the 1990s. Established suburbs such as Dangan and Newcastle had experienced much of their growth prior to the 1990s, although the most recent Census results show that this could be changing.

Table 18.10: Houses by year built (2016)

	Pre 1971	1971 – 1980	1981 - 1990	1991 - 2000	2001 - 2010	2011: -	Unknown year	Total
Bearna (Barna Rural)	12.3%	11.2%	9.5%	19.8%	41.7%	2.4%	3.1%	1188
Bearna (Barna)	2.1%	4.4%	16.9%	34.5%	32.9%	1.8%	7.4%	5516
Galway Rural (part)	7.2%	9.1%	4.5%	5.5%	4.5%	2.7%	0	110
Rahoon	6.5%	9.8%	15.7%	27.1%	32.7%	1.5%	6.7%	1110
Dangan	9.6%	25.1%	30.3%	18.4%	5.2%	0.8%	10.7%	1512
Newcastle	25.4%	47.0%	12.1%	3.2%	2.5%	0.4%	9.4%	713
Menlough	6.1%	22.2%	25.3%	14.6%	17.9%	1.5%	12.4%	1823
Castlegar	5.2%	14.7%	9.8%	15.5%	40.2%	0.6%	13.9%	1566
Ballybrit	8.4%	7.2%	18.1%	32.4%	21.2%	0.3%	12.5%	321
Ballybaan	2.7%	6.6%	6.8%	13.3%	57.4%	16.%	11.6%	4554
Mervue	55.9%	16.8%	7.5%	1.9%	0.3%	0.3%	17.4%	755

Table 18.11 presents the figures for mode of journey to work, college or school and reveals high proportions of journeys by foot in the central or established neighbourhoods such as Dangan, Newcastle, Murrough and in Menlough. Levels of cycling are also in excess of 6% in these EDs. Journeys by foot also exceed 10% in Castlegar, Ballybrit and Ballybaan, but are understandably low in the urban/rural fringe area where vehicle use accounts for more than 50% of journeys. In Bearna, around 80% of people make their journey by car with the consequence that pressure is inevitably placed on the local road infrastructure, the environment and community wellbeing. Around one quarter of people in these EDs travel as a passenger or by bus, including a high proportion of students and school children.

Table 18.11: Journey mode to work, college and school (2016)

	On foot	Bicycle	Public transport	Car / van driver / motorcycle	Car passenger	Other / at home	Not stated
Bearna (Rural)	5.2%	2.0%	3.1%	51.0%	32.0%	4.0%	2.4%
Bearna (Barna)	6.9%	4.1%	11.1%	47.6%	25.6%	2.3%	3.4%

	On foot	Bicycle	Public transport	Car / van driver / motorcycle	Car passenger	Other / at home	Not stated
Galway Rural (pt)	0.1%	0.1%	0%	61.4%	29.5%	0%	3.4%
Rahoon	10.7%	5.7%	4.9%	36.0%	17.7%	1.6%	2.3%
Dangan	43.4%	8.0%	4.1%	26.8%	12.9%	1.3%	3.6%
Newcastle	49.6%	8.5%	4.8%	21.0%	11.5%	0.8%	3.8%
Menlough	34.0%	6.4%	5.8%	35.2%	13.0%	1.5%	4.0%
Castlegar	16.6%	6.3%	12.4%	42.3%	15.3%	1.5%	5.6%
Ballybrit	11.7%	3.2%	16.1%	47.0%	16.3%	1.7%	4.0%
Ballybaan	12.9%	2.9%	13.5%	42.33%	19.2%	1.2%	7.8%
Mervue	19.3%	4.2%	11.6%	37.4%	10.6%	1.4%	15.6%

Table 18.12 shows journey times to work, college or school. These conform to expectations in that journey times are less in the established neighbourhoods of Newcastle and Dangan and are extended in the urban/rural fringe. Most journeys are completed in less than 30 minutes in most EDs, but a further 20% of journeys take between approximately 30 minutes and three-quarters of an hour in the urban/rural fringe. Only 3.5% of journeys exceed three-quarters of an hour. However, given that some urban roads are near to capacity, and that most people travel to work or college by car, journey time is vulnerable to increases in traffic volumes and to incidents giving rise to congestion.

Table 18.12: Journey time to work, college and school (2016)

	< 15 mins	1/4 - 1/2 hour	1/2 - 3/4 hour	3/4 hour - 1 hour	1 hour - 1 ½ hours	> 1 ½ hours	Not stated
Bearna Rural	24.6%	38.8%	23.7%	3.8%	3.5%	1.3%	4.4%
Bearna	22.2%	42.4%	21.0%	3.8%	2.8%	1.5%	6.2%
Rahoon	25.2	33.1%	13.4%	2.1%	1.7%	0.7%	4.8%
Dangan	41.3%	39.5%	8.5%	2.3%	1.3%	0.7%	6.4%
Newcastle	52.6%	32.2%	5.6%	1.3%	1.4%	0.5%	6.5%
Menlough	31.8%	44.4%	12.0%	1.5%	2.0%	1.3%	6.9%
Castlegar	29.0%	38.8%	17.5%	2.8%	2.4%	0.9%	8.5%
Ballybrit	32.3%	39.5%	14.7%	4.1%	2.3%	1.1%	6.0%
Ballybaan	30.2%	36.0%	17.1%	3.0%	2.3%	0.7%	10.8%
Mervue	35.4%	31.6%	9.6%	1.8%	1.2%	0.5%	19.8%

In addition to residential development, areas have been zoned for major retail and light industrial development in Rahoon, along Seamus Quirke Road and east of the River Corrib in the vicinity of the Bodkin and Kirwan Junctions. The National University of Ireland Galway (NUIG) occupies a corridor of land beside the western bank of the River Corrib with teaching and research facilities located north and south of the Quincentenary Bridge, as well as extensive recreation facilities comprising the NUIG Sporting Campus to the north in Dangan.

Large light industrial and commercial estates are found to the east of the N83, particularly in the suburbs of Ballybrit, Parkmore and Briarhill and include the Ballybrit Industrial Park, the City East Business Park, Oldenway Business Park, Briarhill Business Park, the Galway Technology Park and the Parkmore Business Park. Commercial business parks are fewer in number, to the west of the River Corrib, the Galway West Business Park and the Gateway Retail Park are located in the vicinity of Rahoon and Clybaun. A large area is zoned for enterprise and commercial activity between Bóthar Stiofán in Knocknacarra/Clybaun across to the Western Distributor Road. One business park, Galway Business Park, is situated off the N59 Moycullen Road and benefit from proximity to the NUIG Campus.

18.3.2 Character

The study area commences in the rural area to the west and north of Bearna Village. Although the landscape retains elements of a wild and rocky vista there has also been a significant amount of new linear residential development in recent years. This development is adjacent to the few minor roads traversing the study area between which land use is largely low intensity agricultural. The proposed road development follows a corridor just outside of the built up residential areas of Clybaun and Letteragh on the edge of Galway City, but does cross the Dangan townland of established residential development and areas of amenity use to the east.

The same pattern applies east of the River Corrib where the corridor for the proposed road development traverses parts of Ballindooley and Castlegar. Further to the east, the area around Ballybrit includes extensive areas of commercial development and also the Galway Racecourse.

From a Human Health perspective, the health of the population in Galway is broadly similar to other areas within Ireland. In its most recent publication on Health Status and Health Service Utilisation 2010, the CSO provides information of a number of health statuses. The statistics are reflective of the region, in this case, the West of Ireland. It shows, for example, in terms of self-perception of Health Status, 85% of adults perceive their health as being either Very Good or Good. This compares to 89%in Dublin, 87% in the South West and 84% in the Midlands. There are also statistics on doctor diagnosed medical conditions including for example, asthma, chronic bronchitis, diabetes and mental health problems, as well as others. In all cases, prevalence of these conditions is similar to other areas of the country. In general, therefore, the statistics suggest a health status broadly consistent with the Irish population as a whole.

18.3.3 Significance

The proposed road development is intended to provide improved connectivity to the national road network for communities on the western side of the River Corrib which is only possible at present by using one of the four city centre bridge crossings. It will attract traffic from the city centre and suburbs, leading to improved journey time reliability and potentially facilitating the reallocation of the road space to public transport. It will also provide for an improved city centre environment for all due to reduced congestion and improved journey amenity, allowing walking and cycling to become safer, more practical transport modes. At present, bus patronage is less than 10%. Current journey times for both private vehicles and public transport are extended significantly by regular congestion particularly in the vicinity of the Bodkin Junction and Kirwan Roundabout, but also at the Browne Roundabout and along Seamus Quirke Road. Significant community severance is currently experienced along Seamus Quirke Road, the Western Distributor Road and along every section of the existing N6, including areas with important community and retail facilities. Although there are signalised crossings, wait times can be lengthy due to the volume of traffic. In the eastern half of the city at Briarhill, there is a pedestrian underpass, but crossings of any sort are necessarily prevented along much of the existing N6 in Ballybrit by a central barrier. While there are few community facilities in this area, the commercial and industrial estates to the north are important places of employment to which most access occurs by private vehicle.

The economy of Galway City has a strong representation of software, pharmaceuticals, medical devices and engineering businesses. Tourism is also an important economic sector and the city is the gateway to Connemara and the Aran Islands. As well as the economic benefit of the tourism sector, the city’s historic heritage, cultural and arts scene attract large numbers of visitors and provide city residents with a vibrant environment. Galway City itself has various well-known sites and holds numerous event and festivals throughout the year including the Galway Arts Festival, the Galway Food Festival, the Cúirt International Festival of Literature, the Oyster Festival and the Galway Races. In addition, the NUIG Sporting Campus, the River Corrib, Lough Corrib and Galway Bay are also used for walking, fishing, and a variety of water-based activities throughout the year.

High quality transportation access in and out of the city is essential to the sustainability of the city’s growth, the capacity of the tourism sector to drive regional development and to the city’s ability to stimulate economic development across the county, including more economically peripheral areas to the west of the city. To date, most industrial development has occurred in the east of the city where the best connections are to be found via roads to Dublin, Limerick, Cork and the east of the country. However, there are several large industrial or commercial estates which currently have very restricted access, in some cases only to the existing N6. The increasing volume of traffic in these areas impacts significantly on average journey times, especially at peak hours, and presents a threat to continued economic investment.

The route of the proposed road development generally avoids nucleated settlements with the exception of areas such as Dangan, Ballindooley/Ballinfoyle and Castlegar. There are areas of concentrated or linear residential development and also scattered development. Identities have emerged, often associated with historical townlands, local crossroads, schools or sports clubs. These sports facilities, together with the NUIG Sporting Campus, are well used by people living outside of the study area. There are also small family business premises and some equine activity.

18.3.4 Sensitivity

In the current baseline environment, there are limited opportunities for pedestrian crossings along the existing N6 away from dedicated crossing facilities. Combined with long wait times where these facilities are present, this imposes a particularly significant impact on sensitive or vulnerable population subsets such as young people, the elderly and people with disabilities. The CSO data records, rather high levels of disability (all types) in Rahoon (11.1%), Dangan (12.2%) and Newcastle (19.7%) relative to an average of 9.7% for the other EDs in the study area. These are neighbourhoods with a relatively high representation of older people and pockets of social disadvantage as indicated by the Pobal HP Deprivation Index (see also **Section 18.3.5**). Heavy traffic volumes, together with severance, noise and air quality impacts, reduce local quality of life, have potential implications for health and inhibit the ease of movement of people to schools, shops, medical centres and other community facilities. Road crossings can be awkward for those whose mobility is impaired and, away from crossing facilities, can entail an accident risk for all pedestrians. It can also be difficult for drivers to gain safe access to and from busy roundabout junctions. In addition, whilst there are some cycle lanes along the existing N6, these sometimes terminate at junctions without onward facilities, including for crossings. While the level of cycling in Galway City is comparable to other regional cities, the figures are low by an international comparison. Inadequate cycling facilities, poor journey amenity and safety hazards, greatly discourage cycle journeys from the suburbs into the city.

Galway City is an important national tourist destination. The attractiveness of the city to visitors partly depends on city centre traffic volumes remaining manageable and on vehicle access to the centre and the west not being subject to poor journey amenity, delay or congestion. Such factors impact negatively on the visitors' experience and their willingness to recommend Galway as a destination to others.

The proposed road development will also pass through the Galway Gaeltacht as shown in **Figure 18.1.001** and **18.1.002**. The Galway Gaeltacht is an area of cultural distinctiveness that is an important part of the county's identity and an attraction to visitors. This identity could be strengthened by the economic stimulus of the improved accessibility provided by the proposed road development.

In addition, some of the landscape in the west and central parts of the study area is of amenity interest or value. The corridor of the River Corrib is a sensitive landscape feature which is used for walking, rowing and angling and which links the city to its wider hinterland. Much of this corridor is occupied by lands managed by NUIG. These lands are accessible to the general public and are used by both university and non-university sports clubs and as an amenity. The university highlighted the role of these lands in providing for a unified campus and their importance in terms of providing sports and amenity facilities for attracting students and high-calibre staff. The concept of a unified campus has already been impacted by the partial physical severance incurred due to the Quincentenary Bridge on existing N6. Similarly, there are quiet roads and boithríns in the study area which are used for walking locally, including a historic mass paths. In particular, minor roads in the west of the study area are much used for walking, jogging and cycling. The study area is largely free of built development north of the existing N6, although there is much scattered residential development.

Residents consulted in the local community in the study area during the course of the assessment have often acknowledged the potential positive impacts of the proposed road development, noting in particular the potential for shorter travel times due to reduced urban congestion. People have also referred to the prospect for improved connectivity between parts of the city and the benefit this will have both socially and for employment. Concerns were simultaneously expressed regarding perceived environmental and community impacts, many of which mirror those received during the earlier public consultation. Such anxieties can sometimes impact on individuals' health and well-being prior to the commencement of works. Where possible, these concerns have been addressed during the design process or by the proposed mitigation with the net impact discussed in the relevant section of this and other chapters.

18.3.4.1 Identification of vulnerable groups

While every human being should be considered a sensitive receptor, the vulnerable are the most sensitive. These vulnerable groups may be more susceptible to impacts associated with the proposed road development.

Children and adolescents constitute a vulnerable group partly due to their need to be able to move around freely to and from school and recreational activities. They lack the experience and judgement displayed by adults when moving around traffic in public spaces. Studies[13] show that they may also be more sensitive than adults to air pollution and other environmental factors.

Elderly people constitute a very variable group when it comes to their need and scope for moving around the community. Generally speaking, the elderly people are slower in their movements and more health conditions may occur. Elderly people in general have greater sensitivity to air pollution and potential effects on the respiratory system and cardiovascular system and more likely to express anxieties in relation to potential air quality or noise impacts due to the proposed road development. There are many reasons for this sensitivity, including the possible presence of other medical condition such as respiratory or cardiovascular disease. Subtle changes in the environment have the potential to have an adverse effect that would not be experienced by younger more resilient persons. There are other vulnerable groups also, for example, persons with disabilities or persons with mental illness. It is important to note that, in this assessment, it is assumed that all areas contain highly vulnerable individuals including the old, the very young, disabled and persons with disabilities, as well as people who are sick today or who may be sick at the time the proposed road development is being constructed or operational. However, as noted above, there are some particular areas with higher levels of sensitive population subsets than others.

Vulnerable groups of people occur throughout the receiving environment for the proposed road development and include among others, a crèche, schools, nursing home and areas with a higher number of older family groups.

[13] http://www.who.int/ceh/risks/en/

18.3.5 Community Profile

Evidence shows that different communities have varying susceptibilities to health impacts both positive and negative as a result of social and demographic structure, behaviour and relative economic circumstance.

Whilst specific health data for individuals in the vicinity of the proposed road development is confidential and difficult to establish, a community profile has been used to establish the baseline and identify unequal distributions in existing factors such as deprivation or burden of poor health, in order that changes in community exposure to certain health pathways and their degree of impact on the population or community can be assessed.

A group made up of the Health Services Executive, Lenus and the Irish Health Repository have published health profiles for all the Local Authorities areas in Ireland and a health profile is available for both Galway City and County. The most recent profiles published relate to 2015 and have been used to establish a community health profile for the proposed road development.

The Health Profile identified that Galway City:

- "*has the lowest dependency ratio* in Ireland *of 34.9% (i.e. the number of those aged between 0-14 and 65 and over, as a percentage of the number of persons aged between 15 and 64). The national rate is 49.3%*
- *has the second most ethnically diverse population with 23.8% being non-white Irish. It also has the highest proportion of Travellers nationally of 2.3% (national 0.7%)*
- *is the third most affluent local authority area*
- *has the second highest education attainment levels of 45.0% (national rate 30.6%). The proportion of those with primary education only is 9.3% (national rate 15.2%)*
- *has the highest incidence of male malignant melanoma, and slightly above average for male prostate and colorectal cancers (Galway City and County data)*
- *is average or below average for the four main causes of mortality, all cause mortality and suicides (Galway City and County data)*
- in terms of the age breakdown of the population it shows that Galway City, has a relatively higher percentage of the population in the young adult ages from 20-35 and a relatively smaller percentage in the very young and older age groups than the national population. However, this demographic is not unusual for an urban setting in Ireland

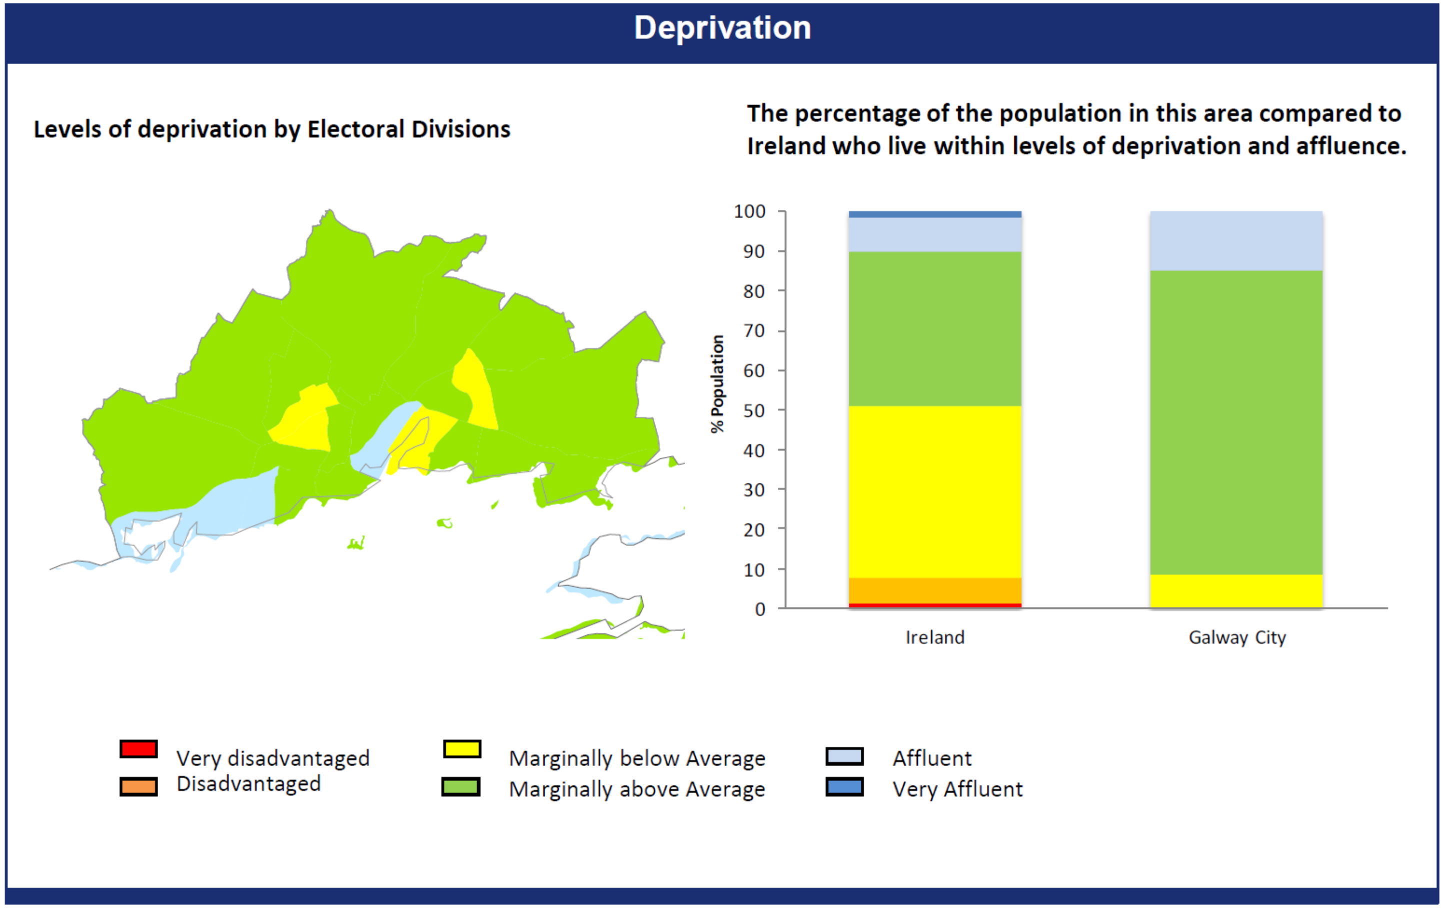
The Health Profile identified that Galway County:

- *Is the tenth most affluent local authority area nationally*
- *The Traveller population of 1.4% is above the national rate of 0.7%*
- *Has a low lone parent rate of 9.3% (national 10.9%)*

- *Has a low birth rate for mothers under 20 years of age at 7.0% (national 12.3%)*
- *Has the highest incidence rate of male malignant melanoma nationally, but is below average for female malignant melanoma, breast cancer, female colorectal cancer and male and female lung cancer (City and County data)*
- *Has average or below average mortality for the four main causes of mortality and for all mortalities (City and County data)*
- *Is below average for male and female deliberate self harm*

In terms of deprivation, the health profile report includes a map which shows deprivation levels as a percentage of population compared to national levels, see **Plate 18.2** for a copy of this map. It should be noted that the data shown on the map are averages and the scale of the map covers a relatively large area and does not give a true reflection of what is happening on a smaller more local scale. Areas which are categorised as affluent will contain small areas which are disadvantaged and similarly areas shown as disadvantaged will contain individuals or groups of considerable advantage. This shows geographically Galway City has relatively large areas which are marginally above average in terms of affluence or defined as affluent. However, there are parts of Galway City which score relatively highly on the Pobal Deprivation Index including the ED which contains the neighbourhood of Newcastle and areas close to the city centre.

Plate 18.2: Deprivation Map for Galway City (*Extract from Health Profile 2015 Galway City*)

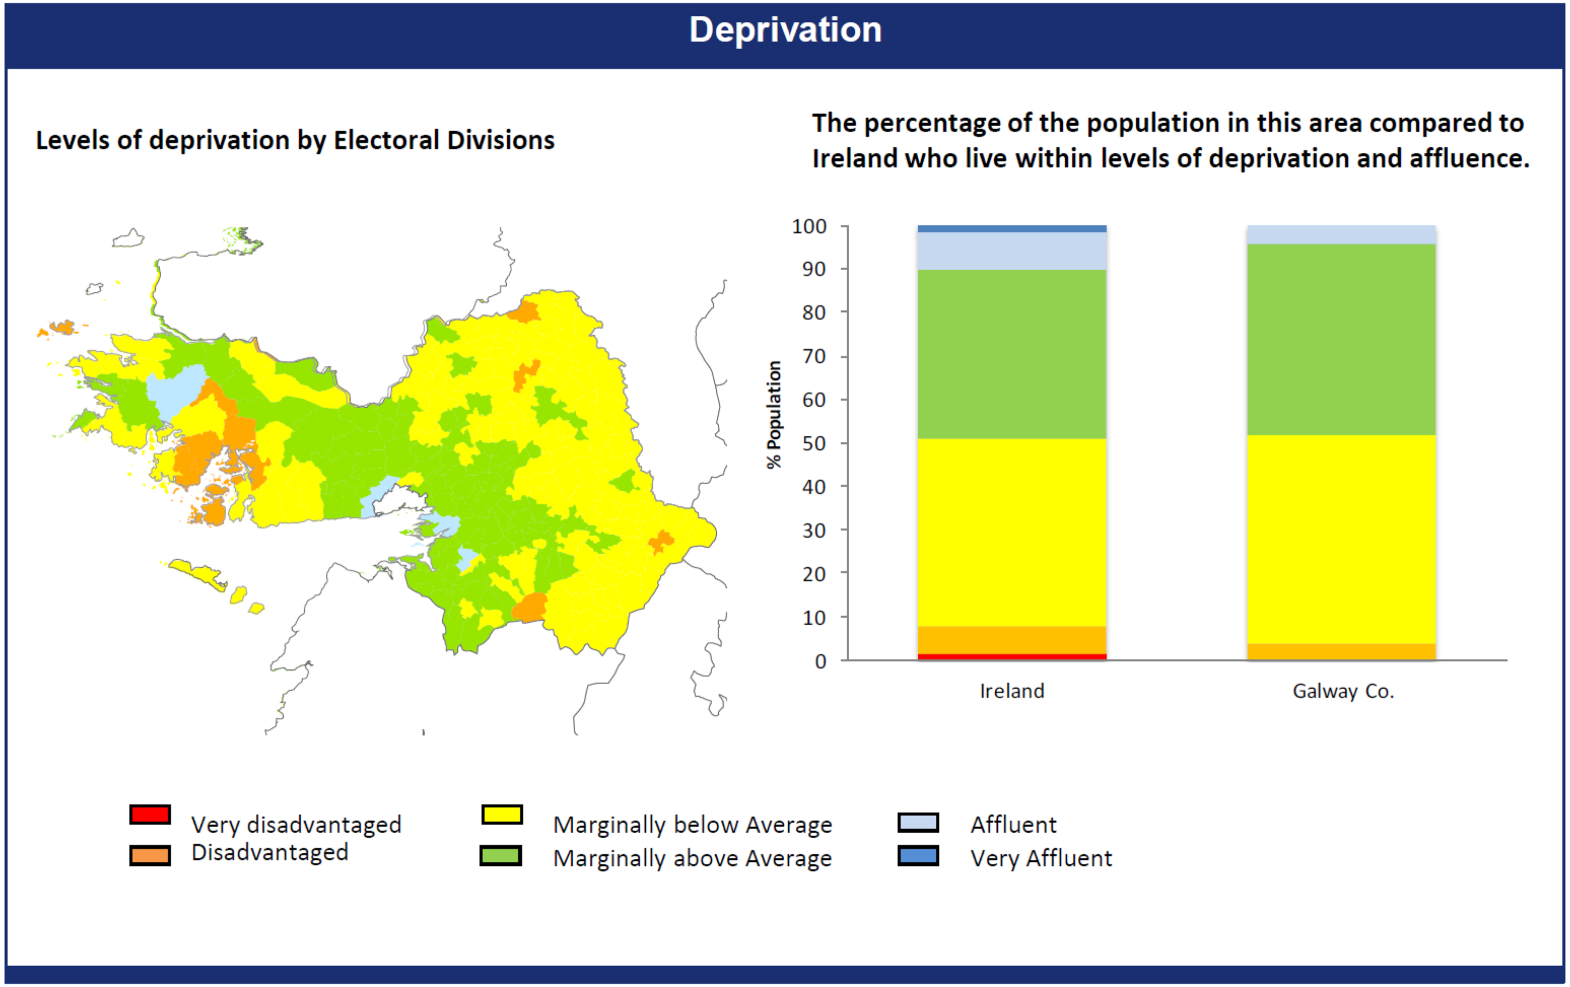


Note: There are parts of Galway City which score relatively highly on the Pobal Deprivation Index including the ED which contains the neighbourhood of Newcastle and areas close to the city centre.

When one looks at the deprivation map for Galway County (see **Plate 18.3** below), one can see an area described as affluent, immediately to the north and west of Galway City. Again as noted above, the data shown on the map are averages and the scale of the map covers a relatively large area and does not give a true reflection of what is happening on a smaller more local scale. Areas which are categorised as affluent will contain small areas which are disadvantaged and similarly areas shown as disadvantaged will contain individuals or groups of considerable advantage.

A copy of the Health Profile reports for Galway City and Galway County are included in **Appendix A.18.1** and **A.18.2** respectively.

Plate 18.3: Deprivation Map for Galway County (*Extract from Health Profile 2015 Galway County*)



18.3.6 Irish Language

18.3.6.1 Context

Irish (or Gaelic) is the national and first official language of the Republic of Ireland and it is among the official languages of the European Union. Despite its official status, the United Nations Educational, Scientific and Cultural Organization (UNESCO) in 2009 declared the Irish language as "definitely endangered" and stated that it may be on its way to disuse. The Census of 2016 recorded that of 1.76 million people in the Republic of Ireland who indicated they could speak Irish, 73,803 said they speak it daily outside the education system, a fall of 3,382 on the 2011 figure.[14] A further 111,473 said they spoke it weekly, while 586,535 said they spoke it less often. Over one in four (421,274) said they never spoke Irish. Of the 73,803 daily Irish speakers (outside the education system), 20,586 (27.9%) lived in Gaeltacht areas.

Irish was the predominant language of the Irish people for most of our recorded history. By the tenth century Middle Irish was spoken throughout Ireland, Scotland and the Isle of Man; indeed, a common Gaelic literary language was used in Ireland and Scotland until the 15th century. Though Gaelic power and culture suffered in the century after the Anglo-Norman invasion, by the end of the thirteenth century "confidence had returned and the educated families of Gaelic Ireland embarked on a 300-year period of tremendous energy in the production of poetry, legal commentaries, translations of European medical treatises and works of genealogy and Irish history."[15] However by the seventeenth century, the language had lost its ascendancy and the dominant land-owning, merchant and professional classes were English.[16] As a result of economic pressures and British government prohibition of the use of Irish in public life, by the eighteenth and early nineteenth century, Irish was largely the language of the poorest sections of society. The Great Famine (1845 – 1849), and the socio-economic upheaval that followed, decimated the language. However, by the end of the nineteenth century, a vibrant language revival movement emerged in the form of the Gaelic League (Conradh na Gaelige). The creation of the Irish Free State institutionalised the language and

… government efforts to promote Irish, especially by maintaining the viability of the Gaeltacht, the remaining Irish-speaking areas, and insisting on compulsory instruction in schools, have thus far attained only limited success.[17]

The term "Gaeltacht" describes areas where the Irish language is considered the vernacular language. Ireland's Gaeltacht's were defined by a Government-appointed commission in 1926 and the boundaries were redrawn in 1956. It amounts to a total of 155 District Electoral Divisions, covering extensive parts of counties Donegal, Mayo, Galway and Kerry, all of which are on the western seaboard, together with parts of counties Cork, Meath and Waterford.

[15] Duffy, 2000, 44.
[16] *Duffy, Atlas of Irish History, 2000*, 94.
[17] *Duffy, Atlas of Irish History, 2000*, 94.

Consolidated figures for numbers of speakers and volume of Irish use in the Gaeltacht, have been available since the mid-1920s with the government-appointed "Coimisiún na Gaeltachta" report of 1926 and the population census of the same year. The former recommended that the Gaeltacht, which until then had no administrative existence, be defined on a two-tier basis – what came to be known as *Fíor Ghaeltacht* (above 80% Irish-speaking) and *Breac-Ghaeltacht* (between 25% and 80% Irish-speaking).

The *Comprehensive Linguistic Study of the use of Irish in the Gaeltacht* (2007)[18] conducted on behalf of the Department of Community, Rural and Gaeltacht Affairs (now the department of Art, Culture and Gaeltacht) updated these definitions into categories based on percentage of daily Irish speakers and sociolinguistic profiles for each type of community:

- Category A (over 67% Irish-speaking)
- Category B (between 44% and 66%)
- Category C (less than 40%)

The position of the Irish language in the Gaeltacht is very fragile as a result of continuous erosion by a wide array of forces including the mass media, the provision of State services through English, popular culture and the historical and contemporary dominant status of the English language in Irish society. Furthermore, there has been a weakening of the language as a result of people coming to live in the Gaeltacht from elsewhere who have little or no Irish. While there is evidence that there is a high level of awareness of the importance of Irish in the community life of the Gaeltacht, there has been a major reduction in the numbers of parents using Irish as the first language of the household and in the use of Irish among young people in the Gaeltacht. With respect to the education system, primary schools contribute greatly in supporting and fostering the language as a community language, but post-primary education is frequently provided outside the Gaeltacht area and/or within a local town where English usage is more prevalent. For a multitude of reasons, Irish has almost ceased to be, and in some cases no longer is, the community language in a number of Gaeltacht areas.

The Government's *20-Year Strategy for the Irish Language 2010 - 2030*[19], has the principal objective of increasing on an incremental basis the use and knowledge of Irish as a community language. Specifically, the Government's aim is to ensure that as many citizens as possible are bilingual in both Irish and English. It is an integral component of the Government's Irish language policy that close attention be given to its place in the Gaeltacht, particularly in light of research which indicates that the language's viability as a household and community language in the Gaeltacht is under threat.

The total population of all Gaeltacht areas in April 2016 was 96,090[20], down 0.6 per cent from 96,628 in 2011. Of these, 63,664 or 66.3 per cent, indicated they could

[18] Comprehensive Linguistic Study of the use of Irish in the Gaeltacht – Principle Findings and Recommendations – 2007: Research Report prepared for the Department of Community, Gaeltacht and Rural Affairs (http://www.pobail.ie/en/AnGhaeltacht/LinguisticStudyoftheGaeltacht/)
[19] http://www.ahrrga.gov.ie/app/uploads/2015/07/20-Year-Strategy-English-version.pdf
[20] CSO 2017, 69.

speak Irish, while 20,586 (21.4% of the total) indicated they spoke Irish daily outside the education system. This represents a fall of 11.2 per cent on the 2011 daily Irish speakers figure of 23,175. The number of people in Gaeltacht areas who indicated they spoke Irish less often than weekly decreased by 0.7 per cent from 16,244 to 16,137.

There are a large number of pre-school, educational, arts, sports, entertainment and employment organisations working on the ground throughout the Gaeltacht. These include community-based companies supported by Udarás na Gaeltachta. There are also a sizeable number of language-based enterprises operating through Irish. The following important organisations are based in the Galway Gaeltacht: Acadamh na hOllscolaíochta, TG4, RTÉ Raidió na Gaeltachta and An Coimisinéir Teanga.

18.3.6.2 The Galway Gaeltacht

The Galway Gaeltacht is the most populous of the country's Gaeltacht areas. It stretches for approximately 100km from Baile Clár, east of Galway City to Cloch na Rois in West Connemara. According to the 2011 Census, there were 48,907 people living in the Galway Gaeltacht. Of those aged 3 or over (a figure of 46,703), 66.3% (or 30,978), indicated an ability to speak some level of Irish. A total of 13,790 stated that they spoke some level of Irish every day (representing 29.5% of the population of the Galway Gaeltacht over the age of 3 years old). Approximately 15,300 of the total Galway Gaeltacht population resides within the suburbs of city.[21]

In 1926, the rural districts with the highest proportion of Irish-speakers were situated in the western half of the country. In 1956, the official Gaeltacht boundaries were officially revised. While the total Gaeltacht population in the state fell by nearly one fifth, the Galway Gaeltacht had an overall loss of just 1%; however, the Fíor–Ghaeltacht areas declined by 12%. The larger Breac-Ghaeltacht areas, which included Galway City, maintained their 1926 level.

The patterns of language usage in the Galway Gaeltacht during the period closely resemble those of 1926. Again, only three rural districts – Galway, Oughterard and Clifden – contained significant proportions of households in which Irish was the sole or main language in normal use. However, in all districts, there is evidence of a shift towards English. The revision of the Gaeltacht boundaries was designed to positively impact on Irish language use in both Breac- and Fíor–Ghaeltacht areas. It redefined the Galway Gaeltacht almost entirely within the boundaries of the three most western and rural districts – Galway, Oughterard and Clifden, omitting English-speaking pockets in these areas, and the Breac-Ghaeltacht areas in the eastern rural districts of Galway. Within the 1926 boundaries, the Gaeltacht in 1956 contained a population of 104,896, but the revised boundaries had a population 28,878.

Between 1956 and 1971, overall population levels in the Galway Gaeltacht declined, but then showed a sharp increase in the 1970s; however, patterns were different between the Galway rural districts and remaining areas. In the 1956-71 period, population levels in this district were stable, while in the 1971-81 period, they increased by 45%. By contrast, Clifden and Oughterard experienced

[21] Galway City Council (2016, 99)

significant population loss until 1971; after which only slight gains were seen up to 1981. Many of these changes are clearly related to the growth of Galway City, with the areas closest to the city experiencing the strongest population growth – in the region of 43%. As the population increased, the ratio of Irish speakers decreased. In the coastal zone between Galway City and Indreabhán (Inverin), population increased by 24%, but there was a language shift to English, particularly close to the city. In Bearna, for example, only 60% of the population were classed as Irish speakers, however this ratio increased to 92% towards the west of the county. Very high levels of Irish speaking (+90%) in the Galway islands were maintained.

Both the demographic and linguistic trends in the country's Gaeltacht areas forced a major reappraisal of government policy in the late 1950s and 1960s. This reappraisal included the abandonment of the policy of relying on agriculture for a sound economic base, and in the provision of a Government department dedicated to the Gaeltacht. As late as 1966, 72% of the workforce of the Galway Gaeltacht was still employed in agriculture. Over the following 15 years, this decreased to 41%. The establishment of Údarás na Gaeltachta in 1980 saw a greater emphasis on industrial development within Gaeltacht areas. From the 1970s onwards, Galway City grew increasingly important as a centre of third-level education and employment. In the recent 2016 Census, amongst the cities in the state, Galway City and its suburbs had the highest proportion of population who spoke Irish on a daily basis (3%).[22]

18.3.6.3 Planning context

The 2000 Planning and Development Act outlined the principle that all Local Authority County Development Plans should set out objectives in relation to the linguistic heritage of Gaeltacht areas within the county in question, these should include:

> *The protection of the linguistic and cultural heritage of the Gaeltacht including the promotion of Irish as the community language, where there is a Gaeltacht area in the area of the development plan*[23]

Subsequent Planning and Development Regulations (2001) from the Department of the Environment, Heritage and Local Government contain, within Article 33, the basis for the requirement that a Language Impact Assessment be prepared for a planning application within a Gaeltacht area.

Significant further requirements for public bodies to ensure better availability and a higher standard of public services, including the planning process, through Irish were enforced under the Official Languages Act, 2003.

The Gaeltacht Act 2012 was enacted with two primary objectives: (a) to provide for a new definition for the Gaeltacht and (b) to make amendments to the structure and functions of Údarás na Gaeltachta. The Act envisages that the Gaeltacht will in future be based on linguistic criteria instead of on geographic areas which has been

[22] http://www.cso.ie/en/releasesandpublications/ep/p-cp10esil/p10esil/gag/
[23] Planning and Development Act 2000, Section 10.2m

the position to date. Language planning at community level will be central to the new definition of the Gaeltacht.

Both Galway City and County Councils have policy goals and objectives in relation to the Gaeltacht and the Irish Language. Of most relevance to the Galway Gaeltacht has been the County Council's *Gaeltacht Local Area Plan 2008–2018* (which was amended in 2013). However, the Variations No. 2a and 2b to the Galway County Development which were adopted incorporate the Bearna Local Area Plan as amended and Gaeltacht Local Area Plan (LAP) as extended into the County Development Plan respectively[24]. This proposed variation, in conjunction with the County Development Plan, will inform and manage the future development of the Bearna and Gaeltacht areas. The Gaeltacht LAP as extended consists of the plan context, strategy, overview of the Districts and settlement plans for An Cheathrú Rua and An Spidéal. A number of other settlements in the Gaeltacht have their own Local Area Plan, for example Maigh Cuillin has a plan in situ until 2019.

18.3.6.4 Language Profile

The proposed road development traverses the following Electoral Divisions (EDs):

- Bearna (part) (County Galway) (CSO Area Code ED 27044)
- Bearna (Galway City) (CSO Area Code ED 26003)
- Rahoon (CSO Area Code ED 26015)
- Dangan (Galway City) CSO Area Code ED 26006
- Galway Rural (Part Rural) (CSO Area Code ED 27052)
- Mionlach (CSO Area Code ED 26010)
- An Caisleán Gearr (CSO Area Code ED 26004)
- Baile An Teampaill (Part Rural) (CSO Area Code ED 27042)
- Baile An Bhriotaihg (CSO Area Code ED 26002)
- Ballybaan (CSO Area Code ED 26001)

Of these, the EDs of Rahoon, Dangan, Galway Rural (Part Rural) and Ballybaan are not within Gaeltacht district, while the western portion of Baile an Teampaill (Ballintemple) is within the Gaeltacht. The proposed road development extends through an area of the Galway Gaeltacht which abuts and surrounds Galway City. Since the 1980s, this area has experienced rapid population growth and urban expansion. Critically the majority of the population is not of Gaeltacht origin and the use of Irish as the "family" language has continued to decline.

Table 18.13 below presents the percentage Irish speaking population (aged 3 years and over) in the District Electoral Divisions through which the proposed road development passes, and percentage of daily Irish use in 2011 and 2016. For this study, daily usage is defined by the number of people (a) speaking Irish daily within

24 http://www.galway.ie/en/services/planning/developmentplansandpolicy/galwaycountydevelopmentplan2015-2021/

and outside the education system and (b) those speaking Irish daily outside the education system only.

Table 18.13: Language usage within the District Electoral Divisions through which the proposed road development will pass (based on CSO Small Area Population Statistics 2011 and 2016)

District Electoral Division	Total Population aged 3 or over		% Irish-Speaking		% Daily Irish Use	
	2011	2016	2011	2016	2011	2016
26003 Bearna (Galway City)	13,564	14,461	52.1%	50.0%	5.6%	4.8%
27044 Bearna (part) (County Galway)	3,462	3,586	66.4%	65.8%	7.9%	6.4%
27052 Galway Rural (Part)	123	146	65.0%	49.3%	8.9%	6.8%
26015 Rahoon	2,854	2,946	42.5%	42.8%	4.0%	2.8%
26006 Dangan (Galway City)	3,572	4,021	50.53%	47.3%	3.2%	2.4%
26010 Mionlach	4,823	4,960	44.8%	43.3%	3.5%	2.9%
26004 An Caisleán Gearr	3,912	3,894	37.0%	35.8%	2.6%	2.6%
27042 Baile An Teampaill (Part Rural)	1,402	1,424	50.7%	50.1%	2.1%	2.9%
26002 Baile An Bhriotaihg	865	915	39.2%	36.9%	3.2%	2.7%
26001 Ballybaan	11,482	12,271	33.8%	31.6%	1.8%	1.8%

These figures indicate that the daily usage of Irish (outside of the education system) within the environs of the proposed road development varies from just less than 2% to less than 8% (though the highest percentage was recorded within the least populated Electoral Division (Galway Rural ED 27052)). It is fair to say that while Irish is a community language within the study area for the proposed road development, it is far from being a dominant or significant one.

18.4 Characteristics of the Proposed Road Development

A detailed description of the proposed road development and construction activities are provided in **Chapter 5, Description of Proposed Road Development** and **Chapter 7, Construction Activities**. This section outlines the characteristics and activities of the proposed road development of relevance to human beings, population and human health.

18.4.1 Construction phase

An east to west build sequence is likely to be adopted and construction may be completed in two concurrent phases or a single overall contract:

- Phase 1 – N6 Coolagh to N59 Letteragh Junction – 9.9km (Including the N59 Link Road North and South)
- Phase 2 – N59 Letteragh Junction to R336 Coast Road west of Bearna - 7.5km

It is estimated that the main construction period will last for approximately 36 months. A variety of construction activities will occur simultaneously at a number of locations along the proposed road development, but will be phased at any particular location.

Construction of the proposed road development will include activities such as excavation, embankment and structural construction, tunnelling, piling, rock breaking and movement of materials within the fenced off working area. This will generate noise, dust and movement of machinery which will impact on human beings, population and human health. The duration of these works will vary. Construction will be undertaken using internationally accepted methods, for example working hours and noise and screens and in a manner which will minimise, as much as possible, any disturbance to the local residents and road users. Refer to **Chapter 7, Construction Activities** for further details of construction activities. Refer to **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration** for details on potential air and noise impacts during construction.

The proposed road development has been designed to avoid as many residential properties as possible, but given the built environment and the linear development of the city with housing along most roads radiating out of the city, its construction will unfortunately and unavoidably result in a number of property demolitions or acquisitions in particular areas. At some locations, a high proportion of the total number of properties in a cluster will be acquired as part of the proposed road development. As well as the direct adverse impact on the householders themselves, this will present a varying negative impact on remaining residents depending on the strength of community interaction that has evolved at each location and the sustainability of community facilities such as schools.

Commencing the description at Bearna, much of the construction work here will occur in a rural setting. However, the high number of one-off dwellings in this area will result in the demolition of some properties. Other residents will be in close proximity to construction works and associated impacts. To the north of Bearna, an overbridge is proposed between the Foraí Maola Road (Na Foraí Maola Junction) and the L5387 Troscaigh Road (Troscaigh Junction) to provide continued access in a north-south direction along both roads. At Ch. 2+500 the proposed road development will sever the L-13215 Ann Gibbons Road with access to the north provided instead by the L1321 Bearna to Moycullen Road which will meet the proposed road development at the Bearna East Roundabout. Temporary realignments will be required on the Aille Road to allow for bridge construction and traffic management at other locations where local roads cross the construction works.

A signalised junction (Cappagh Road Junction) is proposed between the proposed road development and Cappagh Road. This junction will facilitate access to the proposed road development for the community of Boleybeg to the north and for the Western Distributor Road to the south, enabling use of the proposed road development as an alternative to the R336 through Bearna for many journeys. A crèche is also located to the north of the proposed roundabout at Cappagh Road.

Another signalised junction with the Ballymoneen Road (Ballymoneen Road Junction) provides for access to the Rahoon Road and the hinterland around it including Ballyburke, as well for journeys to the communities of Boleybeg and Keeraun to the north-west and Mincloon to the south. A temporary night-time closure of Rahoon Road will be required to facilitate overbridge construction.

The N59 Link Road North and South will be constructed in a largely rural area. Six local access roads will be constructed on the southern section as required, including a realigned entrance to the Rosán Glas Estate. However, there will be a minimum impact on local traffic as most of this section is offline of the current road network. New link road access will be provided to the Gateway Retail Park, replacing the existing access from the Gort na Bró roundabout with a signalised junction. The N59 Letteragh Junction itself will entail large-scale construction works including the excavation of cuttings. A temporary night-time closure of Letteragh Road will be required to facilitate overbridge construction.

The proposed road development then crosses the N59 Moycullen Road in Dangan in the vicinity of the Ard na Locha and Augnacurra estates north of the junction with Circular Road. Night-time closures of the N59 Moycullen Road will be required along with temporary traffic management for diversions. The construction of the River Corrib Bridge will occur through an area of high recreational value at the NUIG Sporting Campus.

East of the River Corrib, a temporary diversion of Coolough Road may be required during the construction phase. The proposed road development will be elevated on a viaduct structure (Menlough Viaduct) east of the Coolough Road before entering the proposed Lackagh Tunnel from where it proceeds to connect with the N84 Headford Road at a grade separated junction. Temporary night-time closure of existing roads may be required at locations such as the Menlo Castle Bóithrín, Bóthar Nua and An Seanbóthar where overbridges are to be constructed.

A temporary diversion of School Road will also be necessary to allow for bridge construction. Major construction works will be required in the vicinity of the N84 Headford Road and N83 Tuam Road and temporary night time closures and diversions may be required. A grade separated junction is proposed with the N83

Tuam Road. An access road connecting with the N83 Tuam Road will provide a connection to six residential properties within the established community of Cappanabornia. Major excavation works will be required on the hill on the eastern side of N83 Tuam Road and for the Galway Racecourse Tunnel. The Parkmore Link Road and City North Business Park Link will be constructed in advance to maintain access. Further east, temporary night time closures of the R339 Monivea Road and Briarhill Business Park Road may be necessary. The existing junction with R339 Monivea Road is regularly congested by commuting traffic heading to the nearby office parks and construction traffic management will be required to minimise construction impacts.

18.4.2 Operational phase

Once operational, the proposed road development will enable the reallocation of existing road space within the city to public transport and smart mobility measures and provide an additional crossing of the River Corrib. This will alleviate congestion within Galway City which will result in reduced air and noise pollution. It will facilitate a more efficient public transport system and the provision of a multi-modal choice of travel including walking and cycling. The transfer of traffic will provide for improved journey times and journey amenity for all road users as well as reduced community severance along existing roads and a reduction in traffic noise along sections of these roads. There will also be positive impacts on general amenity and potentially the well-being and health of the local population due to the transfer of a proportion of the current high volume of traffic from existing busy urban streets. The proposed road development itself will facilitate the crossing of the River Corrib without having to negotiate the city and improve connectivity for the city either side of the River Corrib. It will also provide essential city street links to better distribute traffic.

18.5 Evaluation of Impacts of the Proposed Development

18.5.1 Introduction

This section of the chapter evaluates the potential impacts for the ‘Do-Nothing’ scenario followed by an assessment of impacts for the ‘Do-Something’ scenario during the construction phase and then the operational phase under the headings of journey characteristics, amenity, community severance, economics and tourism, Irish Language and human health.

18.5.2 ‘Do-Nothing’ Impact

18.5.2.1 Journey characteristics

The ‘Do-Nothing’ scenario of the proposed road development assumes the proposed road development is not built and that traffic management plans within the Galway City area are not in place. There is likely to be a continuation and worsening of the poor journey characteristics experienced at present due to traffic congestion. In line with traffic growth factors, traffic volumes will continue to increase along existing routes accessing Galway City. Over half of Galway's working population commutes from surrounding areas and must enter the city via one of the main radial arteries, often connecting to the congested existing N6 to reach employment destinations in the east or west. Regular delays, especially at peak hours, will continue as a characteristic of poor journey time reliability. Rat-runs on local roads which are not designed for such traffic volumes will continue to increase which has an associated safety risk. Such congestion would also undermine the potential to fully realise future development objectives such as the Ardaun LAP. Opportunities for improved public transport and the promotion of sustainable modes of transport such as walking and cycling will be restricted by the need to accommodate vehicle traffic flow.

18.5.2.2 Amenity

The high volume of private and commercial vehicle traffic within the city will also continue to provide for poor journey amenity and discourage walking and cycling together with the associated health benefits. The continuing need to accommodate traffic flow in response to a rising trend in traffic volumes will restrict opportunities to dedicate extra space to pedestrians, cycling and public transport, and make it more difficult for the city to realise its objective of concentrating new development within the city boundary. In addition, the general amenity of people living alongside the existing N6 and other major access roads will continue to be effected by traffic noise and poor air quality.

18.5.2.3 Community severance

The need to accommodate traffic flow restricts opportunities to provide crossing facilities. Combined with the poor journey amenity noted above, this will maintain the high levels of community severance that are currently experienced along major roads such as the existing N6 and could confine some vulnerable groups such as elderly people and children within particular communities surrounded by busy roads. The preceding demographic analysis highlights the presence of relatively high levels of disability in neighbourhoods surrounding the existing N6.

18.5.2.4 Economic and tourism

High traffic volumes combined with congestion will stifle economic development and limit the ability of Galway City and its environs to realise its status as a Gateway City. The city's ability to attract new business and investment will be greatly constrained by regular traffic congestion and poor journey time reliability. A 'Do-Nothing' scenario will also remove the opportunity for improved connectivity to economically peripheral communities in the west of County Galway. Although Galway City is already a major destination for tourism, the potential for tourism development will be inhibited by a continuation of the high level of traffic volumes and congestion. The experience of visitors may be diminished by delays experienced traversing the city and by the experience of heavy congestion on city streets. In particular, high traffic volumes and congestion experienced in an unfamiliar city will reduce the willingness of tourists travelling by car to enter the city centre to visit key destinations and to contribute to the local economy.

18.5.2.5 Irish Language

In the ‘Do-Nothing scenario, the proposed road development is not built, the Irish language usage profile of Galway City and its suburban periphery is likely to be unchanged. However, settlements and industrial activity located within the Gaeltacht areas further west of the city will continue to experience peripherality and disadvantage in terms of long commuting times and transportation delays. The lack of adequate connectivity has been identified as a significant barrier to the long-term sustainable economic development of the Gaeltacht by agencies such as Údarás na Gaeltachta.

18.5.2.6 Human Health

Traffic demands in Galway City and its environs will continue to grow whether the proposed road development proceeds or not (**Chapter 6, Traffic Assessment and Route Cross-Section**). The number of people living in Galway City and its environs has increased and is likely to continue do so as set out in the zoned areas in the City Development Plans. The most recent Census 2016 shows that the population of Galway City has increased by 5.8% since 2011 to 79,934.

Negative impacts (dust, noise, nuisance, etc.) currently experienced by people from traffic congestion on existing routes will continue and potentially increase as traffic increases.

From a noise point of view, the increase in traffic demands on the existing road network will result in increased noise levels over and above the current scenario at properties located along the main national and regional roads. Noise levels at properties identified as ‘hot spots’ and areas for noise management within the Galway City Noise Action Plan (2013–2018) will remain above the threshold noise levels for noise management and are likely to be further increased as a result of increased traffic volumes. Refer to **Chapter 17, Noise and Vibration** for further details on noise impacts in the ’Do-Nothing’ scenario.

In the ‘Do-Nothing’ scenario, traffic congestion will persist within Galway City and its environs with vehicles continuing to go through congested city centre routes with slow average speeds giving the potential for greater particulate emissions. Particulate emissions have received particular attention in recent years given increasing evidence of their health effects.

In the ‘Do-Nothing’ scenario, there would also be potential adverse impacts on social interaction and inclusion due to a persistence of high levels of severance along existing roads and the potential that this has for containing populations within particular neighbourhoods combined with the direct discouragement to the movement of sensitive groups. The risk of road accidents will continue, particularly for pedestrians and cyclists, due to the need to ensure traffic movements which may restrict opportunities for new dedicated crossing facilities and a reduced availability of road space for footpaths or cycle lanes.

18.5.3 'Do-something' - Potential Construction Impacts – Socio-Economics

18.5.3.1 Introduction

As discussed in **Section 18.4.1**, the proposed road development will entail a significant level of construction works over a period of approximately 36 months, although works in individual locations may continue for a few days to a few months. For the most part, construction work will occur in a rural setting, but in some locations there are concentrations of houses, distinct communities or a high density of individual properties. There are potential impacts in relation to residential property demolitions, temporary road closures or diversions, construction traffic and general amenity. Refer to **Chapter 7, Construction Activities** for further details of construction activities.

18.5.3.2 Journey characteristics

Temporary realignments, temporary night-time closures and stop-go arrangements will be required where minor roads meet construction works. Most impacts associated with these arrangements are likely to be imperceptible to slight negative in extent. The temporary diversion of Aille Road will not impact significantly on accesses or use of the road. Temporary night-time closures will present a slight impact at Rahoon Road and Letteragh Road.

Construction works in the area of the N59 Link Road South will occur in a largely rural area and present only slight impacts on local traffic movement. Along the mainline of the proposed road development, only temporary night-time closures of the N59 Moycullen Road are anticipated during which diversions will be provided.

The temporary diversion of Coolough Road (Bóthar Nua) will not impact significantly on access or use of the road. Likewise, a temporary diversion of School Road, Castlegar will not impact significantly on access to Castlegar National School (which includes Beoga pre-school), the nursing home or residential properties as it is a diversion which is immediately off-line of the existing road within the proposed road development.

Major construction works will be required in the vicinity of the N84 Headford Road and N83 Tuam Road. Temporary night time closures and diversions may be required on the N84 Headford Road, N83 Tuam Road, Briarhill Business Park Road and R339 Monivea Road and this will present some slight to moderate negative impacts on the journey time for people using the road at this time.

Refer also to **Table 18.14** and **Table 18.15** which summarises socio-economic impacts, mitigation measures and residual impacts in relation to journey characteristics during construction.

18.5.3.3 Amenity

General amenity

West of River Corrib

In some cases, residents will be in close proximity to construction works with consequent implications for noise emissions, air emissions and visual impacts. During the construction phase noise monitoring will be undertaken at the nearest sensitive locations to ensure construction noise limits are not exceeded. The selection of monitoring locations will be based on the nearest sensitive buildings to the working area as detailed in **Chapter 17, Noise and Vibration**. Refer to **Chapter 17, Noise and Vibration**, **Chapter 16, Air Quality and Climate**, and **Chapter 12, Landscape and Visual** for details on specific respective impacts.

For example, at Na Foraí Maola and the Troscaigh Road, there are over 30 properties that are located close to the route of the proposed road development and which could experience noise or air quality impacts due to construction works. The same observation applies to the proposed signalised junction with Cappagh Road where a crèche is also located. Material excavation, including the likely use of blasting, will be required at Ballard and at Letteragh. There is a cluster of properties in the community of An Chloch Scoilte close to the first of these blasting locations. See also **Chapter 17, Noise and Vibration** and **Chapter 16, Air Quality and Climate** for more details on construction noise and air impacts. Refer to **Chapter 9, Soils and Geology** for details on the blasting locations. Refer to **Chapter 12, Landscape and Visual** for details on visual impacts during construction at this location and other locations across the length of the proposed road development.

During the construction of the N59 Link Road North, there is a likelihood of impacts due to visual intrusion in the vicinity of Barnacranny, including St. James' Church, Bushypark and for visitors to its cemetery (see also **Chapter 12, Landscape and Visual** and **Chapter 17, Noise and Vibration**). To the south, works will be of a moderate scale, including for residential areas located beside connecting access roads from the N59 Link Road South. Only slight to moderate impacts on general amenity prior to mitigation would be anticipated, for example where the link road will be constructed along the edge of the Rosán Glas estate in Rahoon, including realignment works at the entrance to the estate, and similarly slight negative impacts due to realignment of Gort na Bró Road where this provides access to Gort na Bró estate. By comparison, the N59 Letteragh Junction itself will entail large-scale construction works including the extensive excavation of cuttings. Although in a largely rural area, these excavation works will present negative amenity impacts on the nearby small communities at An Chloch Scoilte and Knocknabrona and a proportion of other properties in Ard na Locha and Aughnacurra. See also **Chapter 17, Noise and Vibration**. Similarly, construction works on the N59 Link Road North will entail the excavation of a cutting before its connection with the N59 Moycullen Road. St. James' National School, Bushypark is located close to the construction works for the proposed road development, but neither the school nor its playing fields are located within the proposed development boundary. The route of the mainline of the proposed road development crosses the N59 Moycullen Road at Ard an Locha. Again, refer to the relevant chapters noted above for specific details on potential air, noise and visual impacts at specific locations.

To the east of the N59 Moycullen Road, the design of the proposed road development includes a viaduct across the NUIG Sporting Campus rather than an embankment and therefore provides for permeability beneath the proposed road development, reducing the potential impacts on the campus. The construction of this viaduct however, will have a very significant negative impact on local amenity, including the use of playing fields during the pre-mitigation phase. The sporting campus covers a large area and consists of a number of playing pitches for hockey, GAA and rugby, a sports pavilion and a running track. There will be a direct impact on part of the sports pavilion and on two playing pitches, one of which has flood lighting with the other having planning for conversion to a 3G pitch with flood lighting. During the construction phase, the central part of the Sporting Campus will become a construction site for a period of approximately 18 months. Access across the site will be maintained, but restricted for safety purposes. Construction traffic and works for the River Corrib Bridge will be managed to minimise interference with sporting activities and spectators. The existing sports pitches adjacent to the River Corrib will be unavailable for use while replacement pitches are constructed over a period that is likely to be nine months. However, as set out in **Chapter 15, Material Assets Non-Agriculture**, alternative pitch facilities will be provided to replace the existing pitches directly impacted by the proposed road development. The new facilities will include a floodlit 3G GAA pitch and a floodlit 3G training area. Associated site infrastructure will be provided for the drainage of these pitches along with furniture such as ball-stop netting and modification of the sports pavilion. Once these facilities are constructed they will be available for use within approximately one month.

The viaduct will extend to a bridge crossing of the River Corrib. Access to the bank of the River Corrib which is used as a local amenity and the river itself will be restricted at times during construction. The elevated works will have an impact on amenity use (see also **Chapter 12, Landscape and Visual**, and **Chapter 17, Noise and Vibration**), although the scale of the construction works on the bridge could also attract other temporary interest from members of the public wishing to view the bridge construction.

East of River Corrib

East of the River Corrib there will be a slight negative amenity impact resulting from the location of a proposed construction compound off Menlough Castle Bóithrín. The proposed road development will be elevated on a viaduct structure (Menlough Viaduct) after the Coolough Road. This will introduce construction noise and visual impacts (see **Chapter 12, Landscape and Visual**, and **Chapter 17, Noise and Vibration**). The existing An Seanbóthar unsurfaced road provides a loop connection for occasional walking between the communities of Coolagh and Menlough. It will be used by some construction traffic to access the works and this will impact on local amenity use. Upgrading of the bóithrín will be required to allow for this construction traffic and a subsequent connection to an emergency exit road for eastbound traffic entering the proposed tunnel. Given that the lane is currently free of motorised traffic with the exception of farm access, its use for construction traffic will present a moderate negative impact for some local people who use the Bóithrín for amenity.

The Lackagh Tunnel is located away from residential or amenity use. At the N84 Headford Road, a large proportion of the total number of residential properties will be acquired within the vicinity of the proposed N84 Headford Road Junction. Noise impacts are likely for adjacent properties which remain. The same observation applies in Castlegar in the vicinity of Hynes Bóithrín and School Road. Whilst there is no direct impact on Castlegar National School, the school does have an autistic facility which would be sensitive to construction noise which is assessed below in **Section 18.5.5**. Again, refer to **Chapter 12, Landscape and Visual**, **Chapter 15, Material Assets Non-Agriculture**, **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration** for specific details on air, noise, visual and material asset impacts at specific locations.

An impact on general amenity will apply for at least six households at Cappanabornia which are located beside the N83 Tuam Road. This impact arises from the construction of a new access road in the vicinity of the N83 Tuam Junction and the visibility of construction works on the hill facing these properties on eastern side of the N83 Tuam Road (refer to **Chapter 12, Landscape and Visual**).

A construction works programme will be agreed with Galway Racecourse for the proposed 230m cut and cover tunnel. The programme will involve the cessation of construction works during the summer/autumn racing schedule to avoid disruption to participants and spectators of the racing events. Refer also to economic impacts in **Section 18.5.3.5 - Economic** below.

Residential demolitions and acquisitions

From the outset of the design of the proposed road development every effort was made to avoid property demolitions where possible. However, there are still unfortunately and unavoidably a number of property demolitions that are necessary for the construction of the proposed road development and to secure the many benefits of the proposed road development. A total of 44 residential properties will require demolition with an additional 10 residential properties to be fully acquired.

Refer to **Chapter 15, Material Assets Non-Agriculture** for the precise nature of these potential impacts.

The demolition or acquisition of these properties will be a major negative impact of the proposed road development, both for the occupants and at a community level. There will be a clear and very significant impact on the occupants themselves. In addition, where neighbouring or nearby properties remain, there is likely to be a negative impact, of varying significance, on community ties and the amenity of remaining residents.

<u>West of River Corrib</u>

Five residential properties will be demolished at Na Foraí Maola and two residential properties will be acquired. In addition, one landholding with full planning permission for the construction of a residential property will require full acquisition. The boundary of the community is ill-defined and most of these properties are of relatively recent construction. Nevertheless, there are just over 20 residential properties at this location which includes a cul-de-sac off the local road. Consequently, the impact of the loss of five properties is likely to have a significant negative impact for this small community. Two further properties are being acquired in the community of Ballard where residential development stretches along two minor roads to the north.

One residential property will be demolished at Ballyburke, one off the L-1323 Letteragh and two will be demolished and one acquired at Letteragh. Approaching the N59 Moycullen Road, one property will be acquired and one property demolished at Bushypark beside the N59 Link Road North. Near Dangan, two properties will be demolished and one acquired at Ard na Locha, an estate of four houses and two sites for dwellings, and five properties will be demolished and one acquired in Aughnacurra Crescent, an estate of 14 residential properties. (refer to **Chapter 15, Material Assets Non-Agriculture**). These estates function as small communities which are separated from other residential development along the N59 Moycullen Road. Given the size, the level of impact will have an effect at a community level. The high proportion of premises impacted presents a very significant negative impact on the amenity of the remaining residents.

<u>East of River Corrib</u>

East of the River Corrib, two properties will be demolished in Menlough. Construction of the proposed N84 Headford Road Junction will require the demolition of 14 residential properties at this location out of a total of 22. The loss of a high proportion of established properties in this area represents a major impact for the occupants of the neighbouring houses that are directly affected. While there have been changes in occupancy in recent years and neighbourhood interaction is somewhat discouraged by the heavy traffic on the road, the demolitions will nevertheless present a significant negative community impact on remaining properties. Some occupants may return to live in the immediate area or north of the proposed road development where there are pockets zoned for residential development, although most land to the north of the proposed road development is not currently zoned as residential.

To the east, nine residential properties are proposed for either acquisition or demolition in Castlegar, along Hynes Bóithrín (two demolitions) and on School Road (four demolitions and two acquisitions). A strong sense of community exists here, noting also the community focus on the school. While the number of demolitions is fewer than at the N84 Headford Road, a similar scale of negative impact can be expected on both those directly affected and on those who remain.

Three residential properties are due for demolition in Cappananbornia on the east side of the N83 Tuam Road. One further property is proposed for demolition in Ballybrit and two in Briarhill.

Refer also to **Tables 18.13** and **Table 18.14** which summarises socio-economic impacts, mitigation measures and residual impacts in relation to severance during construction.

18.5.3.4 Community Severance

While any physical severance will be temporary in nature, the construction work in the west of the study area, for example at Na Foraí Maola and Cappagh will introduce a sense of social severance between properties and between areas north and south of the proposed road development even though physical connectivity is maintained. Social severance is likely to be felt most acutely by local residents where family members or friends are located on the far side of the proposed road development. However, given that the scale of construction works here will be less than for locations to the east of the River Corrib, this will be slight in degree. The L13215 Ann Gibbons Road will be permanently severed by the proposed road development and this is discussed further under operational impacts in **Section 18.5.4**.

As discussed in **Section 18.5.3.3**, while restrictions will apply for reasons of safety, continuous access will be maintained to the riverbank walk (or temporary diversion of same) and to the current small number of pitches to the north of the proposed River Corrib crossing at the NUIG Sporting Campus. The more significant severance will therefore be psychological rather than physical.

More significant construction related severance will occur in Castlegar where the effect will be of moderate significance despite the maintenance of connectivity.

It is proposed that construction traffic will travel from the western distributor road north along the Cappagh Road to gain site access. Most residential development is to the east of the Cappagh Road and crossing facilities are provided at the Cappagh Park sports complex. Similarly, it is proposed that construction traffic will travel north along the Coolough Road (Bóthar Nua) to gain site access. Construction traffic along the N84 Headford Road south of the proposed junction will present a slight negative severance impact, although new pedestrian crossing facilities are included in the design of the proposed road development along the N84 Headford Road.

18.5.3.5 Economic

The construction works will generate demand for inputs and services. CSO data indicates a gross construction multiplier of 1.5. As this value encompasses all forms of construction including house building, the figure for infrastructure could be somewhat lower given the more intensive use of machinery and import content. On the other hand, the bulky nature of many construction inputs should ensure that much of the income is retained within the State. Many of these inputs will be purchased across Ireland and will therefore contribute to the national economy, although some purchases, of services in particular, will likely to be made from the local businesses providing an economic benefit to these and to local employment.

Through the construction phase there will be some variation in the numbers of staff working on site. It is anticipated there will be 250-270 staff directly employed on site, rising to 300 staff at peak construction. This level of employment will provide a positive economic impact to the local economy in terms of spending on food and accommodation, although a proportion of workers are likely to already reside in

Galway. The employment multiplier implies the creation of one additional full-time equivalent jobs for every two people employed full-time on the project.

<u>West of River Corrib</u>

Impacts on the NUIG Sporting Campus are as described above under **Section 18.5.3.3 – Amenity**. The impact on sports pitches and the sports pavilion during construction can also be expected to have a slights economic impact due to loss of income from use by non-university clubs.

<u>East of River Corrib</u>

A very significant impact is anticipated on a business located on the N84 Headford Road which bottles water and distributes fruit and vegetables. The impact arises from the effect of landtake on one warehouse and an impact on the company's raw material supply.

The proposed road development will cross Lackagh Quarry which is currently inactive. Whilst the quarry is currently inactive there are rock reserves in the upper bench of the quarry. Refer to **Chapter 9, Soils and Geology** for details on potential impacts on future quarry reserves.

At the N83 Tuam Road, the alignment of the proposed road development between here and the eastern end of the Galway Racecourse Tunnel requires the acquisition of a builders providers store and landtake from other commercial businesses. Businesses, including a car dealership and the An Post sorting centre, could be affected by the need for traffic management during construction. The extensive nature of the works associated with the N83 Tuam Road Junction is likely to have a temporary impact on the visibility for customers of the car dealership, although this can be mitigated. There is also potential for environmental impacts on businesses adjacent to the racecourse in the Parkmore Business Park, some of which are engaged in activities that are potentially sensitive to vibration and air quality. See **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration**.

The proposed Galway Racecourse Tunnel will entail the acquisition of lands and the demolition of stables. It is proposed that the stables will be replaced with temporary stables for the duration of the construction of the proposed tunnel until such time as the permanent stables are provided. Both temporary and permanent stables will need to be of at least equivalent quality to the existing stables. Wells used for watering of the track will also be impacted. Works on the tunnel itself will be timed for periods outside of the racing calendar so as to avoid amenity and economic impacts on the functioning of the racecourse See **Chapter 16, Air Quality and Climate**, **Chapter 17, Noise and Vibration** and **Chapter 15, Material Assets Non-Agriculture** for further detail on these impacts and how they will be mitigated and minimised so as not to interfere significantly with business activities.

Approaching the existing Lynch Junction at Briarhill, the construction phase will have an impact on a car dealership located on the edge of the Briarhill Business Park. This will involve landtake mainly from an area that is currently used for customer parking and there will be a need to reconfigure existing services such as the car wash, fuel pump and underground fuel tanks, parts store and waste facilities. In principle, these can be fitted within the residual lands.

18.5.3.6 Tourism

The construction phase will not have a significant impact on tourism as the construction works are, for the most part, located away from areas visited by tourists. The alignment of the proposed road development means that evidence of construction works will be largely outside of the city centre and would not, for the most part be visible to tourist traffic. Tie-ins with the existing N6 will not impact significantly on traffic flow and the attraction of the city for tourism. Traffic diversions on the N59 Moycullen Road, N84 Headford Road or N83 Tuam Road are only proposed to occur at night and as such should not affect tourist traffic. The main potential issue would be racing events at the Galway Racecourse, but as noted above, construction of the cut-and-cover tunnel will proceed intermittently over a three year period to avoid disruption of racing events. Other tourist destinations include the River Corrib corridor and the NUIG Sporting Campus. Construction of the River Corrib Bridge will have a slight temporary negative amenity impact due to works affecting the impact on the natural setting.

Refer also to **Table 18.14** and **Table 18.15** which summarise socio-economic impacts, mitigation measures and residual impacts in relation to economic activity during construction.

18.5.3.7 Ecosystem Services

Ecosystem services provide many varied benefits that humans freely gain from the natural environment. A properly functioning ecosystem has the capacity to regulate and support the natural environment that contributes to human well-being under categories such as (having regard to the Guidance on Integrating Climate Change and Biodiversity into Environmental Impact Assessment (2013)):

- provisioning services e.g. wild foods, crops, forage and fresh water
- regulating services e.g. filtration of pollutants by wetlands, climate regulation through carbon storage, water cycling, pollination and protection from erosion
- cultural services e.g. recreation, spiritual and aesthetic values, education
- supporting services e.g. soil formation, photosynthesis and nutrient cycling

The environmental assessment of the proposed road development has considered potential impacts on ecosystem services through the assessment of the environmental factors (pathways) through which ecosystem services could be affected such as water, soils, air, noise and general amenity and relied on the assessment detailed in **Chapter 8, Biodiversity** in terms of potential impacts to biodiversity and indirectly to ecosystem services. There are no impacts identified in those assessments which would result in a significant residual impact on ecosystem services during the construction of the proposed road development.

18.5.3.8 Summary

In summary, the construction phase will have mostly slight negative impacts on journey characteristics due to local traffic diversions. More major works would be necessary for the N84 Headford Road and N83 Tuam Road, but any diversions are proposed to occur at night when traffic levels are lowest. There will be visual, air quality and noise impacts on properties closest to the works which are addressed in **Chapter 12, Landscape and Visual**, **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration**, but the principal impact relates the residential demolitions and acquisitions required at various locations within the study area (ref **Chapter 15, Material Assets Non-Agriculture**). In three cases, the demolitions represent a high proportion of the total number of properties at a specific location. While subject to financial compensation as part of the compulsory purchase process, this negative impact will be realised most notably by the occupants, but significant impacts can also be expected at the community level addressed in this chapter due to impacts on local identity and community interactions. Significant construction impacts apply to the NUIG Sporting Campus which will be addressed through mitigation measures during the construction phase and further mitigation measures to maintain the integrity of the complex in the following operational phase (see **Section 18.6** below for the proposed mitigation measures).

18.5.4 'Do-Something' Potential Operational Impacts – Socio-Economics

18.5.4.1 Overview

Once operational, the proposed road development will attract traffic from the city centre and this in itself will provide for improved journey times and journey amenity along existing roads. The transfer of traffic will facilitate the reallocation of road space to public transport and the provision of walking and cycling facilities. As a result, there will be positive impacts on general and journey amenity and the health of the local population. The proposed road development will facilitate vehicle crossings of the River Corrib without having to negotiate the city centre and will provide essential links with city arteries to better distribute traffic. This new River Corrib crossing will also provide connectivity back to the city on both the east and west side of the river. There will be positive impacts for Galway City's economy due to improved accessibility and connectivity for commerce, goods movement, tourism and commuting. There will also be positive impacts for areas in the west of the county for which there will be improved connectivity to the east of the country and further potential for economic growth and tourism.

The operational phase of the proposed road development will also introduce some negative impacts, for example noise and visual intrusion, to areas that are currently quiet and semi-rural. It will also introduce an element of social severance between people living north and south of the proposed road development, who, in principle, will remain part of the same wider community.

18.5.4.2 Journey characteristics

The proposed road development will improve connectivity for Galway City and its environs and also areas in the west of Galway County, including access to the N59 Moycullen Road (for Moycullen, Oughterard and Clifden) and the R366 Coast Road (for Rossaveal and Connemara). Connectivity will be improved between the M6 east of Galway, the M17, the N83 Tuam Road, N84 Headford Road and N59 Moycullen Road. The transfer of a proportion of traffic to the proposed road development will help to relieve the level of traffic currently experienced on the existing N6. It will also provide opportunities for new facilities for pedestrians and cyclists as detailed in the Galway Transport Strategy (GTS).

Refer also to **Table 18.14** and **Table 18.15** which summarise socio-economic impacts, mitigation measures and residual impacts in relation to journey characteristics during operation.

West of River Corrib

As the proposed road development commences to the west of Bearna, it is expected to have a significant positive impact by attracting much of the current traffic flow away from the village of Bearna and the western suburbs of Galway City. This will be particularly significant during the morning and evening peak periods when congestion can occur from the 'Twelve Pins' junction in Bearna all the way into the city or due to vehicles accessing shops in the centre of the village. A reduction in traffic and a significant positive impact is anticipated in the village as a reduced level of traffic is predicted to remain on this section of the existing R336 (see **Chapter 6, Traffic Assessment and Route Cross-Section**). The Bearna LAP proposes that the village centre would, in due course, be provided with an inner relief road such that some of this impact could be expected to occur in the future even in a 'Do-Minimum' scenario. Variation No. 2a to the Galway County Development Plan (2015-2021) which has been adopted incorporates the Bearna LAP into the County Development Plan. However, while a relief road on its own would involve through traffic being directed through built-up parts of Bearna, the proposed road development moves this traffic out of the village core.

The Bearna East Roundabout will facilitate access to the proposed road development for the numerous residential households in the vicinity and to community facilities to the north of Bearna including the Bearna GAA Club and the Barna Golf and Country Club. This improved connectivity represents a net moderate positive impact, although some local residents could experience slight delays in accessing community facilities due to the longer journey to cross the proposed road development where currently there is direct access via a single local road. The Bearna East Roundabout will also provide a link to the N59 Moycullen Road although the current poor standard of this road towards the northern end means that most people wishing to make this connection are more likely to use the N59 Letteragh Junction.

A signalised junction (Cappagh Road Junction) will provide access from the proposed road development to the communities of Cappagh, Boleybeg to the north and to the Western Distributor Road and wider Knocknacarra area to the south. A lot of individual residential development has occurred here in recent years and this junction, along with others in this section, will provide a net moderate positive impact in terms of improved local connectivity and journey amenity while also reducing pressure on unsuitable minor roads. It will also improve journey amenity and contribute to the positive impact of traffic reductions in Bearna. The Cappagh Road Junction also provides connectivity to a crèche which is located to the north of the proposed road development.

Overall, the traffic projections indicate that there is likely to be a modest transfer of traffic from the Western Distributor Road to the proposed road development. The Ballymoneen Road Junction would have a moderate positive impact by providing connectivity to Ballyburke and the Western Distributor Road. The connection north to Rahoon Road via Ballymoneen Road is narrow so most other traffic is expected to use the proposed N59 Link Road South from Letteragh Junction.

The proposed N59 Letteragh Junction itself will be a grade separated junction connecting the proposed road development with link roads to Rahoon Road and the N59 Moycullen Road and will provide a very significant positive improvement in connectivity between the western suburbs of Galway and regional destinations. The N59 Link Road South will also provide a connection with the Letteragh Road and thereby also a connection with the dispersed residential communities of Drum and Tonabrocky. As with the above connections to local communities, this will provide for positive impacts on connectivity and journey amenity given the narrow and sub-standard design characteristics of some local roads. The proposed N59 Link Road South will distribute traffic, from the proposed road development, within the suburban area via its connections with several existing local roads to connect with residential areas, retail parks and community facilities. This will provide a degree of relief from traffic pressure in an area which is currently subject to regular congestion.

The connection provided in the other direction by the N59 Link Road North will relieve the congestion currently experienced by traffic attempting to access the N59 Moycullen from the city, including tourist and other traffic heading towards Clifden. Compared with a ‘Do-Nothing’ scenario, relief from congestion would apply especially at the Browne Roundabout given that right hand turns are prohibited from the preceding junction between the existing N6 and Newcastle Road Upper. The connection would provide a very significant positive impact to journey characteristics. Based on traffic predictions, it would reduce slightly the volume of vehicles on the N59 Moycullen Road into Galway City including Circular Road, Thomas Hynes Road and Newcastle Road Upper where educational and other community facilities are located.

Connectivity for pedestrians and cyclists is provided for in the design of the proposed road development. Crossing facilities for pedestrians are proposed for the junctions at Bearna East, Cappagh and Ballymoneen. A pedestrian footpath is included along the N59 Link Road North and a pedestrian crossing sequence will be included in the signalised junction proposed between the N59 Link Road North and the N59 Moycullen Road. The N59 Link Road North and South will include public lighting and pedestrian refuge islands at junctions. A cycle path will be included along the N59 Link Road South. Cyclists will, however, be encouraged to use the shorter existing urban routes which in most cases will provide more appropriate connections between origins and destinations. Traffic will have been reduced on many of these roads as a consequence of the proposed road development.

East of River Corrib

The N84 Headford Road Junction will permit vehicles using the proposed road development to access Ballindooley, Ballinfoyle, Headford, Ballinrobe and other communities such as Cong to the north of Galway City. As with the N59 Letteragh Junction, it will also permit direct access to the proposed road development without the need to enter Galway City. As such, the junction provides a significant positive impact on journey time and amenity to regional locations. The improved connection will also provide people living in Ballinrobe with the option of using the proposed road development for journeys to Dublin and the east as an alternative to the N5 or the lower capacity R661 and N60 roads through Claremorris.

The new accessibility provided by N83 Tuam Road Junction and the Parkmore Link Road to the City North, Ballybrit, City East and Parkmore Business Parks represents a profoundly positive impact on journey characteristics and for the city's economy given the number of companies located here (see **Section 18.5.4.5** below). The Parkmore and City North Business Park Link Roads will provide accessibility to the Parkmore Industrial Estate to the north and to the Ballybrit and City East Business Parks and Morris Junction to the south. The improved accessibility will significantly reduce peak time congestion at the junction between Ballybrit Crescent, the R339 Monivea Road and the existing N6 at the Lynch Junction. The same observation applies at the Morris Junction with the existing N6.

On-road cycle tracks are proposed for the Parkmore Link Road and the City North Business Park Link Road. Lands to the south are zoned for new development and will benefit from the improved accessibility. The connectivity provided by the Coolagh Junction represents no change with the existing baseline situation, but the transfer of much traffic to the proposed road development will relieve traffic pressure relative to the existing junction and reduce delays at the existing Lynch Junction.

18.5.4.3 Amenity

Journey amenity

The combination of new connectivity and transference of traffic provided by the proposed road development and discussed under journey characteristics will have the effect of reducing journey time in many cases, but also of relieving congestion along the existing N6.

Refer also to **Table 18.14** and **Table 18.15** which summarise socio-economic impacts, mitigation measures and residual impacts in relation to amenity during operation.

<u>West of River Corrib</u>

A slight negative impact will arise from the increase in traffic predicted to occur along the R336 between the centre of Bearna Village and the Bearna West

Roundabout on the proposed road development, although there are no community facilities on this stretch of road.

The transfer of traffic to the proposed road development will reduce the level of traffic currently using the local road network to the north of Bearna and linking onto the Rahoon Road and Letteragh Road to avoid the congestion on the R336 and the Western Distributor Road.

The transfer of traffic to the proposed road development will reduce the level of residual traffic on the R336 and Seamus Quirke Road together with the prospect of congestion on these roads and at the Browne Junction providing at least a moderate positive impact. This will present an opportunity to provide continuous urban cycle lane facilities and more pedestrian and cycling crossing facilities in line with the GTS with a lesser risk of such facilities adding to congestion (see **Section 18.7.3 Cumulative Impacts**).

East of River Corrib

The proposed road development will reduce traffic on the existing N6 western approach to the Kirwan Roundabout, also reducing the prospect of congestion at this location despite a prediction of higher traffic volumes on the N84 Headford Road. This will provide a slight to moderate positive journey amenity impact. It will also present an opportunity to provide improved cycle lane and pedestrian facilities in line with the GTS.

The transfer of traffic to the proposed road development will reduce the level of traffic currently using the local road network between the N84 Headford Road and the N83 Tuam Road, along School Road, Castlegar, to avoid the congestion on the existing N6.

Given the access to the city provided by the proposed road development, traffic volumes at the junction between the N83 Tuam Road and the existing N6 are predicted to be slightly higher (3.7%) under a medium growth scenario by the Design Year (2039). Consequently, there is no change in journey amenity for drivers wishing to use the existing junction between School Road or Bothar an Chóiste to Castlegar and the N83 Tuam Road, although peak time use by commuters of this minor road will be reduced by the availability of the proposed road development itself and by reduced traffic on the existing N6 west of the N83 Tuam Road Junction. A 36% reduction in AADT is predicted on the existing N6 in Ballybrit under a medium growth scenario compared with the ‘Do-Minimum’ scenario, along with reduced traffic at the Lynch Junction and Ballybrit Crescent Junction in Briarhill, and at the junction between the existing N6 and the R446 at Doughiska. At all these locations, there will be at moderate-significant positive impact on journey amenity. There will also be opportunities to provide improved facilities for the safety and journey amenity of pedestrians and cyclists.

For users of the proposed road development itself the journey amenity of drivers and passengers using the River Corrib Bridge will be enhanced by the view north and south along the river, including of the ruins of Menlo Castle. This represents a slight positive impact on journey amenity, but one realised by the large number of people using the proposed road development including tourists travelling west to Connemara.

General amenity

West of the Corrib

Traffic volumes on the section of the proposed road development to the north of Bearna are expected to be over 11,000 AADT under a medium growth scenario by the Design Year (2039), but will vary seasonally given summer tourism traffic. General amenity impacts relating to environment effects such as visual intrusion and noise are likely where residential properties are located close to the proposed road development, for example at the Cappagh Road Junction where private properties are located to the immediate north and south. These impacts are addressed in **Chapter 12, Landscape and Visual** and **Chapter 17, Noise and Vibration**. A large increase in traffic volumes will occur on the Cappagh Road albeit from a low baseline level. This will affect the amenity of a small number of properties to the south towards the suburban residential area where the road is necessarily wider. A large increase in traffic volumes is also predicted for the Ballymoneen Road, north and south of the proposed junction.

No significant amenity impact at a community level is presented by the proposed N59 Link Road North and South from the proposed N59 Letteragh Junction. On the southern link, traffic is distributed onto several minor roads and the road itself is largely separated from residential development. The northern link connects with the N59 Moycullen Road immediately to the north of Bushypark Church.

St. James’ School in Bushypark is located a short distance to the south of the proposed road development, but the school lies outside the proposed development boundary. There will be a slight residual negative general amenity impact on use of the playing ground due to the traffic noise, although this will be mitigated by screening. The remaining houses in the estates at Ard na Locha and Aughnacurra will incur an amenity impact due to the proximity of the proposed road development (see **Chapter 17, Noise and Vibration**).

There is a negative general amenity operational impact to the east of the N59 Moycullen Road where the proposed road development will be elevated above the NUIG Sporting Campus on a viaduct prior to the crossing of the River Corrib. Whilst the provision of a viaduct structure will provide access to the north and south of the Sporting Campus and the River Corrib during the operational phase, maintaining connectivity and permeability beneath the proposed road development, the NUIG Sporting Campus will require a new Sporting Campus Plan and Strategy. A best fit analysis was undertaken as part of the assessment which identified the possible reconfiguration of the Sporting Campus, part of which includes the replacement of the two pitches with a a floodlit 3G sports pitch and 3G training area and associated site infrastructure such as ball netting (refer to **Chapter 15, Material Assets Non-Agriculture**). From an amenity perspective there is also a negative impact on visitors to Menlo Castle on the east bank of the river. The positive impact on journey amenity for drivers on the proposed road development must also be acknowledged in this context.

East of River Corrib

To the south of the N84 Headford Road junction, a 38% increase in traffic is predicted to the Kirwan Roundabout, representing a moderate negative amenity impact, noting also the presence of Saint Francis National School and Ballinfoyle Church on this road. Additional pedestrian crossings have recently been provided on the N84 Headford Road.

Whilst there is no direct impact on Castlegar National School, the school does have an autistic facility which would be sensitive to traffic noise (see **Chapter 17, Noise and Vibration** and **Section 18.5.5** below). The proposed road development will have a positive impact by reducing traffic volumes on School Road, Castlegar, which, along with Bóthar an Chóiste, is currently used by morning and evening commuters as a rat-run (see **Section 18.5.4.4** below). Spellman's Boithrín is currently unsurfaced and in poor condition, but forms part of a circular walk that is used daily for access to the school. The nearby Hynes' Boithrín will be severed, but mainly provides only farm access to fields. Alternative access will be provided from School Road, Castlegar to these farm lands. (see **Chapter 14, Material Assets Agriculture**).

At the Parkmore Link Road, east of the N83 Tuam Road, a crossing point is included in the design of the proposed road development to allow for an historic mass path connecting Castlegar and the small community of Parkmore and a historic graveyard to a mass rock beside Galway Racecourse (see **Chapter 13 Archaeology, Architectural and Cultural Heritage**). Only light use is made of the path, but it is well maintained by the local community. There will be a significant negative residual impact on amenity use of the path compared with the existing environment due to the extensive new road network.

The proposed location of the Galway Racecourse Tunnel means that there will be no direct amenity impacts on the racecourse racing events during operation. New permanent access will be available to the N83 Tuam Road via the Parkmore Link Road and much improved access will be possible from the existing N6 such that the net impacts will be positive.

18.5.4.4 Community severance

Distinct physical severance is presented by two permanent road closures proposed along the length of the proposed road development. The first of these is at the northern end of Anne Gibbons Road in the western section of the study area. For most local residents, the severance impact is only slight, but occupants of properties closest to the proposed road development would entail a diversion to the south before returning north on the Bearna to Moycullen Road. Hynes Boithrín will also be severed, but currently provides access solely to fields and some amenity use.

West of River Corrib

The proposed road development will result in a projected reduction in traffic volumes in the east of Bearna Village by over 73% in the Design Year (2039) under a medium growth scenario compared with the 'Do-Minimum' Scenario. This will have a significant positive impact in terms of relief from severance especially away from crossing facilities during peak periods. This significant positive impact applies especially to the use of community facilities. A positive impact will also apply to the Church of Mary Immaculate and to Bearna Primary School on the R336 to the east of the village. Although there are tentative plans for the school to transfer to a new location at some time in the future, most parents must currently drop off their children at the roadside.

To the north, there will be an impact on neighbourhood or social severance as the proposed road development runs between residences at Na Foraí Maola. A similar impact can be anticipated on the Troscaigh Road where there is another cluster of residential properties. A degree of physical severance will arise from the additional distance required to reach the proposed overbridge at Ch. 1+375 from either location, particularly for local residents walking to nearby friends or family. However, the new connectivity provided between the two settlements also provides for relief from severance as currently there is no physical connection between the two communities. A significant impact will arise from the severance of the Ann Gibbon’s Road. This will require residents at the northern end of the road to access locations to the north by detouring 800 metres south to the junction with the Bearna Moycullen Road. Most traffic on this road heads south into Bearna Village, but some of residents also travel north to enter the city via Paddy’s Cross and Rahoon Road.

Elsewhere in this area, to mitigate physical severance, crossing facilities for pedestrians have been included in the design of the proposed road development where junctions exist. There will be a residual level of social severance for scattered communities and housing to the north of the proposed road development as many people express a sense of attachment to Bearna Village.

At Cappagh Road there are properties on either side of the proposed junction, but physical severance will be slight as crossing facilities are available. However, traffic volumes are expected to increase to the south of the junction, potentially affecting access to pitches located to the west of the Cappagh and presenting a slight negative impact, mainly for cyclists given the presence of crossing facilities.

The N59 South Link Road will connect to the Western Distributor Road via Millars Road in Gort na Bró Road. As a result, there will be additional traffic on this road, but this represents only a slight new severance impact on the Gaelscoil Mhic Amhlaigh and Millars Lane soccer pitches, both of which are already well-serviced with pedestrian crossing facilities. New residential development is also proposed for this location. The N59 Link Road North avoids any severance impact until its connection with the N59 Moycullen Road just north of St. James’ Church in Bushypark. Most access to the church is by car and traffic volumes are only predicted to increase slightly, although a footpath does run along the western side of the N59 Moycullen Road and signalised crossing facilities are proposed for the junction between the N59 Link Road North and the N59 Moycullen Road.

The elevation of the proposed road development above playing fields at the NUIG Sporting Campus provides no direct physical severance impact, but rather an impact on amenity. Traffic volumes are predicted to reduce slightly in the Design Year compared with a ‘Do-Nothing’ scenario on Thomas Hynes Road and Newcastle Road, but no significant change in existing severance is anticipated.

East of River Corrib

The proposed road development will introduce a degree of social severance between the small historic community of Coolagh and Menlough to the north. To the east, at the N84 Headford Road Junction, there will be moderate physical and social severance due to the presence of the junction. Physical severance along the N83 is already high due to current traffic volumes, although any new severance is minimised by the inclusion of signalised crossings at the slip roads to the proposed road development. Some new severance can be expected on the Headford Road south due to the increased traffic volumes that are predicted into the city.

No significant severance will be experienced in Castlegar, including for students at Castlegar National School, local residents or for visitors to the new nursing home. Commuting traffic using School Road, Castlegar as a ‘rat run’ is expected to be reduced due to the availability of the proposed road development. To the east at the proposed N83 Tuam Road Junction there is social severance between a line of private properties in Two-Mile-Ditch on the road to the north of the junction and the community of Castlegar. Current pedestrian journey amenity is poor in this area and will be slightly improved by the inclusion of a footpath in the design. Any severance of the Lisheen (fort) at Parkmore east of Galway Racecourse during the construction phase will be mitigated in the operational phase by the new access road and parking provided to the south of the proposed road development.

Refer also to **Table 18.14** and **Table 18.15** which summarises socio-economic impacts, mitigation measures and residual impacts in relation to severance during operation.

18.5.4.5 Economic

The proposed road development will deliver a profoundly positive impact for the Galway economy due to improved accessibility and connectivity for commerce, goods movement and commuters. There will also be positive impacts for communities in the west of the county for whom there will be improved connectivity to the east of Country Galway. There will be improved accessibility for very many businesses, but also direct and indirect negative impacts on others due to the route of the proposed road development.

West of River Corrib

Some loss of passing trade can be expected for a few businesses in Bearna and on the R336, including a small service station due to the transfer of traffic from the R336 to the proposed road development. As local traffic is expected to remain on the existing road these impacts will be slight.

The N59 Link Road North and South will provide much improved access for both customers and deliveries to the Gateway Retail Park and to business parks located off the N59 Moycullen Road and Newcastle Road Upper. Some of the congestion in the vicinity of Browne Roundabout and along Seamus Quirke Road will be relieved benefitting retail and other businesses in these locations. This improved access represents a significant positive impact.

East of River Corrib

Lackagh Quarry is no longer an active quarry. However, there are quarry reserves in the upper benches, some of which will be sterilised as a result of the proposed road development (refer also to **Chapter 9, Soils and Geology**). On the east side of the N84 Headford Road, improved new access will be provided to one commercial business property, although construction works will impact on part of the business' raw material source (see **Section 18.5.3.5**). This impact will be addressed as part of the land acquisition process and financial compensation.

At the N83 Tuam Road, whilst the proposed road development will present some temporary visibility impacts on a car dealership during construction (see **Section 5.3.5**), it will be provided with improved and safer access to the business from the City North Business Park Link in the operational phase. The proximity of the business to the proposed road development will also be a positive factor for familiarity and accessibility. The improved access to the An Post sorting centre located here represents a significant positive impact for this business.

The proposed Parkmore Link Road will provide new access between the N6 and N83, including use of Morris Junction. Currently the only access to the numerous business parks in the area is from the existing N6 and as a result there is major congestion occurring on a daily basis, particularly during peak hour traffic. Consequently, the new link road will provide a profoundly positive economic impact by facilitating connectivity and accessibility for deliveries to numerous businesses and for employees. This link road will also facilitate the provision of the walking, cycling and bus routes as set out in the GTS for the Ballybrit, City East and Parkmore Industrial estates, with the added health benefits of being able to walk or cycle to work.

The Parkmore Link Road will make use of an existing cul-de-sac access road serving Hewlett Packard and Boston Scientific. Boston Scientific recently acquired lands to the east of the existing IDA road comprising the former APC site, a total area of 12.6 hectares. The alignment of the link road has been designed to take account of Boston Scientific's plans to expand the existing facility and utilise the acquired APC site. This expansion involves the redevelopment of the existing buildings and their integration with the new facilities within the APC site. The first phase of the expansion plans includes the construction of a building immediately adjacent to and interlinked with the existing northern building. This will allow product and people to move throughout the expanded site without the need to move from a controlled sterile environment. Elsewhere, it will be necessary for vehicles and workers to cross the link road to access other parts of the landholding that are included in future phases of the expansion plans. Through traffic on the Parkmore Link Road will interrupt the movement of product and people within the Boston Scientific campus. A negative impact can be expected due to severance, but the proposed Parkmore Link Road itself will have a net positive impact by providing a direct transport link, which will be well serviced by public transport between the Parkmore and Ballybrit Business Parks, the N83 Tuam Road, the existing N6 and the proposed road development.

The proposed road development will pass below the Galway Racecourse in a dedicated tunnel. Some modest net loss of car parking is likely, but new permanent stables and facilities will be provided to replace those demolished during construction. These stables and facilities will need to be of an equal or higher standard to the existing buildings. Event day access is already available to the N83 Tuam Road, but this access will be much improved due to the Parkmore Link Road. When all measures are realised, a net positive economic impact can be anticipated.

By improving access between the existing N6 and the business parks in this area, the proposed road development will reduce congestion at Ballybrit Crescent Junction and Lynch Junction and this will have a positive impact on access to businesses at this location. This improved accessibility will apply also to a car dealership on the edge of Briarhill Business Park, although this may be accompanied by some loss of customer parking space and the presence of an elevated section of the proposed road development which will affect visibility from Ballybrit Crescent. The dealership's visibility to the east will be reduced, but it will remain very visible from the existing N6 and highly visible from the proposed road development. A positive impact will derive from the effect of reduced congestion at the Ballybrit Crescent Junction.

18.5.4.6 Tourism

Once operational the proposed road development will provide for improved connectivity between the important tourism destinations of Connemara and West County Galway and points of arrival to the east. This will help to sustain tourist numbers and to provide new tourism development opportunities while contributing to the economic development in a peripheral economic region. The proposed road development will enter an attractive rocky area west of the River Corrib that is typical of Connemara. This landscape therefore represents a gateway to the West. Visitors will quickly experience this setting following the elevated vista of the river. At present, this landscape is only encountered west of Bearna. Overall, the proposed road development's contribution to tourism represents a very significant positive impact.

A significant positive impact also arises from the reduction in congestion along the existing N6 and other roads into Galway City due to the transfer of a proportion of traffic to the proposed road development. This will also contribute to making the city more accessible, encouraging visitors to County Galway and the West to travel into the centre of the city to see attractions with less anxiety over traffic conditions. Combined with the potential for the reallocation of road space to pedestrians and cyclists provided by the GTS, this will contribute positively to the tourism experience in Galway. A positive introduction to Galway will also be provided by the new crossing of the River Corrib which will enhance journey amenity and encourage people to visit this part of the city's fringe. Improved access to the Galway Racecourse, including from the north, could also help to stimulate event attendance.

18.5.4.7 Ecosystem Services

There are no impacts identified which would result in a significant residual impact on ecosystem services during the operation of the proposed road development.

18.5.4.8 Summary

The operational phase will provide for significant, and in some cases very significant or profound, positive impacts on journey time, connectivity and journey amenity affecting journeys for all purposes and benefitting people living in the city or in its outskirts, businesses and visitors or tourist traffic. Particular positive impacts apply to the new connectivity between the existing N6 and N83 Tuam Road, improved connectivity for people living in rural areas in the west of the study area, and to reduced congestion along urban parts of the existing N6. The improved connectivity to West County Galway will stimulate economic development in this region, strengthening the integrity of the Galway Gaeltacht and the Irish language. The transfer of a proportion of through traffic will benefit people living in the vicinity of the existing N6 and provide an opportunity to improve additional public transport and facilities for pedestrians and cyclists under the Galway Transport Strategy. There are some negative impacts in terms of social severance (but less so physical severance) and the general amenity of people living in rural areas near the proposed road development to which they might have been attracted by the prevailing peacefulness of the surroundings. There will be very significant impact on the NUIG Sporting Campus as a result of the proposed road development. A flood lit 3G sports pitch and 3G training pitch and associated site infrastructure such as goal post netting will replace the lost pitches, but a new Sporting Campus Plan and Strategy will be required (refer to **Chapter 15, Material Assets Non-Agriculture**). Overall, the net effect of socio-economic aspects relating to Human Beings is assessed to be a distinct positive impact.

18.5.5 Irish Language - Potential Construction and Operational Impacts

There is a low-level of daily Irish usage among the population of the area directly affected by the proposed road development, and where it exists, the use of Irish is particularly concentrated in an education context. While population is increasing; the use of Irish-language is not growing in parallel. The proposed road development will not have any significant impact on the use of Irish into the future. However, it is noted that an improved road network would facilitate further migration and economic growth into the wider Galway Gaeltacht and as the west of County Galway have higher levels of unemployment and deprivation than the areas around Galway City, the proposed road development, by improving access to employment opportunities to the east of the city, will facilitate Irish speakers to commute more easily from their own communities and lessen the need to re-locate for economic reasons. Equally the proposed road development will make Gaeltacht areas to the west of Galway City more attractive for residential and commercial development as a result of a greatly improved road network. In this context, it will be the responsibility of Galway County Council, Galway City Council and Údarás na Gaeltachta among others to ensure that the use of the Irish language is promoted and encouraged among new residents.

Amongst the guiding principles that inform the proposed Gaeltacht Plan (Galway County Council 2017) is that the Planning Authority will “support an appropriate level of services and infrastructure to support existing and future growth and sustainable development in a manner that protects and is complementary to the environment, heritage, character and amenities of the Gaeltacht villages.”

In the course of consultation undertaken for this assessment, Údarás na Gaeltachta have indicated that they are in favour of the development of the N6 Galway City Ring Road (GCRR) around Galway City as it will “give more efficient access to the Gaeltacht area and the Connemara area west of the city". Údarás na Gaeltachta[25] stated that the new road would have a "very beneficial impact effect" on attracting new industries to the Gaeltacht and Connemara area, encouraging existing business to expand and would support existing businesses to have a more efficient access to their markets and personnel. Overall, it is considered that the proposed road development will have a positive impact on the economic and social viability of the entire Gaeltacht area.

In conclusion, the proposed road development will have a *Moderate Positive Impact* on the status of Irish as a community language within the Galway Gaeltacht area.

18.5.6 Human Health - Potential Construction and Operational Impacts

This section addresses health impacts under three main headings as per the methodology discussed in **Section 18.2.5.4 - Health Protection**, **Section 18.2.5.5 - Health Improvements** and **Section 18.2.5.6 - Improving Services**. Health protection covers the health effects of the proposed development arising from noise, vibration, air emissions, water and soil contamination and psychological issues. These are all discussed further below.

18.5.6.1 Health Protection

Noise

It is noted that despite the extents of the proposed road development and the overall construction period, the potential noise impact on any individual receptor during construction will be limited as the activity in any one location will be limited in scale and time. Thus, the potential for human health effects will be similarly limited.

The potential noise impacts are assessed in **Chapter 17, Noise and Vibration** in accordance with the relevant NRA Guidelines. The results of the baseline noise monitoring and potential impacts which are described in full in **Chapter 17, Noise and Vibration** have been compared against the relevant noise guidelines to determine if any human health effect is likely.

As discussed previously in **Section 18.2.5.4**, the potential health effects of noise can include

- Noise-Induced Hearing Impairment
- Interference with Speech Communication
- Disturbance at schools
- Sleep Disturbance
- Hypertension and Cardiovascular Disease

[25] Correspondence from Tadhg Ó Conghaile, Stiúrthóir Forbatha Réúigiunach Pobail & Pleanála Teanga, Údarás na Gaeltachta, dated 21 December 2017

As noted in **Section 18.2.4.5**, any effects demonstrated are more likely at higher noise levels. Many effects are only demonstrated with ambient noise in excess of 70dB. The results of the noise assessment detailed in **Chapter 17, Noise and Vibration** indicate that there is no receptor which will receive this volume of noise for any sustained period therefore health effects of noise from the proposed road development will not be significant. This is discussed further below.

<u>Construction Phase</u>

The noise assessment detailed in **Chapter 17, Noise and Vibration** identified that during the construction phase of the proposed road development there is potential for some temporary moderate to significant impacts on nearby residential and business properties due to noise emissions from certain construction activities. The application of binding noise limits and hours of operation, along with implementation of appropriate noise control measures, will ensure that potential noise impacts are kept to a minimum. As detailed in **Section 7.6.2** of **Chapter 17, Noise and Vibration** the construction contract documents will clearly specify the construction noise criteria which the construction works must operate within which align with the Schedule of Commitments included in the CEMP in **Appendix A.7.5**. The Contractor undertaking the construction of the works will be obliged to take specific noise abatement measures and comply with the recommendations of *BS 5228-1:2009+A1:2014 Code of Practice for Noise and Vibration Control on Construction and Open Sites - Noise* and the European Communities (Noise Emission by Equipment for Use Outdoors) Regulations, 2001 and the NRA *Good Practice Guidance for the Treatment of Noise during the Planning of National Road Schemes* 2013. Therefore, significant noise impacts during construction will not arise and no adverse health effects are predicted during construction.

<u>Operational Phase</u>

The noise assessment for the operational phase of the proposed road development indicates that without mitigation measures the potential noise levels at a number of receptors exceeded the specified noise mitigation criteria and necessary mitigation measures have been specified. Once such measures are implemented, it was shown that the vast majority of locations comply with the adopted criterion. For those minor areas which do not meet the design goal, the predicted noise level for the operational phase is within 3dB of the design goal or less than the predicted noise level in the do-minimum scenario.

Many properties along the existing roads that currently experience high levels of traffic will experience a notable reduction in noise levels depending on the distance from the road, traffic volume changes and speed reductions.

Baseline noise levels are important to consider when assessing human health impacts. Human perceptions of sound intensity are such that changes of less than 3dB are usually not perceived. If noise levels do not increase by at least 3dB there will be no adverse outcome over than experienced prior to the change. In this regard a threshold of 3dB is appropriate to identify a change in noise levels which can be reliably perceived by humans.

As mentioned earlier the WHO night time noise guidelines are for communities rather than individual residences and in addition it is important to remember that the levels are not thresholds. Nevertheless, individuals will always be concerned with the potential effects on them and therefore, it is useful to use these levels in attempting to attribute significance to changes in noise levels.

The significance of human health impacts as per the criteria referred to above in **Table 18.7** are as follows:

- If the L_{night} immediately outside a residence is below 55dB the Human Health impact is Imperceptible
- If the existing L_{night} immediately outside a residence is below 55dB and it increases by more than 3dB but remains below 60dB the Human Health impact is Slight Negative
- If the existing L_{night} immediately outside a residence is below 55dB and it increases by more than 3dB and to a level above 60dB the Human Health impact is Moderately Negative.

As mentioned above the proposed road development, by diverting traffic away from heavily populated areas overall has benefits in terms of community night-time noise. Therefore, the overall health effect would be positive. However, this is of little comfort to individuals who actually experience an increase in noise and the potential noise impacts on individual properties have been assessed and mitigation measures proposed in **Chapter 17, Noise and Vibration**.

Site Specific Operational Noise Impacts

Ch. 0+000 to 2+800 (R336 to Bearna East Roundabout)

The vast majority of receptors are below 55dB L_{night} in this area. At Bearna West Roundabout there is only a predicted increase of 1dB over the 'Do-Nothing' scenario at levels above 55dB L_{Night}. Therefore, no negative human health impacts are predicted.

Ch. 2+800 to 7+600 (Bearna East Roundabout to N59 Letteragh Junction)

All receptors are below 55dB L_{Night} in this area. Therefore, no adverse human health impacts are predicted.

Ch. 7+600 to 9+300 (N59 Letteragh Junction to River Corrib Bridge)

The vast majority of receptors are below 55dB L_{Night} in this area. At Bushypark along the N59 Moycullen Road where levels are above 55dB L_{Night}, there is only a predicted increase of 1dB over the 'Do-Nothing' scenario. In addition, some of the receptors around the N59 Moycullen Road are predicted to have L_{Night} above 55dB but there is relatively little change from the 'Do-Nothing' scenario with no increase in excess of 2dB. Therefore, no adverse human health impacts are predicted.

St James's School at Bushypark is not identified as having any significant negative impact.

Ch. 9+300 to 12+100 (River Corrib Bridge to N84 Headford Road Junction)

The vast majority of receptors are below 55dB L_{Night} in this area. Any that are above this level show little of no change from 'Do-Nothing' Scenario. Therefore, no negative human health impacts are predicted.

Ch. 12+100 to 14+000 (N84 Headford Rd Junction to N83 Tuam Road Junction)

The vast majority of receptors are below 55dB L_{Night}. At the N83 Tuam Road Junction where predicted levels are above 55dB L_{Night}, there is only a predicted increase of 1 or 2dB over the 'Do-Nothing' scenario. Therefore, no negative human health impacts are predicted.

Castlegar National School and the associated Beoga Pre-school are not identified as having any significant negative impact. This is of particular significance given the specific facilities at Castlegar School for children suffering from Autistic Spectrum Disorder.

Ch. 14+000 to 17+500 (N83 Tuam Rd Junction to Coolagh Junction)

The vast majority of receptors are below 55dB L_{Night} in this area. While some receptors are predicted to be above 55dB L_{Night}, there is only a predicted increase of up to 3dB, but not over 3dB, over the 'Do Nothing' scenario in those cases.

The Galway Clinic does go above 55dB L_{Night} but as mentioned the change is only 3dB. This is less than the more than 3dB threshold mentioned above so the impact on the Galway Clinic is assessed as Imperceptible. Therefore, no negative human health impacts are predicted.

Overall using the criteria for the significance of human health impact detailed in **Table 18.6** the impact rating in relation to noise is slight and no negative human health impacts are predicted.

Vibration

The potential vibration impacts as a result of the proposed road development both during construction and operation have been assessed in **Chapter 17, Noise and Vibration**. Overall the predicted impact from vibration is very low and characterised as not significant. While there may be some degree of local vibration transmitted during some aspects of construction, such as blasting or drilling, these will typically be of short duration and very localised and occur only during construction hours. Given the short duration it will not have any negative health impacts.

The potential vibration impact during the operational phase as detailed assessed in **Chapter 17, Noise and Vibration** is predicted as being not significant. Therefore there will be no negative health impacts.

Using the criteria for the significance of human health impact detailed in **Table 18.6** above the potential impact caused by vibration is assessed as Imperceptible.

Air Quality

As discussed previously in **Section 18.2.4.5**, provided the air quality standards are not exceeded one can be confident that there will be no adverse effect on human health due to air emissions. This is discussed further below.

As is detailed in **Chapter 16, Air Quality and Climate**, certain sensitive receptors have been identified in the study area for the proposed road development and dusts that are likely to be generated during the construction phase are normally heavier and larger particles. As these are heavier, they tend to fall rapidly to the ground and have a very limited level outside the actual construction site. There are potential occupational health issues for the works which would require for example the use of respiratory protection equipment in certain phases. However, as also pointed out in **Chapter 16, Air Quality and Climate**, in the event of such large dust leaving the site, by nature of its' relatively large size, that is greater than 10 microns, it is not respirable and will not have significant human health effects.

It is also noted that despite the extents of the proposed road development, the potential air quality impact on any individual receptor will be limited as the activity in any one location will be limited in scale and time. Thus, the potential for human health effect will be similarly limited.

The potential air quality impacts are assessed in **Chapter 16, Air Quality and Climate** in accordance with the relevant TII Guidelines. The results of the baseline air quality monitoring and potential impacts which are described in full in **Chapter 16, Air Quality and Climate** have been compared against the reliable air quality standards both during the construction and operational phases to determine if any health effect is likely.

The proposed road development is predicted to have a negligible impact on air quality, as defined in **Chapter 16, Air Quality and Climate**[26], across the study area during the construction phases and as such an imperceptible impact on human health. Whilst some areas of the study area will l experience a slight negative impact on air quality during the operational phase all air quality levels will remain well within air quality standards and as such there will be an imperceptible impact on human health. Site specific impacts during operation are further detailed below.

<u>Site Specific Operational Air Impacts</u>

Ch. 0+000 to 5+650 (R336 to Ballymoneen Road Junction)

These areas are predicted to have a negligible[26] air quality impact during the operational phase and therefore there will be no health effect.

Ch. 5+650 to 7+600 (Ballymoneen Road Junction to N59 Letteragh Junction)

This area is identified as having a slight negative impact at the N59 Moycullen Road in terms of NO_2 in the operational phase but this is a relative increase only and all levels remain well within air quality standards. All other impacts on air are assessed as negligible and therefore there will be no health effect.

Ch. 7+600 to 9+300 (N59 Letteragh Junction to River Corrib Bridge)

This area is predicted to have a negligible[26] air impact during the operational phase and therefore there will be no health effect.

Ch. 9+300 to 12+100 (River Corrib Bridge to N84 Headford Road Junction)

Some receptors in this area are identified as having a slight negative impact in terms of NO_2 in the operational phase but this is a relative increase only and all levels

[26] Where the impact magnitude of the changes in concertation of PM_{10} is imperceptible, then the impact description is negligible.

remain well within air quality standards. All other impacts on air are assessed as negligible[26] and therefore there will be no health effect.

Ch. 12+100 to 14+000 (N84 Headford Rd Junction to N83 Tuam Road Junction)

Some receptors in this area are identified as having a slight negative impact in terms of NO_2 in the operational phase but this is a relative increase only and all levels remain well within air quality standards. All other impacts on air are assessed as negligible[26] and therefore there will be no health effect.

Ch. 14+000 to 17+500 (N83 Tuam Rd Junction to Coolagh Junction)

This area is predicted to have a negligible[26] air quality impact during operational phase and therefore there will be no health effect.

Water

As is identified in **Chapter 10, Hydrogeology** and **Chapter 11, Hydrology** no negative impact from either surface water, or groundwater is anticipated. In this regard human health effects will not occur.

The hydrogeology assessment concluded that given the mitigation proposed there is a slight residual impact from the proposed road development with respect to groundwater quality as a resource. In terms of the quantity of groundwater available within the aquifer (the yield of the resource) there will be an imperceptible effect at the regional scale. It did state that some individual wells will be affected in terms of flow or water quality, however there will be no impact in potable water quality as alternative supplies will be utilised if necessary. At all times water quality standards will be observed to ensure public health.

In addition, the River Corrib is the main source of water for the city of Galway. Abstraction of the water is located 1.7km downstream from the proposed River Corrib Bridge and therefore at risk to pollution from the proposed road development, particularly during the construction phase. Stringent mitigation and control of potential polluting activities associated with construction activities will be implemented which will significantly reduce the risk of impact.

The operational phase also presents a pollution risk to this supply both from accidental spillages and from routine road run-off discharges. Design pollution control measures have been put in place to reduce the risk.

Given that all residual water supplies will comply with water quality standards the potential impacts on human health are assessed as Imperceptible.

In addition, in the broader context, the flood risk assessment has demonstrated that there is no significant flooding impact arising from the proposed development and hence no potential impact on human health.

<u>Water quality</u>

As detailed in **Chapter 10, Hydrogeology** and **Chapter 11, Hydrology**, there has been considerable attention given to ensuring that there will be no adverse effect on water quality. Where necessary mitigation measures are put in place to ensure continued supply of high quality and safe drinking water. The vast majority of residences in the area receive their water by mains which will continue to be monitored in the normal way.

No adverse effect on water quality is predicted and therefore there will be no health effect.

Flooding

The design of the construction and operational phase of the proposed road development has considered the risk of flooding at every step. This applies particularly of course to the area in the immediate vicinity of the River Corrib. The design of the construction of the River Corrib Bridge and ancillary works will ensure that there is no increased risk of flooding and indeed flood protection measures have been included and therefore there will be no health effect.

Soils

Soil Contamination

As detailed in **Chapter 9, Soils and Geology** there are no known areas of contaminated lands crossed by the proposed road development. While it is not anticipated that any of the construction or operational works would lead to soil contamination the contractor will be obliged to monitor the construction at all stages. In the event that any source of contamination is identified, in excavation or other means, this would have to be addressed at that time in consultation with statutory bodies such as the EPA. This will ensure that even in the unlikely event a source of contamination is discovered that appropriate mitigation measures will be put in place to ensure no adverse effect on human health.

Radon

The area of Galway which the proposed road development traverses is in a high radon area. As noted previously in **Section 18.2.5.7**, it is only when radon builds up in buildings that are inhabited by human beings that the health risk occurs. During construction, there will be excavations and tunnelling activities. This will have the potential to cause some release of radon. However, this will almost instantaneously be dissipated and will be harmless. Radon escape from rock will take the path of least resistance. Radon is escaping all the time but when it escapes to the open air there are no health effects.

The excavation and tunnelling activities will, if it has any effect at all on radon, and it is most likely that it will have none, actually divert radon away from residences rather than towards them as the radon may find an easier route to surface via the excavations rather than its current route. That is people which may be at risk because they live and work in a high radon area, will be not be at a higher risk because of the proposed construction or indeed operation of the proposed road development.

The potential human health impact of the construction and operational phases of the proposed road development with regards to radon are assessed as imperceptible.

Psychological

As set out in **Chapter 15, Material Assets Non-Agriculture**, the proposed road development has been designed to avoid as many properties as possible but given the built environment and the linear development of the city with housing along every road radiating out of the city its construction will unfortunately and unavoidably result in a number of property acquisitions or demolitions. Numerous alternatives have been considered as detailed in **Chapter 4, Alternatives Considered**, however the conclusion of the consideration of the alternatives is that the proposed road development represents the optimum transport solution and has avoided the greatest number of known and immovable constraints and is the option that overall has the least environmental impact taking all other potential environmental impacts into account. The people living in these homes have genuine concerns that their lives will be adversely affected. Many have lived in the area many years or indeed all of their lives. In the event of an approval of the Protected Road Scheme and Motorway Scheme and approval under Section 51 of the Roads Act 1993 (as amended), by An Bord Pleanála and subject to the availability of funding, Notice to Treat will be served firstly on owners, lessees and occupiers of the dwelling houses and commercial properties to be acquired, within six months of the scheme becoming operative, unless an application has been made for Judicial Review, in which case the Notice to Treat[27] will be served in accordance with the provisions of Section 217 (6A) of the Planning and Development Act 2000 as inserted by the Compulsory Purchase Orders (Extension of Time Limits) Act 2010. Compensation will be agreed or determined by the property arbitrator as soon as possible after service of Notice to Treat. After compensation has been agreed or determined and satisfactory title has been produced, part payment can be made while the claimant remains for an agreed period in the property to be acquired. This will facilitate the claimant in removing uncertainty and will facilitate arrangements being made, as early as possible, to secure a replacement property.

The community will also experience annoyance from the temporary impacts of traffic management and other effects during the construction phase. As against this there is the potential reduction in annoyance amongst road users in the operational phase where there are reduced journey times.

Whilst individual annoyance cannot be discounted, annoyance in itself is not a health effect. There is no evidence that there are any significant effects on human health from simply transient levels of annoyance. In these circumstances the negative impacts is assessed at Slight. In addition, while there may be positive impacts of reduced annoyance for those not stuck in traffic there is little evidence of positive impacts on human health and the positive impact is assessed also as Slight.

It is worth noting that the proposed road development will remove a lot of congestion from the city centre and the potential for conflict between vehicular traffic and pedestrians and cyclists, thereby reducing the potential number of collisions and possible fatalities. Not only would the avoidance of fatalities and

[27] This notice requests landowners to submit their claim for compensation for lands being taken under the Protected Road Scheme or Motorway Scheme. This is the initial step in the acquisition of property and lands.

serious injuries have a very significant positive impact on an individual basis, any such injury or fatality would have a huge adverse impact on the individual's family, friends and colleagues such as that there can be a wider impact on the psychological health of the community.

The Do-Nothing scenario has potential for adverse psychological impacts. Progressively longer journey times and uncertainty will be associated with increased annoyance at least and at worst impact on psychological health.

As detailed in **Section 18.5.3** and **18.5.4** the proposed road development will cause a degree of physical and social severance. Where severance does occur there is potential for psychological impact. Loneliness can occur if someone feels cut off for example. As against this there may be positive psychological effects where improved connectivity permits greater ease of movement around the city. This would potentially facilitate closer connections with friends or relatives which might be deterred if journeys were perceived to be lengthy or difficult.

Overall, therefore, the assessment of the psychological impact on a population of community basis will be overall positive. However, one cannot escape the fact that certain individuals particularly those whose homes are to be compulsory acquired may not experience the community benefit.

18.5.6.2 Health Improvement

As detailed in **Section 18.5.3** and **18.5.4**, the proposed road development has the potential to bring with it, significant socio-economic benefits. It will facilitate transport of goods and people in a timely, reliable and efficient manner. The full economic benefit will be realised once the proposed road development is completed. Accessibility to businesses and community facilities in Galway City and its environs and the Business Parks in Parkmore and Ballybrit will be better facilitated by the proposed road development and the resulting reduction in congestion. It will also bring with it benefits to business and public facilities in Galway City centre by reducing noise and air pollution. This all translates into an increased potential for economic prosperity for the Western Region, with Galway City as a thriving city at the core, which in turn will play a part in reviving the Irish economy.

Whilst the benefits are applicable to Galway City and County, it may be particularly felt in the West of Galway. As was identified earlier in this chapter, the deprivation map detailed in the HSE Health Profile for County Galway identifies many of the most deprived areas of Galway County as being to the west of the city in Connemara. These areas are amongst those most likely to get a socio-economic benefit from the proposed road development. As set out in **Section 18.2.5.5** an improvement in socio-economic circumstances can contribute to improving the health and wellbeing of socio-economically deprived communities. It therefore follows that the socio-economic benefits of the proposed road development will also contribute to health benefits.

The provision of an additional crossing of the River Corrib will facilitate the reduction of congestion on city centre roads, and allow the reallocation of road space in the city network to non-motorised modes of transport, thereby facilitating the effective implementation of all the elements contained in the Galway Transport Strategy, namely the improvement of public transport, cycling and walking measures and provides the opportunity for health improvements.

As detailed in **Chapter 3, Need for the Proposed Road Development**, the proposed road development will enable the reallocation of existing road space within the city to public transport and smart mobility measures and as such facilitate the full implementation of the GTS. It will facilitate a more efficient public transport system and provide for of a multi-modal choice of travel including walking and cycling. Analysis of the traffic model shows a 21% increase in cycling with the full implementation of the GTS with a small decrease in walking largely due to people switching from walking to cycling or public transport, however, there will be an overall benefit in terms of opportunities to exercise and the associated health benefits. The increased opportunities to exercise due to an environment more amenable to walking and cycling, will also facilitate the social interaction among neighbours which may be currently be inhibited by excessive traffic all of which provide significant opportunities for health improvement.

Increased opportunities for exercise also has the potential to bring benefits in terms of human health. Exercise is a well-recognised method of reducing risk in terms of obesity, diabetes, hypertension, cardiovascular disease and osteoporosis amongst other conditions. There are also significant psychological benefits and studies have consistently shown self-reported well-being is significantly higher in those who frequently exercise.

One of the project objectives as set out in **Chapter 3, Need for the Proposed Road Development** is safety. The proposed road development is designed to optimal safety levels. It is well established that roads which are designed to safe standards are associated with reduced accident levels. The proposed road development also has the added benefit of moving the traffic away from pedestrian traffic reducing the opportunities for pedestrian injury or death. It introduces opportunities for safer travel for cyclists with the introduction of cycle measures included in the GTS.

The proposed road development would further improve access to health care through enhanced public and private transport connectivity, and may facilitate faster and safer emergency response through improved road capacity and resilience. Ambulances being able to get to an emergency situation in minutes as opposed to being delayed in heavy traffic has obvious benefits for health and could potentially be lifesaving. The study by Lyon et Al, referenced in the literature review in **Section 18.2.5.7**, reinforces this point by showing that there is an improved survival rate with out-of-hospital cardiac arrests with more rapid response times from the emergency services. This improvement is equally important in relation to the heading below under improving services.

18.5.6.3 Improvement of Access to Services

For vehicle drivers the ability to access services will be improved by the proposed road development. The diversion of traffic away from busy city centre streets will mean that people will be able to access shops, restaurants, cinemas and other services easier with less delays.

Similarly, for people needing to cross the city centre to access services, they will be facilitated by the proposed road development. This will be particularly so for those living on the west of the River Corrib. There will also be a more efficient and reliable connectivity to the national road network. This is particularly important in an Irish context as many major health services are situated in Dublin for example, the new National Children's Hospital.

There is also the potential for the proposed road development to improve access to services for non-motorised transport users to reach key services. As previously mentioned the diversion of traffic away from the city centre will facilitate public transport both in the form of buses and taxis. Reduction in traffic will also facilitate cycling and pedestrian access to services particularly around currently heavily used city streets.

It is clear therefore that with regards to access to services the proposed road development impact is overwhelmingly positive. That being said, certain individuals albeit very few, who are living or accessing areas in the immediate vicinity of the proposed road development, would for reasons of severance or road closures have to detour somewhat from their current routes. Once they do access the transport links, however, they too will benefit from improved access to services.

18.5.6.4 Summary

In summary, health protection covers the health effects of the proposed development arising from noise, vibration, air emissions, water and soil contamination and psychological issues. The results of the baseline noise monitoring and potential impacts set out in **Chapter 17, Noise and Vibration** have been assessed and no negative human health impacts are predicted as a result of noise emissions. The predicted impact from vibration is very low and characterised as not significant. Therefore, the potential impact caused by vibration is assessed as Imperceptible.

The proposed road development is predicted to have a negligible[28] impact on air quality across the study area during the construction phases and as such an imperceptible impact on human health. Whilst some areas of the study area will experience a slight negative impact on air quality during the operational phase all air quality levels will remain well within air quality standards and as such there will be an imperceptible impact on human health.

Given that all residual water supplies will comply with water quality standards the potential impacts on human health are assessed as Imperceptible. No adverse effect on water quality is predicted and therefore there will be no health effect. In addition, in the broader context, the flood risk assessment has demonstrated that there is no significant flooding impact arising from the proposed road development and hence no potential impact on human health. There are no predicted impacts on human health as a result of soil contamination or radon.

[28] Where the impact magnitude of the changes in concertation of PM_{10} is imperceptible, then the impact description is negligible.

The people living in homes to be acquired or demolished for the construction of the proposed road development have genuine concerns that their lives will be adversely affected. Many have lived in the area many years or indeed all of their lives.

The proposed road development will remove a lot of congestion from the city centre and the potential for conflict between vehicular traffic and pedestrians and cyclists, thereby reducing the potential number of collisions and possible fatalities. The proposed road development will cause a degree of physical and social severance. Where severance does occur there is potential for psychological impact. Loneliness can occur if someone feels cut off for example. As against this there may be positive psychological effects where improved connectivity permits greater ease of movement around the city. This would potentially facilitate closer connections with friends or relatives which might be deterred if journeys were perceived to be lengthy or difficult.

Overall, therefore, the assessment of the psychological impact on a population of community basis will be overall positive. However, one cannot escape the fact that certain individuals particularly those whose homes are to be compulsory acquired may not experience the community benefit.

The potential impacts of the proposed road development in the operational phase will be largely positive with significant opportunities for health improvements. These include, but are not limited, to improved access to services including emergency services, the potential for socio-economic development with the associated health improvements. The provision of an additional crossing of the River Corrib will facilitate the reduction of congestion on city centre roads, and allow the reallocation of road space in the city network to non-motorised modes of transport, thereby facilitating the effective implementation of all the elements contained in the Galway Transport Strategy, namely the improvement of public transport, cycling and walking measures and provides the opportunity for health improvements with the increased opportunities for exercise. The proposed road development would further improve access to health care through enhanced public and private transport connectivity, and may facilitate faster and safer emergency response through improved road capacity and resilience.

18.6 Mitigation Measures

18.6.1 Socio-economics

Specific proposed mitigation measures for potential socio-economic impacts are listed in **Tables 18.13** and **18.14**, many of which have been included in the design of the proposed road development. These include the provision of crossing facilities at the Foraí Maola Road, Troscaigh Road, Bearna to Moycullen Road L1321, Cappagh Road and Ballymoneen Road junctions to facilitate pedestrian and/or cyclist crossings of the proposed road development. Pedestrian crossing facilities are also proposed at the terminus of the N59 Link Road North Junction at the N59 Moycullen Road (Bushypark Junction) and at the slip road connections with the N84 Headford Road Junction. Cycle lanes are proposed to facilitate access to the Miller’s Lane pitches and Gort na Bró and at the N84 Headford Road Junction.

The following specific mitigation measures are proposed to improve journey amenity, amenity and minimise severance:

- Provide pedestrian crossing facilities at junctions with minor roads serving local rural communities
- Provide temporary visual screening from construction works at St. James' Church Cemetery in Bushypark and at St. James' School, Bushypark
- Provide pedestrian crossing facility at Bushypark Junction with N59 Link Road North during construction and operation
- Avoid any prolonged severance and minimise duration of use by construction traffic of An Seanbóthar
- Provide for alternative access along the bank of the River Corrib, along with prior advice for walkers, if access restrictions apply due to construction of the overhead bridge crossing
- Phase construction works to minimise impacts on racing events at Galway Racecourse
- Provide directional signage for access to car dealership and An Post sorting centre on N83 Tuam Road during construction
- Provide pedestrian crossing facilities at N84 Headford Road Junction during construction and operation
- Provide a footpath within the proposed development boundary along School Road, Castlegar
- Provide directional signage for a Briarhill Business Park, including a car dealership located here during both the construction
- Take measures to ensure that cul-de-sacs or adjacent lands are not used for illegal parking in the operational phase

Outside of the proposed development boundary associated with the proposed road development itself, it is recommended that the relevant authorities take measures to enhance the local connectivity provided and consequently its value and acceptability to the local community. Whilst not required as part of the proposed road development it will provide further benefits for the community. Such measures could include the widening of sections of narrow, currently substandard rural roads in the western section of the study area. The extension of public footpaths and cycle paths included in the design to ensure that these are not isolated, but provide connectivity to community facilities and other pedestrian and cyclist facilities.

The proposed road development will facilitate the implementation of the walking, cycling and public transport measures set out in the GTS. The transference of traffic from the existing N6 through Galway City to the proposed road development will provide an opportunity for improved pedestrian and cycle paths and crossing facilities, including continuity at major junctions and a modal shift to alternatives to the private car. Improved walking and cycling journey amenity is contingent on these appropriate facilities being provided. When implemented, such facilities will provide a significant improvement to pedestrian and cyclist journey amenity combined with reduced severance.

As discussed in **Chapter 15, Material Assets Non-Agriculture**, the proposed road development traverses the NUIG Sporting Campus on a viaduct. During construction, restricted access across the construction area at the NUIG Sporting Campus facilities will be maintained.

Alternative pitch facilities will be provided to replace the existing pitches directly impacted by the proposed road development. The facilities include a floodlit 3G GAA pitch and a floodlit 3G training area and associated site infrastructure for the drainage of these pitches and furniture such as ball-stop netting. The proposed road development also intercepts the existing sports pavilion resulting in direct impacts to its western end and the building will be modified as follows:

- the existing western plant room, 1 no. changing room, 1 no. storage area, 1 no. weights area and associated access hallways on both ground floor and upper levels will be demolished
- the western plant room and its associated plant will be relocated
- construction and reconfiguration of the internal and external walls, roof, windows and door locations

Temporary stables will be provided for Galway Racecourse during the construction of the proposed road development until such time as the Galway Racecourse Tunnel is complete and the permanent stables are constructed.

18.6.2 Irish Language

Mitigation measures proposed to protect the Irish Language are as follows:

- During construction, all public notifications and all public project updates are to be provided in both Irish and English languages
- While it is expected that day-to-day communications involved in the construction of the proposed road development will be through the English language, the Main Contractor shall have the capacity to communicate and correspond through the use of the Irish language and to devote adequate and proportionate staff resources to dealing with any individual wishing to correspond and communicate through the Irish language
- Placenames shall be cited in accordance with the relevant Placename Order issued under the Official Languages Act 2003

18.6.3 Human Health

Mitigation measures proposed for the potential air quality, noise, water and soils are specified in **Chapter 9, Soils and Geology**, **Chapter 10, Hydrogeology**, **Chapter 11, Hydrology**, **Chapter 16, Air Quality and Climate** and **Chapter 17, for Noise and Vibration** and the key mitigation measures which apply to human health are outlined below and are also in the respective chapters listed above. The implementation of these mitigation measures, emissions, including air and noise will be adequately controlled to ensure no adverse effect on human health.

18.6.3.1 Noise

The key noise mitigation measures include:

- Use of a Low Noise Road Surface
- Use of noise barriers as detailed in **Table 17.14**
- Control measures for construction works. Noise control measures that will be considered include the selection of quiet plant, enclosures and screens around noise sources, limiting the hours of work and noise monitoring. The contractor will be required to conduct construction noise predictions prior to works taking place and put in place the most appropriate noise control measures depending on the level of noise reduction required at any one location. The Contractor undertaking the construction of the works will be obliged to take specific noise abatement measures and comply with the recommendations of *BS 5228-1:2009+A1:2014 Code of Practice for Noise and Vibration Control on Construction and Open Sites - Noise* and the European Communities (Noise Emission by Equipment for Use Outdoors) Regulations, 2001
- Construction hours will mostly take place during daytime hours Monday to Friday. It will be necessary to work overtime (including weekends) and night shifts at certain critical stages during the project. Over the expected 36-month construction phase there will be up to 10 weeks of night-time working along different sections of the proposed road development primarily to facilitate bridge works over existing roads
- During the construction phase noise monitoring will be undertaken at the nearest sensitive locations to ensure construction noise limits outlined in **Table 17.1** of **Chapter 17, Noise and Vibration** are not exceeded. It is recommended that noise control audits are undertaken at regular intervals throughout the construction programme, as part of the noise and vibration management of the construction of the proposed road development which will be set out in the construction contract requirements
- In terms of blast design control, specific guidance will be obtained from the recommendations contained within *BS 5228-2:2009+A1:2014 Code of Practice for Noise and Vibration Control on Construction and Open Sites – Vibration* in relation to blasting operations in addition to experienced blast control techniques used by the contractor. Ref **Chapter 17, Noise and Vibration** for further details
- In the case of vibration levels giving rise to human discomfort, in order to minimise such impacts, the following measures shall be implemented during the construction period:
    - A clear communication programme will be established to inform adjacent building occupants in advance of any potential intrusive works which may give rise to vibration levels likely to exceed perceptible levels. The nature and duration of the works will be clearly set out in all communication circulars
    - Alternative less intensive working methods and/or plant items shall be employed, where feasible
    - Appropriate vibration isolation shall be applied to plant, where feasible

  - Cut off trenches to isolate the vibration transmission path shall be installed where required
  - In the case of impact piling or demolition works for instance, a reduction in the input energy per blow shall be considered where required
  - Monitoring will be undertaken at identified sensitive buildings, where proposed works have the potential to be at or exceed the vibration limit values

- Property condition surveys will be offered for all buildings within 50m of the proposed development boundary and those within 150m of proposed blasting works along the proposed road development. Property condition surveys will also be carried out at buildings and structures considered appropriate relative to their proximity to the works.

18.6.3.2 Air

The implementation of 'standard mitigation for air' as state in the TII Guidelines include:

- Spraying of exposed earthwork activities and site haul roads during dry weather
- Provision of wheel washes at exit points
- Control of vehicle speeds and speed restrictions. It is proposed that site traffic is restricted to 20km/hr. This will help to minimise the occurrence of dust re-suspension
- Sweeping of hard surface roads

In addition, the following measures will be implemented:

- A public communication strategy will be implemented by the Contractor which will outline procedures to inform members of the community on activities that may be disruptive, further details are contained in **Appendix A.7.5 Construction Environmental Management Plan**. This appendix also includes details of a complaints register which will be implemented during the construction phase
- Exhaust emissions from vehicles operating within the site, including trucks, excavators, diesel generators or other plant equipment, will be controlled by the contractor through regular servicing of machinery
- During dry periods when dust generation is likely or during windy periods, construction areas and vehicles delivering material with dust forming potential will also be sprayed with water, as appropriate
- Areas where materials will be handled and stockpiled will be positioned away from main site access roads. These areas will also be designed to minimise their exposure to wind – all stockpiles shall be kept to the minimum practicable height with gentle slopes
- There shall be no long-term stockpiling on site and storage time will be minimised

- Material drop heights from plant to plant or from plant to stockpile will be minimised
- Water suppression will be used during the demolition of buildings
- Crushing and concrete batching plant will be located as far from sensitive receptors as is reasonably practicable. All storage bins and transfer points will be covered. Silos will be fitted with reverse jet air filters
- Dust screens will be implemented at locations where there is the potential for air quality impacts during the construction phase, i.e. at locations where sensitive receptors are located within 100m of the works
- Employee awareness is also a most important way that dust may be controlled on any site. Staff training and the vigilant management of operations ensure that all dust suppression methods are implemented and continuously inspected
- Dust deposition monitoring will be conducted at a number of locations in the vicinity of the proposed road development. At a minimum, monitoring will be carried out at the two nearest sensitive receptors at locations where works of a ‘major’ scale is proposed while works are taking place in proximity, refer to **Section 16.5.3.1** of **Chapter 16, Air Quality and Climate**.

18.6.3.3 Water and Soil

The key water and soil measures to prevent pollution, flooding and soil contamination include:

- Measures have been incorporated into the design of the proposed road development will protect water quality and soils and also prevent any significant flooding, thus avoiding any potential health impacts
- During construction, the contractor shall implement the Construction Environmental Management Plan as set out in **Appendix A.7.5**

18.6.3.4 Demolitions and Acquisitions – Psychological Effects

In the event of an approval of the Protected Road Scheme and Motorway Scheme and approval under Section 51 of the Roads Act 1993 (as amended), by An Bord Pleanála and subject to the availability of funding, Notice to Treat will be served firstly on owners, lessees and occupiers of the dwelling houses and commercial properties to be acquired, within six months of the scheme becoming operative, unless an application has been made for Judicial Review, in which case the Notice to Treat[29] will be served in accordance with the provisions of Section 217 (6A) of the Planning and Development Act 2000 as inserted by the Compulsory Purchase Orders (Extension of Time Limits) Act 2010. Compensation will be agreed or determined by the property arbitrator as soon as possible after service of Notice to Treat. After compensation has been agreed or determined and satisfactory title has been produced, part payment can be made while the claimant remains for an agreed

[29] This notice requests landowners to submit their claim for compensation for lands being taken under the Protected Road Scheme or Motorway Scheme. This is the initial step in the acquisition of property and lands.

period in the property to be acquired. This will facilitate the claimant in removing uncertainty and will facilitate arrangements being made, as early as possible, to secure a replacement property.

18.7 Residual Impacts

18.7.1 Socio-economics

18.7.1.1 Journey characteristics

Once operational, the proposed road development will provide a very significant positive residual impact in terms of improved connectivity across and beyond the city, including to national roads via the junctions included as part of the proposed road development. This will maximise the transfer of cross-city movements to the new road infrastructure, thus releasing and freeing the existing city centre and inner suburbs from congestion caused by traffic trying to access a city centre bridge to cross the River Corrib. Residual impacts respective to each identified impact and impact type are listed in the final column of **Table 18.14** and **Table 18.15**.

18.7.1.2 Amenity

The proposed road development will have a positive residual impact on journey amenity on most city roads by encouraging a transfer of through and other traffic, reducing congestion particularly at major junctions. Some transference of traffic will occur to arterial roads connecting with junctions on the proposed road development, but overall the reduction in traffic on the major road arteries will provide a residual positive contribution to journey and general amenity in the city. There will be particular benefits for pedestrians and cyclists as the transfer of traffic will allow for an improvement in relevant facilities together with opportunities for more public transport as proposed in the GTS.

The pattern of residential development in the study area means that the construction of the proposed road development will impact directly on a high proportion of residential properties at several locations. There will be an inevitable very significant negative impact on most of the householders who are directly impacted by compulsory purchase. As the proportion of properties to be acquired or demolished at three locations is high in relation to the total number of properties in that area, a significant negative residual impact could occur at a community level for those households that remain.

There will be a significant residual amenity impact on visitors to Menlo Castle on the east bank of the river due to the presence of the River Corrib Bridge. The residual impacts on NUIG Sporting Campus remain as very significant in the absence of a new University Sports Masterplan. The proposed road development will be elevated across the Sports Campus, removing the two centrally located grass GAA pitches. In tandem with this the existing context of the existing sporting changing facilities setting and curtilage will be altered completely. An appropriate level of master planning and implementation of the following would reduce the residual impact to moderate:

1. The Sporting Campus at Dangan will require a new Sporting Campus Plan and strategy to re-accommodate the removed pitches and ancillary Sports Pavilion. This must be in line with the University's overall strategic sport's vision
2. The removal of the existing sports fields will require replacement by similar or more likely improved facilities which allow for the more intensive use of the remaining reduced Campus footprint
3. Utilities, roads and access and egress routes around the Campus will require complete re-planning to re-integrate with the proposed road development
4. The remaining sports pitches will require remodelling to accommodate a more intensive use of the existing Campus footprint
5. The landscape setting of the existing Campus will need to be developed to screen the visual effects of the proposed River Corrib Bridge from the surrounding pitches
6. Ancillary supporting facilities such as car parking and changing facilities will require remodelling

The residual impact on NUIG Sporting Campus post compensation cannot be assessed as the compensation to be agreed as part of the land acquisition is outside the scope of the EIA process.

18.7.1.3 Community Severance

The transfer of through and other traffic from more central areas of the city will allow space for improved and new crossing facilities for both pedestrians and cyclists in line with the GTS. Crossing facilities are also included for junctions between national, secondary and local roads and the proposed road development. These facilities will have the effect of reducing any residual impact arising from severance due to the road development itself.

18.7.1.4 Economic

The improved connectivity will help to stimulate economic development and the potential for development of the tourism sector in West County Galway. The proposed road development will have a significant positive residual impact in this regard. The availability of connections between the proposed road development and existing business parks in the west, and especially the east, of the city will also have a very significant, and in some cases, profoundly, positive economic impact due to improved access to these businesses. However, some businesses will be directly impacted by the route of the proposed road development and a few of these will be acquired or their current operations modified. These negative impacts will be addressed as part of the land acquisition process and financial compensation.

18.7.2 Irish Language

The proposed road development is expected to have a Moderate Positive residual impact on the status of Irish as a community language within the Galway Gaeltacht area.

18.7.3 Human Health

18.7.3.1 Health Protection

From a community perspective overall, there are potential benefits in terms of human health protection. These arise from overall reductions in noise levels in built-up areas and potential improvements in air quality in these areas. Unfortunately, there are individuals who have slight negative impacts because of their proximity to the proposed road development. The implementation of the mitigation measures will result in a residual slightly positive impact.

Similarly, from a psychological health point of view overall from community perspective the impacts of the proposed road development are assessed as being positive. Again, there are individuals who may be adversely affected and principal among these are likely to be those whose homes are to be compulsorily acquired. The residual impact will be positive.

18.7.3.2 Health Improvements

There is the potential for a very significant opportunity for health improvements associated with the proposed road development. These include the potential for economic development as well as tourism which in itself is associated with an improvement in health status. There is the potential for improvements in social health with a reduction in unemployment and particularly long-term unemployment. Such a potential if realised will bring with it benefits including reduced inequality in society. There is also potential for increased opportunity to exercise. There is the potential for reduced traffic accidents with a corresponding reduction in mortality and morbidity. Ease of access and egress has the potential to improve social interaction. It also will allow quicker and more reliable access for emergency services such as ambulances. The residual impact will be positive.

18.7.3.3 Improvement of Access to Services

There is potential for significant improvement in access to services. The benefits of this apply to both the residents of Galway City and beyond. Easier access to national road network will allow greater availability of national services such as major hospitals and others. This may be of particular benefit to those living to the west of the city including as far as Connemara. Decreased traffic in built-up areas of Galway City will allow easier access to the services such as retail, cinema, restaurants and other services. It may also encourage people outside of Galway, who are currently deterred from entering the city by traffic concerns to visit and access the services. The residual impact will be very positive.

18.7.4 Cumulative Impacts

Cumulative impacts are defined as the combination of many minor impacts creating one larger, more significant impact (NRA, 2009 and EPA 2017). Cumulative impacts consider existing stresses on the natural environment as well as developments that are underway and in planning.

Following a review of the committed projects and the planning files for Galway City and County Council, the cumulative impacts of the proposed road development on human beings, population and human health with the following have been assessed:

- The planning registers for Galway City and County Council
- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- M6 Motorway (operational)
- M6 Motorway Service Area (Rathmorrissy Interchange) (pre-planning)
- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)
- N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction)
- Galway Harbour Port Extension (planning stage)
- Galway Transport Strategy (GTS), which includes the following:
    - Investigation of prospective sites to the east of the city for Park and Ride
    - Bearna Greenway
    - Galway to Oughterard (part of the Galway to Clifden) Greenway
    - Galway City to Oranmore (part of the Galway to Dublin) Cycleway
- Galway City Development Plan 2017–2023
- Galway County Development Plan 2015–2021
- Bearna Local Area Plan 2007–2017
- Gaeltacht Local Area Plan 2008–2018
- Údarás na Gaeltachta's Strategic Plan 2014–2017
- Ardaun Local Area Plan 2018–2024

No projects or plans other than those listed in this chapter were identified as having potential cumulative impacts.

18.7.4.1 Socio-Economics

The proposed road development will improve accessibility both within and to/from Galway City and connectivity between areas outside of the city including Connemara, the East and North West. As a result, there are significant potential positive impacts which will benefit economic and regional development, including tourism. The proposed road development will have a positive cumulative socio-economic impact with the proposed roads projects listed above and with the proposed the Galway Harbour Project.

The proposed road development could also stimulate new physical commercial or tourism development. These developments would be subject to planning assessment given the objectives set out in the Galway City and Galway County Development Plans to consolidate development and to provide for balanced sustainable development. They will also be subject to Appropriate Assessment to avoid any adverse impacts on sensitive landscapes and natural habitats. These considerations apply also to the largely rural area surrounding the city, noting that the proposed road development will be used for a proportion of commuting journeys as well as for regional journeys. The transfer of some of these journeys to the proposed road development away from the existing N6 is a significant positive impact, but any cumulative impacts on settlement patterns will be monitored and addressed in future development and local area plans.

The proposed road development will provide an opportunity to fully implement the GTS and to provide for improved public transport and facilities for pedestrians and cyclists. For example, the reduced volume of traffic on the existing N6 will present an opportunity to greatly improve the continuity of cycle lanes, including at junctions, and to add more pedestrian crossings, while minimising impacts on traffic flow. Once implemented, this will have a very significant impact on safety and the journey amenity of pedestrians and cyclists, and on general environmental quality if this contributes to a modal transfer from vehicles. In summary the cumulative impacts of the projects and plans listed above in association with the proposed road development are positive.

18.7.4.2 Irish Language

Having considered the proposed road development in tandem with other relevant plans or projects identified above, it is considered that no significant negative cumulative impact upon the status of Irish as a community language will occur.

18.7.4.3 Human Health

It is not considered that there will be any negative cumulative effects on human health. The distances between the projects noted above and the proposed road development results in no cumulative noise or air quality impacts. There is potential that reduced journey times and fewer unforeseen delays could have a potential benefit on psychological health. Any projects which make roads safer and reduce the probability of road accidents and fatalities can only be seen in positive terms from a human health perspective. The cumulative health benefits of the proposed road development with the GTS are further assessed below.

Quantification of cumulative health benefits with the GTS

The cumulative health benefits of the proposed road development with the GTS were assessed by using the Western Regional Model to quantitatively measure some of the health, accessibility and social inclusion[30] impacts once the proposed road development and the GTS were fully implemented.

[30] It should be noted that this analysis represents an assessment of those elements of Health, Accessibility and Social inclusion which can be measures using model outputs from the WRM. As such, these outputs are not representative of all the benefits/disbenefits which result from the implementation of the GTS under these categories.

<u>Physical Activity Analysis</u>

The assessment indicates that the total number of people cycling, over a 24-hour period in Galway City, will increase by approximately 21% cyclists as a result of the implementation of the GTS and associated cycling infrastructure improvements. This increase in cyclists will result in a reduced risk of premature deaths for those who are new to cycling and currently exercise infrequently. By comparison, results from the assessment indicate that pedestrian trips (trips which use walking only to get from origin to destination) in Galway City are expected to decrease marginally (less than 1% reduction) across the full 24-hour period. The reduction in pedestrian activity in Galway City is mostly as a result of people transferring to cycling or using the improved public transport services implemented as part of the Galway Transport Strategy.

<u>Accessibility Analysis</u>

The changes in accessibility for key locations were determined on a zone by zone basis. This was undertaken using a visual representation of the changes in journey times between the 'Do-Nothing' and 'Do-Something' Scenarios for cycling, public transport and private car. **Plates 18.4** to **18.6** below represent the changes in journey time (on average) required to access NUIG, GMIT, Galway University Hospital, Galway Clinic, Bons Secours and the industrial estates at Ballybrit and Parkmore when the GTS has been implemented for car, cycling and public transport. **Plate 18.4** illustrates that, in general, most zones experience a decrease in car journey times. There are however, a small number of zones, mostly in the city centre, which are expected to experience an increase in car journey times to access key sites. This is as a result of the public transport priority measures, such as private vehicle restrictions on Salmon Weir Bridge, which make accessing these areas by car more difficult.

Plate 18.4: Changes in Car Accessibility

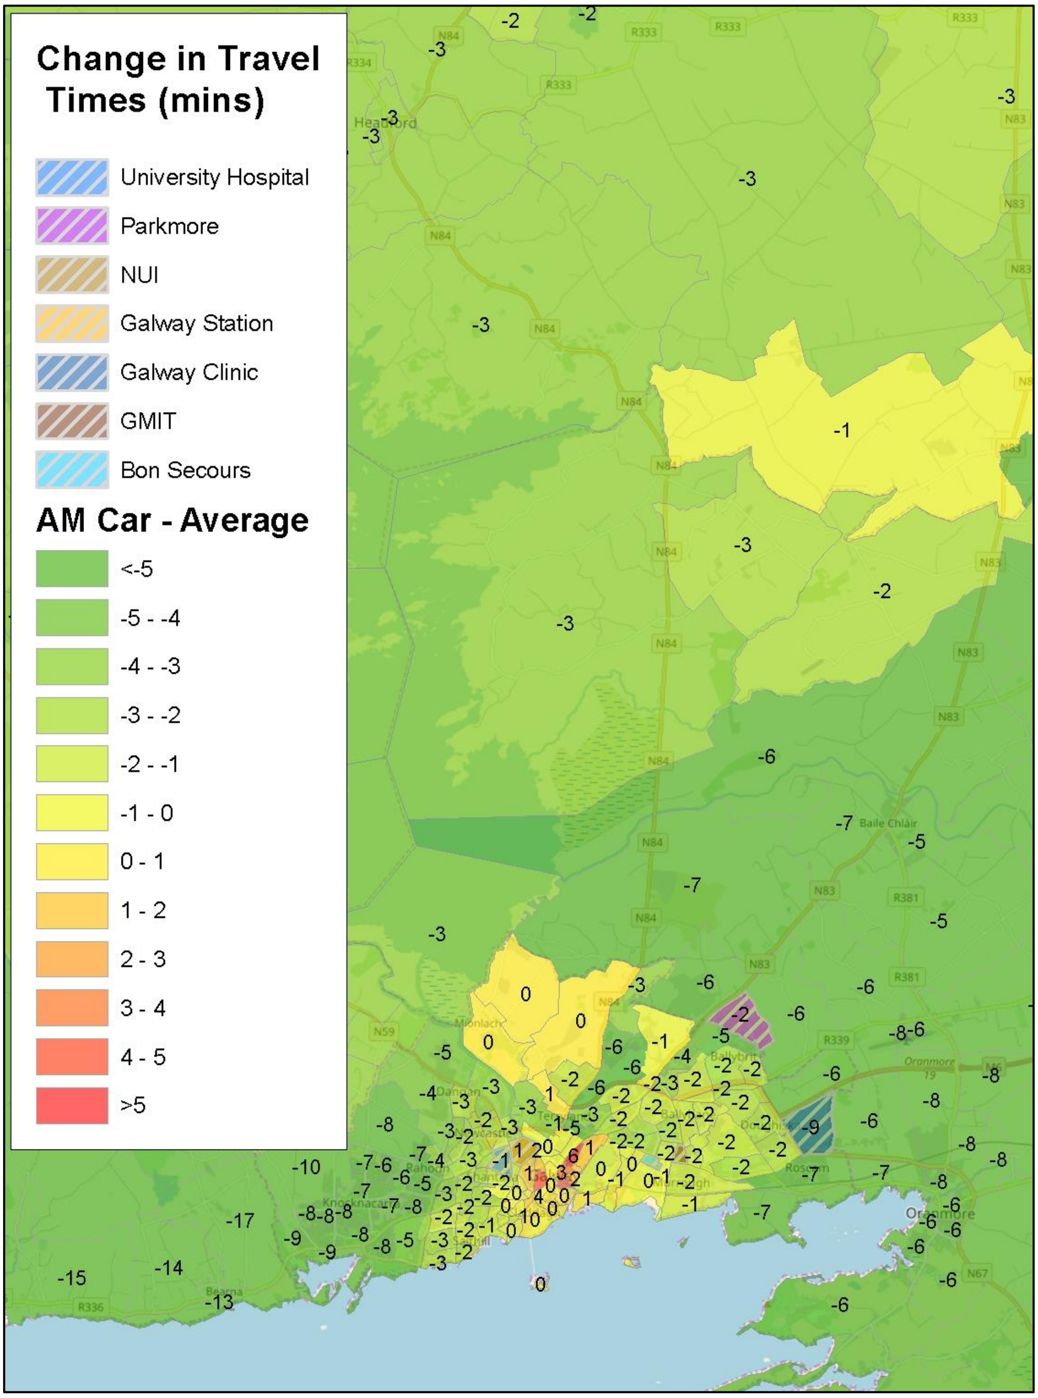

Plate 18.5 illustrates that all zones will experience improved cycling journey times.

Plate 18.5: Changes in Cycling Accessibility

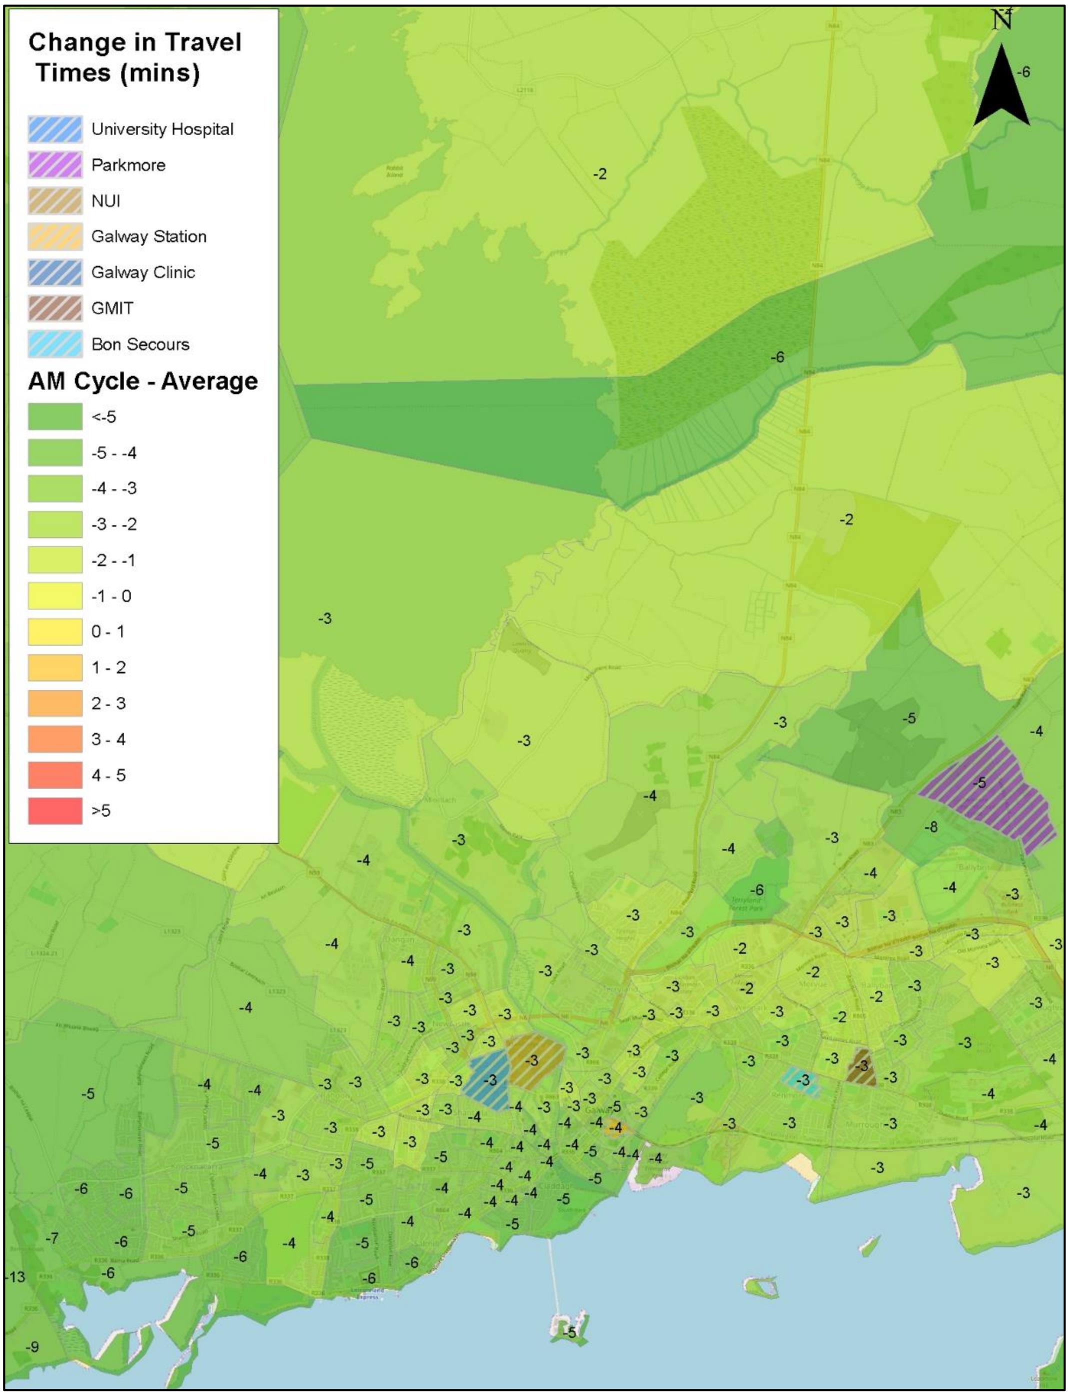

Plate 18.6 illustrates that, in general, most zones experience a decrease in public transport journey times. There are however, a small number of zones which are expected to experience an increase in public transport journey times as they will not be served as directly by public transport once the changes in bus routes proposed as part of the GTS are implemented.

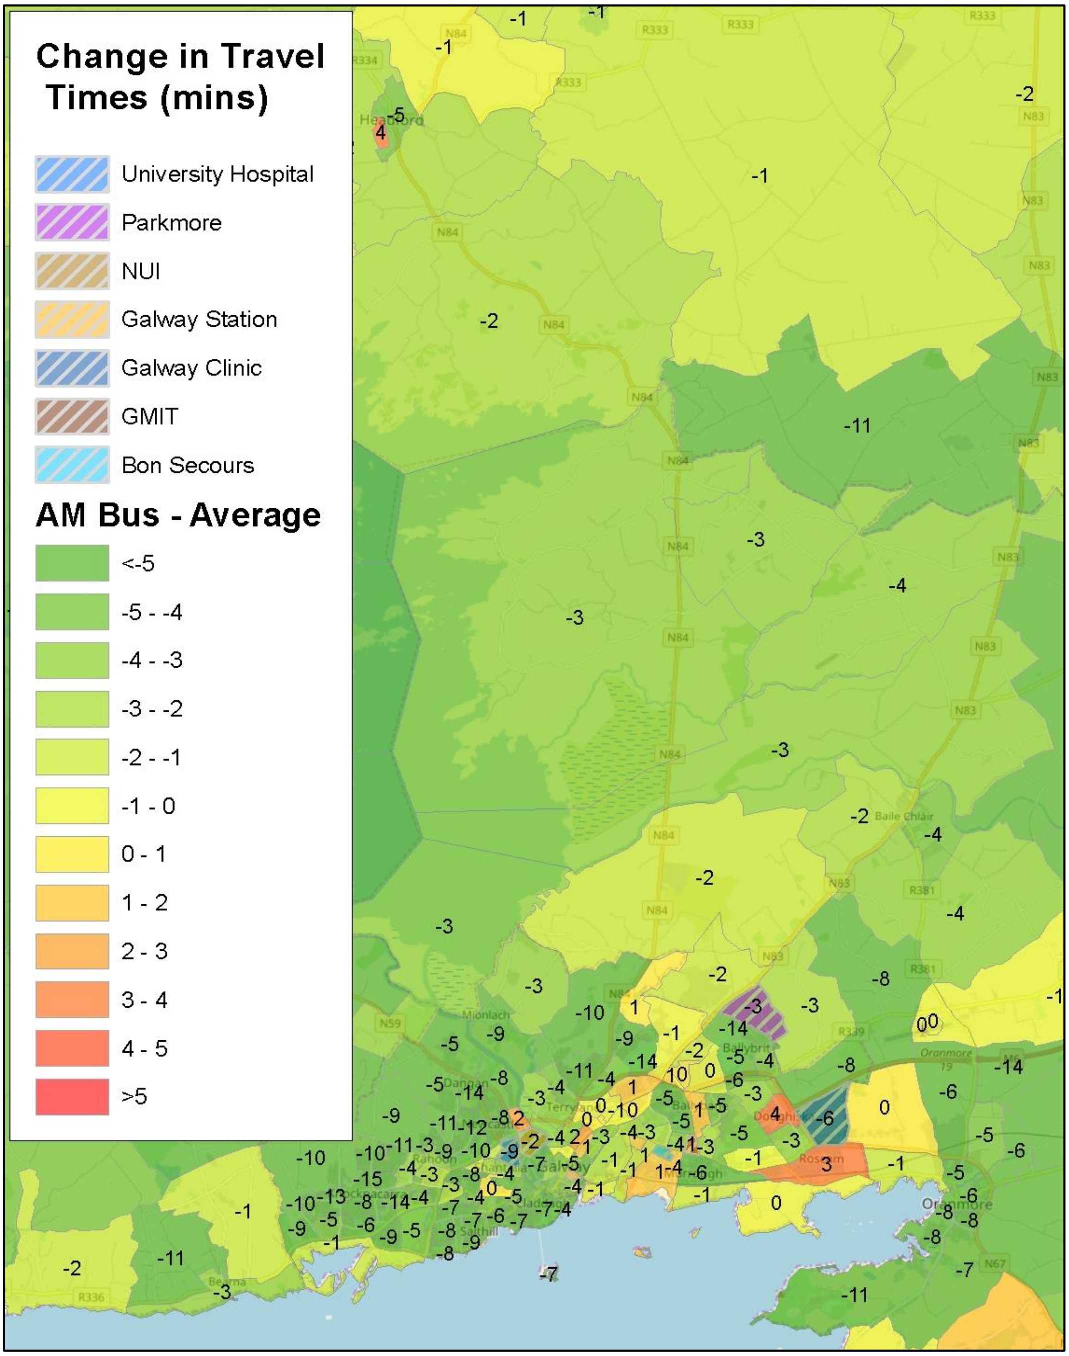
Plate 18.6: Changes in Public Transport Accessibility



<u>Social Inclusion Analysis</u>

Outputs from the traffic model have also been used to assess the impacts of the Galway Transport Strategy in terms of Social Inclusion. For this assessment, the outputs from the economic module (produced using the software Tuba) were used to visually identify which locations would benefit or suffer disbenefits as a result of the GTS. The benefits in this instance are measures in terms of journey time saving. These benefits/disbenefits were then compared against the deprivation index for the same locations to illustrate graphically how the benefits of the proposed road development are distributed among affluent and less affluent areas. **Plates 18.7** and **18.8** below illustrate the car trips and public transport trips benefits experienced by each model zone following the implementation of the GTS measures and compare these to the deprivation index for that zone.

Plate 18.7: Social Inclusion - Car

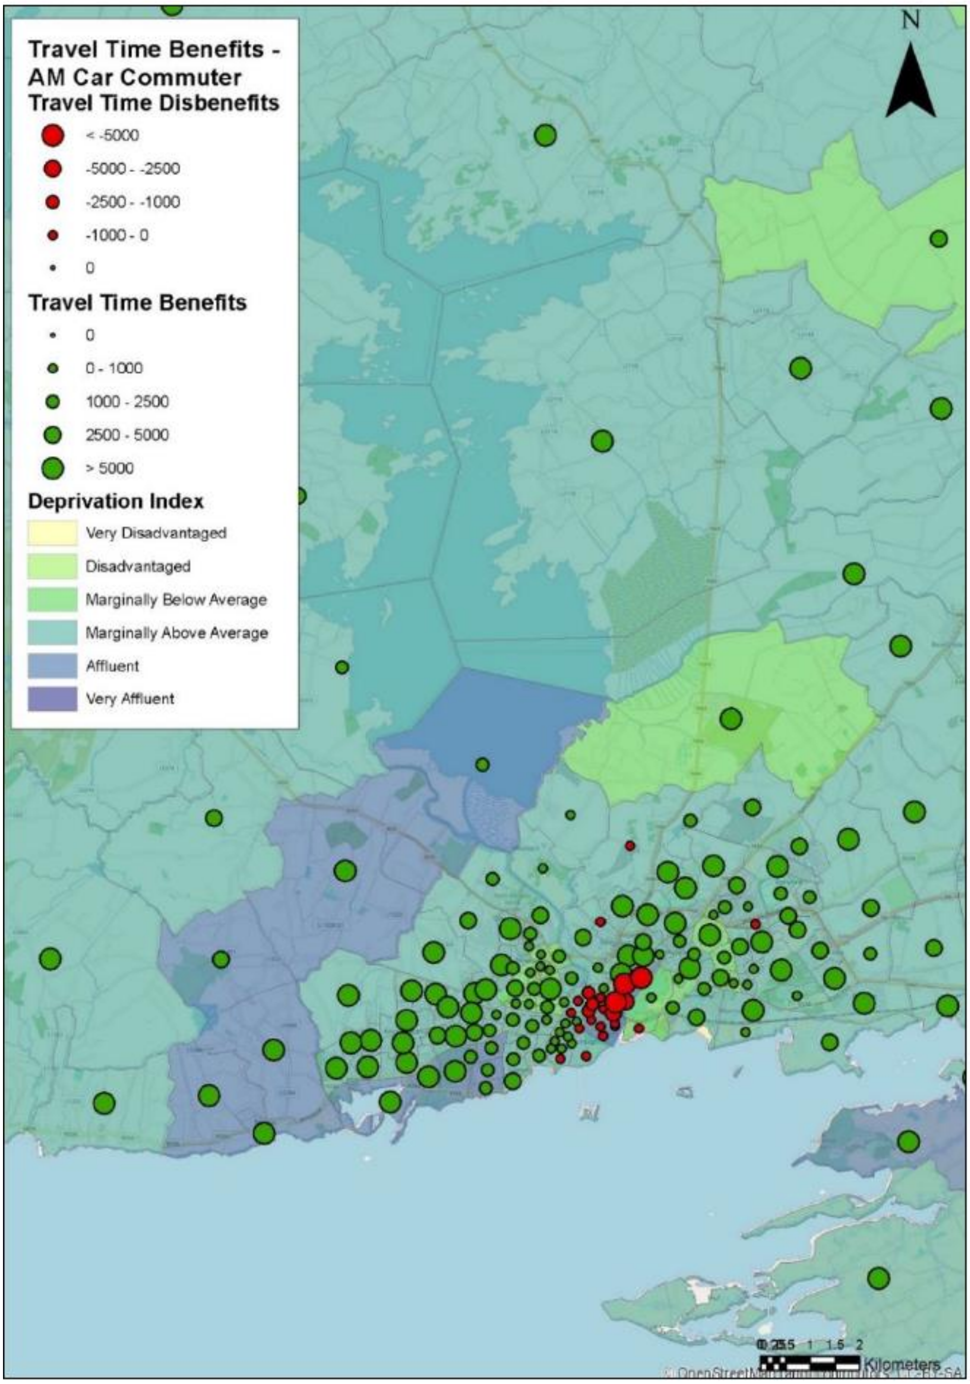


Plate 18.8: Social Inclusion – Public Transport

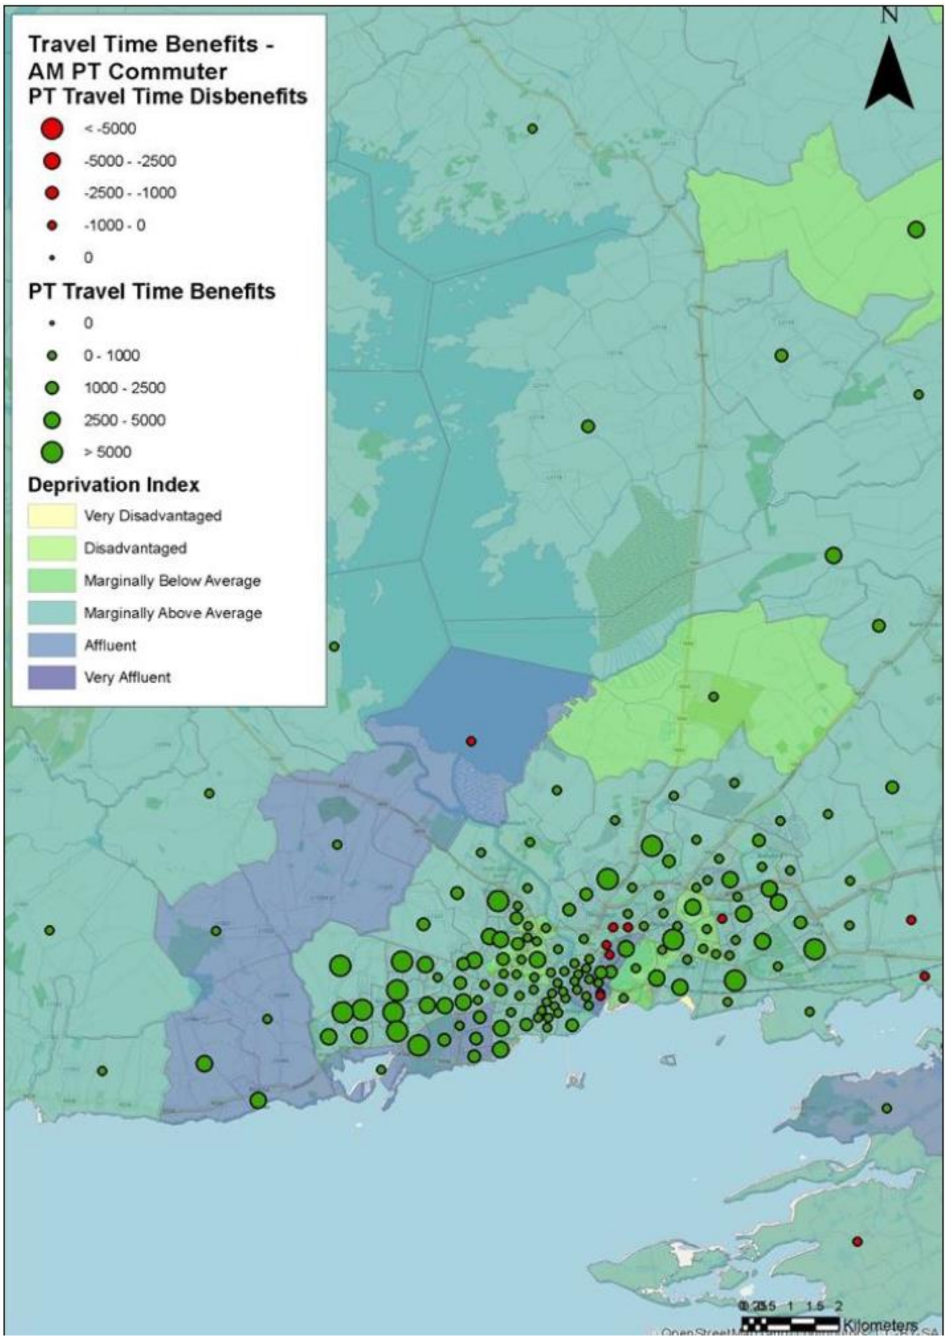

These maps show that most zones will experience an improvement in journey times for all trips from those zones. Some city centre zones however, will experience increase in journey times by car following the implementation of the GTS measures. This is a result of public transport priority measures and public realm enhancements in the city centre which will increase travel time for some car trips into and around the city centre. With respect to **Plate 18.8**, a small number of zones are seen to experience marginal disbenefits as a result of bus route changes which give these zones less direct access to the public transport network. Comparison of these benefits with the deprivation index show that, in general, the benefits of the proposed road development are distributed evenly between disadvantaged and more affluent areas.

18.8 Summary

18.8.1 Socio-Economics

A socio-economic assessment of the proposed road development was carried out and focused on aspects such as journey patterns, amenity and community severance, business, tourism, employment, ecosystem services and use of the Irish language. Data for the assessment was collected primarily through a review of relevant documents and information gathered through the extensive public consultation. This data was supported by site and home visits and local discussions with residents, businesses, schools and representatives of other community facilities. Furthermore, a Language Impact Assessment (LIA) for the proposed road development was undertaken.

A summary of socio-economic impacts, mitigation measures and residual impacts is provided in **Tables 18.14** and **18.15** below. Overall, the proposed road development will provide a much needed bypass of Galway City for regional traffic heading to destinations to and from the west of Galway, such as Connemara, to the rest of Ireland. As such, it will provide a very significant reduction in journey times. It will improve the accessibility of Galway City to its main markets by facilitating the crossing of the River Corrib without the need to go through the central suburbs of the city and connect to the national road network. This will increase the connectivity of key strategic services within Galway, such as NUIG and Galway University Hospital, to the national road network. It will also improve the accessibility of Gaeltacht areas to the remainder of the county and country, thereby facilitating reductions in the economic and social disadvantages of the Gaeltacht areas. It will also reduce the journey times of traffic heading to various parts of the city from destinations in its rural hinterland, including areas such as that north of Bearna. This will open up new opportunities for residents to access more distant parts of Galway City, for instance for employment.

The transfer of this traffic from more central locations will improve journey amenity for all users of the existing road infrastructure. In particular, it will open up road space for the provision of improved and more continuous pedestrian and cycle facilities and provide opportunities for new public transport in line with the objectives of the GTS. The transfer of traffic will contribute to improve amenity and general well-being of communities living within or beside busy urban roads. Community severance will be reduced through a moderation or reversal of the trend towards increased road traffic and through the opportunity to provide new crossing facilities.

The proposed road development has been designed to avoid as many residential properties as possible, but given the distribution of development and the presence of linear development of the city with housing along most roads radiating out of the city, its construction will unfortunately and unavoidably result in a number of property demolitions or acquisitions with some concentrations in particular areas. At some locations, a high proportion of properties will be acquired as part of the proposed road development. As well as the direct negative impact on the householders themselves, this will present a varying negative impact on remaining residents and at a community level depending on the strength of community interaction that has evolved at each location and the sustainability of community facilities such as schools. There will, also be some loss of amenity for a small number of residents living in the vicinity of the proposed road development, particularly in the east of the study area and where major junctions are located. In several locations, and particularly in Na Foraí Maola and the vicinity of the N59 Moycullen Road, the N84 Headford Road and in Castlegar, there will be a significant impact on local communities due to the need to acquire or demolish a high proportion of existing properties during construction in these areas. The proposed road development will have an impact on approximately 6.750ha of lands zoned residential by Galway City and County Council.

The eastern section of the proposed road development impacts several businesses. It will cross Lackagh Quarry which is currently inactive. Whilst the quarry is currently inactive, parts of the upper benches will be sterilised as a result of the proposed road development. At the N84 Headford Road, a very significant impact is anticipated during the construction phase on a company located here which bottles water and distributes fruit and vegetables. The impact arises from the effect of landtake on one warehouse and an impact on the company’s raw material supply. At the N83 Tuam Road there will be impacts on commercial properties, with the acquisition of a builders’ providers store and landtake from other businesses. A car dealership and An Post sorting centre could be affected by the need for traffic management during construction, but will have safe access in the operational phase of the road. There will also be an acquisition of a builders’ providers store at Ballybrit and some landtake from a car dealership at Briarhill. All of these impacts will be addressed as part of the land acquisition process and through financial compensation, but again these businesses represent the livelihoods of many individuals and so impacts will be moderate to significant. The proposed road development will have an impact on approximately 8.100ha of lands zoned commercial or industrial by Galway City Council.

The proposed road development will have a very significant negative residual impact on the NUIG Sporting Campus at Dangan, although this can be reduced to moderate with appropriate master planning as described in **Section 18.7.1.2**. Two pitches, one of which has planning permission for conversion to a 3G pitch with flood lighting, and part of a sports pavilion will be lost. A new 3G pitch and training pitch with flood lighting will be provided as a replacement. The sports facility will be permanently impacted by the presence of an overhead viaduct carrying the road towards the crossing of the River Corrib. There will be no physical severance, but the crossing will impact on the amenity of users of the sports facility and amenity use of the riverside.

The proposed location of the Galway Racecourse Tunnel means that there will be no direct amenity impacts on the racecourse business or racing events during operation. New permanent access will be available to the N83 Tuam Road via the Parkmore Link Road and much improved access will be possible from the existing N6 such that the net impacts will be positive.

Furthermore, the proposed road development will have a significant positive impact on the Galway economy by reducing traffic congestion which currently constrains economic growth and competitiveness. The improved connection provided with destinations to the west of Galway City will have a positive impact on the potential for economic development and continued growth in tourism numbers. The transfer of a proportion of traffic from existing urban roads could also help to draw more visitors into the city with consequent benefits for tourism-related businesses and the economy. Similarly, the improved connectivity with Connemara and locations to the west will help to attract tourism investment and related economic development.

Ecosystem services provide many varied benefits that humans freely gain from the natural environment. A properly functioning ecosystem has the capacity to regulate and support the natural environment that contributes to human well-being. The potential impacts on ecosystem services were considered through the assessment of the environmental factors (pathways) through which ecosystem services could be affected such as water, soils, air, noise and general amenity and relied on the biodiversity assessment in terms of potential impacts to biodiversity and indirectly to ecosystem services. There are no impacts identified in those assessments which would result in a significant residual impact on ecosystem services during the construction of the proposed road development.

18.8.2 Irish Language

In relation to the Irish language, there is a low-level of daily Irish usage among the population of the area directly affected by the proposed road development, and where it exists, the use of Irish is particularly concentrated in an education context. While population is increasing, the use of Irish as a community language is not growing in parallel. The proposed road development will not have any significant impact on the use of Irish into the future. However, it is noted that an improved road network may facilitate further migration and economic growth into the wider Galway Gaeltacht and as the west of County Galway have higher levels of unemployment and deprivation than the areas around Galway City, the proposed road development, by improving access to employment opportunities to the east of the city, will facilitate Irish speakers to commute more easily from their own communities and lessen the need to re-locate for economic reasons. Equally, as noted above, the proposed road development will make Gaeltacht areas to the west of Galway City more attractive for residential and commercial development. In this context, it will be the responsibility of Galway County Council, Galway City Council and Údarás na Gaeltachta among others to ensure that the use of the Irish language is promoted and encouraged among new residents.

18.8.3 Human Health

The potential health impacts due to the proposed road development were also assessed. The health assessment in the context of EIA focuses the attention of the assessment on likely significant effects, i.e. on effects that are deemed likely to occur and, if they were to occur, would be expected to be significant (as per the requirements of the EIA Directive).

The health assessment focused on three main areas: *health protection, health improvement and improving services*. A review of current and emerging guidance on assessing health in EIA was undertaken in addition to a literature review on the impacts of health from road developments.

18.8.3.1 Health Protection

The data collected in relation to the protection of human health focused on the results of technical assessments (such as noise, air, soil and water) dealt with elsewhere in **Chapter 9, Soils and Geology**, **Chapter 10, Hydrogeology**, **Chapter 11, Hydrology**, **Chapter 16, Air Quality and Climate** and **Chapter 17, for Noise and Vibration** and their mitigation to establish any potential hazard directly attributed to what is proposed.

These technical assessments provided elsewhere in the EIA Report use standards[31] (such as air quality standards) in order to identify whether significant impacts will arise or not. It is important to point out that health standards do not only exist to protect robust groups within the population, but are primarily intended to protect the vulnerable. The standards are set at levels for which there will be no significant health effects, but do not exclude each and every effect, i.e. slight or moderate health effects are possible even below the levels at which health based standards would apply.

Construction noise is expected to have some negative effects; however it will be short term and limited by work practices and restricted working hours. The results of the noise modelling carried out for the operational phase shows that there may be potential noise impacts on residential properties adjacent to the proposed road development, but that the implementation of low noise road surfacing and noise barriers will mitigate these potential impacts. The noise assessment also shows that there will be a benefit for a significant number of people within the city due to a proportion of current traffic being transferred from their current routes. On the basis of WHO night-time noise guidelines, there will be beneficial effects for the community living along existing roads where traffic will be reduced. Those few residences that may exceed the 55dB level do so by only small margins and are not considered to be enough to have significant health impacts.

Air quality has been considered in both the construction and operational phases. Given the proposed mitigation measures with regards to control of dust and other air emissions during the construction phase and the relative limited period of time duration, air quality impacts are not expected to have an adverse effect on human health during the construction phase. Detailed modelling based on worst case traffic scenarios identify that Air Quality Standards will not be breached thereby protecting the vulnerable such as asthmatics, the elderly, the very young or the sick in general.

Adverse effects on soils, water quality or quantity are not predicted either during the construction or the operational phases.

Whilst some annoyance during the construction phase is to be expected, this will be of limited duration and is not usually considered to be a health effect. There are potential psychological benefits in terms of reduced journey times, unforeseen delays etc. as well as movement of traffic away from currently congested and more populated areas. The transfer of a proportion of traffic to inherently safer roads, together with the prospect of reduced traffic accidents and fatalities is also an

[31] The term standards in this instance covers guidelines for example noise guidelines as such standard are not currently available.

important potential benefit. This does not take away from the adverse effects on individuals whose homes are to be compulsorily acquired. As noted above, the proposed road development has been designed to avoid as many properties as possible, but there remains a significant number of property acquisitions and, although subject to financial compensation[32], it is important to recognise that these individuals may experience stress and anxiety as a result of this process.

18.8.3.2 Health Improvement and Improvement of Access to Services

The data used to assess opportunities for health improvements and access to services included information gathering during the extensive public consultations including a meeting with University Hospital Galway and data extracted from the traffic model to identify accessibility to services.

There is potential for socio-economic gain including economic growth and development of tourism as a result of the proposed road development and it is well recognised that improved socio-economic status will have a positive impact on health outcomes. There is potential for increased employment and reduced unemployment particularly long-term unemployment. If this is achieved, there will also be benefits in terms of social health including decreased social inequality.

Other opportunities for health improvements associated with the proposed road development include a potential decrease in road traffic accidents, the potential for creating opportunities for improved public transport and an improved environment for cycling and walking within the city centre roads previously occupied by heavy traffic.

The cycling measures of the GTS, which can be fully implemented once the proposed road development is operational, will lead to a considerable increase in cyclists within Galway City. This increase in cycling will lead to an overall increase in the health benefits for those who currently do not cycle. The substantial improvements in cycling and public transport infrastructure due to the GTS will result in a marginal decrease in pedestrian activity (less than 1%) as some existing pedestrians are expected to switch from walking to public transport and cycling.

A quantification of some of the accessibility and social inclusion benefits of the proposed road development and all the GTS measures demonstrate that there will be improvements in accessibility and social inclusion for almost all parts of Galway City. In general, the measures will lead to reduced journey times by all modes and will improve accessibility to key locations within the city and more importantly none of the more disadvantaged areas experience any disbenefits.

There is potential for more efficient access to emergency services including ambulances as a result of the proposed road development. There is also the potential for increased opportunities to exercise with the associated health benefits.

[32] Compensatory measures for the loss of land, buildings and other injurious affection will form part of the land acquisition process and will be agreed at a later date with a valuer. Compensation does not form part of the EIA process and is therefore not considered further.

There are significant opportunities for improved access to services. This will include those living within Galway City and its environs and those in the west of Galway. For those within Galway City and its environs, reduced traffic along city streets will facilitate access to services including health centres. For those living outside of Galway City there is the potential for improved access to the national road network and thereby access to other services including national hospitals. For those who require to cross the city centre to access services the proposed road development offers particular benefits. While this would be of benefit to all, it will be of particular benefit those living to the west of the River Corrib.

Overall, therefore the impacts of the proposed road development on human health are primarily positive. From a community perspective, there are clear benefits in terms of health protection, opportunities for health improvements and access to services. There are however a limited number of individuals, primarily those living close to the proposed road development for whom there may be slight adverse outcomes in terms of noise and air quality. These will be minimised through the use of mitigation measures.

18.8.3.3 Summary

In summary from a human health perspective, the proposed road development will have no significant adverse effects on human health and the proposed road development and the full implementation of the GTS will have positive impacts on human health.

Table 18.14: Summary of Construction Impacts - Socio-economic

Nature of Impact	Location / Sub-Group	Current situation	Construction Impact	Significance	Duration	Extent	Proposed Mitigation	Residual Impact
Journey characteristics	Major roads: N59 Moycullen Road, N84 Headford Road, N83 Tuam Road, R339 Monivea Road	n/a	Temporary night time closures and diversions of these roads which carry significant traffic including at night	Slight to Moderate negative	Short term	Medium	Traffic management to minimise delays	Slight negative
Journey characteristics	Where minor roads meet construction works	n/a	Slight diversions or Stop / go arrangements	Imperceptible to slight negative	Short term	Medium	Traffic management to minimise delays	Imperceptible
Journey characteristics	Rahoon Road & Letteragh Road	n/a	Temporary night time closures	Slight negative	Short term	Few	Avoid extended night time closures	Imperceptible to Slight negative
General amenity	Rosán Glas estate	n/a	Construction of link road beside estate and new access connection	Slight to moderate negative	Short term	Medium	Minimise access disruption to estate. Temporary visual screening	Slight negative
General amenity	Gort na Bró estate	n/a	Realignment of Gort na Bró Road which provides access to estate	Slight negative	Short term	Medium	Minimise access disruption to estate and gaelscoil.	Imperceptible to Slight negative
General amenity	Bushypark Church	Local community facilities	Construction traffic movements impacting on use of church and adjacent cemetery	Slight negative	Short term	Medium	Traffic management and temporary visual screening from construction works	Imperceptible to slight negative
General amenity	NUIG Sporting Campus	Sports and amenity use	Noise and visual impacts, loss of use of playing pitches and modification of the sports pavilion, as the central part of the	Very significant negative	Medium term	Many	Construction traffic and works for the River Corrib Bridge will be managed to minimise	Significant negative

Nature of Impact	Location / Sub-Group	Current situation	Construction Impact	Significance	Duration	Extent	Proposed Mitigation	Residual Impact
			sporting campus will become a construction site				interference with sporting activities and spectators. Provision of a floodlit 3G GAA pitch, a floodlit 3G training area and associated site infrastructure such as drainage of these pitches and ball-stop netting and modification of the sports pavilion	
General amenity	River Corrib crossing	Amenity use	Noise and visual impacts	Mix of positive and significant negative for different receptors	Medium term	Medium	Minimise duration of any restrictions on access below the bridge works and advice of alternative routes	Moderate negative – positive on balance.
General amenity	An Seanbóthar	Amenity use	Construction vehicle movement	Moderate negative	Short term	Few	Avoid severance and minimise duration of use by construction traffic	Slight to Moderate negative
General amenity	Cappanabornia (beside N83 Tuam Road)	Residential area of 6 houses with direct access to the N83 Tuam Road	Construction of new access road to dwelling and removal of direct access to the N83 Tuam Road. Visual impacts due to the construction of the proposed N83 Tuam Road Junction	Significant negative	Medium term	Few	Minimise disruption to access. Visual and noise barriers. Refer also to **Chapter 12, Landscape and Visual** and	Moderate negative (access)

Nature of Impact	Location / Sub-Group	Current situation	Construction Impact	Significance	Duration	Extent	Proposed Mitigation	Residual Impact
							Chapter 17, Noise and Vibration	
General amenity – property demolition and acquisition (private level)	Route of proposed road development	Rural area with a high number of one-off dwellings and semi-urban areas	Demolitions of 44 and acquisition of 10 dwellings	Significant to Profound negative (owners & occupants)	Permanent	Many	In the event of an approval of the Protected Road Scheme and Motorway Scheme and approval under Section 51 of the Roads Act 1993 (as amended), by An Bord Pleanála and subject to the availability of funding, Notice to Treat will be served firstly on owners, lessees and occupiers of the dwelling houses and commercial properties to be acquired, within six months of the scheme becoming operative, unless an application has been made for Judicial Review, in which case the	Subject to financial compensation as part of the compulsory purchase process

Nature of Impact	Location / Sub-Group	Current situation	Construction Impact	Significance	Duration	Extent	Proposed Mitigation	Residual Impact
							Notice to Treat33 will be served in accordance with the provisions of Section 217 (6A) of the Planning and Development Act 2000 as inserted by the Compulsory Purchase Orders (Extension of Time Limits) Act 2010. Compensation will be agreed or determined by the property arbitrator as soon as possible after service of Notice to Treat. After compensation has been agreed or determined and satisfactory title has been produced, part payment can be made while the claimant remains for an agreed period in the property to be acquired. This will	

[33] This notice requests landowners to submit their claim for compensation for lands being taken under the Protected Road Scheme or Motorway Scheme. This is the initial step in the acquisition of property and lands.

Nature of Impact	Location / Sub-Group	Current situation	Construction Impact	Significance	Duration	Extent	Proposed Mitigation	Residual Impact
							facilitate the claimant in removing uncertainty and will facilitate arrangements being made, as early as possible, to secure a replacement property. Refer Chapter 15, (community level) Material Assets	
General Amenity - demolitions (community level)	Na Foraí Maola / Troscaigh	Semi-dispersed community	Acquisition or demolition of 7 properties (+1 site with planning for a dwelling) with impact on local community	Significant negative (wider community)	Long term	Medium	Public Communications Strategy as set out in the CEMP which will include procedures to inform members of the community who will be directly affected by the construction phase on schedules for any activity of a particularly disruptive nature which is likely to impinge on their property.	Significant to Moderate negative

Nature of Impact	Location / Sub-Group	Current situation	Construction Impact	Significance	Duration	Extent	Proposed Mitigation	Residual Impact
General Amenity - demolitions (community level)	Ard an Locha	Small residential estate	Acquisition or demolition of 3 properties (+2 site with planning for a dwelling) with impact on wider community	Very significant negative (wider community)	Long term	Few	Consult and liaise with residents in local community	Significant negative
General amenity – demolitions (community level)	Aughnacurra, Bushypark	Small residential estate	Acquisition or demolition of 6 properties representing a high proportion of the wider community	Very significant negative (wider community)	Long term	Medium	Consult and liaise with residents in local community	Significant negative
General amenity – demolitions (community level)	N84 Headford Road,	Linear residential development, mainly on one side of road	Demolition of 14 properties representing a high proportion of the wider community	Very significant negative (wider community)	Long term	Medium	Consult and liaise with residents in local community	Significant to negative
General amenity – demolitions (community level)	Castlegar	Residential area including school and other community facilities	Acquisition or demolition of 7 properties representing a high proportion of the wider community	Very significant negative (wider community)	Long term	Medium	Consult and liaise with residents in local community	Significant negative
Severance	Locations north and south of the proposed road development in west of study area, School Road, N59 Moycullen Road, N84 Headford Road & N83 Tuam Road	No north-south severance, but high traffic volumes on some roads	Physical and social severance during construction phase	Moderate to slight negative	Short term	Few-medium	Allow for vehicle, pedestrian / cycle crossing	Slight negative
Severance	N84 Headford Road	High volume of existing traffic	Road to be used by construction traffic	Slight negative	Short term	High	Minimise vehicle movements during peak traffic hours	Imperceptible to Slight negative

Nature of Impact	Location / Sub-Group	Current situation	Construction Impact	Significance	Duration	Extent	Proposed Mitigation	Residual Impact
Severance	NUIG Sporting Campus	n/a	Construction of proposed bridge over River Corrib	Significant negative	Short term	Medium	Maintain continuous, if restricted access	Slight negative (physical severance)
General economic	NUIG Sporting Campus	Rental of sports pitches and facilities and some related use of accommodation.	Some loss of this income due to unavailability of pitches.	Slight negative	Short term	Medium	-	Slight negative
Economic	Business on the N84 Headford Road	Business which bottles water and distributes fruit and vegetables	Landtake on one warehouse and an impact on the company's raw material supply and potential business impact	Very significant negative	Long term	1 business	Subject to financial compensation as part of the compulsory purchase process	Subject to financial compensation as part of the compulsory purchase process
Economic	Business on the N83 Tuam Road	Hardware / builders providers	Full acquisition of business	Very significant negative	Permanent	1 business	Subject to financial compensation as part of the compulsory purchase process	Subject to financial compensation as part of the compulsory purchase process
Economic	Business on the N83 Tuam Road	Car dealership	Dust and noise impacts during construction. Partial landtake and possible effect on visibility of business during construction	Moderate negative	Short term	1 business	Noise and dust control measure during construction. Signage to direct accessibility	Slight-moderate negative
Economic	Business on the N83 Tuam Road	Postal business	Partial landtake. Traffic management and access	Slight to moderate negative	Short term	1 business	Signage to direct accessibility	Slight negative

Nature of Impact	**Location / Sub-Group**	**Current situation**	**Construction Impact**	**Significance**	**Duration**	**Extent**	**Proposed Mitigation**	**Residual Impact**
Economic	Businesses in Parkmore Business Park	Business park	Potential impact from noise, dust or vibration during tunnel works	Slight to Significant negative	Short term	Medium (approx. 6 businesses)	Noise and dust control measure during construction. Tunnel works will be undertaken in compliance with the CEMP in **Appendix A.7.5**	Imperceptible to slight negative
Economic	Galway Racecourse	Galway Racing Festival and tourism venue	Partial landtake, construction of a cut-and-cover tunnel, removal of stables, temporary loss of some car parking and some other facilities	Significant negative	Short term	Principally one business	Works phased to minimise racing events. Replacement of stables and well	Slight negative during construction.
General amenity (trainers & spectators)	Galway Racecourse	Major community and tourism facility	Cut-and-cover tunnel construction. Temporary loss of car parking	Potentially significant negative	Medium term	Many	Construction works phased to minimise impacts on racing events	Slight negative during construction
Economic	Car dealership Briarhill Business Park	Business visible from existing N6 and Ballybrit Crescent	Dust and noise impacts during construction. Partial landtake requiring a reconfiguration of services on the residual lands and possible effect on visibility of business during construction	Very significant negative	Some short term, mostly long term	1 business	Noise and dust control measure during construction. Signage to direct accessibility	Significant negative
Economic	Tourism	Attraction of city as a tourist destination significantly affected by traffic congestion	Construction work located away from city centre and existing through routes. Possible impact on traffic movements on N59	Slight negative	Short term	Many businesses dependent on tourism	Minimise road closures or diversions	Imperceptible (during construction)

Nature of Impact	**Location / Sub-Group**	**Current situation**	**Construction Impact**	**Significance**	**Duration**	**Extent**	**Proposed Mitigation**	**Residual Impact**
			Moycullen Road, N84 Headford Road & N83 Tuam Road					

Table 18.15: Summary of Operational Impacts - Socio-economic

JOURNEY CHARACTERISTICS								
Nature of Impact	**Location / Sub-Group**	**Current situation**	**Operational Impact**	**Significance**	**Duration**	**Extent**	**Proposed Mitigation**	**Residual Impact**
Journey time and connectivity	Regional	Long and congested connection between M6 east of Galway and N83 Tuam Road, N59 Moycullen Road and R336 west	Much reduced travel time and avoidance of regular congestion	Profound positive	Long term	Very many	-	Profound positive
Journey time	Mainly local Galway City	Prolonged journey time on existing N6 through Galway City and regular congestion.	Reduced incidence or scale of congestion due to transference of much traffic	Very significant positive	Long term	Very many	-	Very significant positive
Journey time	Bearna and western Galway suburbs	Regular delays in Bearna Village particularly during morning and peak hours including the holiday season	Transference of high proportion of traffic from Bearna Village and reduced incidence of congestion	Significant positive	Long term	Many	-	Significant positive
Connectivity	Small communities and residential development north of Bearna Village	Access to the city and east only via minor roads with light traffic	Direct access to proposed road development via Bearna East Roundabout	Significant positive	Long term	Medium	-	Significant positive
Connectivity	Between proposed road development and Boleybeg / Western Distributor Road	Access to the city and east via minor roads with light traffic or Western Distributor Road	More direct access to the proposed road development via Cappagh Road Junction	Moderate positive	Long term	Many	-	Moderate positive
Connectivity	Ballymoneen and Western suburbs	Dependence on Western Distributor Road for access	Direct access to the proposed road development via Ballymoneen Junction	Moderate positive	Long term	Many	-	Moderate positive

JOURNEY CHARACTERISTICS								
Nature of Impact	**Location / Sub-Group**	**Current situation**	**Operational Impact**	**Significance**	**Duration**	**Extent**	**Proposed Mitigation**	**Residual Impact**
Connectivity	N59 Moycullen Road	Poor access between N59 Moycullen Road north of Galway and Rahoon or the busy existing N6 to the south	Alternative access via links road north and south of N59 Letteragh Junction to the proposed road development. Relief from congestion at Browne Junction.	Very significant positive	Long term	Very many	-	Very significant positive
Connectivity	N84 Headford Road	Access between N84 Headford Road and Kirwan Roundabout	Alternative access from the N84 to the proposed road development	Significant positive	Long term	Many	-	Significant positive
Connectivity	N83 Tuam Road	Access between N83 Tuam Road and Connemara or local business parks	Access to proposed road development from the N83 Tuam Road Junction	Very significant positive	Long term	Very many	-	Very significant positive
Connectivity	Parkmore Link Road	Limited access between the Parkmore Business Park, the N83 Tuam Road and the existing N6	Access to Parkmore, City East and Ballybrit Industrial Estates	Profound positive	Long term	Very many		Profound positive
Journey time	Ballybrit Crescent and Lynch Junctions	Frequent congestion and delay at these junctions and with existing N6 traffic	Transference of traffic to proposed road development and Parkmore Link Road providing for reduced traffic delays and congestion	Very significant positive	Long term	Very many	-	Very significant positive

AMENITY – Journey amenity								
Nature of Impact	**Location / Sub-Group**	**Current situation**	**Operational Impact**	**Significance**	**Duration**	**Scale**	**Proposed Mitigation**	**Residual Impact**
Journey amenity	R336 between centre of Bearna Village and Bearna West Roundabout	Existing R336 can be busy, especially at weekend and during holiday season	Increase in traffic on this section, but mainly during week days	Slight negative	Long term	Medium	None proposed	Slight negative
Journey amenity (traffic-related)	Browne Roundabout & Seamus Quirke Road	Regular congestion at these locations particularly during peak hours and weekends	Transfer of a proportion of traffic to the proposed road development and reduced risk of congestion	Moderate positive	Long term	Very many	Implementation of GTS measures to improve journey amenity for pedestrian and cyclists	Significant positive
Journey amenity (traffic-related)	Kirwan Roundabout	Regular congestion at this location and at the Bodkin Roundabout	Transfer of a proportion of traffic to the proposed development and reduced risk of congestion	Slight-Moderate positive	Medium – long term	Very many	Opportunity to improve journey amenity for pedestrian and cyclists	Significant positive
Journey amenity (traffic-related)	N83 Tuam Road / existing N6 junction	Regular congestion at this location	Transfer of a proportion of traffic to the proposed road development, but also facilitating traffic on the proposed road development to the city centre via the N83 Tuam Road	Slight negative to Slight positive	Medium – long term	Very many	None proposed	Slight negative to Slight positive
Journey amenity (traffic-related)	Lynch Junction and Doughiska Junction	Regular congestion at these locations	Transfer of a proportion of traffic to the proposed development and reduced risk of congestion	Moderate-significant positive	Medium – long term	Very many	Opportunity to improve journey amenity for pedestrian and cyclists	Moderate positive

AMENITY – Journey amenity								
Nature of Impact	**Location / Sub-Group**	**Current situation**	**Operational Impact**	**Significance**	**Duration**	**Scale**	**Proposed Mitigation**	**Residual Impact**
Journey amenity (views)	River Corrib Bridge	N/a	Elevated view for drivers north and south of the River Corrib Corridor including of Menlo Castle	Moderate positive	Long term	Very many	-	Moderate positive-

AMENITY – General amenity								
Nature of Impact	Location / Sub-Group	Current situation	Operational Impact	Significance	Duration	Scale	Proposed Mitigation	Residual Impact
General amenity (environmental)	Cappagh Road and Ballymoneen Road	Quiet rural area. Scattered residential development with suburban development to south	Impacts on general amenity due to increased traffic volumes	Significant negative	Long term	Medium	Screen planting and noise mitigation where required. Refer also to **Chapter 12, Landscape and Visual** and **Chapter 17, Noise and Vibration**	Moderate negative
General amenity (environmental)	Northern link from Letteragh Junction	Scattered residential development	Impacts on general amenity due to noise or visual intrusion	Significant negative	Long term	Few	Screen planting and noise mitigation where required. Refer also to **Chapter 12 Landscape and**	Moderate to Significant negative

AMENITY – General amenity								
Nature of Impact	Location / Sub-Group	Current situation	Operational Impact	Significance	Duration	Scale	Proposed Mitigation	Residual Impact
							Visual and **Chapter 17, Noise and Vibration**	
General amenity (environmental)	Bushypark & Aughnacurra	Residential development	Impacts on general amenity due to noise or visual intrusion	Significant negative chapters	Long term	Medium	Screen planting and noise mitigation where required. Refer also to **Chapter 12, Landscape and Visual** and **Chapter 17, Noise and Vibration**	Moderate to Significant negative
General amenity (environmental)	St. James' National School, Bushypark	School and playing grounds	Impacts on general amenity due to noise or visual intrusion	Significant negative	Long term	Medium	Screen planting and noise mitigation where required. Refer also to **Chapter 12, Landscape and Visual** and **Chapter 17, Noise and Vibration**	Moderate negative
General amenity (environmental)	NUIG Sporting Campus	Sports pitches	Proposed road development on a viaduct splitting the sporting campus in two requiring a reconfiguration of	Very Significant negative	Long term	Many	Provision of a floodlit 3G GAA pitch, a floodlit 3G	Very significant but can be reduced to

AMENITY – General amenity								
Nature of Impact	Location / Sub-Group	Current situation	Operational Impact	Significance	Duration	Scale	Proposed Mitigation	Residual Impact
			pitches, the modification of the sports pavilion and a new Sporting Campus Plan and Strategy				training area and associated infrastructure for such as drainage of these pitches, as ball-stop netting and modification of the sports pavilion.	moderate subject to appropriate master planning. Subject also to financial compensation as part of the compulsory purchase process
General amenity (environmental)	River Corrib and river banks	Riverside walk and Menlo Castle	Noise and visual impacts from proposed river bridge	Significant negative	Long term	Medium	Retain existing vegetation. Noise barriers. Refer also to **Chapter 12, Landscape and Visual** and **Chapter 17, Noise and Vibration**	Significant negative
General amenity	School Road, Castlegar	Narrow road used partly as a commuting rat-run and with discontinuous roadside footpaths.	Transfer of ‘rat run’ traffic from School Road to the proposed road development	Slight positive	Long term	Medium	Overbridge on School Road to include footpath and extend to at least to tie-in with existing road	Moderate positive

AMENITY – General amenity								
Nature of Impact	Location / Sub-Group	Current situation	Operational Impact	Significance	Duration	Scale	Proposed Mitigation	Residual Impact
General amenity	Mass path Parkmore	Quiet and well-maintained footpath elevated above surrounding area	Severance of path, but with new connectivity and informal crossing facility, but also loss of amenity value	Significant negative. (Positive on connectivity)	Long term	Few	Screen planting	Significant negative (Positive on connectivity)
General amenity (environmental)	Galway Racecourse	Horse racing	Proposed road development placed in tunnel beside racecourse. Improved access and reduced congestion.	Slight positive	N/a	Very many	N/a	Slight positive

SEVERANCE								
Nature of Impact	**Location / Sub-Group**	**Current situation**	**Operational Impact**	**Significance**	**Short / Long term / perm**	**Scale**	**Proposed Mitigation**	**Residual Impact**
Relief from severance	Bearna Village	Some severance in the centre of the village especially at peak times	Transfer of much traffic to the proposed road development	Significant positive	Long term	Medium	-	Significant positive
New severance and relief from severance	Na Foraí Maola and Troscaigh	Rural area with scattered linear residential development	Social and physical severance. Foraí Maola road diverted to Troscaigh Junction. But also positive impact of new connection with Troscaigh	Moderate negative. Moderate positive	Long term	Few	Diversion of local road included in design	Moderate negative. Moderate positive
New severance	L13215 Ann Gibbons Road	Rural area with scattered linear residential development	Road severed. Most community facilities to south, but north bound traffic will now have to divert south and to the Bearna Moycullen Road	Significant negative for householders on northern end of the Ann Gibbons Road	Long term	Few	-	Significant negative
New severance	North of Bearna Village	Rural area with scattered linear residential development	Crossing facilities mitigate physical severance, but psychological severance created between areas to north and south	Moderate negative	Long term	Many	Include pedestrian crossing facilities at junctions	Slight negative
New severance	Cappagh Road	Low traffic volumes	Higher traffic volumes presenting new severance at sports pitches to south	Moderate negative	Long term	Medium	Crossing facilities in place, but impact outside of area of-proposed road development	Moderate negative
New severance	Gort na Bró Miller’s Lane	Light traffic	Some additional traffic	Slight negative	Long term	Medium	None proposed	Slight negative

SEVERANCE								
Nature of Impact	**Location / Sub-Group**	**Current situation**	**Operational Impact**	**Significance**	**Short / Long term / perm**	**Scale**	**Proposed Mitigation**	**Residual Impact**
New severance	Coolagh and Menlough	Narrow rural roads	Degree of new social severance due to presence of proposed road development	Slight negative	Long term	Medium	-	Slight negative
New severance	N84 Headford Road to existing N6	Moderate traffic volumes	Increase in traffic accessing proposed N84 Headford Road Junction and physical presence of junction	Moderate negative	Long term	Medium	Provide pedestrian crossing facilities at community facilities.	Slight negative

ECONOMIC								
Nature of Impact	**Location / Sub-Group**	**Current situation**	**Operational Impact**	**Significance**	**Short / Long term/ permanent**	**Scale**	**Proposed Mitigation**	**Residual Impact**
Passing trade	R336 and Bearna	Some passing trade including for service stations on R336 Coast Road / Tuam Road	Reduction in passing traffic but improved access to premises	Slight negative	Long term	Few	None proposed	Slight negative
Access	Gateway Business Park	Access via Seamus Quirke Road subject to regular congestion	Alternative of more direct access to proposed road development	Significant positive	Long term	Medium	-	Significant positive
Access	N59 Moycullen Road &	Business park access via N59 Moycullen Road subject to congestion and indirect access to existing N6.	Alternative of access to proposed road development via link road	Significant positive	Long term	Medium	-	Significant positive

ECONOMIC								
Nature of Impact	**Location / Sub-Group**	**Current situation**	**Operational Impact**	**Significance**	**Short / Long term/ permanent**	**Scale**	**Proposed Mitigation**	**Residual Impact**
	Newcastle Road Upper							
Access	Car dealership and postal centre on the N83 Tuam Road	Direct access on to busy N83 Tuam Road	Improved access to N83 Tuam Road from start of City North Business Park Link. Good visibility of businesses maintained	Moderate positive	Long term	Two businesses	-	Moderate positive
Access	Parkmore Business Park, City East and Ballybrit Industrial Estates	Limited access between the Parkmore Business Park, the N83 Tuam Road and the existing N6.	Much improved access to N83 Tuam Road and proposed road development	Profound positive	Long term	Very many	-	Profound positive
General economic	Galway Racecourse	Access via existing N6 and event day access to N83 Tuam Road	Requirement to replace stables and other facilities. Proposed tunnel to the north of the racetrack. Improved general access, including to the N83 Tuam Road	Net moderate positive	Long term	One major business and ancillary businesses , including during events	-	Net moderate positive
Access	Briarhill Business Park	Access to existing N6	Reduced congestion expected at Ballybrit Crescent and Lynch Junction. New access north to N83 Tuam Road via Parkmore Link Road	Significant positive	Long term	medium	-	Significant positive

ECONOMIC								
Nature of Impact	**Location / Sub-Group**	**Current situation**	**Operational Impact**	**Significance**	**Short / Long term/ permanent**	**Scale**	**Proposed Mitigation**	**Residual Impact**
Access, land take	Car dealership, Briarhill Business Park	Access to existing N6	Reconfiguration of services on the residual lands are required with improved access with the reduced congestion on the existing road network	Negative impact from landtake combined with some positive impact from improved access	Long term	One business	Provide directional signage	Subject to financial compensation as part of the compulsory purchase process
Tourism	Galway City and locations to west	High congestion in city and poor connectivity to Connemara	Reduced congestion and improved connectivity	Very significant positive	Long term	Very many	-	Very significant positive

19 Major Accidents, Inter-Relationships, Interactions and Cumulative Impacts

19.1 Introduction

This chapter of the EIAR presents an assessment of the vulnerability of the proposed road development to risks of major accidents and/or disasters including the methodology used for the assessment (**Section 19.2**). The methodology used to assess interaction/inter-relationship and cumulative impacts is presented in **Section 19.3**, with the assessment of the interaction/inter-relationship of impacts between the various environmental factors as a result of the proposed road development in **Section 19.4** and an assessment of the cumulative impacts of the proposed road development with other projects in **Section 19.5**. Potential transboundary impacts are included in **Section 19.6** and this chapter concludes with references (**Section 19.7**).

19.1.1 Vulnerability of the proposed road development to risks of major accidents and/or disasters

Article 3 of the EIA Directive as amended by Directive 2014/52/EU requires that:

"The effects referred to in paragraph 1 on the factors set out therein shall include the expected effects deriving from ***the vulnerability of the project to risks of major accidents and/or disasters that are relevant to the project concerned****".*

Furthermore, Annex IV (8) (*Information Referred to in Article 5(1) (Information for the Environmental Impact Assessment Report*) of the EIA Directive as amended by Directive 2014/52/EU states that the EIAR shall contain:

"A description of the expected significant adverse effects of the project on the environment deriving from the ***vulnerability of the project to risks of major accidents and/or disasters which are relevant to the project concerned****. Relevant information available and obtained through risk assessments pursuant to Union legislation such as Directive 2012/18/EU of the European Parliament and of the Council[1]or Council Directive 2009/71/Euratom[2] or relevant assessments carried out pursuant to national legislation may be used for this purpose provided that the requirements of this Directive are met.* ***Where appropriate, this description should include measures envisaged to prevent or mitigate the significant adverse effects of such events on the environment and details of the preparedness for and proposed response to such emergencies****."*

[1] (*) Directive 2012/18/EU of the European Parliament and the Council of 4 July 2012 on the control of major-accident hazards involving dangerous substances, amending and subsequently repealing Council Directive 96/82/EC (OJ L 197, 24.7.2012, p. 1).

[2] (**) Council Directive 2009/71/Euratom of 25 June 2009 establishing a Community framework for the nuclear safety of nuclear installations (OJ L 172, 2.7.2009, p. 18)'.

Section 19.2 of this chapter presents an assessment of the vulnerability of the proposed road development to risks of major accidents and/or disasters which are relevant to the proposed road development.

19.1.2 Interactions and Inter-relationships

Article 3 (1) of the EIA Directive as amended by Directive 2014/52/EU requires that:

"The environmental impact assessment shall identify, describe and assess in an appropriate manner, in the light of each individual case, the direct and indirect significant effects of a project on the following factors: (a) population and human health; (b) biodiversity, with particular attention to species and habitats protected under Directive 92/43/EEC and Directive 2009/147/EC; (c) land, soil, water, air and climate; (d) material assets, cultural heritage and the landscape; ***(e) the interaction between the factors referred to in points (a) to (d)****.*

Also, pursuant to section 50(3)(b) of the Roads Act 1993 (as amended) the EIAR (or EIS as then was under the Roads Act) is to contain:

"50(3)(b) a description of the aspects of the environment likely to be significantly affected by the proposed road development, including in particular—

- *human beings, fauna and flora,*
- *soil, water, air, climatic factors and the landscape,*
- *material assets, including the architectural and archaeological heritage, and the cultural heritage,*
- *the inter-relationship between the above factors,*

The interaction of effects within the proposed road development in respect of each of the environmental factors, listed in Article 3(1) of the EIA Directive, have been identified and addressed in detail in the respective chapters in this EIAR. This chapter however, presents a summary of each assessment of the interaction (inter-relationship) of impacts, from the proposed road development, between the various environmental factors.

Section 19.4 of this chapter presents an assessment of the interaction/inter-relationship of impacts between the various environmental factors as a result of the proposed road development.

19.1.3 Cumulative Impacts

Annex IV (5)(e) of the EIA Directive as amended by Directive 2014/52/EU requires that the EIAR shall contain:

"*A description of the likely significant effects of the project on the environment resulting from, inter alia:*

(e) the ***cumulation of effects*** *with other existing and/or approved projects, taking into account any existing environmental problems relating to areas of particular environmental importance likely to be affected or the use of natural resources;*

Furthermore, Annex IV (5) states that the EIAR shall contain:

"The description of the likely significant effects on the factors specified in Article 3(1) should cover the direct effects and any indirect, secondary, ***cumulative****, transboundary, short-term, medium-term and long-term, permanent and temporary, positive and negative effects of the project. This description should take into account the environmental protection objectives established at Union or Member State level which are relevant to the project".*

Also, pursuant to section 50(3)(c) of the Roads Act 1993 (as amended) the EIAR (or EIS as then was under the Roads Act) is to contain:

"(c) a description of the likely significant effects (including direct, indirect, secondary, ***cumulative****, short, medium and long-term, permanent and temporary, positive and negative) of the proposed road development on the environment resulting from—*

- *the existence of the proposed road development,*
- *the use of natural resources,*
- *the emission of pollutants, the creation of nuisances and the elimination of waste"*

Section 19.5 of this chapter presents an assessment of the cumulative impacts of the proposed road development with other projects.

19.2 Major Accidents and Disasters

19.2.1 Introduction

This section presents an assessment of the likely significant adverse effects of the proposed road development on the environment arising from the vulnerability of the proposed road development to risks of major accidents and/or disasters that are relevant to the proposed road development.

As mentioned previously, this assessment is necessary following changes to the EU legislation. Article 3 of the EIA Directive as amended by Directive 2014/52/EU states the need to assess "*the expected significant adverse effects of the project on the environment deriving from the vulnerability of the project to risks of major accidents and/or disasters that are relevant to the project concerned*".

The underlying objective of the assessment is to ensure that appropriate precautionary actions are taken for those projects which "*because of their vulnerability to major accidents and/or natural disasters, are likely to have significant adverse effects on the environment"*.

Based on the requirements of the new EIA Directive, this chapter answers the following questions:

- To what major accidents and/or disasters could the proposed road development be vulnerable?
- Could these major accidents and/or disasters result in likely significant adverse environmental effect(s) and if so what would these be?

- What measures are in place, or need to be in place, to prevent or mitigate the likely significant adverse effects of such events on the environment?

This assessment is set out as follows:

- **Section 19.2.2** sets out the methodology used
- **Section 19.2.3** describes characteristics of the major accidents and/or disasters that may be relevant to the proposed road development
- **Section 19.2.4** details the risk screening process to determine what major accidents and/or disasters to which the proposed road development could be vulnerable
- **Section 19.2.5** provides a summary of the output of the risk screening process
- **Section 19.2.6** details the assessment of the vulnerability of the proposed road development to major accidents and/or disasters identified during the risk screening process
- **Section 19.2.7** describes measures to mitigate the likely significant impacts of such events on the environment
- **Section 19.2.8** describes residual impacts
- **Section 19.2.9** provides a summary

19.2.1.1 Key definitions relevant to this assessment

At the time of undertaking this assessment, there was no clear definition of the term "major accident and/or disaster" in the context of the EIA Directive. Achieving a common terminology is a challenge as various disciplines have developed specific terminology for the assessment of risks and impacts. The following definitions have been adopted for this EIAR following a review of SEC (2010) 1626 – Risk Assessment and Mapping Guidelines for Disaster Management and ISO 31010 – Risk Management.

Hazard is a dangerous phenomenon, substance, human activity or condition that may cause loss of life, injury or other health impacts, property damage, loss of livelihoods and services, social and economic disruption, or environmental damage (*in technical settings, hazards are described quantitatively by the likely frequency of occurrence of different intensities for different areas, as determined from historical data or scientific analysis*).

Natural hazard: Natural process or phenomenon that may cause loss of life, injury or other health impacts, property damage, loss of livelihoods and services, social and economic disruption, or environmental damage (*natural hazards are a sub-set of all hazards. The term is used to describe actual hazard events as well as the latent hazard conditions that may give rise to future events. Natural hazard events can be characterised by their magnitude or intensity, speed of onset, duration, and area of extent (UNISDR, 2009)*).

Disaster risk[3] is characterised as a hazard which has potential to incur community losses, encompassing assets, life, health and livelihoods, giving significance to disaster events at a personal and local scale. Disaster risk can also be defined as, hazards which could cause a locality to require assistance from an outside state, which could relate to international aid, or a local authority requiring assistance from another local authority.

A *natural disaster*, in the context of the proposed road development, is a naturally occurring phenomenon such as an extreme weather event (e.g. storm, flood, temperature) or ground-related hazard events (e.g. subsidence, landslide, earthquake) with the potential to cause an event or situation that meets the definition of a major accident as defined above.

Accident is an undesirable event resulting in damage or harm. Natural disaster events refer to natural occurrences, and are not defined to include events caused by humans (however natural events can be exacerbated by human intervention – development exacerbating flooding etc.). This gives reason to the inclusion of both terms 'accident' and 'disaster' within the Directive to ensure there is certainty that both man-made and naturally caused hazards are considered.

Vulnerability is defined as the 'exposure and resilience' of the proposed road development to the risks associated with major accidents and/or disasters. Vulnerability is influenced by sensitivity, adaptive capacity, and magnitude of impact (*the characteristics and circumstances of a community, system or asset that make it susceptible to the damaging effects of a hazard. (UNISDR, 2009)*).

Low likelihood is defined for the purposes of this assessment, as events that may occur during the lifetime of the proposed road development, so no more than once for the construction phase, and no more than once for the operational phase. The construction period of the proposed road development has been estimated at three years, the minimum operational period can be estimated at 120 years as this is the design life of the structures per DN-STR-03012 (Design For Durability).

The following definition has been derived from *S.I. No. 209/2015 - Chemicals Act (Control of Major Accident Hazards Involving Dangerous Substances) Regulations 2015 (COMAH Regulations 2015)* and the *Framework for Major Emergency Management* prepared by the National Steering Group in Ireland for Major Emergency Management:

A *major accident*, in the context of the proposed road development, is defined as an event that threatens immediate or delayed serious damage to human health, welfare and/or the environment and requires the use of resources beyond those of the road authority or its contractors. Serious damage includes the loss of life or permanent injury and/or permanent or long-lasting damage to an environmental receptor that cannot be restored through minor clean-up and restoration efforts. The significance of this effect takes into account the extent, severity and duration of harm and the sensitivity of the receptor.

[3] Risk is a combination of the consequences of a hazard (event) and the associated likelihood/probability of its occurrence.

19.2.2 Methodology

19.2.2.1 Introduction

The starting point for the scope and the methodology of this assessment is that the proposed road development is designed and will be built and operated in accordance with best practice. Ensuring that the proposed road development is designed safely and will thus operate safely has been to the forefront of the design process. Additionally, at the forefront of the design process was the need to ensure that the proposed road development is capable of being constructed safely and without risk to health, can be maintained safely, and complies with all relevant health and safety legislation. This approach has allowed all identified risks to be managed such that, where possible, the hazards that result in risks are mitigated (manage hazard source, manage pathway between source and receptor, manage receptor) or eliminated (eliminate source, remove pathway between source and receptor, remove receptor).

The methodology for assessing the vulnerability of the proposed road development to risks associated with major accidents and/or disasters is a risk analysis based approach and is based directly on the requirements of the new EIA Directive (2014/52/EU), the draft 2017 EPA Guidelines on the Information to be contained in Environmental Impact Assessment Reports, Draft, August 2017 and the European Commission (2017) Environmental Impact Assessment of Projects – Guidance on the preparation of the Environmental Impact Assessment Report. (Office for Official Publications of the European Communities 2017).

This risk analysis based approach is derived from documentation prepared by the European Commission such as:

- The Risk Assessment and Mapping Guidelines for Disaster Management[4]
- Directive 2007/60/EC (EU Floods Directive)
- Directive 2008/96/EC (Road Infrastructure Safety Management)
- Directive 2004/54/EC (minimum safety requirements for tunnels in the Trans-European Road Network)
- Directive 91/689/EEC (on hazardous waste)
- Directive 2012/18/EU (control of major-accident hazards involving dangerous substances)
- Directive 2000/60/EC (EU Water Framework Directive)
- Directive 2006/118/EC (Groundwater)

The assessment covers the identification of potential hazards associated with major accidents and/or disasters, their likelihood, and the potential resulting consequences thereof. The assessment has focused on three main areas:

- Consideration of the vulnerability (exposure and resilience) of the proposed road development to risks of major accidents/and or disasters

[4] European Commission, Commission Staff Working Paper, SEC(2010) 1626 final.

- Identification of the types of major accidents and/or disasters that are relevant to the proposed road development and the likelihood of their occurrence
- Description of the expected significant adverse effects of the proposed road development on the environment (environmental factors) arising from the vulnerability of the proposed road development to risks of major accidents and/or disasters

Eliminating, isolating and mitigating identified risks was undertaken during the design and environmental evaluation process for the proposed road development. Design and mitigation measures identified and included to reduce or avoid risks of major accidents and/or disasters are considered to be part of the design, as they reduce the likelihood and consequence of risk events, for the purposes of this assessment. Such measures are detailed within **Section 19.2.4**.

19.2.2.2 Legislation and Guidelines

The following paragraphs set out the requirements of the EIA Directive as amended by Directive 2014/52/EU in relation to major accidents and/or disasters.

Article 3 of the EIA Directive as amended by Directive 2014/52/EU

"The effects referred to in paragraph 1 on the factors set out therein shall include the expected effects deriving from ***the vulnerability of the project to risks of major accidents and/or disasters that are relevant to the project concerned****".*

Furthermore, Annex IV (8) (*Information Referred to in Article 5(1) (Information for the Environmental Impact Assessment Report*) of the EIA Directive as amended by Directive 2014/52/EU states that the EIAR shall contain:

"A description of the expected significant adverse effects of the project on the environment deriving from the ***vulnerability of the project to risks of major accidents and/or disasters which are relevant to the project concerned****. Relevant information available and obtained through risk assessments pursuant to Union legislation such as Directive 2012/18/EU of the European Parliament and of the Council[5]or Council Directive 2009/71/Euratom[6] or relevant assessments carried out pursuant to national legislation may be used for this purpose provided that the requirements of this Directive are met.* ***Where appropriate, this description should include measures envisaged to prevent or mitigate the significant adverse effects of such events on the environment and details of the preparedness for and proposed response to such emergencies.****"*

Furthermore, Recital 15 of the EIA Directive as amended by Directive 2014/52/EU states that:

"(15) In order to ensure a high level of protection of the environment, precautionary actions need to be taken for certain projects which, because of their vulnerability to major accidents, and/or natural disasters (such as flooding, sea

[5] (*) Directive 2012/18/EU of the European Parliament and the Council of 4 July 2012 on the control of major-accident hazards involving dangerous substances, amending and subsequently repealing Council Directive 96/82/EC (OJ L 197, 24.7.2012, p. 1).
[6] (**) Council Directive 2009/71/Euratom of 25 June 2009 establishing a Community framework for the nuclear safety of nuclear installations (OJ L 172, 2.7.2009, p. 18)'.

level rise, or earthquakes) are likely to have significant adverse effects on the environment. For such projects, it is important to consider ***their vulnerability (exposure and resilience) to major accidents and/or disasters, the risk of those accidents and/or disasters occurring and the implications for the likelihood of significant adverse effects on the environment****. In order to avoid duplications, it should be possible to use any relevant information available and obtained through risk assessments carried out pursuant to Union legislation, such as Directive 2012/18/EU of the European Parliament and the Council*[7] *and Council Directive 2009/71/Euratom*[8]*, or through relevant assessments carried out pursuant to national legislation provided that the requirements of this Directive are met."*

The requirement to assess the vulnerability of a development to risks associated with major accidents and/or disasters is also referenced in the draft 2017 EPA *Guidelines on the information to be contained in an EIAR* as follows:

"*To address unforeseen or unplanned effects the Directive further requires that the EIAR takes account of the vulnerability of the project to risk of major accidents and /or disasters relevant to the project concerned and that the EIAR therefore explicitly addresses this issue. The extent to which the effects of major accidents and / or disasters are examined in the EIAR* ***should be guided by an assessment of the likelihood of their occurrence (risk). This may be supported by general risk assessment methods or by systematic risk assessments required under other regulations e.g. a COMAH (Control of Major Accident Hazards involving Dangerous Substances) assessment***".

19.2.2.3 Data sources and Consultations

A desktop study of environmental assessments undertaken by each of the specialists who contributed to the preparation of this EIAR was completed. Each environmental specialist considered routine events (those predicted to happen or which are likely to happen) and non-routine events (which 'might' happen) in their assessment of likely significant effects on the environment and provided mitigation measures to eliminate or reduce the risk to the lowest degree possible. The assessment in this chapter makes reference to these assessments where relevant rather than duplicating them. Therefore, this chapter only considers low likelihood but potentially high consequence events. The screening process to determine low likelihood but potentially high consequence events associated with major accidents and/or disasters is set out in **Sections 19.2.2.4** below.

Key to comprehensively understanding the potential consequences of major accidents and disasters in the context of the proposed road development was gaining an understanding of common region-specific accident and/or disasters events. In particular, it was necessary to identify the factors that result in natural disasters. Therefore, emergency service organisations, local authority personnel, and regional authority personnel responsible for responding to and coordinating the response to

---

[7] Directive 2012/18/EU of the European Parliament and the Council of 4 July 2012 on the control of major-accident hazards involving dangerous substances, amending and subsequently repealing Council Directive 96/82/EC (OJ L 197, 24.7.2012, p. 1).

[8] Council Directive 2009/71/Euratom of 25 June 2009 establishing a Community framework for the nuclear safety of nuclear installations (OJ L 172, 2.7.2009, p. 18).

the fallout of major accidents and/or disasters, and indeed for the future planning of responses to such incidents were consulted.

The following emergency service providers and local and regional authorities were consulted:

- Galway City Council
- Galway County Council
- Galway County Council fire department
- An Garda Síochána traffic corps
- An Garda Síochána operations
- Department of Defence
- Health Service Executive – emergency management
- Major Emergency Group West Region

This consultation, as expected, highlighted that weather events are the principal hazards encountered with respect to road operation in the region - be it rainfall, wind, or icy conditions and their potential contribution to natural disasters such as landslides and ground subsidence and major accidents such as vehicular collisions.

In conjunction with local, regional, and emergency organisations, means of enhancing the resilience of the proposed road development to major accident and disaster events were discussed. Such discussions focused on the provision of access to the proposed road development, the provision of warning systems to warn users of incidents in advance of hazards, and the management and operation of the proposed road development.

19.2.2.4 Assessment Methodology

The potential for hazards associated with major accidents and/or disasters to result in a significant adverse environmental effect was assessed. The approach adopted considers hazards that may produce environmental consequences, the likelihood of these consequences occurring, considering planned mitigation, and the acceptability of the subsequent risk to the receiving environment. The process included:

- identifying hazards
- screening these hazards
- defining the impact
- assessing the likelihood of occurrence
- assessing the remaining risks

The assessment was undertaken at a route-wide level but, where relevant, reflects locations that were considered more vulnerable to risks associated with identified potential major accidents and/or disasters.

The key features underlying the assessment of the vulnerability of the proposed road development to major accident and/or disaster risk events are that:

- only risks with a feasible source-pathway-receptor model were considered as part of the appraisal
- tunnels proposed as part of the proposed road development are classified as Category C in accordance with *European Agreement concerning the International Carriage of Dangerous Goods by Road (ADR).* This limits access to the proposed road development to materials of Class C and lesser thus limiting the unrestricted carriage of classes of dangerous goods

In terms of the assessment methodology, the following approach has been adopted:

- no additional risk modelling was undertaken for this assessment. Instead, the risk modelling and the analysis completed as part of the design and environmental evaluation of the proposed road development were utilised
- the assessment was completed via a review of available documentation and legal and regulatory requirements
- where information was not available, reference and regard was had to existing empirical information. For example, regard was had to empirical information regarding collision rates associated with single carriageway and motorway projects. Such information was then utilised to determine safety benefits consequent to the development of the proposed road development

Identification of Environmental Receptors

The assessment considered human beings, population and health, biodiversity, land, soil, water, air quality and climate, noise and vibration, material assets (both agriculture and non-agriculture), archaeology, architecture and cultural heritage, and the landscape, and interactions of these factors as per the requirements of the EIA Directive and the draft 2017 EPA Guidelines. For the purpose of assessment, an environmental receptor was therefore considered to be any of these. Relevant environmental receptors for this assessment therefore included:

- members of the public and local communities
- infrastructure and the built environment (including material assets)
- the natural environment, including ecosystems, land and soil quality, air quality and climate, noise and vibration, surface and groundwater resources, and landscape
- the historic environment, including archaeology and architectural and cultural heritage

Factors considered in determining whether potential adverse effects are significant included:

- the geographic extent of the effects. Effects beyond the extents of the proposed development are considered significant
- the duration of the effects. Effects which are permanent (i.e. irreversible) or long lasting are considered significant

- the severity of the effects in terms of number, degree of harm to those affected and the response effort required. Effects which trigger the mobilisation of substantial civil emergency response effort are considered significant
- the sensitivity of the identified receptors
- the effort required to restore the affected environment. Effects requiring substantial clean-up or restoration efforts are considered significant

For the proposed road development, a significant adverse effect is considered to mean the loss of life or permanent injury, and/or permanent or long-lasting damage to an environmental receptor. The significance of this effect takes into account the extent, severity, duration of harm, and the sensitivity of the receptor.

Identification and Screening of Risks

Risk identification involved collating data from existing sources of information and collating risks identified during design and environmental evaluation process.

To identify whether a risk has the potential for a significant adverse effect on an environmental receptor or for death or permanent injury, three components needed to be present: a source, a pathway (between source and receptor) and a receptor. As such, the assessment uses the following conceptual model:

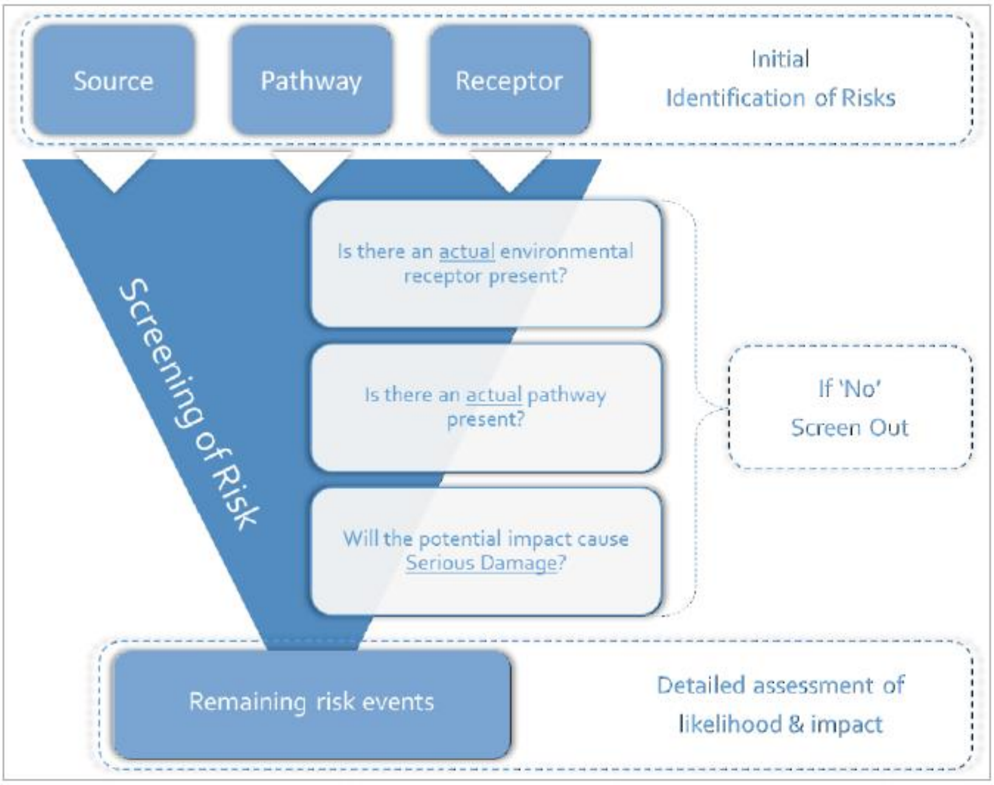
- the source is the original cause of the hazard, which has the potential to cause harm, for example a vehicle travelling on the proposed road development or adverse weather events
- the pathway is the route by which the source can reach the receptor, for example a vehicular accident or flooding
- the receptor which is the specific component of the environment that could be adversely affected if the source reaches it (e.g. environmental habitat damaged via vehicular accident or flooding, loss of life due to vehicular accident or flooding)

Risk events which do not have all three components were screened out from the assessment.

The following screening process was used to identify those risk events requiring further consideration within the assessment (**Plate 19.1**):

- is there a potential source, pathway and receptor? If not, no further assessment required
- is there a relevant environmental receptor present in the locations where the risk event could occur, and a pathway whereby the source of harm can reach the receptor? If not, no further assessment required
- does the potential impact on the environmental receptor meet the definition of a significant adverse effect? If not, no further assessment required

Plate 19.1: Risk Screening Process



For those risk events which were not screened out during this three-step process, the following steps were followed:

- Define impact for each remaining risk event
- Access likelihood of remaining risk events occurring
- Access likely significant impact
- Appraise risk management options

This then formed the basis for recommending additional mitigation measures, if any, as appropriate.

Define impact for each remaining risk event

The worst case impact(s) on environmental receptors was identified for each event which remained, determined where necessary by consultation with relevant environmental specialists to answer the question

> *'could this event constitute a major accident or disaster in terms of the definitions provided?'*

Assess Likelihood of remaining risk events occurring

The likelihood of the reasonable worst case environmental effect(s) occurring was then evaluated taking into account:

- the likelihood of the risk event occurring considering the measures already embedded into the design, proposed mitigation measures and the execution of the proposed road development
- the likelihood that an environmental receptor could be affected by the risk event

Likelihood assessments were not always quantitative. However, all assessments evaluated whether the effect (for example, loss of life) was a possible outcome of the risk event.

This evaluation of the likelihood refers to existing assessments as well as risks identified through consultation with relevant environmental specialists, emergency service providers and local authority personnel responsible for major accident and disaster response, with reference to the definition of low likelihood but high consequence events.

Assess likely significant impact

The events not screened out are assessed in **Section 19.2.6**. The assessment of the events which remained following the screening process is presented in an Environmental Risk Record (**Table 19.1**). This record details the impact (the reasonable worst consequence if the hazard occurred), assesses the likelihood of the hazard occurring, and assesses the consequent risk. As part of this assessment embedded mitigation which reduces the hazard, the likelihood of the hazard, and significance of the potential risk consequent to the hazard is detailed. Ultimately it will be determined whether the risk could constitute a major accident and/or disaster and, if so, whether the risk has been mitigated to the greatest degree possible.

Appraise Risk Management Options

The risks that could not be screened out and reached this final step in the assessment process are low probability but potentially high consequence events. They are events which cannot feasibly be mitigated in the design or eliminated completely. For this reason, they are events for which the feasible method of mitigating against them lies in developing procedures to manage their potential consequences.

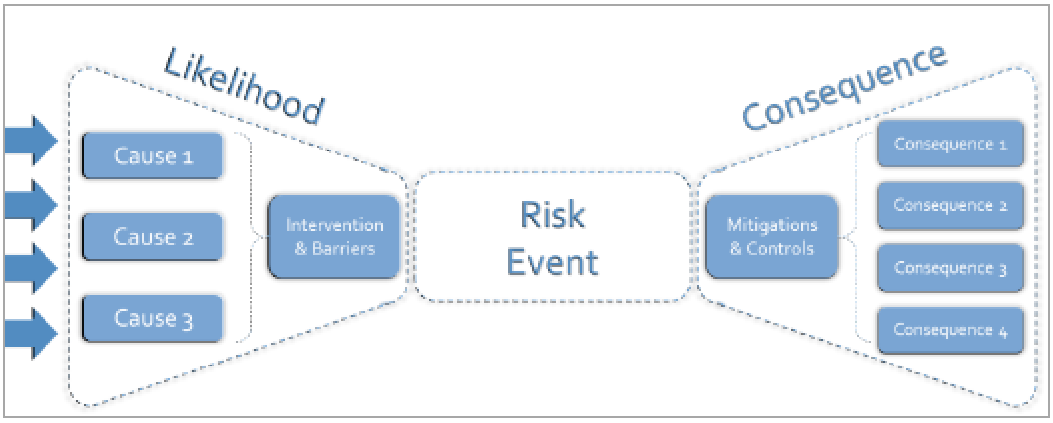
The mitigation hierarchy used as part of this assessment is as follows:

- adapt proposed processes such that either the likelihood or the impact of the risk event is reduced
- control the risk, by ensuring that appropriate control measures are in place (e.g. emergency response) so that if a risk event should occur, it can be controlled and managed appropriately

As noted, eliminating, isolating and mitigating identified risks was undertaken during design and environmental evaluation process for the proposed road development. Measures were identified and included to reduce or avoid risks associated with major accidents and/or disasters and included as part of the design considered in this assessment. Risk management measures considered following the screening process outlined above cannot therefore be classified as embedded, and consequently that is why they are limited to adapting processes to mitigate the consequence of risks and controlling the risks events as best possible.

Plate 19.2 shows the principles of managing risk, where measures to prevent a risk event occurring are barriers or intervention measures, or mitigation measures and putting controls in place should an event occur (for example, firewater containment measures).

Plate 19.2: Principles of Managing Risk



19.2.3 Characteristics of Major Accidents and / or Disasters

The major accidents and disasters considered in this assessment are low likelihood but potentially high consequence events (major accidents and/or disasters).

All low consequence events, whatever their likelihood, do not meet the definition of major accidents and/or disasters. For example, minor spills, silt control, and dust emissions which may occur during construction, but would be limited in area and volume and temporary in nature do not meet the definition of a major accident and/or disaster. Such events have already been considered and mitigated for as part of the design of the proposed road development.

Low likelihood is defined for the purposes of this assessment, as events that may occur during the lifetime of the proposed road development, so no more than once for the construction phase, and no more than once for the operational phase. The construction period of the proposed road development has been estimated at three years, the minimum operational period can be estimated at 120 years as this is the design life of the structures per DN-STR-03012 (Design For Durability). 120 years is not an upper boundary for low likelihood. Very low likelihood events are also included in the assessment, for example flood events which may only occur at most once in every 1,000 years (Flood Risk Assessment). Measures were incorporated into the design to reflect what is reasonable for such events, considering their potential consequence.

19.2.4 Risk Screening Process

This section details the Screening Process and the conclusions of assessments undertaken as part of the design and environmental evaluation process. These earlier assessments took cognisance of the design measures and mitigation measures included to reduce the significance of risks associated with major accidents and/or natural disasters. Risks are screened such that only low likelihood but potentially high consequence events remain. **Section 19.2.5** then details the assessment of these remaining risk events.

Regard has been had to the requirements of the Eurocodes with respect to structural and geotechnical design requirements. Utilisation of the Eurocodes manages the hazards and consequent risks associated with natural disasters (seismic activity, ground related movements). Their utilisation ensures that high quality resilient designs are produced.

Aside from structural and geotechnical design, all other design has been completed in accordance with best practice and national standards (for example, TII Publications). Reference to such standards are provided below as required.

Regard has been had to the requirements of the EIA Directive, the draft 2017 EPA guidelines, and documentation prepared by the European Commission as detailed in **Section 19.2.2**. Documentation prepared by the European Commission, in particular the Directives noted, place an emphasis on ensuring that proposed developments are resilient and safe. Their utilisation ensures that high quality resilient designs are produced thereby ensuring that the vulnerability of the proposed road development to risks associated with major accidents and/or disasters is minimised to the greatest degree possible.

19.2.4.1 Safety

As noted previously, ensuring that the proposed road development is designed safely and will thus operate safely has been to the forefront of design development. To regularise and embed this principle within design development, safety assessments were undertaken for the proposed road development to inform the identification and assessment of hazards and consequent risks. Assessments included health and safety design risk assessments in accordance with the Safety, Health and Welfare at Work (Construction) Regulations 2013, design reviews, and safety assessments undertaken as part of the transport appraisal. The results of these assessments are enveloped within design of the proposed road development and environmental evaluation as detailed throughout this EIAR.

Regard was had to features external to the proposed road development which could contribute a potential source of hazard to the proposed road development. This information was obtained from a desk based study. Such features include, but are not limited to:

- Presence of Control of Major Accidents and Hazards (COMAH) sites
- Potentially hazardous ground conditions
- Proximity to other infrastructure (road, energy)

COMAH sites, and their associated risks, were scoped out of the assessment due to their distance from the proposed road development[9]. Additionally, the tunnels are proposed as tunnel Category C in accordance with ADR which imposes its own limitations with respect to the carriage of dangerous goods, often associated with COMAH sites, on the proposed road development.

Hazardous ground conditions were assessed as part of the ground conditions assessment above.

Proximity to other infrastructure, especially road infrastructure, was assessed via the preparation of a road safety impact assessment per TII PE-PMG-02001 (Road Safety Impact Assessment). The purpose of Road Safety Impact Assessment (RSIA) is to undertake a strategic comparative analysis of the impact on the safety performance of the road network of different planning alternatives for a new road or a substantial modification to the existing network. The requirements of TII PE-PMG-02001 and the assessments therein are derived from EU Directive 2008/96/EC on Road Infrastructure Safety Management (RISM). Issues highlighted (for example safety of vulnerable road users) as part of the RSIA were targeted for improvement as part of the project objectives.

19.2.4.2 Vehicle Usage

The proposed road development has been designed to accommodate vehicular traffic, thus, there is a consequent potential for vehicular accident events. The likelihood of such events is minimised to the greatest degree possible by designing the geometric layout of the proposed road development in accordance with national requirements (TII Publications) which contain criteria for achieving a desirable level of performance in terms of road safety, operational, economic and environmental effects, and sustainability. The geometric layout has been subjected to safety audits per TII GES-TY-01024 (Road Safety Audit). The purpose of such audits is to ensure that the road safety implications of the proposed road development is fully considered for all users of the road and other users affected by the development. The requirements of TII GES-TY-01024 and the assessments therein are derived from EU Directive 2008/96/EC (Road Infrastructure Safety Management (RISM)).

Vehicular accident events can be exacerbated by interaction with obstacles in the path of errant vehicles, similarly errant vehicles can exacerbate risk events – such as the risk of bridge collapse consequent to vehicular collision. A risk assessment was undertaken in accordance with GE-TBU-01010 (NRA BD2 Safety Barrier Risk Assessment) and GE-TBU-01019 (NRA TB 11 NRA TD 19 and Forgiving Roadsides). This assessment identified locations where it is necessary to provide vehicular restraint systems to reduce the severity and potential consequences of vehicular accident events, and consequently related events such as bridge strike events (bridge collapse) and errant vehicles interacting with sensitive environmental receptors (discharge of pollutants into sensitive groundwater receptors).

[9] The closest COMAH site Cold Chon, Oranmore is approximately 2.15km from the closest point of the proposed development boundary.

In addition to physical mitigation such as vehicle restraint systems, operational measures have been incorporated into the design which will act to mitigate the potential consequences of vehicle accident events such as a vehicle breakdown or fire. Access points have been provided that will enable efficient access for emergency services and make their response times more efficient and reduce the potential significance of consequences, i.e. any incidents will not be exacerbated by delayed response or the inability to access an event location.

Additionally, intelligent transport systems (communication and traffic control systems including variable messaging gantries, automatic barriers at tunnel entrances, real time monitoring and control of road traffic and flows, automatic incident detection in tunnels) have been incorporated into the design which will act to mitigate the potential consequences of major accidents and/or disasters by forewarning motorists of incidents on the network (adverse weather events, incident on network, network closure).

The proposed road development has been designed in accordance with best practice and includes measures as noted. However, there remains the possibility of vehicular accident events. The three components - source, pathway, and receptor remain. It is not possible to eliminate the source (vehicular traffic) and receptors (environmental receptor, human life). The pathway is restricted because of the restraint systems, though not eliminated. In addition, restraint systems themselves can act as hazards. They are included where the consequences of the vehicle striking the barrier are considered to be less serious than those that would result if the barrier were not in place. Such restraint systems will temper the consequences and likelihood of major accidents and/or disasters associated with vehicular accident events; however, it is not possible to entirely discount the possibility of major accident and/or disaster events with respect to vehicular accident events. This is the case as the loss of life or permanent injury cannot be categorically discounted.

It is therefore not possible to rule out low likelihood but potentially high consequence vehicle accident events and the vulnerability of the proposed road development to such events. Therefore, vehicular accidents are further assessed in **Section 19.2.5**.

19.2.4.3 Construction Activities

The proposed road development has been designed to ensure that it is capable of being constructed safely and without risk to health. Safe construction, and the preparation of method statements, will be the responsibility of the Contractor. Construction related hazards are capable of being managed where construction safe systems of work are implemented by the Contractor. The events identified within this section of the EIAR are equally applicable to construction and operation of the proposed road development.

In addition to the design measures and mitigation measures which are included to reduce the potential for impacting environmental receptors, a Construction Environmental Management Plan (CEMP) (see **Appendix A.7.5**) has been prepared which sets out measures to bolster the design and mitigation measures and further minimise the consequences and likelihood of impacting environmental receptors. This plan summarises the overall environmental management strategy to be adopted and implemented during the construction phase of the proposed road development.

It sets out the need to prepare an 'Incident Response Plan' during the construction phase. Such a plan would include measures to ensure that accidental spillages, sediment, erosion, and pollution do not impact on the receiving environment, consequently this plan sets out many of the mitigation and operational measures detailed in the foregoing chapters of this EIAR.

Post construction, the CEMP will be developed into an Environmental Operating Plan for the operational phase ensuring operational mitigation measures are enforced. This plan will be utilised by the road authority and will set out measures to ensure that accidental spillages, sediment, erosion, and pollution do not impact on receiving environment. Again, this reflects the operational mitigation measures detailed in this EIAR, in particular the Schedule of Environmental Commitments presented in **Chapter 20, Summary of Environmental Commitments and Residual Impacts**. The specific events which may arise during construction are screened within the following sections.

19.2.4.4 Tunnels and Bridges

Major accident and/or disaster events can be exacerbated by tunnels and their confined nature. Therefore, it was necessary to identify appropriate standards of safety and operational requirements for tunnels and incorporate them into the design of the proposed road development. In this respect requirements were derived from DN-STR-03015 (BD78/99 – Design of Road Tunnels) and EU Directive 2004/54/EC (minimum safety requirements for tunnels in the Trans-European Road Network)[10]. In accordance with DN-STR-03015 a Tunnel Design and Safety Consultation Group was established. Meetings were held with emergency service personnel to facilitate the contribution of their specific specialist knowledge and experience to determine requirements for tunnel design.

EU Directive 2004/54/EC (transposed into Irish Law by SI 213 of 2006) sets out minimum safety requirements for tunnels in the Trans-European Road Network and requires risk based analysis to steer tunnel design. The Directive sets out the requirement for managing the risks associated with fire events within tunnels. Following assessment as per the Directive, the risk level (for tunnels incorporated in the proposed road development) was determined to be low (Category C per ADR was determined, refer below). This determination steered the selection of design criteria. Design criteria selected ensure that the likelihood and consequence of events (including fire, operational, breakdown) are mitigated and managed. The following design measures, including measures for the operation of the tunnel are incorporated into the design of the proposed road development to mitigate the likelihood and consequence of events:

- the structural resistance to fire is a key aspect of any tunnel due to the high fire loads in such a confined environment. Design is required to rigorous fire curves. The tunnel structures have been designed to be capable of resisting the Rijkswaterstaat (RWS) fire curve for a minimum of 120 minutes. Provisions, such as fibre reinforced concrete or sacrificial cover, have also been included in the design to reduce the risk of spalling - a phenomenon whereby portions of

[10] Applicable to tunnels of length greater than 500m, notwithstanding regard was had to the requirements therein.

concrete fall off the tunnel lining during a fire therefore reducing the overall performance of the structure due to reduced concrete depth (thereby minimising the likelihood of collapse due to fire events)

- access to the tunnels has been provided for emergency services from each side to facilitate ease of access during any incidents
- emergency cross passages and walkways, to aid emergency egress, have been included per DN-STR-03015 (Design of Road Tunnels) at 100m spacing, this ensures that should risk events occur persons can exit the tunnel in a timely manner (thereby minimising the risk of persons becoming trapped within the affected bore)
- tunnel safety systems have been included in the design and will contribute to the management of the tunnel and will therefore assist in maintaining adequate levels of safety management. These include tunnel fire watermain, hose reels, traffic control measures (to forewarn motorists of incidents), automatic fire detection and alarm (warning emergency service providers to ensure a speedy response), automatic fire suppression, PA system, emergency lighting, safety signage, CCTV, and drainage systems for firefighting water and fuel spills (all runoff water collected to prevent discharge to sensitive environmental receptors)
- tunnel drainage systems have been designed to transfer spillages (hydrocarbons, chemicals) which may occur within the tunnel directly to a spillage containment area where it will be contained until it can be safely removed and disposed
- spillage containment areas are external to the tunnels allowing them to be managed in an open and safe environment as opposed to a confined environment
- regard was had to EU Directive 2004/54/EC regarding the carriage of dangerous goods. In this respect, regard was had to the European Agreement concerning the International Carriage of Dangerous Goods by Road (ADR). Tunnel categorisation per ADR is based on the assumption that there are three major dangers in tunnels: (i) explosions, (ii) release of toxic gas or volatile toxic liquid and (iii) fires. The tunnel category, is assigned by the competent authority (Transport Infrastructure Ireland in Ireland) to a given road tunnel for the purpose of restricting the passage of transport units carrying dangerous goods. The recommended tunnel category for Lackagh Tunnel and Galway Racecourse Tunnel is 'C' in accordance with the ADR. The considerations which contributed to this are as follows:
    - Tunnel Category C requires that no article or substance which would be reasonably likely to explode, dangerously react, produce a flame or dangerous evolution of heat or produce dangerous emissions of toxic, corrosive or flammable gases or vapours are permitted to utilise the tunnel[11]
    - Tunnel Category C is recommended due to the expected low frequency of dangerous goods vehicles which would utilise the proposed road development due to the availability of alternative routes to accommodate same

[11] Reference to the ADR is required to identify gradation of consequences associated with various substances.

- Tunnel Category C is recommended as there would be a need and desire for heavy goods vehicles to use the tunnel to access retail and service industries throughout the city and county and therefore must be accommodated
- An advanced intelligent transport system will be implemented to control access to the entire network and in particular to the tunnels

Adopting Tunnel Category C as per ADR minimise the risks associated with the carriage of dangerous goods on the proposed road development and the potential hazards that may result in major accidents and/or disaster events.

As part of the design of the proposed road development the necessity to introduce mechanical ventilation in the design of the tunnels was considered. The need for such a measure was deemed unnecessary in accordance with the requirements of EU Directive 2004/54/EC and DN-STR-03015 (BD78/99 - Design of Road Tunnels). It was deemed unnecessary as the tunnels are less than 500m in length and facilitate natural ventilation.

Bridge strike events have also been considered as part of the risk assessment and the structural design of structural elements for the proposed road development has been undertaken in accordance with the Eurocodes and national design standards (TII Publications).

Structures incorporated into the proposed road development have been designed in accordance with best practice and includes mitigation and operational measures. However, there remains the possibility of structure accident and disaster events, particularly tunnel events. The three components – source, pathway, and receptor remain. It is not possible to eliminate the source (vehicular traffic) and receptors (human beings and natural environment). The pathway is restricted, though not eliminated through the implementation of fire suppression systems, vehicle restraint systems, adequate access for emergency services and holding tanks for tunnel runoff). Such systems will reduce the consequences and likelihood of major accidents and/or disasters; however, it is not possible to entirely discount the possibility of major accident and/or disaster events with respect to structure related events. This is the case as the loss of life or permanent injury cannot be categorically discounted.

It is therefore not possible to rule out low likelihood but potentially high consequence of a structure collapse or fire event and the vulnerability of the proposed road development to such events. Therefore, structure collapse and tunnel events are further assessed in **Table 19.1** in **Section 19.2.5**.

19.2.4.5 Services

Hazards identified relate to those associated with undertaking works on utilities (electrocution, gas explosion, burst watermain). Extensive consultation took place with utility service providers to ensure that a resilient and safe design was developed (appropriate protection measures and appropriate design criteria).

This interaction resulted in the incorporation of design measures to reduce or eliminate the consequences of potential risk events. The following measures are incorporated into the design to minimise or eliminate the consequences and likelihood of major accident and/or disaster events:

- all service diversions have been agreed with utility service providers. All service diversions must be undertaken in accordance with utility service providers requirements, all of which place health and safety to the fore
- safe construction, and the preparation of method statements, will be the responsibility of the Contractor. As noted previously, at the forefront of design development was the need to ensure that the proposed road development is capable of being constructed safely and without risk to health, can be maintained safely, and complies with all relevant health and safety legislation

Notwithstanding the fact that the utility diversions have been designed in accordance, and will be undertaken by or on behalf of the Contractor in line, with utility service provider requirements, there remains the possibility of additional diversions. Despite the extensive consultation there may still be some unknown services. The survey and information received from utility service providers covered the extent of the proposed road development, however, anomalies exist between these and interpretation is required. Further, even if a comprehensive map of all ground based infrastructure, and indeed overhead infrastructure, could be obtained, there is no guarantee that such conditions remain static, particularly so in the urban environment.

Thus, the three components - source, pathway, and receptor will remain. It is not possible to eliminate all sources (electric cabling, gas mains) and receptors (human beings, environmental receptors). The pathway is restricted but not eliminated, mitigation measures such as extensive consultation with providers and undertaking utility surveys have been undertaken but the pathway remains. Such mitigation will reduce the likelihood of major accidents and/or disaster events; however, it is not possible to entirely discount the possibility of major accident and/or disaster events with respect to utility service events. This is the case as the loss of life or permanent injury cannot be categorically discounted.

It is therefore not possible to rule out low likelihood but potentially high consequence utility service events (electrocution or gas explosion) and the vulnerability of the proposed road development to such events. Therefore, utility service events are further assessed in **Table 19.1** in **Section 19.2.5**.

19.2.4.6 Ground Conditions

The geotechnical design of the proposed road development has been undertaken in accordance with the national design standards (for example TII Publications), the Eurocodes, and best practice. This ensures a resilient and safe design. Ground investigations were undertaken which provided design criteria upon which to base the design of earthworks and foundations. Design criteria were utilised which reduce the consequences and likelihood of major accidents and/or disaster events associated with soils and geology by ensuring that a resilient design is prepared (safety factors etc.).

The ground investigations undertaken identified hazards such as poor ground conditions and karstic conditions. The results of these investigation were utilised in the design of the proposed road development to ensure that a resilient design was developed and to reduce the consequences and likelihood of events (bridge collapse due to inadequate foundations/bearing capacity, earthworks collapse due to utilisation of inadequate design criteria, earthworks collapse due to inadequate information of ground conditions).

Additionally, determining geotechnical design criteria required significant interaction with the various environmental specialists. This interaction resulted in the incorporation of design measures to reduce or eliminate the consequences of potential risk events. The following measures are incorporated into the design to minimise or eliminate the consequences and likelihood of major accident and/or disaster events:

- in flood prone areas a drainage layer is included to ensure hydraulic conductivity thus preventing water build-up which may result in or exacerbate flooding
- granular fill is proposed for embankments to ensure that sediment does not enter sensitive watercourses or groundwater bodies and impact environmental receptors (groundwater or watercourse pollution). In particularly sensitive areas the use of a geotextile separator is proposed
- in environmentally sensitive areas appropriate protection systems are included to avoid damage to environmental receptors (such as protection layer over Limestone pavement, rock fall ditches, flood bunding)
- with respect to the construction of Lackagh Tunnel, a construction methodology has been proposed which places safety to the fore so as to eliminate the risk of tunnel collapse. The development of this methodology has been influenced by geotechnical investigation which determined appropriate design criteria. Refer to **Chapter 9, Soils and Geology** and **Appendix A.7.3** for further information
- blasting operations during construction will be subject to re-calibration based on site specific conditions and will only be undertaken by appropriately qualified persons (minimises risks associated with blast rock)

In addition to design measures, horizontal movement and vibration monitoring (rock mass monitoring, karst ground areas) will be implemented to ensure that movements will not result in hazards which could cause major accident and/or disaster events, during the construction or operation of the proposed road development. This is essential as hazard events often arise from natural events (heavy rainfall etc.) and the only feasible means of mitigating the impacts of such events is to ensure a resilient design is prepared, as detailed above, and that appropriate control measures (monitoring, response times) are implemented during both the construction and operation of the proposed road development.

The geotechnical design for the proposed road development has been designed in accordance with best practice and includes design measures and mitigation measures as noted. There still remains however, the possibility of geotechnical events. Despite the ground investigations and assessment complete unknown ground conditions remain as the investigations undertaken were targeted to areas of interest and the results had to be interpolated for the areas in-between. It is not possible to map all ground based hazards. Further, even if all ground based hazards could be identified at this point, there is no guarantee that such conditions will remain constant given the karstic nature of the ground.

The three components - source, pathway, and receptor will remain. It is not possible to eliminate all sources (karstic conditions, weather events) and receptors (human beings, environmental receptors). The pathway is restricted, though not eliminated through design and mitigation measures. Such measures will temper the likelihood of major accidents and/or disasters; however, it is not possible to entirely discount the possibility of major accident and/or disaster events with respect to ground condition events. This is the case as the loss of life or permanent injury cannot be categorically discounted (engulfment due to earthworks collapse or events triggered by ground related events).

It is therefore not possible to rule out low likelihood but potentially high consequence of ground collapse events and the vulnerability of the proposed road development to such events. Therefore, ground collapse events are further assessed in **Table 19.1** in **Section 19.2.5**.

19.2.4.7 Hydrogeology

Potential hydrogeological impacts of the proposed road development were evaluated in accordance with TII DN-DNG-03065 (Road Drainage and the Water Environment). This standard reflects the requirements of the following:

- The EU Water Framework Directive (WFD) 2000/60/EC
- The Groundwater Directive 2006/118/EC
- European Communities Environmental Objectives (Groundwater) Regulations 2010
- European Communities Environmental Objectives (Surface Water) Regulations 2009
- European Communities (Drinking Water) (No.2) Regulations 2007
- European Communities (Quality of Salmonid Waters) Regulations 1988
- Water Services Acts 2007 – 2013

The hydrogeological investigations undertaken identified groundwater levels and groundwater movement. The results of these investigation were utilised in the design of the proposed road development to ensure that a resilient design was developed and to reduce the consequences and likelihood of events (groundwater contamination of an aquifer due to inadequate information, groundwater inundation to tunnels or onto road surface due to inaccurate design criteria).

Additionally, determining design criteria with respect to hydrogeology required significant interaction with the various environmental specialists. This interaction resulted in the incorporation of design measures to reduce or eliminate the consequences of potential risk events (pollution to groundwater bodies or aquifers, groundwater flooding). The following measures are incorporated into the design to minimise or eliminate the consequences and likelihood of major accident and/or disaster events:

- A risk assessment in accordance with TII DN-DNG-03065 was undertaken (groundwater vulnerability and aquifer classification). This assessment was supplemented by site specific hydrogeological risk assessments. This standard and the associated assessment takes into account climate change requirements (appropriate protection measures to prevent groundwater contamination as a result of the proposed road development was determined and included in the design)

- Based on the spillage risk assessment (refer to **Chapter 10, Hydrogeology**) the risk of a serious spillage occurring has an annual probability of less than 0.5% and is considered acceptable per TII DN-DNG-03065. Notwithstanding the low risk of serious spillage, additional spillage protection measures are included at each drainage outfall location, these spillage containment areas prevent the contamination of groundwater and surface water bodies by providing 25m^3 of containment for accidental spillages of hydrocarbons and chemicals per DN-DNG-03022 (Drainage Systems for National Roads). During a spillage event, the spill will be collected by the drainage network and conveyed towards the outfall where a penstock will divert the spill to the spillage containment area where it will be contained until it can be safely removed and disposed
- Hydrogeological information has been utilised to determine design requirements, for example, hydrogeological assessment information has been utilised to determine waterproofing and groundwater inundation levels for the proposed Lackagh Tunnel and Galway Racecourse Tunnel thereby reducing the potential for the proposed road development to flood during operation and result in major accidents and/or disasters
- The proposed road development has been designed considering the hydrogeological assessment information to determine design elevations thereby reducing the potential for the proposed road development to flood during operation and result in major accidents and/or disasters. Similarly, a drainage layer has been included in the design at appropriate locations to ensure hydraulic conductivity is maintained
- The results of the hydrogeological assessment have been used to determine tunnel waterproofing requirements thereby reducing the potential for the proposed road development to flood during operation and result in major accidents and/or disasters

The hydrogeological design of the proposed road development has been designed in accordance with best practice and includes design measures and mitigation measures but as noted, there remains the possibility of hydrogeological accident and disaster events. Despite the extensive investigations and assessment, unknown ground conditions remain as the investigations undertaken were targeted to areas of interest and the results had to be interpolated for the areas in-between. Further, even if all ground based hazards could be identified, there is no guarantee that such conditions remain constant, given the karstic nature of the ground.

The three components - source, pathway, and receptor remain. It is not possible to eliminate all sources (karstic conditions or weather events) and receptors (human beings and environmental receptors) and the pathway is restricted, though not eliminated through design measures and mitigation. Such measures will reduce the likelihood of major accidents and/or disaster events; however, it is not possible to entirely discount the possibility of major accident and/or disaster events with respect to hydrogeology events (groundwater contamination or groundwater inundation). This is the case as the loss of life or permanent injury cannot be categorically discounted (drowning due to groundwater inundation or harm consequent to groundwater contamination).

It is therefore not possible to rule out low likelihood but potentially high consequence hydrogeological events (flooding or groundwater contamination) and the vulnerability of the proposed road development to such events. Therefore, hydrogeological events are further assessed in **Table 19.1** in **Section 19.2.5**.

19.2.4.8 Hydrology

The drainage design for the proposed road development was undertaken in accordance with TII DN-DNG-03065 (Road Drainage and the Water Environment).

Based on the spillage risk assessment (refer to **Chapter 11, Hydrology**) the risk of a serious spillage occurring has an annual probability of less than 0.5% and is considered acceptable per TII DN-DNG-03065. Notwithstanding the low risk of serious spillage, additional spillage protection measures are included at each drainage outfall location, these spillage containment areas prevent the contamination of groundwater bodies or surface water by providing 25m^3 of containment for accidental spillages of hydrocarbons and chemicals per DN-DNG-03022 (Drainage Systems for National Roads). During a spillage event, the spill will be collected by the drainage network and conveyed towards the outfall where a penstock will divert the spill to the spillage containment area where it will be contained until it can be safely removed and disposed.

As per this standard and the European Union: Directive on the Assessment and Management of Flood Risks (2007/60/EC) a Flood Risk Assessment (FRA) was undertaken for the proposed road development. The proposed road development is essential infrastructure and is therefore considered to be ‘highly vulnerable development’ according to the Flood Risk Management Plan Guidelines. The FRA considered fluvial, pluvial, and groundwater flooding. Both the FRA and TII DN-DNG-03065 standard take into account climate change requirements.

The results of the FRA were utilised to determine design criteria to reduce the likelihood of major accidents and/or disaster events associated with flooding by ensuring that a resilient design was prepared (waterproofing and freeboard above maximum water level). The results of the FRA were utilised in the design of the proposed road development to ensure that a resilient design was developed and to reduce the likelihood of events (flood inundation to tunnels or onto road due to inadequate design criteria or flooding to assets adjacent to the proposed road development).

The FRA resulted in the incorporation of design measures to reduce or eliminate the consequences of potential events (flooding). Without appropriate flood relief design the proposed road development would have the potential to significantly impact on drainage in its vicinity and exacerbate flood risk. The following measures are incorporated into the design to minimise or eliminate the consequences and likelihood of major accidents and/or disaster events:

- mitigation measures to neutralise the flood impact to the Twomileditch – ‘Significant Pluvial Flood Risk’. With the mitigation in place the loss of flood storage is compensated and there is a moderate to significant positive impact on flooding and flood risk in the Twomileditch and N83 Tuam Road area

- the potential flood risk for the Lackagh Tunnel and Galway Racecourse Tunnel is rated as representing a moderate flood risk. This risk is associated with the potential for elevated groundwater table under more extreme 1000-year flood events and climate change conditions. The tunnels are to be fully sealed and groundwater ingress will be prevented
- the proposed tunnels, by virtue that waters require pumping to the foul sewer, retain a residual flood risk e.g. pump failure. This residual risk is mitigated through proposed regular inspection and maintenance procedures
- road drainage outfalls discharging to receiving surface and groundwaters without flood flow attenuation, could increase downstream and cause local flooding at the discharge points. This has been mitigated in the drainage design through suitably sized attenuation ponds and outlet flow controls
- potential blockages to culverts and bridges on streams and the lack of maintenance could present a localised residual flood risk. This residual risk is mitigated through proposed regular inspection and maintenance procedures
- residual risk of localised flooding on the proposed road carriageway due to blockages/failure within drainage network. This residual risk is mitigated through proposed regular inspection and maintenance procedures
- this residual flood risk can be managed through a program of regular inspection and maintenance of drainage facilities that includes, gullies, inspection chambers, pipes, culverts, outfalls, attenuation ponds and infiltration basins

The drainage design of the proposed road development has been completed in accordance with best practice and includes design measures and mitigation measures as noted above. However, there remains the possibility of hydrological (flooding or water pollution) events.

The three components - source, pathway, and receptor will remain. It is not possible to eliminate all sources (karstic conditions or weather events) and receptors (human beings and environmental receptors). The pathway is restricted, though not eliminated through design measures and mitigation measures. Such measures will reduce the likelihood of major accidents and/or disaster events; however, it is not possible to entirely discount the possibility of major accident and/or disaster events with respect to hydrology events (pump failure, interaction with hydrogeology). This is the case as the loss of life or permanent injury cannot be categorically discounted.

It is therefore not possible to rule out low likelihood but potentially high consequence hydrological events (flooding or water contamination) and the vulnerability of the proposed road development to such events. Therefore, hydrological events are further assessed in **Table 19.1**.

19.2.5 Risk Screening Summary

When undertaking this screening process, a number of low likelihood but potentially high consequence events were identified for a number of disciplines. These events are applicable to both the construction and operational phases of the proposed road development.

The events requiring further assessment are:

- Vehicular Events
- Structural Collapse Events
- Tunnel Fire Events
- Service Utilities Events
- Ground Conditions Related Events
- Hydrogeological Events
- Hydrological Events

The assessment of these events is detailed in **Table 19.1**.

19.2.6 Major Accidents and/or Disasters Assessment

The assessment of the risk of major accidents and/or disasters that were not screened out is presented in this section.

Table 19.1 presents hazards which remained following the screening process, defines the impact (the reasonable worst consequence if the hazard occurred), assesses the likelihood of the hazard occurring, and assesses the consequent risk. As part of this assessment embedded mitigation which reduces the hazard, the likelihood of the hazard, and significance of the potential risk consequent to the hazard is detailed. Ultimately it will be determined whether the risk could constitute a major accident and/or disaster and, if so, whether the risk has been mitigated to the greatest degree possible.

Table 19.1: Environmental Risk Record

Impact (Reasonable Worst Consequence if event did occur)	Could this event constitute a major accident or disaster in terms of the definitions provided?	Likelihood of hazard occurring	Assessment and Management of Consequent Risk	Details of the preparedness for and proposed response to such events
Vehicular Events				
Vehicular accident event resulting in loss of life or permanent injury or permanent or long-lasting damage to an environmental receptor that cannot be restored through minor clean-up and restoration efforts.	Yes, loss of life or permanent injury may result. Yes, permanent or long-lasting damage to an environmental receptor that cannot be restored through minor clean-up and restoration efforts may result.	Vehicular accident events cannot be discounted. Such events are likely to occur during the operation of the proposed road development. This assessment examines the implications of low likelihood but potentially high consequence vehicular accident events (multi-vehicle collision resulting in a large number of fatalities). Damage to an environmental receptor may occur. Such damage can occur via discharge of hazardous (e.g. hydrocarbon oils, corrosive or toxic liquids) materials to the existing environment. In this case the risk is that of impacting groundwater or surface water, which may result in impacts on humans or ecological receptors. If a vehicular accident event occurs it may result in events external to	The proposed road development has been designed in accordance with best practice and national standards ensuring that the proposed road development is designed safely and will thus operate safely. Vehicular restraint systems have been incorporated into the design of the proposed road development to reduce the severity and potential consequences of vehicular accident events, where they may occur. Access points have been provided that will enable efficient access for emergency services and make their response times more efficient and reduce the severity and potential consequences of vehicular accident events, where they may occur i.e. incidents will not be exacerbated by delayed response or the inability to access an event location.	Emergency service organisations, local authority personnel, and regional authority personnel are responsible for responding to and coordinating the response to the fallout of major accidents and/or disasters, including vehicular accident events. In this regard a Major Emergency Plan is prepared and operated by these organisations. As part of the design process for the proposed road development representatives of these organisations were consulted and measures were incorporated into the design to enhance response to the fallout of major accidents and/or disasters, including vehicular accident events.

Impact (Reasonable Worst Consequence if event did occur)	Could this event constitute a major accident or disaster in terms of the definitions provided?	Likelihood of hazard occurring	Assessment and Management of Consequent Risk	Details of the preparedness for and proposed response to such events
		the proposed road development, such as fire events. Any potential air quality, noise, landscape and visual, material assets, architectural and cultural heritage impacts will not be permanent or long lasting.	Intelligent transport systems have been incorporated into the design which will act to mitigate the potential consequences of major accidents and/or disasters by forewarning motorists of incidents on the network (adverse weather events, incident on network, network closure). The drainage system has been designed to contain fuel / oil spills using spillage containment areas, penstocks and hydrocarbon interceptors. Spills will not discharge into the receiving environment in the event of a major spillage event as the pathway can be blocked with the implementation of the above measures. .	All reasonably practical measures have been included in the design of the proposed road development to reduce the severity and potential consequences of low likelihood but potentially high consequence vehicular accident events. Appropriate precautionary measures have been included in the design of the proposed road development to reduce the severity and potential consequences of vehicular accident events. The road authority will be responsible for responding to and coordinating the response to events on the network (environmental clean-up of oil spills, managing traffic flows etc.) and maintenance (removing hazards which may result in risk events, fixing vehicular restraint systems). With regard to implementation

Impact (Reasonable Worst Consequence if event did occur)	Could this event constitute a major accident or disaster in terms of the definitions provided?	Likelihood of hazard occurring	Assessment and Management of Consequent Risk	Details of the preparedness for and proposed response to such events
				of the schedule of environmental commitments and response to environmental incidents an Environmental Operating Plan for the operational phase is prepared and operated by the Road Authority based on the CEMP in **Appendix A.7.5**. No additional mitigation measures are required.
Structural Collapse Events				
Structural collapse (bridge collapse, tunnel collapse) event resulting in loss of life or permanent injury or permanent or long-lasting damage to an environmental receptor that cannot be	Yes, loss of life or permanent injury may result. Yes, permanent or long-lasting damage to an environmental receptor that cannot be restored through minor clean-up and restoration efforts may result.	Structural collapse events are extremely rare but their potential consequences are significant. They cannot be discounted as collapse may occur due to events outside the control of the designer, contractor, or road authority, for example, act of terrorism, other third party interference, or other unusual circumstances. Impacts on an environmental receptor may occur. Such impacts include surface or groundwater quality (collapse into	Structures have been designed taking account of the potential for vehicle strike incidents. The severity and potential consequence of strike events has been reduced via the introduction of vehicular restraint systems. All structure foundations have been designed taking cognisance of anticipated ground conditions, appropriate foundations have been proposed taking cognisance of same and thus reducing likelihood of structural collapse events due to ground conditions.	Structural collapse due to negligent inspection/ maintenance has been discounted as the road authority in Ireland undertake inspections on all structural assets on a regular basis. The road authority will be responsible for responding to and coordinating the response to events on the network (environmental clean-up - oil spills, managing traffic flows etc.) and maintenance

Impact (Reasonable Worst Consequence if event did occur)	Could this event constitute a major accident or disaster in terms of the definitions provided?	Likelihood of hazard occurring	Assessment and Management of Consequent Risk	Details of the preparedness for and proposed response to such events
restored through minor clean-up and restoration efforts.		watercourses); human beings, population and health; or biodiversity Any potential air quality, noise, landscape and visual, material assets, architectural and cultural heritage impacts will not be permanent or long lasting.	Access points have been provided that will enable efficient access for emergency services and make their response times more efficient and reduce the severity and potential consequences of events, where they may occur i.e. incidents will not be exacerbated by delayed response or the inability to access an event location. Particular attention has been paid to the potential for collapse of drill and blast tunnels. Permanent tunnel stability at Lackagh Tunnel will be provided by a cast in-situ reinforced concrete lining. Fibre reinforced concrete or sacrificial cover, has been included in the design of tunnels to reduce the risk of spalling - a phenomenon whereby portions of concrete fall off the tunnel lining during a fire therefore reducing the overall performance of the structure due to reduced concrete depth (including sacrificial cover minimises the	(removing hazards which may result in risk events, fixing vehicular restraint systems). With regard to implementation of the schedule of environmental commitments and response to environmental incidents a CEMP has been prepared and included in **Appendix A.7.5** and will feed into the Environmental Operating Plan for the operational phase and operated by the Road Authority. All reasonably practicable measures have been included in the design of the proposed road development to reduce the severity and potential consequences of low likelihood but potentially high consequence structural events. Appropriate precautionary measures have been included in the design of the proposed road development to reduce

Impact (Reasonable Worst Consequence if event did occur)	Could this event constitute a major accident or disaster in terms of the definitions provided?	Likelihood of hazard occurring	Assessment and Management of Consequent Risk	Details of the preparedness for and proposed response to such events
			likelihood of collapse due to fire events). Intelligent transport systems have been incorporated into the design which will act to mitigate the potential consequences of major accidents and/or disasters by forewarning motorists of incidents on the network (adverse weather events, incident on network, network closure).	the severity and potential consequences of structural events. No additional mitigation measures are required.
Tunnel Fire Events				
Tunnel events (explosions, fire) resulting in loss of life or permanent injury or permanent or long-lasting damage to an environmental receptor that cannot be restored through minor clean-up	Yes, loss of life or permanent injury may result. Yes, permanent or long-lasting damage to an environmental receptor that cannot be restored through minor clean-up and restoration efforts may result.	Such tunnel events are extremely rare but their potential consequences are significant. Tunnel events are rare because extensive preventative and mitigatory systems are incorporated into tunnels to reduce the severity and potential consequences of tunnel events (fire, partial or total tunnel collapse vehicular accident event, spillage or fuel or other hazardous liquids). In addition to physical mitigation such as vehicle restraint systems, operational	Structures have been designed taking account of vehicular strike incidents and the severity and potential consequence of strike events has been reduced via the introduction of vehicular restraint systems. The proposed road development has been designed in accordance with best practice and European standards ensuring that the proposed road development is designed safely and will thus operate safely. Access points have been provided that will enable efficient access for	Emergency service organisations, local authority personnel, and regional authority personnel are responsible for responding to and coordinating the response to the fallout of major accidents and/or disasters, including vehicular accident events. In this regard a Major Emergency Plan is prepared and operated by these organisations. As part of the development of the proposed

Impact (Reasonable Worst Consequence if event did occur)	Could this event constitute a major accident or disaster in terms of the definitions provided?	Likelihood of hazard occurring	Assessment and Management of Consequent Risk	Details of the preparedness for and proposed response to such events
and restoration efforts.		measures have been incorporated into the design which will act to mitigate the potential consequences of vehicle accident events such as a vehicle fire events within the tunnel. Low likelihood but potentially high consequence tunnel events cannot be discounted as events may occur due to events outside the control of the designer, contractor, or road authority. For example, act of terrorism, other third party interference, or other unusual circumstances. Tunnel events require particular regard due to their confined nature (any event may escalate quickly). Damage to an environmental receptor may occur. Such damage can occur via discharge of materials to the existing environment (fuel, oil, gas). In this case the risk is that of impacting groundwater or surface water, which may result in impacts to human beings, or ecological receptors	emergency services and make their response times more efficient and reduce the severity and potential consequences of events, where they may occur i.e. any incidents will not be exacerbated by delayed response or the inability to access an event location. Tunnels are naturally ventilated reducing the potential for smoke/gas accumulation. Intelligent transport systems have been incorporated into the design which will act to mitigate the potential consequences of major accidents and/or disasters by forewarning motorists of incidents on the network (adverse weather events, incident on network, network closure). The drainage system has been designed to retain fuel/oil spills and not discharge this to the receiving environment (blocking pathway) and thus impact an environmental receptor.	road development representatives of these organisations were consulted and design measures were incorporated into the design to enhance response to the fallout of major accidents and/or disasters, including tunnel events. The Road Authority will be responsible for responding to and coordinating the response to events on the network (environmental clean-up - oil spills, managing traffic flows etc.) and maintenance (removing hazards which may result in risk events, fixing vehicular restraint systems). With regard to implementation of the schedule of environmental commitments and response to environmental incidents a CEMP has been prepared and included in **Appendix A.7.5** and will feed into the Environmental

Service Utility Events				
Service events (explosions from gas mains, flooding from burst watermains, fire from striking electric cabling, electrocution from striking electric cabling, fire) resulting in loss of life or permanent injury or permanent or long-lasting damage to an environmental receptor that cannot be restored through minor clean-up and restoration efforts.	Yes, loss of life or permanent injury may result. Yes, permanent or long-lasting damage to an environmental receptor that cannot be restored through minor clean-up and restoration efforts may result.	This assessment examines the implications of low likelihood but potentially high consequence service events (electrocution, gas explosion, burst watermain). Damage to an environmental receptor may occur. Such damage can occur via discharge of materials to the existing environment (e.g. gas from the existing gas network). In this case the risk is that of impacting groundwater or surface water, which may result in impacts to humans or ecological receptors. Any potential air quality, noise, landscape and visual, material assets, architectural and cultural heritage impacts will not be permanent or long lasting.	All service diversions have been agreed with utility service providers. All service diversions must be undertaken in accordance with utility service providers' requirements, all of which place health and safety to the fore. Safe construction, and the preparation of method statements, will be the responsibility of the Contractor. As noted previously, at the forefront of design development was the need to ensure that the proposed road development is capable of being constructed safely and without risk to health, can be maintained safely, and complies with all relevant health and safety legislation.	Service events risk can be managed through implementation of a safe system of work. The road operator will be responsible for responding to and coordinating the response to events on the network (environmental clean-up - oil spills, managing traffic flows etc.) and maintenance (removing hazards which may result in risk events, fixing vehicular restraint systems). With regard to implementation of the schedule of environmental commitments and response to environmental incidents, a CEMP has been prepared and included in **Appendix A.7.5** and will feed into the Environmental Operating Plan for the operational phase and

Ground Conditions Related Events				
Ground related events (ground collapse) resulting in loss of life or permanent injury or permanent or long-lasting damage to an environmental receptor that cannot be restored through minor clean-up and restoration efforts.	Yes, loss of life or permanent injury may result. Yes, permanent or long-lasting damage to an environmental receptor that cannot be restored through minor clean-up and restoration efforts may result.	Ground related collapse events are extremely rare but their potential consequences are significant. They cannot be discounted as collapse may occur due to events outside the control of the designer, contractor, or road authority. For example, natural phenomena, natural events - extreme rainfall. Damage to an environmental receptor may occur. Such damage can occur via collapse of an element of the proposed road development resulting in damage to the ancillary operational elements of the proposed road development, for example the drainage system which may result in discharge of materials to the existing environment (fuel, oil, gas, hazardous liquids). In this case the risk is that of impacting groundwater or surface water, which may result in impacts to humans or ecological receptors.	The proposed road development has been designed in accordance with best practice and national standards ensuring that the proposed road development is designed safely and will thus operate safely. Access points have been provided that will enable efficient access for emergency services and the road operator and make their response times more efficient and reduce the severity and potential consequences of events, where they may occur i.e. any incidents will not be exacerbated by delayed response or the inability to access an event location. Embankments/cuttings have been designed taking cognisance of anticipated ground conditions, appropriate foundations have been proposed taking cognisance of same and thus reducing likelihood of structural collapse events due to ground conditions.	Structural collapse due to negligent inspection / maintenance has been discounted as the Road Authority in Ireland undertake inspections on all assets. The road operator will be responsible for responding to and coordinating the response to events on the network, including service events (environmental clean-up, fixing vehicular restraint systems etc). In this regard a CEMP has been prepared and included in **Appendix A.7.5** and will feed into the Environmental Operating Plan for the operational phase and operated by the Road Authority. All reasonable practicable measures have been included in the design of the proposed road development to reduce

			potential consequences of major accidents and/or disasters by forewarning motorists of incidents on the network (adverse weather events, incident on network, network closure).	consequences of hydrological related events. No additional mitigation measures are required.

19.2.7 Mitigation Measures

Following the assessment of the proposed road development, under the heading of vulnerability to major accidents and/or disasters, it is concluded that no further mitigation measures beyond those already incorporated and described above and elsewhere in this EIAR are required.

19.2.8 Residual Impacts

The potential for low likelihood but potentially high consequence major accident and/or disaster events remains, although the possibility is extremely unlikely. These events have been considered throughout the design process and measures have been included in the design to reduce the severity and potential consequences of such events.

19.2.9 Summary

This section presented an assessment of the likely significant adverse effects of on the environment arising from the vulnerability of the proposed road development to risks of major accidents and/or natural disasters. The risk assessment identified and quantified risks due to the proposed road development focusing on: unplanned, but possible and plausible events occurring during the construction and operational phases. From examining all plausible risks associated with the proposed road development, the scenarios which are considered to be the highest risk in terms of a major accident and/or disaster included:

- vehicular events
- structural collapse events
- tunnel fire events
- service utilities events
- ground conditions related events
- water related events

The outcome of the assessment identified that while these events would have ‘very serious’ consequences should they occur; the risk is considered ‘unlikely.’ These events have been considered throughout the design process and measures have been included in the design to reduce the severity and potential consequences of such events.

19.3 Methodology used to assess interactions and cumulative impacts

19.3.1 Guidance

As described previously in **Section 19.1**, the requirement to address interactions of effects and cumulative impacts is set out in the EIA Directive as amended by Directive 2014/52/EU on the assessment of the effects of certain public and private projects on the environment and in the Roads Act 1993, as amended.

This chapter has been prepared in accordance with the following guidance:

- EPA (2017) Guidelines on the Information to be contained in Environmental Impact Assessment Reports, Draft, August 2017
- European Commission (2017) Environmental Impact Assessment of Projects – Guidance on the preparation of the Environmental Impact Assessment Report. (Office for Official Publications of the European Communities 2017)
- EPA (2015) Revised Guidelines on the Information to be contained in Environmental Impact Statements, Draft, 2015
- EPA (2015) Advice Notes on Current Practice in the Preparation of Environmental Impact Statements, Draft, 2015
- EPA (2003) Advice Notes on Current Practice in the Preparation of Environmental Impact Statements, 2003
- EPA (2002) Guidelines on the Information to be contained in Environmental Impact Statements, 2002
- European Commission (1999) Guidelines for the Assessment of Indirect and Cumulative Impacts as well as Impact Interactions, (Office for Official Publications of the European Communities 1999)

19.3.2 Assessment Methodology

At the initial stage of preparing the EIAR for the proposed road development, the potential for significant interactions of impacts and cumulative impacts were examined and any potential impacts were identified. These potential impacts were included in the scope and addressed in the baseline and impact assessment studies for each of the relevant environmental factors and were also addressed in the design of the proposed road development.

There were numerous discussions and communications including workshops and meetings between the environmental specialists and the design team throughout the design process which helped to identify and minimise the potential for significant interactions of impacts and cumulative impacts arising in the first instance.

The interaction of impacts within the design of the proposed road development and the mitigation measures relative to those interactions in respect of each of the environmental factors have been identified and addressed in detail in the respective chapters dealing with each environmental factor in this EIAR. Thus no additional mitigation is proposed in this chapter. This chapter presents a summary of each assessment of the interaction (inter-relationship) of impacts (from the proposed road development) between the various environmental factors and summarises the mitigation measures relative to those interactions.

The matrix and expert opinion approaches, as outlined in the EU Guidelines (1999), were used in the identification of the potential for significant interactions of impacts. Refer to **Tables 19.2** for the matrix of potential interactions.

Similarly, cumulative impacts arising from the interaction between the proposed road development and other projects in respect of each of the environmental factors have been identified and addressed in detail in the respective chapters dealing with each environmental factor in this EIAR. This chapter however, presents a summary of these individual cumulative assessments with other projects and considers the cumulative effect of the entirety of the project as a whole with other projects. No additional mitigation measures are proposed in this chapter.

19.3.3 Definitions

The following definitions are generally used in the description of cumulative impacts or interaction of impacts.

Cumulative effects are defined in EC guidance (2017)[12] as: "*Changes to the environment that are caused by activities/projects in combination with other activities/projects*". EC guidance (2017) also states that "*it is important to consider effects not in isolation, but together, that is cumulatively". Cumulative effects are changes to the environment that are caused by an action in combination with other actions. They can arise from*

- *The interaction between all of the different projects in the same area*
- *The interaction between various impacts within a single project"*

Cumulative effects are also defined in EPA guidance (2017)[13] as "*The addition of many minor or significant effects, including effects of other projects, to create larger, more significant effects*".

The EU guidelines (1999)[14] use slightly different definitions as follows:

Cumulative Impacts: Impacts that result from incremental changes caused by other past, present or reasonably foreseeable actions together with the project.

Impact Interactions: The reactions between impacts whether between the impacts of just one project or between the impacts of other projects in the area.

The term '*impact interactions'* is equivalent to the term '*inter-relationship of* effects'. The EU guidelines (1999) accept that their definitions overlap to a certain

[12] European Commission (2017) Environmental Impact Assessment of Projects – Guidance on the preparation of the Environmental Impact Assessment Report
[13] Environmental Protection Agency (2017) Guidelines on the Information to be contained in Environmental Impact Assessment Reports. Draft, August 2017
[14] European Commission (1999) Guidelines for the Assessment of Indirect and Cumulative Impacts as well as Impact Interactions

extent. The EU guidelines also refer to '*Cross-Media Impacts'*, in which the impact in one environmental medium may also have an indirect impact on another medium.

19.4 Interaction of Impacts

19.4.1 Matrix of Impacts

All environmental factors are inter-related to some extent, and the relationships can range from tenuous to inextricable. The interactions between the identified environmental impacts have already been considered and assessed within the individual chapters of this EIAR. There have been numerous discussions and communications including workshops and meetings between the environmental specialists and the design team throughout the design process which helped to identify and minimise the potential for significant interaction of impacts. Measures to minimise impacts have been incorporated into the design and are also included in all of the assessments and the residual impacts have been assessed.

For example, where it has been established in **Chapter 11, Hydrology** that there will be an increase in suspended solids or pollutants during construction arising from earthworks, then **Chapter 8, Biodiversity** has assessed the effect of that on aquatic flora and fauna. Measures to minimise impacts of suspended solids or pollutants have been designed with consideration to those interactions and have been incorporated into both the hydrology and biodiversity chapters and the residual impacts on both hydrology and biodiversity have been assessed. Similarly, where **Chapter 16, Air Quality and Climate** and **Chapter 17, Noise and Vibration** have established that there will be air and noise emissions during both the construction and operational phases, **Chapter 18, Human Beings, Population and Human Health** has assessed the effect of those emissions on human health and **Chapter 8, Biodiversity** has assessed the effects of those emissions on sensitive flora and fauna. Measures to minimise the air and noise emission impacts have been designed with consideration to those interactions and have been included in the assessments and the residual impacts have been identified.

Table 19.2 presents the potential interactions between the environmental factors in a matrix format. It examines the potential for the environmental factor or issue in the left hand column to have an impact on the environmental factor listed in the top row of the matrix as a result of the proposed road development. As discussed above, these potential interactions of impacts were identified throughout the design process and measures addressing these impacts have already been included within the individual chapters of this EIAR. The paragraphs following **Table 19.2** present an assessment of the potential interactions of impacts, mitigation measures and residual impacts. This assessment is based on information contained within this EIAR and the outcome of discussions and interactions between the environmental specialists and the design team.

If there is the potential for an impact during the construction phase, this is indicated by a 'C'. An 'O' indicates the potential for an impact during the operational phase and 'CO' indicates the potential for an impact during both phases. If it is considered that there will be no potential for an impact, this is indicated by 'none'.

For example, the construction of the proposed road development will require construction traffic movements (left hand column) which could potentially generate negative impacts ("C") on a number of environmental factors (top row of table) such as air quality and climate, noise and vibration, biodiversity, human beings, population and human health, material assets (both agriculture and non-agriculture) and the risk of major accidents and/or natural disasters. These environmental factors could then in turn result in (secondary/indirect) impacts on other environmental factors. For example, excavation activities will generate material (direct impact on soil and rock resource) some of which will require transportation (secondary impact on construction traffic) and disposal (secondary impact on resource capacity offsite). Air emissions (secondary impact) arising from this construction traffic could subsequently impact on human beings, population and human health. All of these interactions and secondary/indirect impacts have been considered in each of the respective chapters of this EIAR.

19.4.2 Potential Interactions

All of the potential impacts arising from the potential interactions were identified at a very early stage in the design process and in the EIAR preparation. They were therefore addressed in the design of the proposed road development and in the environmental baseline and impact assessment studies. As a result, the potential impacts were either avoided altogether through design measures or they were addressed through specific mitigation measures. This early identification process helped to identify and minimise the potential for significant interactions of impacts arising. The potential impacts and mitigation measures are discussed further below.

19.4.2.1 Overview of Traffic Interactions

Construction Phase

The construction of the proposed road development will require construction traffic movements which could potentially generate negative impacts on a number of environmental factors such as air quality and climate, noise and vibration, biodiversity, human beings, population and human health, visual impact, material assets (both agriculture and non-agriculture) and the risk of major accidents and/or natural disasters.

The level of construction traffic generation is dependent on the types, intensity and duration of construction activities taking place. For example, if there are significant volumes of excavated material or demolition materials which require disposal offsite or if significant materials are required to be imported on site, these activities have the potential to generate significant construction traffic volumes.

Construction traffic movements have the potential to generate a visual impact as well as air quality and noise and vibration emissions which could potentially negatively impact on human beings, population and human health. The generation of construction traffic will also result in road diversions and general short term disruption for people and properties in the area which could potentially negatively impact on material assets. In addition, construction traffic has the potential to negatively impact on biodiversity arising from severance, disturbance and mortality. Finally, there is a potential interaction between construction traffic and the risk of major accidents and/or natural disasters arising from the risk of a major traffic accident occurring during the construction phase.

Operational Phase

Operational traffic and the physical presence of the proposed road development could potentially generate negative impacts on the same environmental factors identified for the construction phase above.

19.4.2.2 Interaction of Traffic with Air Quality and Climate

Construction Phase

An air quality assessment of construction traffic impacts was carried out and the results show that all of the predicted concentrations are in compliance with the air quality standards (Refer to **Table 16.20** of **Chapter 16, Air Quality and Climate**). Therefore, significant residual impacts from construction traffic on air quality and subsequently human beings, population and human health will not arise.

During the construction phase of the proposed road development, 150,000 tonnes per year of CO_2 are estimated to be generated (arising from all construction activity, not just construction traffic), assuming a 36-month construction programme. Ireland has committed to achieve a 20% reduction in non-Emission Trading Scheme (ETS) greenhouse gas emissions by 2020 (relative to 2005 levels). The emissions predicted to be produced during the construction phase of the proposed road development constitutes 0.39% of Ireland's 2020 CO_2 limit under the EU Climate Change and Renewable Energy Package. These emissions will occur for the duration of the construction phase. Measures to mitigate these potential impacts on climate are outlined in **Section 16.6** of **Chapter 16, Air Quality and Climate** and include measures such as the implementation of an energy management system and a Construction Traffic Management (CTMP) (as presented in the CEMP in **Appendix A.7.5**). The overall conclusion of the air quality and climate assessment is that with the implementation of such mitigation measures, no significant residual impacts on air quality climate will arise during the construction phase.

Operational Phase

An air quality assessment during the operational phase of the proposed road development was carried out and the results show that all of the predicted concentrations are in compliance with the air quality standards (Refer to **Table 16.20** of **Chapter 16, Air Quality and Climate**). Therefore, significant residual impacts from construction traffic on air quality and subsequently human beings, population and human health will not arise.

19.4.2.3 Interaction of Traffic with Noise and Vibration

Construction Phase

Construction traffic will generate noise emissions and there is a potential for noise impacts from construction traffic along public roads. A noise and vibration assessment of the noise emissions due to construction traffic identified that all bar three roads (Bearna to Moycullen, Cappagh Road and Bóthar Nua) will experience a potential increase in noise in the order of less than 3dB over a worst case scenario of a 12-month construction period.

The Bearna to Moycullen Road will experience an increase of 3dB and whilst this is perceptible the overall noise level along this road is of low to moderate level, calculated at 56dB $L_{Aeq,\,T}$ at 10m from the road edge and the overall impact is deemed to be moderate, short-term. Cappagh Road will experience an increase of 8dB and whilst this is perceptible the overall noise level along this road is of low to moderate level, calculated at 56dB $L_{Aeq,\,T}$ at 10m from the road edge and the overall impact is deemed to be moderate, short-term. Bóthar Nua will experience an increase of 7dB and whilst this is perceptible the overall noise level along this road is calculated at 62dB $L_{Aeq, T}$ at 10m from the road edge and the overall impact is deemed to be major, short-term.).

These impacts will be short-term and the use of best practice noise control measures, hours of operation, scheduling of works within appropriate time periods, will ensure impacts are controlled as far as practicable during the construction phase along public roads. Therefore, significant residual impacts from construction traffic on noise and subsequently human beings, population and human health will not arise.

Vibration impacts relating to construction traffic will be limited given the low generation of vibration from vehicles along well maintained roads. Therefore, significant residual impacts from construction traffic on vibration and subsequently human beings, population and human health will not arise.

Operational Phase

Traffic during the operational phase of the proposed road development will generate new noise emissions. Noise levels will be increased at the majority of noise sensitive locations along the length of the proposed road development. Whilst noise levels of varying increases and impact magnitudes are calculated at the assessment locations, the incorporation of a low noise road surface and the use of noise barriers along the roadside boundary will reduce noise levels to within the design goal of 60dB L_{den} or to the pre-existing Do Minimum noise levels at the majority of noise sensitive locations. Residual noise levels at a small number of locations will remain above the 60dB L_{den} design goal by 1 to 2dB. The noise assessment has concluded that changes in road traffic noise levels will be negligible to major in accordance with DMRB guidance, however the overall impact at the properties taking account of typical population response to the absolute noise levels under consideration across the study area is negligible to moderate.

Overall, noise levels will be increased at properties along the route of the proposed road development once operational and a change in the noise environment will occur. The proposed road development, however, has been designed to reduce operational noise levels to within national design guidelines through the incorporation of detailed noise mitigation measures. The number of properties along its route is relatively low compared to those within the city centre which are currently exposed to significantly higher noise levels from passing road traffic. The reduction in high volumes of traffic traversing the city centre will result in a moderate to major positive noise impact to an extensive number of noise sensitive properties along the existing road network.

Therefore, significant residual impacts from operational traffic on noise and subsequently human beings, population and human health will not arise.

19.4.2.4 Interaction of Traffic with Biodiversity

Construction Phase

The generation of traffic during the construction phase has the potential to negatively impact on biodiversity resulting in temporary severance or disturbance issues. Construction traffic and other construction activities such as watercourse crossings can present as a temporary barrier and/or hazard to mobile species such as otter, bats, badger, and fish potentially resulting in temporary severance and/or mortality. Furthermore, the physical presence of construction traffic can result in temporary disturbance to these species. Mitigation measures have been incorporated into **Chapter 8, Biodiversity** to address these potential impacts. These include measures such as exclusion zones around badger setts, construction measures for working along watercourses and strict controls on temporary crossing points over watercourses and temporary crossing points for bats. As a result of the implementation of such mitigation measures, significant residual impacts on biodiversity due to construction traffic will not arise.

Operational Phase

The generation of traffic and the physical presence of the proposed road development during the operational phase has the potential to negatively impact on biodiversity resulting in severance, disturbance and mortality issues. Mobile species such as bats, barn owls and other birds could potentially collide with traffic or structures resulting in mortality. The flight paths of bats could also potentially be severed due to the physical presence of the proposed road development. Furthermore, the introduction of lighting in otherwise unlit areas could potentially negatively impact bat activity.

As discussed previously, these types of impact interactions were identified at a very early stage in the design and environmental assessment process. As a result, the potential impacts were either avoided altogether through design measures or they were addressed through specific mitigation measures in the relevant EIA chapters. For example, the choice of the design of the River Corrib Bridge included an objective to minimise potential ecological impacts on birds due to collision risks and bats. Mammal underpasses and the Castlegar Wildlife Overpass were all designed with an objective to minimise the barrier effect for bats. Landscape planting has specifically been designed to minimise barn owl and bat mortality arising from collisions with traffic. Further mitigation measures have also been incorporated into **Chapter 8, Biodiversity** to further address these potential impacts. As a result of the implementation of design measures and other mitigation measures, significant residual impacts on biodiversity due to operational traffic and the physical presence of the proposed road development will only arise in relation to the Peregrine falcon. The presence of the proposed road development has the potential to permanently displace nesting Peregrine falcon from the nest site at Lackagh Quarry Refer to **Chapter 8, Biodiversity** for further details.

19.4.2.5 Interaction of Traffic with Soil, Water Quality and Resource and Waste Management

Construction Phase

During the construction phase, there is the potential for interaction between soil, water quality, resource and waste management and construction traffic. As mentioned previously, if excavated materials or demolition materials require disposal offsite or if construction materials are required to be imported, these activities have the potential to generate construction traffic volumes. For example, excavation activities will generate material (direct impact on soil and rock resource) some of which will require transportation (secondary impact on construction traffic) and disposal (secondary impact on resource capacity offsite). Construction traffic will also produce sediment runoff through potential spillage of saturated silts and peat slurry during the haulage of materials. This has the potential to impact on water quality. The interaction of water quality with human beings and biodiversity is discussed further below.

During the design process, every effort was made to balance the import and export volumes of materials thereby minimising construction traffic generation in the first instance. In addition, the Construction and Demolition Waste Management Plan (as presented in the Construction Environmental Management Plan (CEMP) in **Appendix A.7.5**) has been prepared to ensure that waste arising during the construction and demolition phase will be managed and disposed of in a way that ensures compliance with the provisions of the Waste Management Acts 1996-2011 and associated Regulations (1996-2011) to ensure that optimum levels of reduction, re-use and recycling are achieved. Furthermore, the Construction Traffic Management (CTMP) (as presented in the CEMP in **Appendix A.7.5**) has been prepared to ensure that construction traffic will be managed and monitored safely and efficiently throughout the construction phase. As a result of the implementation of mitigation measures such as the CEMP and the design measures, significant residual impacts from material imports and exports on construction traffic will not arise.

19.4.2.6 Interaction of Traffic with Material Assets

Construction Phase

The generation of construction traffic will result in road diversions and general short term disruption for properties in the area which could potentially negatively impact on residential, commercial and agricultural areas.

There are two locations where temporary road diversions will be in place in order to construct bridge structures at Ch. 3+300 Aille Road L5384 and Ch. 13+150 School Road, Castlegar L2134. Temporary night-time closure of existing roads may be required where overbridges are to be constructed at locations such as the Rahoon Road, Letteragh Road, N59 Moycullen Road, Menlo Castle Bóithrín, Bóthar Nua, An Seanbóthar, N84 Headford Road, N83 Tuam Road, Briarhill Business Park Road and R339 Monivea Road. The north end of the Anne Gibbons road will also be permanently closed with property access to the south maintained.

As detailed in the CEMP (**Appendix A.7.5**), the Contractor will put in place a Public Communications Strategy which will include procedures to inform members of the community who will be directly affected by the construction phase on schedules for any activity of a particularly disruptive nature which is likely to impinge on their property such as blasting, demolition, road closures and diversions, pile driving and any mitigating actions that are being taken (shielding, restriction on work hours, etc.) to minimise such disruption.

Furthermore, the Construction Traffic Management (CTMP) (as presented in the CEMP in **Appendix A.7.5**) has been prepared to ensure that construction traffic will be managed and monitored safely and efficiently throughout the construction phase. Therefore, significant residual impacts will not arise.

Operational Phase

The north end of the Anne Gibbons road will also be permanently closed with property access to the south maintained.

The indirect interaction of traffic with material assets is assessed elsewhere under the heading of air quality, noise and vibration, landscape and visual and human beings, population and human health.

19.4.2.7 Interaction of Traffic with Human Beings, Population and Human Health

Construction Phase

Construction traffic will be restricted to the designated haul routes. There will however be a temporary increase in traffic on these routes during construction, affecting the journey amenity of other road users and the general amenity of local residents. There will also be a requirement for some temporary road diversions and night time closures which would mainly result in slight negative impacts on journey time. As a result, there will be a slight impact for some people due to an increase in journey times. The Construction Traffic Management Plan included in the CEMP in **Appendix A.7.5** has been prepared to ensure that construction traffic will be managed and monitored safely and efficiently throughout the construction phase and includes designated traffic routes, timings and parking arrangements to be updated by the contractor prior to the commencement of construction.

The potential for impacts on human beings, population and human health arising from air and noise emissions generating from construction traffic was also identified. Refer to **Sections 19.4.2.2** and **19.4.2.3** above. Significant residual impacts from construction traffic on air quality and noise and vibration and subsequently human beings, population and human health will not arise.

Employment will be generated during the construction phase and will provide a positive economic impact to the local economy in terms of spending on food and accommodation, although a proportion of workers are likely to reside in Galway. The employment multiplier for similar infrastructure projects has been estimated at 1.5, implying the creation of one additional full-time equivalent jobs for every two people employed full-time on the construction of the proposed road development.

Social severance of communities will arise during construction due to works such as the movement of construction traffic, although physical connectivity will be maintained with the exception brief temporary restrictions to movement.

Some agricultural properties will also experience severance. Temporary alternative access routes and permanent utility diversions will be required during construction.

Operational Phase

During operation, some commercial properties such as service stations will experience a reduction in passing trade due to the diversion of traffic from some areas in Galway City and its environs.

The proposed road development will alleviate traffic congestion within Galway City and its environs and will therefore have a positive impact on the local and the larger regional population of Galway and the western region. This will improve the quality of life of those living within Galway City due to a reduction in traffic volumes and congestion, reduced pollution and reduced social and physical severance. The redistribution of traffic will significantly improve traffic movement in Galway City and its environs overall, thereby making it easier for people to work and travel through the city. The diversion of traffic from Galway City Centre to the proposed road development and the consequent freeing up of road space for pedestrian, cyclist and public transport use will result in a positive indirect impact on journey times and journey amenity. Along the route of the proposed road development, the presence of the road itself will remain a source of social severance, although physical connectivity will be maintained.

19.4.2.8 Interaction of Traffic with Risks of Major Accident and/or Disaster

Construction and Operational Phase

The vulnerability of the proposed road development to risks associated with major accidents and/or disasters was assessed. A major traffic collision was identified as such an event. Although, the consequence of this is ‘very serious’, resulting in mass injury or loss of life, the likelihood is considered to be low. All possible measures have been included in the design of the proposed road development to reduce the severity and potential consequences of low likelihood but potentially high consequence vehicular accident events. Appropriate precautionary measures have been included in the design of the proposed road development to reduce the severity and potential consequences of vehicular accident events.

19.4.2.9 Overview of Soil Interactions

Construction Phase

The construction of the proposed road development will include soil activities such as earthworks and excavations. These activities will generate air, noise and vibration emissions which could potentially create negative impacts on a number of environmental factors such as air quality and climate, noise and vibration, biodiversity, human beings, population and human health, material assets (both agriculture and non-agriculture).

The level of emissions generation is dependent on the types, intensity and duration of construction activities taking place. For example, if there are significant volumes of excavated material or demolition materials which require disposal offsite or if significant materials are required to be imported on site, these activities have the potential to generate construction noise and dust. These interactions are discussed further below in the interactions of air emissions and noise and vibration emissions.

Earthwork movement and excavations will also create landscape and visual impacts and generate waste materials. These are discussed further below.

19.4.2.10 Interaction of Air Emissions with Human Beings

Construction Phase

The construction of the proposed road development will require earthworks, particularly during site clearance and excavation. These activities have the potential to generate significant air emissions (dust) which could potentially negatively impact on human beings under the environmental topic of both human beings, population and human health and material assets (both agriculture and non-agriculture). In general, any additional airborne concentrations of particulate matter arising from construction would be small and very local to the construction activity (minimising human exposure). Particles generated by most construction activities tend to be larger than 10µm in diameter which are too large to enter the human lungs. An assessment was carried out of the potential dust impacts at locations where the main construction activities will take place and where the construction compounds will be located (Refer to **Section 16.5** of **Chapter 16, Air Quality and Climate**). The results of the assessment indicate that there are a number of receptors located within 100m of the construction activities/construction compounds where there is potential for significant soiling effects to arise with standard dust control mitigation measures in place. These soiling effects could impact both residential, commercial and agricultural areas for example and also in ecologically sensitive areas such as Lough Corrib cSAC.

Further mitigation measures have been designed to minimise the impact of dust and other air emissions during the construction phase. (Refer to **Section 16.6.2** of **Chapter 16, Air Quality and Climate**). These measures are based on best practice as outlined in the British Research Establishment (BRE) document ‘Controlling particles, vapour and noise pollution from construction sites’ and the Institute of Air Quality Management (IAQM) ‘Guidance on the assessment of dust from demolition and construction’, 2016. Furthermore, dust screens will be implemented at locations where there is the potential for air quality impacts during the construction phase as outlined in **Section 16.5.3** of **Chapter 16, Air Quality and Climate** i.e. at locations where sensitive receptors are located within 100m of the works.

Dust deposition and $PM_{10}/PM_{2.5}$ monitoring shall be carried out to confirm the effectiveness of the mitigation measures. The residual impact on air quality during the construction phase will not be significant following the implementation of mitigation measures outlined above.

As noted above, the results of the air quality assessment show that all of the predicted concentrations are in compliance with the air quality standards (Refer to **Table 16.20** of **Chapter 16, Air Quality and Climate**). Therefore, significant residual impacts on air quality and subsequently human beings, population and human health will not arise.

Operational Phase

Air emission from traffic on the proposed road development during the operational phase have the potential to generate negative impacts on human beings, population and human health.

The potential impact on air quality during the operational phase was assessed. Pollutant concentrations were provided at the worst-case receptors, i.e. those properties that are closest to the affected links. (Refer to **Section 16.5.4** of **Chapter 16, Air Quality and Climate**). The pollutants assessed included NO_2, PM_{10}, $PM_{2.5}$, CO and Benzene. The results of the assessment show that the predicted changes in concentration of all the pollutants are in compliance with the air quality standards. Therefore, significant residual impacts from operational traffic on air quality and subsequently human beings, population and human health will not arise.

Air quality improvements will improve at a number of locations during the operational phase due to decreases in annual average daily traffic (AADT) levels. The reduction in traffic will result in a localised improvement of air quality in these regions, which will be particularly evident where sensitive receptors are adjacent to roadways and traffic reductions are substantial. Refer to **Table 16.28** of **Chapter 16, Air Quality and Climate** for further details. Therefore, positive impacts will arise for human beings, population and human health at a number of locations due to the improvement in air quality during the operational phase.

19.4.2.11 Interaction of Air Emissions with Biodiversity

Construction Phase

As noted above construction activities such as earthworks, particularly during site clearance and excavation have the potential to generate significant air emissions (dust) which could potentially negatively impact on biodiversity. An assessment was carried out of the potential dust impacts at locations where the main construction activities will take place and where the construction compounds will be located. The results of the air assessment indicate that with standard dust control mitigation measures in place there is still potential for significant soiling effects to arise in ecologically sensitive areas such as Lough Corrib cSAC.

As noted above further mitigation measures have been designed to minimise the impact of dust and other air emissions during the construction phase. In addition to those measures noted above, a 2m dust screen will be provided at the locations in the areas of the overlap of the proposed road development and the Lough Corrib cSAC.

Dust deposition and PM_{10}/$PM_{2.5}$ monitoring shall be carried out to confirm the effectiveness of the mitigation measures. The residual impact on air quality during the construction phase will not be significant following the implementation of mitigation measures outlined above.

Operational Phase

Air emission from traffic on the proposed road development during the operational phase also have the potential to generate negative impacts on biodiversity.

An assessment was carried out on the potential for air pollution to impact on the Lough Corrib cSAC due to operational traffic under the headings of nitrogen compounds, Volatile Organic Compounds (VOC), metals/dust and ammonia at the River Corrib Bridge between Ch. 9+250 and Ch. 9+600, between Ch. 9+800 and Ch. 10+100 at Menlough, and Lackagh Tunnel between Ch. 10+450 and Ch. 11+450. The assessment shows that all predicted NO_x concentrations are in compliance with the Air Quality Standard for the protection of vegetation. The proposed road development contribution to the NO_2 dry deposition rate along the 200m transect from the proposed road edge was also calculated as detailed in **Table 16.23** of **Chapter 16, Air Quality and Climate**. The maximum increase in the NO_2 dry deposition rate is approximately 20% of the critical load for the lower boundary limit of inland and surface water habitats of 5-10kg(N)/ha/yr (TII 2011). Even with the addition of background levels, compliance with the critical load is achieved.

No critical load limits exist for VOCs for the protection of vegetation. An assessment of emissions of benzene was carried out for the proposed road development and predicted concentrations including background levels were well within the air quality standard for the protection of human health. Significant impacts arising from metals/dust and ammonia will not arise as they are all in compliance with the air quality standards. The air quality standards been developed to protect the environment as a whole. Refer to **Chapter 16, Air Quality and Climate** for further details. In summary, significant residual impacts from operational traffic air pollutants on vegetation along the route of the proposed road development are not likely.

19.4.2.12 Interaction of Noise and Vibration Emissions with Human beings

Construction Phase

Construction traffic movements and construction activities such as blasting, rock breaking and general earthworks have the potential to generate significant noise and vibration emissions which could potentially negatively impact on human beings under the environmental topic of both human beings, population and human health and material assets. A number of examples of locations where blasting and drilling may be required (which have the potential to experience impacts) are provided below.

Construction of the N59 Link Road North involves deep excavation towards the N59 Moycullen Road tie in, therefore a substantial volume of soil and rock excavation will be required which will likely require drill and blasting excavation.

The closest noise sensitive locations are approximately 50m from the excavation works. In the absence of specific noise mitigation measures, it is likely that construction noise limits during, day, evening and weekend periods will be exceeded, specifically during the intermittent use of high noise activities (rock drilling, crushing and breaking, if required). The use of specific noise mitigation measures will be applied in this area therefore including scheduling of works, choice of plant and screening.

Construction of the N59 Letteragh Junction involves an extensive area of cutting which will likely require drill and blast excavation. The closest noise sensitive locations are approximately 25m from the excavation works. Whilst excavation works will take place within the cutting area, it is likely that crushing and regrading works will take place within the proposed site compound located along the N59 link Road North which is set back from noise sensitive properties. Notwithstanding the above, given the close distances of excavation works to noise sensitive properties, the use of controlled noise mitigation measures will be required in this area to reduce construction noise levels at the nearest noise sensitive locations.

Construction of the Lackagh Tunnel will be undertaken in an east to west direction using drill and blast techniques. The tunnel portal and main works area will be within the proposed site compound at Lackagh Quarry. The closest noise sensitive properties to the tunnel are over 500m away and hence are well set back from the main excavation works in this area.

Construction of the N84 Headford Road Junction and the cutting on the eastern side of Lackagh Quarry will involve substantial earthworks for both cutting and embankment construction. There will be a large cutting into the eastern face of Lackagh Quarry within the eastern end of this section of the proposed road development which is located some 300m from the nearest noise sensitive locations. Construction of the N84 Headford Road Junction will involve extensive engineered fill works to cross the existing N84 Headford Road with an element of cutting required for slip roads. The closest noise sensitive locations are within 40 to 50m from these works and hence there is potential for construction noise levels to exceed daytime, evening and weekend construction noise criteria in the absence of noise mitigation measures.

As detailed previously, these potential impacts were identified at a very early stage in the design and environmental assessment process. As a result, the potential impacts have been addressed through specific mitigation measures in **Chapters 9, Soils and Geology** and **17, Noise and Vibration** and in the CEMP in **Appendix A.7.5**.

For example, the schedule of commitments specify that the contractor, undertaking the construction of the works, will be obliged to take specific noise abatement measures and in particular blast design control must comply with the best practice outlined in British Standard BS 5228 – 1: 2009 +A1 2014: *Code of practice for noise and vibration control on construction and open sites – Noise* and the NRA (now TII) guidelines *Good Practice Guideline for the Treatment of Noise during the planning of National Road Schemes* (National Roads Authority, 2014). Refer also to **Chapter 17, Noise and Vibration**.

Furthermore, a designated noise liaison officer will be appointed to site during construction works. Clear forms of communication will be established between the contractor and residents in noise sensitive areas in proximity so that residents or occupants of businesses are aware of the likely duration of activities likely to generate higher noise or vibration. All noise complaints will be logged and followed up in a prompt fashion by the liaison officer.

Mitigation measures have also been considered for potential vibration impacts. The TII Guidelines recommend that in order to ensure that there is no potential for vibration damage during construction, vibration from construction activities should be limited to the values set out in **Table 17.3** of **Chapter 17, Noise and Vibration**.

On review of the likely vibration levels associated with construction activities, it may be concluded that the construction of the proposed road development is not expected to give rise to vibration that is either significantly intrusive or capable of giving rise to structural or cosmetic damage to buildings. Property condition surveys will be offered for all buildings within 50m of the proposed development boundary and those within 150m of proposed blasting works along the proposed road development. Property condition surveys will also be carried out at buildings and structures considered appropriate relative to their proximity to the works. Mitigation measures have also been proposed for vibration sensitive manufacturing facilities within the industrial estates at Parkmore and Ballybrit, refer to **Chapter 17, Noise and Vibration** for further details.

The results of the construction noise and vibration assessments have been taken into account in the assessment of human health (Refer to **Chapter 18, Human Beings, Population and Health**) and concludes that significant residual impacts from noise and vibration emissions (arising from construction traffic and other construction activities) on human health will not arise.

Operational Phase

The noise emission sources from the proposed road development during the operational phase will be from traffic. These emissions have the potential to negatively impact on human health. Traffic noise levels have been calculated at many noise sensitive locations along the length of the proposed road development and mitigation has been identified for a number of locations (Refer to **Table 17.13** of **Chapter 17, Noise and Vibration**). The mitigation measures required to reduce traffic noise levels are specified based on the predicted noise levels for the Design Year of 2039. The results of the modelling exercise show that noise mitigation is required for 102 properties along the route of the proposed road development for this Design Year.

Measures to reduce operational noise levels along the proposed road development include the use of a Low Noise Road Surface (LNRS) to reduce noise generated at source and the use of noise barriers to reduce noise levels along the propagation path between the source (proposed road development) and the specific receivers (houses, schools, churches etc.). These screens may be constructed as earth bunds, proprietary noise barriers or a combination of both. The use of a low noise road surface (LNRS) will provide a mean reduction in traffic noise level of -2.5dB compared to Hot Rolled Asphalt (HRA) along the length of the mainline of the proposed road development and along the main junction slip roads accessing the

N59 Moycullen Road, N84 Headford Road, N83 Tuam Road and existing N6 in addition to the N59 Link Road North and South as part of the proposed road development. **Table 17.14** of **Chapter 17, Noise and Vibration** summarises the noise barrier requirements for the proposed road development.

During the operational phase, noise levels will be increased at the majority of noise sensitive locations along the length of the proposed road development. Whilst noise levels of varying increases and impact magnitudes are calculated at the assessment locations, the incorporation of a low noise road surface and the use of noise barriers along the roadside boundary will reduce noise levels to within the design goal of 60dB L_{den} or to the pre-existing Do Minimum noise levels at the vast majority of noise sensitive locations. Residual noise levels at a small number of locations will remain above the design goal but are within 3dB of the design goal or are less than the predicted noise level in the Do-Minimum scenario. The assessment has concluded that changes in road traffic noise levels will be negligible to major in accordance with DMRB guidance, however the overall impact at the properties taking account of typical population response to the absolute noise levels under consideration across the study area is negligible to moderate.

Overall, noise levels will be increased at properties along the route of the proposed road development once operational and a change in the noise environment will occur. The proposed road development, however, has been designed to reduce operational noise levels to within national design guidelines through the incorporation of detailed noise mitigation measures. The number of such properties along its route is relatively low compared to those within the city centre which are currently exposed to significantly higher noise levels from passing road traffic. The reduction in high volumes of traffic traversing the city centre will result in a moderate to major positive noise impact to an extensive number of noise sensitive properties along the existing road network.

The results of the operational noise assessments have been taken into account in the assessment of human health (Refer to **Chapter 18, Human Beings, Population and Health**) and concludes that significant residual impacts from noise emissions (arising from operational traffic) on human health will not arise. Equally there will be no significant residual impacts on material assets arising from noise emissions.

19.4.2.13 Interaction of Vibration Emissions with Soil

Construction Phase

The soils and geology assessment also considered the potential vibration impacts arising from blasting and tunnelling on geology and in particular at the locations described above such as the Lackagh Tunnel. As noted previously, these potential impacts were identified at a very early stage in the design and environmental assessment process. As a result, the potential impacts have been addressed through specific mitigation measures in the **Chapters 9, Soils and Geology** and **17, Noise and Vibration** and in the CEMP in **Appendix A.7.5**. For example, ground settlement, horizontal movement and vibration monitoring will be implemented during construction activities to ensure that the construction does not exceed the design limitations.

In situations where the site specific blast design has determined that blasting is not feasible in a particular location due to excessive ground vibrations, alternative extraction methods such as hydraulic breaking, hydraulic splitting, chemical splitting and electrical disintegration may be implemented and monitored. Monitoring will be implemented during blasting, during excavation of cuts, for overburden slopes steeper than 1V:2H (V= vertical slope, H = horizontal slope) and rock slopes steeper than 1V:1.5H.

A geotechnical expert will be appointed by the contractor and will be present to monitor the surrounding ground vibrations near sensitive receptors during blasting works. In the unlikely event that the blast vibration limit at the surface is exceeded, blasting works will cease on site until it is understood the basis for the increased vibration. The blast design will then be recalibrated and blasting works will proceed with continued monitoring.

The tunnelling construction methodology at Lackagh Tunnel has specifically considered potential impacts on geology and in particular the Annex I habitats at the surface, namely Limestone pavement and Calcareous grassland. Again, a geotechnical expert will be appointed by the contractor and will be present to monitor the rock mass stability during their construction period. In the unlikely event that instability within the rock mass is observed, additional support measures will be installed to ensure that there is no impact to the surface above. The additional rock support measures comprise ground anchors, rock bolts, rock dowels, rock mesh, shotcrete or a combination of these measures, designed to the relevant design standards and best practice guidance documents. However, based on the conservative design approach it is considered that the risk of instability will be avoided and additional support measures will not be required.

Furthermore, a geotechnical expert will be appointed by the contractor and will be present to monitor the vibrations at the surface, including the areas of Limestone pavement, during blasting works for the construction of Lackagh Tunnel and its Western Approach. The blast target vibration limit is defined as 20% more conservative than the conservative design approach vibration limit of 25mm/sec at the ground surface which includes areas of Limestone pavement, which provides an added factor of safety to the construction works to ensure that blasting will not impact the structural integrity of the Limestone pavement. In the unlikely event that the blast target vibration limit at the surface is exceeded, blasting works will cease on site until it is understood the basis for the increased vibration. The blast design will then be recalibrated and blasting works will proceed with continued monitoring.

Therefore, significant residual vibration impacts from blasting/tunnelling (arising from construction activities) on soils and geology will not arise.

19.4.2.14 Interaction of Noise and Vibration Emissions with Biodiversity

Construction Phase

The biodiversity assessment also considered the potential impacts of blasting at the locations identified above including potential impacts on wintering birds at Ballindooley Lough.

As noted above, these potential impacts were identified at a very early stage in the design and environmental assessment process. As a result, the potential impacts have been addressed through specific mitigation measures in the **Chapters 8, Biodiversity**, **9, Soils and Geology** and **17, Noise and Vibration** and in the CEMP in **Appendix A.7.5**.

For example, blasting associated with the eastern approach to Lackagh Quarry (Ch. 11+800 to Ch. 12+100) and the cutting at Castlegar (Ch. 12+550 to Ch. 13+650) will be carried out between the months of April to September (inclusive) to minimise the exposure of wintering birds at Ballindooley Lough to blasting-related disturbance. Refer also to **Chapter 8, Biodiversity**, **Chapter 9, Soils and Geology** and **Chapter 17, Noise and Vibration**.

The biodiversity assessment also considered the potential impacts of disturbance to the Peregrine falcon due to noise. Despite the mitigation measures proposed, a significant residual impact on Peregrine falcon due to noise during construction remains. Refer also to **Chapter 8, Biodiversity**.

Therefore, the only significant residual impacts from noise emissions (arising from construction traffic and other construction activities) on biodiversity is disturbance to the Peregrine falcon.

Operational Phase

There will be a significant residual impact on Peregrine falcon due to potential noise disturbance from road traffic during the operation of the proposed road development.

19.4.2.15 Interaction of Biodiversity with Human Beings

Construction and Operational Phase

Interactions exist with biodiversity whenever human beings interact with the natural environment. These could be realised in two ways by:

- activities giving rise to impacts on biodiversity
- the presence ecosystem services, with biodiversity at the heart, which have the capacity to regulate and support the natural environment that contributes to human well-being

In the context of the proposed road development, potential impacts arise due to the presence of biodiversity and the benefits that biodiversity provides in terms of amenity or passive enjoyment of the landscape. The design of the proposed road development took cognisance of ecosystem services and sought to protect water quality and air quality and prevent soil erosion. It also sought to maintain local biodiversity which can be enjoyed by human beings.

The River Corrib for example is used by many people for recreational purposes, both on the water (rowing or angling) and along its banks (walking). Many species including Otter and bats, fish including salmonids, and birds utilise this corridor also. Angling is directly reliant on biodiversity. The River Corrib is an important salmonid river and consequently of importance for angling, therefore the protection of river water quality is essential for both biodiversity and amenity of the River Corrib corridor. Equally the presence of the fauna listed above and the flora along the river sides makes it an enjoyable place to walk or row, enhancing a person's recreational experience and contributing to their well-being. The proposed road development does not impact on this ecosystem service, which ultimately contributes to human well-being.

The interaction between biodiversity and human beings has been considered for example in the design of the River Corrib Bridge. Factors such as no piers in the water which would minimise impacts on aquatic biodiversity and amenity use of the river, type of structure to minimise bird collision risk and the aesthetics appearance of the bridge were all considered in the design thus protecting this ecosystem.

The principal focus of amenity activity is the River Corrib corridor, but interaction of biodiversity and human beings and well-being occurs throughout the study area. Some other natural environments, for example wetlands east of the River Corrib in the vicinity of Menlough and Ballindooley, contribute regulating and cultural ecosystem services by moderating water flow and acting as habitat for valued wildlife species. Natural environments such as peatlands and limestone have a role in filtering water quality in the study area with potential economic and health implications, although the role of biological processes is greater in the former. Vegetation such as hedgerows, treelines and woodland also have a role in noise attenuation and air quality regulation. Potential impacts for the above interactions on water quality or soil erosion would apply mainly during the construction phase. Measures have been taken however, to mitigate these through the sediment control and pollution prevention controls described in the CEMP in **Appendix A.7.5** and on biodiversity in **Section 8.6** of **Chapter 8, Biodiversity**.

19.4.2.16 Interaction of Archaeology, Architectural and Cultural Heritage with Biodiversity

Construction and Operational Phase

There is a potential for the archaeological trench testing along the route of the proposed road development to impact on biodiversity. These potential impacts will be the same as those identified in **Chapter 8, Biodiversity** as a result of the construction of the proposed road development.

These is also an interaction between architectural and cultural heritage with biodiversity with the design of the River Corrib Bridge. This crossing of the River Corrib, will introduce a dominant new feature into its landscape corridor which will have an impact on the heritage of Menlo Castle. Menlo Castle is also a maternity roost of the Lesser Horseshow bat. The design of the River Corrib Bridge took cognisance of these constraints and mitigation measures such as additional planting are provided, however significant residual impacts will continue to arise on the lowland landscape valley of the River Corrib, and the setting of Menlo Castle.

19.4.2.17 Interaction of Archaeology, Architectural and Cultural Heritage with Human Beings

Construction and Operational Phase

The proposed road development will impact on archaeological, architectural and cultural heritage features which are of interest and importance to the local people. As noted previously, these potential impacts were identified at a very early stage in the design and environmental assessment process. As a result, the potential impacts have been addressed through specific mitigation measures in a number of chapters such as **Chapter 13, Archaeological, Architectural and Cultural Heritage, Chapter 12, Landscape and Visual** and **Chapter 18, Human Beings, Population and Human Health**. For example, the setting of Menlo Castle provides an area for amenity use. There is a potential for a change in the amenity of this area if there is a change in the setting as a result of the River Corrib Bridge. This is discussed further under the heading of the interaction of landscape and visual with human beings. Menlo Castle is an important element of this setting. Whilst the proposed archaeological mitigation measures will record the current context of Menlo Castle, they will not fully remove the residual impact of the proposed road development on the setting of Menlo Castle – post mitigation the operation of the proposed road development will have an indirect moderate negative impact on the castle.

Other interaction examples include an occupied thatched cottage at Castlegar which is also a protected structure which will be demolished to facilitate the construction of the proposed road development. Prior to demolition, the thatched cottage will be subject to a full measured, written and photographic survey. This will be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. There is also a mass path located at Parkmore which is of heritage and amenity value for local people. The design of the Parkmore Link Road was revised to maintain access along this mass path. Archaeological testing and a written and photographic record prior to construction will also be carried out. Once the recommended mitigation measures have been applied (to the mass path and thatched cottage), there will be no residual impact on the archaeological, architectural or cultural heritage resource as a result of the construction of the proposed road development

19.4.2.18 Interaction of Landscape and Visual with Material Assets and Human Beings, Population and Human Health

Construction and Operational Phase

The landscape character and existing views in the area will change during both the construction and operational phases of the proposed road development. This impact has the potential to interact with people, both in terms of landscape and visual impacts where they live, work and their use and “experience” of surrounding amenities.

Lighting impacts both from the proposed road development itself and from traffic using the proposed road development during operation have the potential to impact on people. Similarly, lighting impacts from construction compounds during winter months have the potential to impact on people, depending on where they are situated.

Mitigation measures are proposed to minimise impacts during construction and include the implementation of the CEMP; provision of hoarding; careful location of storage areas to avoid impacting on residential and commercial properties and trees; and the decommissioning and reinstatement of construction compound areas to their pre-construction condition at the end of the construction contract.

The introduction of the proposed road development will change the views and landscape character of the area in varying degrees, some areas will require mitigation planting to screen impacts, other areas will experience views of the proposed road development. These changes have the potential to impact on people, especially in residential areas.

During the operation stage, visual impacts will arise from the physical built presence of the proposed road development, including its significant structures, elevated embankments, deep cuttings, traffic usage and additional illumination both fixed and from vehicles, especially where the proposed road development is on embankment or at junctions and bridging locations. In open views, embankments have the potential for visual obstruction and significant visual intrusion. Deep cuttings can also result in significant change to the visual nature of landscape continuity. These visual impacts have the potential to significantly impact on material assets non-agriculture such as such as residential areas. As discussed previously, these potential interactions of impacts were identified at a very early stage in the design process and many of them have been addressed/minimised through design measures and also through specific mitigation measures in the relevant EIA chapters.

For example, measures for the mitigation of potential noise impact will be required at a number of locations along the proposed road development, especially where residential properties are in close proximity to the carriageway. Such noise impacts and mitigation measures are considered in detail in **Chapter 17, Noise and Vibration**. Mitigation measures will involve the provision of barriers or earth bunds or a combination of such features. While initially these features may increase the visual presence of the proposed road development, they also provide for immediate visual screening of the proposed road development and its associated traffic. In the majority of circumstances these features can also be appropriately incorporated into the proposed landscaping measures.

The proposed road development also includes for realignments/tie-ins to existing national, regional and local roads, together with drainage works and accommodation measures, all of which have potential for localised visual impacts. Local road realignment is important as many residential properties tend to be located along such roads and local direct impacts can arise.

A full schedule and description of visual impacts on properties is set out in the Visual Impact Schedule (VIS) Tables in **Appendix A.12.1** and on **Figures 12.1.01** to **12.1.14**.

In the pre-establishment stage, 71 of the 351 locations (c.20%) will have an imperceptible impact. A further 167 locations (c.48%) will have a slight or moderate short-term impact. Eighty-four locations (c.24%) will have significant or very significant short-term visual impact. The remaining 29 locations (c.8%) will experience profound short-term negative visual impact associated with the presence and early operation stage of the proposed road development.

As landscape measures establish and mature the level of visual impact will gradually recede so that in the post-establishment stage some 156 locations (c.44%) will have an imperceptible impact. A further 140 locations (c.40%) will have a slight or moderate medium-term impact. Thirty-four locations (c.10%) will have significant or very significant medium-term visual impact. The remaining 21 locations (c.6%) will continue to experience profound medium and longer-term negative visual impact associated with the proposed road development. Refer to **Figures 12.1.01** to **12.1.14** for locations of properties.

The properties with on-going significant and very significant visual impact are either located in more remote and rural areas and are in proximity to the proposed road development, or are in suburban areas and are located directly adjacent to the proposed road development.

19.4.2.19 Interaction of Landscape and Visual and Biodiversity

Construction and Operational Phase

The construction phase will require site clearance and will result in the removal of a variety of habitats. This biodiversity (and landscape) impact, such as the removal of a woodland area, has the potential to permanently interact with the landscape character and amenity (and biodiversity) of an area. In addition, there is a potential for a change in biodiversity (such as introduction/spread of non-native invasive plant species) to negatively impact on landscape and visual aspects.

These potential interactions of impacts were identified at a very early stage in the design and environmental assessment process and have been addressed through specific mitigation measures, such as planting, in the relevant EIA chapters. For example:

- Mitigation measures to avoid the introduction or spread of non-native invasive plant species to Moycullen Bogs NHA during construction or operation have been detailed in the Non-native Invasive Species Management Plan which forms part of the CEMP in **Appendix A.7.5**
- To minimise the loss of habitat associated with the proposed road development, there are also areas within the proposed development boundary which are included for mitigation planting where general construction works will not be undertaken. These are shown on **Figures 8.23.1** to **8.23.14**
- Planting of woodland, hedgerow and grassland habitats along the proposed road development as detailed in the landscape drawings (**Figures 12.2.01** to **12.2.14**) will provide compensatory habitat for some bird species. In some instances, such as in large areas of improved agricultural grassland with no vegetated field boundaries, this will improve the diversity of bird habitat
- Sections along the proposed road development, will be planted with dense low growing scrub cover (e.g. blackthorn) to discourage Barn owls from foraging near the proposed road development. The planting will be of a density to minimise the lag time between planting and obtaining sufficient ground cover to deter foraging Barn owl
- In areas where there is a high probability that Barn owls regularly attempt to cross the proposed road development (the section of embankment between Ch. 9+600 and Ch. 10+100), lines of closely spaced (approximately 2m centres) trees, greater than 3m in height, will be planted along the top of the embankments of the proposed road development; outside of the safety barrier and clear zone. The understorey will also be densely planted. This is to present a solid vegetated barrier to deflect Barn owl from these high-risk areas and/or force birds to fly over the proposed road development above the road traffic
- Specific landscape planting mitigation measures have been proposed to preserve flight paths for bats during both construction and operational phases. The Castlegar Wildlife Overpass is a critical component of the strategy and specific landscape planting has been designed on the approach to and over the overpass. The overpass will allow bats to fly across the proposed road development between the roosts and foraging habitats on the north side and Coopers Cave and foraging areas to the south at this location
- An area of habitat enhancement for the purposes of offsetting the loss of suitable bat habitat due to the proposed road development within the known core foraging area of the Menlo Castle Lesser horseshoe bat population is included with in the proposed development boundary. Hedgerows in this area will be augmented and thickets of hazel, hawthorn, holly and oak will be provided in several of the fields to create pockets of wood and grassland habitat. Grazing will continue on the lands as it has been shown that this improves the quality of this type of habitat for Lesser horseshoe bats. Connectivity to foraging areas will also be secured through tying the proposed planting strips to hedgerows and woodland edges. Planting of new hedgerows in fields between the proposed road development and Menlo Castle will improve the foraging resources of this core foraging area. Such planting will include additional native hedgerows planted across the existing fields to increase the lengths of hedgerows close to

the proposed new roost for Lesser horseshoe bats. The fields will still be grazed and the hedgerows can be fitted with field gates as required providing gaps are kept to a minimum.

The landscape planting mitigation measures proposed will significantly reduce the level of biodiversity residual impact.

19.4.2.20 Interaction of Landscape and Visual and Archaeology, Architectural and Cultural Heritage

Construction and Operational Phase

There is a potential for a change in the setting of archaeological, architectural and cultural heritage features if there is a change in landscape character or views. For example, the proposed road development, including a c.650m long bridge at the crossing of the River Corrib, high embankments and a c.320m long viaduct at Menlough will introduce a dominant new feature into its landscape corridor. The new bridge in particular will be prominent along the River Corrib and NUIG Sporting Campus and from Menlo Castle, while the embankments and viaduct on the east of the River Corrib cross a very remote and elevated semi-natural landscape. The bridge and viaduct, and particularly traffic on the structures, will also be visible where elevated vantage points on the west side of the river allow for viewing across the River Corrib valley.

Given the existing environment, and the nature of this section of the proposed road development, integration will be slow and structures such as the bridge and viaduct will permanently influence landscape character. There will be a profound short-term and very significant medium negative impact on local landscape character. In addition, there will be a significant archaeological, architectural and cultural heritage impact on Menlo Castle and its demesne. Mitigation measures such as landscape planting in the vicinity have been proposed to soften the impacts however significant residual landscape impacts will continue to arise on the lowland landscape valley of the River Corrib, and the setting of Menlo Castle.

19.4.2.21 Interaction of Soil and Water Quality with Human Beings, Population and Human Health and Material Assets

Construction Phase

The construction works will involve considerable earthworks throughout the proposed road development area including cuttings and embankments, tunnels, bridges and viaducts and the movement earthworks materials both within the proposed road development boundary and outside of the proposed road development boundary (quarries, borrow pits etc.). These works and other construction activities have the potential to impact on water quality, water supplies, people and material assets. These potential impacts were considered at a very early stage and pollution control measures have been incorporated into the design and specified in the CEMP.

As detailed in the CEMP in **Appendix A.7.5** and in **Section 11.6** of **Chapter 11, Hydrology**, a suite of mitigation measures has been proposed and include an Incident Response Plan (IRP) and Sediment, Erosion and Control Plan (SECP). Stringent mitigation and control of potential polluting activities associated with construction activities is proposed which will significantly reduce pollution risk. Stringent controls are proposed to limit the risk of untreated sediment run-off entering the water body and to minimise the risk of construction spillages of concrete and hydrocarbons into these waters (refer also to the CEMP in **Appendix A.7.5**). Specifically, there will be no in-stream works at the River Corrib channel associated with the construction of the river bridge crossing that fully spans the River Corrib channel, so as to protect the major downstream drinking water abstraction to the Galway City Water Treatment Plant at Terryland.

Mitigation measures to address impacts on water supplies from wells have also been considered (Refer to **Chapter 10, Hydrogeology**) and will include measures such as replacement wells, connections to mains supplies or financial compensation for wells which will be lost during the construction phase. Monitoring will also be carried out at some locations and standard mitigation measures and aquifer specific mitigation measures will also be employed for protection of groundwater. These measures will ensure that significant residual impacts on water supplies will not arise

Operational Phase

Potential pollution impacts during the operational phase (such as from operational traffic) on water quality have also been considered. The operational phase presents a potential pollution risk to the Terryland water supply both from accidental spillages and from routine road run-off discharges. However, pollution control measures have been designed and put in place to significantly reduce the risk. The proposed drainage system design incorporates a range of pollution control features to limit the water quality impact to receiving waters. These include filter drains, grassed surface water channels, petrol and oil interceptors, detention ponds, wetlands and infiltration basins and spillage containment areas. The use of filter drains and grassed surface water channels are proposed in non-sensitive groundwater areas (granite bedrock areas west of N59 Moycullen Road) where possible and closed (sealed) drainage systems are proposed in the highly vulnerable Karst Aquifer region east of the N59 Moycullen Road. A treatment wetland will be provided upstream of the attenuation pond at all proposed surface water outfalls and upstream of all infiltration basins outfalling to ground, from the mainline and its associated link roads of the proposed road development. Treatment wetlands are designed to capture the first flush rainfall events.

In addition to the treatment wetlands, oil and petrol interceptors along with spillage containment areas will also be placed upstream of all surface water outfalls and groundwater infiltration basins. The oil and petrol interceptor and isolated spillage containment areas provide protection against both minor and major road spillages. An operational spillage assessment for the proposed road development was carried out for all outfalls, both surface and groundwater, and the results show low risk of impact from serious accidental spillage involving a HGV. In conclusion, residual water quality impacts on these watercourses will be slight during the operational phase. Therefore, significant negative cumulative impacts will not arise.

19.4.2.22 Interaction of Soil and Water Quality with Biodiversity

Construction Phase

As noted above, the construction of the proposed road development has the potential to impact on water quality. This in turn has the potential to impact on biodiversity. These potential impacts were considered at a very early stage and pollution control measures have been incorporated into the design and specified in the CEMP.

As noted above a suite of mitigation measures including an IRP and SECP have been proposed which will significantly reduce pollution risk. Stringent controls are proposed to limit the risk of untreated sediment run-off entering the water body and to minimise the risk of construction spillages of concrete and hydrocarbons into these waters. As noted above there will be no in-stream works at the River Corrib channel associated with the construction of the river bridge and this will minimise effects on Lough Corrib cSAC and European designated sites downstream.

A section of Lackagh Tunnel passes under an area of Qualifying Interest (QI) Annex I habitats, namely Limestone pavement and Calcareous grasslands, within the Lough Corrib cSAC. Given the presence of Annex I habitats, the design of the tunnel and its approaches includes measures such as stabilisation of Lackagh Quarry Face around the eastern tunnel portal in order to prevent rock mass instability and slope instability, careful selection of the tunnel construction methodology, retaining systems and blast design limitations.

Furthermore, during the construction of Lackagh Tunnel the supported rock face of Lackagh Quarry Face and retaining walls for the Western approach will be monitored for movement. A geotechnical expert will be appointed, by the contractor and will be present to monitor the rock mass stability during the construction period for these specific works. In the unlikely event that instability within the rock mass is observed, additional support measures will be installed to ensure that there is no impact to the surface above. The additional rock support measures comprise ground anchors, rock bolts, rock dowels, rock mesh, shotcrete or a combination of these measures, designed to the relevant design standards and best practice guidance documents. However, based on the conservative design approach it is considered that the risk of instability will be avoided and additional support measures will not be required.

A geotechnical expert will be appointed by the contractor and will be present to monitor the vibrations at the surface, including the areas of Annex I habitats, during blasting works for the construction of Lackagh Tunnel and the Western Approach. The blast target vibration limit is defined as 20% more conservative than the conservative design approach vibration limit of 25mm/sec at the ground surface which includes areas of Annex I habitats, namely Limestone pavement and Calcareous grasslands, which provides an added factor of safety to the construction works to ensure that blasting will not impact the structural integrity of the Limestone pavement. In the unlikely event that the blast target vibration limit at the surface is exceeded, blasting works will cease on site until it is understood the basis for the increased vibration. The blast design will then be recalibrated and blasting works will proceed with continued monitoring. Therefore, significant residual impacts will not arise.

Potential impacts on biodiversity arising from the introduction of material derived from a different lithology were also identified at an early stage in the design process. Specific mitigation measures have been included to address these impacts (Refer to **Section 9.5** of **Chapter 9, Soils and Geology**). For example, to prevent impact to the local peatland habitats, described in **Chapter 8, Biodiversity**, fill limitations at specific locations have been identified (Refer to **Table 9.18** of **Chapter 9, Soils and Geology**). Therefore, significant residual impacts will not arise.

Operational Phase

Potential pollution impacts during the operational phase (such as from operational traffic) on water quality and biodiversity have also been considered. The interaction assessment outlined above for soil and water with human beings is the same as that for biodiversity and significant negative cumulative impacts will not arise.

During the operational phase, monitoring of the rock mass stability will continue. The rock and overburden retaining systems in Lackagh Quarry and the Western Approach will continue to be monitored as part of the operational maintenance schedule. In the extremely unlikely event that instability within the rock mass is observed additional support measures as outlined above for the construction phase will be installed to ensure that there is no impact to the structural integrity of the Annex I habitats. However, based on the conservative design approach, (the installed composite support system and monitoring during construction) it is considered that the risk of instability will be avoided and additional support measures will not be required.

The measures described above were taken into account in the biodiversity assessment of this EIAR and in the NIS. The conclusion of the NIS was that the construction or operation of the Lackagh Tunnel and approaches will not affect the structural integrity of the rock mass supporting QI habitats in Lough Corrib cSAC or affect the conservation objective attributes and targets supporting the conservation condition of the QI habitats and species of Lough Corrib cSAC. Therefore, significant negative cumulative impacts will not arise.

Furthermore, during the operational phase of the proposed road development inspection and maintenance will occur to ensure that the infiltration basins continue to operate as intended for the design life of the proposed road development. If karst features and potential pathways are found to be present during inspection, then the Karst Protocol developed for the construction phase will be implemented to ensure that no preferential pathways have formed within the infiltration basin. Therefore, significant residual impacts will not arise.

19.4.2.23 Interaction of Water Quantity with Human Beings, Population, and Human Health and Material Assets

Construction and Operational Phase

Flooding can effect properties, including dwelling, commercial, industrial and agricultural or to effect journey movements. There are potential impacts on journey connectivity and amenity, residential amenity, economic activity and human health. The proposed road development as part of the design and environmental evaluation process has undergone a detailed Flood Risk Assessment in accordance with the DoEHLG Planning System and Flood Risk Management Guidelines for Planning Authorities. The assessment identified the sources of flood risk to the proposed road development from fluvial, pluvial and groundwater sources, but not from a coastal source as the proposed road development is sufficiently set back and elevated above the coastal zone. Overall the assessment has concluded that the design of the proposed road development minimises flood risk to the development itself and is rated as having a low probability of flooding.

A potential significant flood risk impact to lands including residential properties has been identified in the vicinity of the N83 Tuam Road Junction, resulting in the permanent encroachment and loss of some of the flood storage area from this flood risk area. Flood relief mitigation measures involving improved land and road drainage, provision of compensation storage and storm water pumping to the Terryland Basin have been designed, which when implemented will result in providing a residual moderate to significant positive impact by reducing the risk of serious flooding in this area.

At all other locations along the proposed road development, there will only be slight to imperceptible impacts on flood risk as very minimal encroachment of floodplains occur and design measures in the form of large culverts and stormwater attenuation ponds are included in the design. Residual flood risks exist at the drainage outfalls and their associated attenuation ponds and at the various culverts due to potential blockages. It should be noted however, the culverts have been sized with additional capacity for climate change impacts, controlled overflow systems are in place and there will be a program of regular inspections and maintenance and therefore the risk of blockages is slight.

Therefore, significant negative cumulative impacts will not arise.

19.4.2.24 Interaction of Water Quantity with Biodiversity

Construction and Operational Phase

The interaction of water quantity with biodiversity is the same as that presented above for the interaction of water quantity with human being, population and health and material assets. Significant negative cumulative impacts will not arise.

19.4.2.25 Interaction of Resource and Waste Management with Human Beings

Construction and Operational Phase

The interaction of resource and waste management with human beings, under the environmental topic of both human beings, population and human health and material assets, was considered. For example, the demolition of residential properties will generate demolition waste which will require transportation and disposal off site. Transportation requires construction traffic which can generate noise and air emissions which can impact on people. This has been addressed previously in **Sections 19.4.2.1** to **19.4.2.3** above.

During the design process, every effort was made to balance the import and export volumes of materials thereby minimising construction traffic generation in the first instance. In addition, the Construction and Demolition Waste Management Plan (as presented in the Construction Environmental Management Plan (CEMP)) has been prepared to ensure that waste arising during the construction and demolition phase will be managed and disposed of in a way that ensures compliance with the provisions of the Waste Management Acts 1996-2011 and associated Regulations (1996-2011) to ensure that optimum levels of reduction, re-use and recycling are achieved. Furthermore, the Construction Traffic Management (CTMP) (as presented in the CEMP) has been prepared to ensure that construction traffic will be managed and monitored safely and efficiently throughout the construction phase. As a result of the implementation of mitigation measures such as the CEMP and the design measures, significant residual impacts will not arise.

Lackagh Quarry will also be fully acquired to facilitate the construction of the proposed road development. This will result in a moderate impact on soils and geology due to the loss of a portion of future quarry or pit reserves. This will also result in a significant impact on a material asset impact. Financial Compensation for this impact is to be agreed by a valuer at a later stage after appropriate liaison with the property owners affected. Financial compensation does not form part of the EIA process and is therefore not considered further.

19.4.2.26 Interaction of Material Assets with Human Beings

Construction and Operational Phase

As described in **Chapter 15, Material Assets, Non Agriculture**, the proposed road development will cross through lands populated by residential and commercial properties on the outskirts of Galway City and include both agriculture lands and lands zoned for development. The proposed road development has been designed to avoid as many properties as possible, but given the distribution of development and the presence of linear type development of the city with housing along most roads radiating out of the city, its construction will unfortunately and unavoidably result in a number of property demolitions or acquisitions with some concentrations in particular areas. As well as the direct negative impact on the householders themselves, this will present a varying negative impact on remaining residents and at a community level depending on the strength of community interaction that has evolved at each location and the sustainability of community facilities such as schools. In several locations, and particularly in Na Foraí Maola and Troscaigh and the vicinity of the N59 Moycullen Road, the N84 Headford Road and in Castlegar, there will be a significant impact on local communities due to the need to acquire or demolish a high proportion of existing properties in these areas. It is important to recognise that the people whose homes will be subject to compulsory purchase across the route of the proposed road development have genuine concerns that their lives will be adversely affected. Many have lived in the area many years, or indeed, all of their lives.

In the event of an approval of the Protected Road Scheme and Motorway Scheme and approval under Section 51 of the Roads Act 1993 (as amended), by An Bord Pleanála and subject to the availability of funding, Notice to Treat will be served firstly on owners, lessees and occupiers of the dwelling houses and commercial properties to be acquired, within six months of the scheme becoming operative, unless an application has been made for Judicial Review, in which case the Notice to Treat will be served in accordance with the provisions of Section 217 (6A) of the Planning and Development Act 2000 as inserted by the Compulsory Purchase Orders (Extension of Time Limits) Act 2010. Compensation will be agreed or determined by the property arbitrator as soon as possible after service of Notice to Treat. After compensation has been agreed or determined and satisfactory title has been produced, part payment can be made while the claimant remains for an agreed period in the property to be acquired. This will facilitate the claimant in removing uncertainty and will facilitate arrangements being made, as early as possible, to secure a replacement property.

19.4.2.27 Interaction of Risks of Major Accident and/or Disaster and Human Beings, Population and Human Health

Construction and Operational Phase

The vulnerability of the proposed road development to risks associated with major accidents and/or disasters was assessed and potential interactions with human beings. A number of events were identified (Refer to **Table 19.1** above) such as major traffic collision (as described previously), hydrological and hydrogeological events, structural collapse events, tunnel fire events, service utility events and ground collapse events. As above, although, the consequence of these events is ‘very serious’, potentially resulting in mass injury or loss of life, the likelihood is considered to be low. The potential for low likelihood but potentially high consequence major accident and/or disaster events remains, although the possibility is extremely remote. All reasonably practicable measures have been included in the design of the proposed road development to reduce the severity and potential consequences of low likelihood but potentially high consequence events. Refer to **Section 19.2** above for further details.

19.4.2.28 Interaction of Risks of Major Accident and/or Disaster and Air Emissions, Noise and Vibration Emissions

Construction and Operational Phase

The vulnerability of the proposed road development to risks associated with major accidents and/or disasters and potential interactions with air, noise and vibration emissions was also assessed. A number of events were identified (Refer to **Table 19.1** above) such as major traffic collision (as described previously), structural collapse events, tunnel fire events, service utility events and ground collapse events. As above, although, the consequence of these events is 'very serious', potentially resulting in significant air, noise and vibration emissions, the likelihood is considered to be low. The potential for low likelihood but potentially high consequence major accident and/or disaster events remains, although the possibility is extremely remote. All reasonably practicable measures have been included in the design of the proposed road development to reduce the severity and potential consequences of low likelihood but potentially high consequence events. Refer to **Section 19.2** above for further details.

19.4.2.29 Interaction of Risks of Major Accident and/or Disaster with Soil, Water and Biodiversity

Construction and Operational Phase

The vulnerability of the proposed road development to risks associated with major accidents and/or disasters and potential interactions with soil, water and biodiversity was also assessed. A number of events were identified (Refer to **Table 19.1** above) such as major traffic collision (as described previously), hydrological and hydrogeological, structural collapse events, tunnel fire events, service utility events and ground collapse events. As above, although, the consequence of these events is 'very serious', potentially resulting in pollution of water or contamination of soil with the consequential impacts on biodiversity or direct impacts on biodiversity as a result of ground collapse, the likelihood is considered to be low. The potential for low likelihood but potentially high consequence major accident and/or disaster events remains, although the possibility is extremely remote. All reasonably practicable measures have been included in the design of the proposed road development to reduce the severity and potential consequences of low likelihood but potentially high consequence events. Refer to **Section 19.2** above for further details.

19.4.2.30 Interaction of Risks of Major Accident and/or Disaster with Material Assets

Construction and Operational Phase

The vulnerability of the proposed road development to risks associated with major accidents and/or disasters and potential interactions with material assets was also assessed. A number of events were identified (Refer to **Table 19.1** above) such as major traffic collision (as described previously), hydrological and hydrogeological, structural collapse events, tunnel fire events, service utility events and ground collapse events. As above, although, the consequence of these events is 'very serious', potentially resulting in impacts to properties, the likelihood is considered to be low. The potential for low likelihood but potentially high consequence major accident and/or disaster events remains, although the possibility is extremely remote. All reasonably practicable measures have been included in the design of the proposed road development to reduce the severity and potential consequences of low likelihood but potentially high consequence events. Refer to **Section 19.2** above for further details.

19.4.3 Summary

All of the potential impacts arising from the potential interactions were identified at a very early stage in the design process and in the EIAR preparation. They were therefore addressed in the design of the proposed road development and in the baseline and impact assessment studies. As a result, the potential impacts were either avoided altogether through design measures or they were addressed through specific mitigation measures. This early identification process helped to identify and minimise the potential for significant interactions of impacts arising. The assessment presented above of the interactions of the potential impacts did not identify the need for any additional mitigation measures.

19.5 Cumulative Impacts

19.5.1 Introduction

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects could cumulatively result in a likely significant environmental impact. Cumulative impacts arising from the interaction between the proposed road development and other projects for each of the environmental factors have been identified and addressed in detail in the respective chapters. The results of these cumulative assessments are also summarised below.

Cumulative impacts are defined as the combination of many minor impacts creating one larger, more significant impact (NRA, 2009 and EPA 2017). Cumulative impacts consider existing stresses on the natural environment as well as developments that are underway and in planning.

Following a review of the committed projects and the planning files for Galway City and County Council, the following projects and plans which are either in place, or proposed, were considered to have the potential for cumulative impacts to increase the significance of the impacts predicted for the proposed road development are listed below:

- The planning registers for Galway City and County Council
- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- M6 Motorway (operational)
- M6 (M17/M18) Motorway Service Area (pre-planning)
- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)

- N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction)
- Galway Harbour Port Extension (planning stage)
- Galway Transport Strategy (GTS), which includes the following:
  - Investigation of prospective sites to the east of the city for Park and Ride
  - Bearna Greenway
  - Galway to Oughterard (part of the Galway to Clifden) Greenway
  - Galway City to Oranmore (part of the Galway to Dublin) Cycleway
- Galway City Development Plan 2017–2023
- Galway County Development Plan 2015–2021
- Bearna Local Area Plan 2007–2017
- Gaeltacht Local Area Plan 2008–2018
- Údarás na Gaeltachta's Strategic Plan 2014–2017
- Ardaun Local Area Plan 2018–2024

19.5.2 Human Beings, Population and Human Health

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant effect on human beings, population and human health.

Of the list of projects and plans listed in **Section 19.5.1** the following have been assessed in relation to human beings, population and health as they have the potential for cumulative impacts in respect to this environmental topic:

- The planning registers for Galway City and County Council
- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- M6 Motorway (operational)
- M6 (M17/M18) Motorway Service Area (pre-planning)
- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)
- N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction)
- Galway Harbour Port Extension (planning stage)
- Galway Transport Strategy (GTS), which includes the following:
  - Investigation of prospective sites to the east of the city for Park and Ride
  - Bearna Greenway
  - Galway to Oughterard (part of the Galway to Clifden) Greenway
  - Galway City to Oranmore (part of the Galway to Dublin) Cycleway

- Galway City Development Plan 2017–2023
- Galway County Development Plan 2015–2021
- Bearna Local Area Plan 2007–2017
- Gaeltacht Local Area Plan 2008–2018
- Údarás na Gaeltachta's Strategic Plan 2014–2017
- Ardaun Local Area Plan 2018–2024

19.5.2.1 Socio-Economics

The proposed road development will improve accessibility both within and to/from Galway City and connectivity between Galway City and areas outside of the city including Connemara, the East and North West of Ireland. As a result, there are significant potential positive impacts which will benefit economic and regional development, including tourism. The proposed road development will have a positive cumulative socio-economic impact with the proposed roads projects listed above and with the Galway Harbour Project.

The proposed road development could also stimulate new physical commercial or tourism development. These developments would be subject to planning assessment given the objectives set out in the Galway City and Galway County Development Plans to consolidate development and to provide for balanced sustainable development. They will also be subject to Appropriate Assessment to avoid any adverse impacts on sensitive landscapes and natural habitats. These considerations apply also to the largely rural area surrounding the city, noting that the proposed road development will be used for a proportion of commuting journeys as well as for regional journeys. The transfer of some of these journeys to the proposed road development away from the existing N6 is a significant positive impact, but any cumulative impacts on settlement patterns will be monitored and addressed in future development and local area plans.

The proposed road development will facilitate the full implementation of the GTS and to provide for improved public transport and facilities for pedestrians and cyclists. For example, the reduced volume of traffic on the existing N6 will present an opportunity to greatly improve the continuity of cycle lanes, including at junctions, and to add more pedestrian crossings, while minimising impacts on traffic flow. Once implemented, all these measures will have a very significant impact on safety and the journey amenity of pedestrians and cyclists, and on general environmental quality if this contributes to a modal transfer from vehicles.

In summary the cumulative impacts of the projects and plans listed above in association with the proposed road development are positive.

19.5.2.2 Irish Language

Having considered the proposed road development in tandem with other relevant plans or projects identified above, it is considered that no significant negative cumulative impact upon the status of Irish as a community language will occur.

19.5.2.3 Human Health

It is not considered that there will be any negative cumulative effects on human health. The distances between the projects noted above and the proposed road development results in no cumulative noise or air quality impacts. There is potential that reduced journey times and fewer unforeseen delays could have a potential benefit on psychological health. Any projects which make roads safer and reduce the probability of road accidents and fatalities can only be seen in positive terms from a human health perspective. The cumulative health benefits of the proposed road development with the GTS are further assessed below.

Quantification of cumulative health benefits with the GTS

The cumulative health benefits of the proposed road development with the GTS were assessed by using the Western Regional Model to quantitatively measure some of the health, accessibility and social inclusion[15] impacts once the proposed road development and the GTS were fully implemented.

<u>Physical Activity Analysis</u>

The assessment indicates that the total number of people cycling, over a 24-hour period in Galway City, will increase by approximately 21% as a result of the implementation of the GTS and associated cycling infrastructure improvements. This increase in cyclists will result in a reduced risk of premature deaths for those who are new to cycling and currently exercise infrequently. By comparison, results from the assessment indicate that pedestrian trips (trips which use walking only to get from origin to destination) in Galway City are expected to decrease marginally (less than 1% reduction) across the full 24-hour period. The reduction in pedestrian activity in Galway City is mostly as a result of people transferring to cycling or using the improved public transport services implemented as part of the Galway Transport Strategy.

<u>Accessibility Analysis</u>

The changes in accessibility for key locations were determined on a zone by zone basis. This was undertaken using a visual representation of the changes in journey times between the ‘Do-Nothing’ and ‘Do-Something’ Scenarios for cycling, public transport and private car. The results of this assessment showed that in general, most zones experience a decrease in car journey times. There are however, a small number of zones, mostly in the city centre, which are expected to experience an increase in car journey times to access key sites. This is as a result of the public transport priority measures, such as private vehicle restrictions on Salmon Weir Bridge, which make accessing these areas by car more difficult. In general, most zones also experience a decrease in public transport journey times. There are however, a small number of zones which are expected to experience an increase in public transport journey times as they will not be served as directly by public

---

[15] It should be noted that this analysis represents an assessment of those elements of Health, Accessibility and Social inclusion which can be measured using model outputs from the WRM. As such, these outputs are not representative of all the benefits/disbenefits which result from the implementation of the GTS under these categories.

transport once the changes in bus routes proposed as part of the GTS are implemented.

Social Inclusion Analysis

Outputs from the traffic model have also been used to assess the impacts of the Galway Transport Strategy in terms of Social Inclusion. For this assessment, the outputs from the economic module (produced using the software Tuba) were used to visually identify which locations would benefit or suffer disbenefits as a result of the GTS. The benefits in this instance are measured in terms of journey time saving. These benefits/disbenefits were then compared against the deprivation index for the same locations to assess how the benefits of the proposed road development are distributed among affluent and less affluent areas. The results of this assessment showed that most zones will experience an improvement in journey times for all trips from those zones. Some city centre zones however, will experience increase in journey times by car following the implementation of the GTS measures. This is a result of public transport priority measures and public realm enhancements in the city centre which will increase travel time for some car trips into and around the city centre. With respect to public transport, a small number of zones are seen to experience marginal disbenefits as a result of bus route changes which give these zones less direct access to the public transport network. Comparison of these benefits with the deprivation index show that, in general, the benefits of the proposed road development are distributed evenly between disadvantaged and more affluent areas and no disbenefits were experienced in the most disadvantaged areas.

19.5.3 Material Assets – Non Agriculture

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant effect on material assets – non agriculture.

Of the list of projects and plans listed in **Section 19.5.1** the following have been assessed in relation to material assets non-agriculture:

- The planning registers for Galway City and County Council
- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- M6 Motorway (operational)
- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)
- N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction)
- Galway Harbour Port Extension (planning stage)
- Galway Transport Strategy (GTS), which includes the following:
    - Investigation of prospective sites to the east of the city for Park and Ride

- Bearna Greenway
- Galway to Oughterard (part of the Galway to Clifden) Greenway
- Galway City to Oranmore (part of the Galway to Dublin) Cycleway

Although the proposed road development overlaps with other proposed projects such as the GTS measures, none of the projects or plans have been identified that will result in a significant negative cumulative impact with the addition of the proposed road development upon material assets non-agriculture.

19.5.4 Material Assets – Agriculture

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant effect on agriculture.

Of the list of projects and plans listed in **Section 19.5.1** the following have been assessed in relation to material assets agriculture:

- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- M6 Motorway (operational)
- M6 (M17/M18) Motorway Service Area (pre-planning)
- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)
- N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction)
- Galway Transport Strategy (GTS), which includes the following:
  - Investigation of prospective sites to the east of the city for Park and Ride
  - Bearna Greenway
  - Galway to Oughterard (part of the Galway to Clifden) Greenway
  - Galway City to Oranmore (part of the Galway to Dublin) Cycleway

The cumulative impact on regional agriculture is appraised by assessing the impact on agriculture in County Galway due to the landtake for the proposed road development in combination with other recently constructed and planned roads (M6, N83/N18, N59 Maam Cross to Oughterard and Moycullen Bypass). These recently constructed and planned roads in combination with the proposed road development will require <1% of the agricultural area of County Galway (346,881 ha). When considered along with upward agricultural productivity trends[16] the cumulative impact on agriculture in County Galway is not significant.

There are cumulative impacts from the built M6 Motorway Scheme on four individual land parcels at the eastern end of the proposed road development. While there are significant cumulative impacts individually on these four[17] land parcels

[16] From 2010 – 2016 cattle numbers and sheep numbers increased 7% and 25% respectively – source CSO Table AAA08 and DAFM website.

[17] MO 751, MO 752, MO 754, and MO 758.

within the study area, the overall cumulative impacts on agriculture is not significant.

19.5.5 Air Quality and Climate

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant effect on air quality and climate.

Of the projects and plans listed in **Section 19.5.1** the following have been assessed in relation to air quality and climate:

- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- M6 Motorway (operational)
- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)
- N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction)
- Galway Transport Strategy (GTS), which includes the following:
  - Investigation of prospective sites to the east of the city for Park and Ride
  - Bearna Greenway
  - Galway to Oughterard (part of the Galway to Clifden) Greenway
  - Galway City to Oranmore (part of the Galway to Dublin) Cycleway

The traffic data used in the assessment for future years, considers development proposed for the Galway area as listed above and incorporates the cumulative impacts of these projects into the do-minimum traffic data used in this EIAR. No major construction works are envisaged to take place in such proximity to the proposed road development which would significantly impact on dust levels. The cumulative impacts are considered by incorporating background concentrations into predicted values and existing traffic volumes. Negative significant cumulative impacts on air quality will not arise.

The main objective of the GTS is to address the current and future transport requirements of Galway City and its environs. This includes the provision of new transport infrastructure. The proposed road development has been assessed with reference to the of the Galway Transport Strategy measures. Negative significant cumulative impacts on air quality will not arise.

19.5.6 Noise and Vibration

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant effect on noise and vibration.

Of the list of projects and plans listed in **Section 19.5.1** the following have been assessed for cumulative impacts in relation to noise and vibration:

- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- M6 Motorway (operational)
- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)
- N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction)
- Galway Transport Strategy (GTS), which includes the following:
    - Investigation of prospective sites to the east of the city for Park and Ride
    - Bearna Greenway
    - Galway to Oughterard (part of the Galway to Clifden) Greenway
    - Galway City to Oranmore (part of the Galway to Dublin) Cycleway

The traffic data used as part of the noise impact assessment is based on future modelled scenarios taking account of other committed plans and projects listed above which have the potential to generate traffic volumes within the study area. Further details on the traffic modelling forecasts are set out in **Chapter 6, Traffic Assessment and Route Cross Section**.

The cumulative traffic noise impacts have been assessed at each of the receptor locations considered as part of this assessment. During the Do-Nothing scenario, road traffic flows along the existing road network have been modelled and the cumulative traffic noise level calculated. For the modelled Do-Something scenarios, road traffic along the existing road network coupled with traffic along the proposed road development are combined to obtain a cumulative traffic noise level. The assessment takes account of any alignment alterations to the existing roads and junctions and the re-distribution of traffic along the existing road network as a result of the proposed road development.

In this regard the cumulative road traffic noise impacts are incorporated into the calculated operational noise levels set out in **Table 17.13** and **Table 17.15** of **Chapter 17, Noise and Vibration**.

In relation to cumulative construction impacts, other committed significant construction projects have been reviewed in the vicinity of Galway City and County including the N59 Maam Cross to Oughterard Road Project (consented and pre-construction), N59 Moycullen Bypass (consented and pre-construction) and M6(M17/M18) Motorway Service Area (pre-planning). All of these projects are set back at considerably distances from the proposed road development such that if under construction at the same time, no cumulative noise and vibration impacts would occur.

Whilst there is the potential to be other small local construction activities across the study area during the construction phase, for the purposes of this assessment it has been assumed that works associated with the proposed road development will be the dominant noise and vibration source at any one location.

19.5.7 Landscape and Visual

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant landscape and/or visual effect. The projects and plans listed in **Section 19.5.1** were assessed in relation to landscape and visual.

The construction and operational stages of the proposed road development give rise to significant, very significant and profound landscape and visual impacts. These impacts are generally focused within the immediate corridor of the proposed road development on the urban/rural edge of the city. To the west and north of the city much of the lands along the corridor are identified for agricultural and/or amenity uses. Further sports and amenity developments are likely within the grounds of NUIG Sporting Campus on the west bank of the River Corrib. While there are some small areas of residential zoning at Ballymoneen, Rahoon, Letteragh, Ballindooley and Castlegar, development in these areas is unlikely to give rise to significant landscape and visual impacts or cumulative impacts. An area of enterprise, industrial and related zoning is indicated to the north and east of Galway Racecourse, but much of these lands are already developed within Parkmore Business Park.

The eastern end of the proposed road development falls within the area covered by the Draft Arduan Local Area Plan (LAP) 2017. This Draft LAP proposes major development in the area, including new residential and commercial developments on c.81 hectares of an overall LAP area of c.164 hectares on the east side of the city. The existing M6/N6 corridor runs through the centre of the Draft LAP area and the proposed road development ties-in to the existing road infrastructure within the Draft LAP area. While the Draft LAP envisages significant changes to the landscape and visual setting of the area, it is likely that the measures proposed will be delivered on a phased basis over a long period of time. Nevertheless, depending on timing of delivery, scope exists for some limited or nonsignificant cumulative landscape and visual impacts to arise.

The Galway Transport Strategy (GTS) also envisages further transport-related developments, including public transport and cycleway and greenway measures. However, these measures are unlikely to further adversely impact the landscape or visual setting along the proposed road development.

The Galway Harbour Port Extension project is at planning stage. However, if permitted, it is not expected that any significant cumulative landscape or visual effects will arise because of the separation distance between the proposed road development and the port location.

Other projects, such as the M17 Galway to Tuam Road Project (operational); the N18 Oranmore to Gort Road Project (operational); the N17 Tuam Bypass (operational); the M6 Motorway (operational); M6(M17/M18) Motorway Service Area (pre-planning); the N59 Maam Cross to Oughterard Road Project (consented and pre-construction); and the N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction), are considered too distant from the proposed road development to give rise to cumulative landscape and/or visual effects.

In summary it is considered that there is limited potential for any significant cumulative impacts with other planned or potential developments and that these will not further increase the adverse or negative impacts associated with the proposed road development.

19.5.8 Archaeological, Architectural and Cultural Heritage

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant effect on archaeological, architectural and cultural heritage. Of the list of projects and plans listed in **Section 19.5.1** the cumulative impacts of the proposed road development on archaeology, architecture and cultural heritage with the following projects and plans have been assessed:

- N59 Maam Cross to Oughterard Road Project
- M17 Galway to Tuam Road Project
- N18 Oranmore to Gort Road Project
- N17 Tuam Bypass
- M6 Motorway
- Proposed Galway Harbour Port Extension
- Galway Transport Strategy (GTS), which includes the following:
    - Investigate prospective sites to the east of the city for Park and Ride
    - Bearna Greenway
    - Galway to Oughterard (part of the Galway to Clifden) Greenway
    - Galway City to Oranmore (part of the Galway to Dublin) Cycleway
- Galway City Development Plan 2017–2023
- Galway County Development Plan 2015–2021

No proposed developments have been identified that will result in a significant negative cumulative impact with the addition of the proposed road development upon the archaeological, architectural and cultural heritage resource.

The proposed Galway to Oughterard (part of the Galway to Clifden) Greenway will see the reopening of the railway line and potentially the repair of railway heritage features. The proposed road development will impact on a portion of the original railway line route where it passes through Dangan Lower. Sections of the railway line have been removed over the years due to differing activities, meaning that the proposed road development will result in a slight negative cumulative impact on the route of the original railway line. The proposed Galway to Oughterard Greenway scheme will have a positive impact on the cultural heritage of the area, which will help to offset the potential negative cumulative impact associated with the proposed road development. No negative residual impacts have been identified in association with the route of the former railway.

19.5.9 Soils and Geology

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant effect on soils and geology. Of the list of projects and plans listed in **Section 19.5.1** the following have been assessed for cumulative impacts with respect to soils and geology:

- The N59 Oughterard to Maam Cross
- M17/N18 Gort to Tuam PPP Scheme
- Galway Harbour Port Extension
- Galway Transport Strategy (GTS), which includes the following:
    - Investigate prospective sites to the east of the city for Park and Ride
    - Bearna Greenway
    - Tuam Road Bus Corridor Scheme
    - Expansion of Public Bike Hire Scheme
- Galway City Development Plan 2017–2023
- Galway County Development Plan 2015–2021

Cumulative soils and geology impacts can occur when other projects in the locality have similar soils and geology potential impacts as the proposed road development. Cumulative impacts are assessed based on the residual impact of these impacts on the proposed projects.

The following feature/construction activity impacts are identified in some of the projects and plans, listed above, and are also present in the proposed road development:

- Peat Removal/Disposal
- Impact to Geological Heritage Sites
- Contaminated Ground
- Loss of agricultural land and solid geology
- Haulage of material

As part of the environmental evaluation of the proposed road development the residual impact from peat removal/disposal, geological heritage sites and contaminated ground is imperceptible. Due to the mitigation measures considered in the other projects, the residual impact of those projects is also considered imperceptible. Therefore, the cumulative impact of these impacts is imperceptible.

The cumulative impact for:

- peat removal/disposal is considered to be imperceptible as peat is intended to remain within the proposed development boundary for each respective project

- geological heritage sites is considered to be imperceptible as none of the projects indicate that geological heritage sites or county geological sites will be impacted. The Galway Transport Strategy specifically outlines that it will seek to protect such sites from any inappropriate measures
- contaminated ground is considered to be imperceptible as the Galway City Development Plan (2017-23) waste management policy contains policy to ensure that proposals on contaminated lands include appropriate remediation measures

Loss of agricultural land and solid geology and haulage of material, whether imported or sourced from site, are activities that are also considered on other projects. Mitigation measures for other projects include the reduction and minimisation of removal or disposal of material off-site and the reuse of such material whether in construction fill or in designated material deposition areas. Consideration has been given to the extent of material which will be imported, exported or disposed and their combined impact. The cumulative impact is considered to remain unchanged as the combination of the impact will not increase the magnitude of the impact from small adverse.

The significance of the impact of the proposed road development operational activities is imperceptible and is considered not to change in combination with the other projects.

Therefore, there are no other plans or projects that are likely to result in a significant effect on soils and geology cumulatively with the proposed road development.

19.5.10 Hydrogeology

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant effect on hydrogeology.

Of the list of projects and plans listed in **Section 19.5.1** the following have been assessed for cumulative impacts with respect to hydrogeology:

- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)
- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- Galway Harbour Port Extension (planning stage)
- Galway Transport Strategy (GTS)

The hydrogeological baseline has identified that the groundwater bodies in the study area have a number of existing stresses in the form of discharges from wastewater treatment systems, septic tanks, road runoff, quarrying and agriculture. These potential pollutant sources have the potential to impact the groundwater environment in the form of reducing water quality by increased contaminants. On the basis of the design and mitigation measures employed for the proposed road development to accommodate and maintain the existing groundwater body (GWB) sub-catchments there will be no alteration of groundwater pathways that could modify the impacts from existing pollutant sources.

The zone of influence from the N59 Maam Cross to Oughterard Road Project and N83/N18 projects occurs within separate groundwater sub catchments to those identified for the proposed road development and as such any impacts from these projects will not impact on the groundwater systems that the proposed road development straddles.

The proposed Galway Harbour Port Extension is located within the same GWB sub-catchment as the proposed road development but is located significantly downgradient of the proposed road development in transition coastal waters.

The Galway Transport Strategy includes some realignment of local roads but these do not incorporate cuttings or structures that could impact on groundwater.

The cumulative impact of the proposed road development with existing stresses on the hydrogeological environment and those in development or in planning has been considered. On the basis of the design and mitigation measures employed for the proposed road development there will be no alteration of groundwater pathways and hence no enhanced impact from existing pollutant sources within groundwater bodies. Furthermore, those new developments being constructed or proposed are located in different GWB sub catchments or located significantly downgradient so as not to cumulate impacts.

On this basis the cumulative impacts of the above projects with the proposed road development is imperceptible.

19.5.11 Hydrology

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant effect on hydrology. Of the list of projects and plans listed in **Section 19.5.1** the following have been assessed for cumulative impacts with respect to hydrology:

- M17 Galway to Tuam Road Project (operational)
- N18 Oranmore to Gort Road Project (operational)
- N17 Tuam Bypass (operational)
- N59 Maam Cross to Oughterard Road Project (consented and pre-construction)
- N59 Maigh Cuilinn (Moycullen) Bypass Road Project (consented and pre-construction)
- Proposed Galway Harbour Port Extension (planning stage)
- Galway Transport Strategy (GTS)
- Galway City Development Plan 2017–2023
- Galway County Development Plan 2015–2021

The hydrological baseline has identified that the surface water features in the study area have a number of existing stresses in the form of discharges from surface water drainage systems, road runoff and agricultural activities and loss of natural flood plains. These sources have the potential to impact the existing hydrological environment in the form of reducing water quality by increased contaminants or by increasing flood risk. On the basis that the design and mitigation measures employed for the proposed road development will maintain or improve water quality in existing catchments, there are no significant hydrological residual impacts associated with the proposed road development.

The Galway County Development Plan 2015-2021 and Galway City Development Plan 2017-2023 set out a series of objectives for appropriate management of surface water and water quality of the existing environment. This will ensure that future planning applications are developed using design criteria to ensure that no there is no hydrological impact on receiving watercourses or surface water sewers associated with planned developments. This will typically be achieved in terms of flood risk and stream morphology by utilising sustainable drainage systems (SuDS) and restricting surface water runoff discharge rates to meet that of greenfield runoff rates and volumes. Therefore, the residual impact associated with future proposed or planned developments on the hydrological environment is imperceptible.

The M17/M18 Tuam to Gort Motorway Project has recently completed construction. The portion of the M17 and Tuam Bypass (circa 26km) that lies north of the existing R339 Galway to Caltra Road, lies within the catchment of the River Corrib. The portion of the M17/M18 to the south of the R339 lies within the catchment of Galway Bay for the Oranmore River, Clarin River, Kilcolgan River, Gort River and Lough Coole turlough system. This M17/M18 scheme has been designed with a modern road drainage system and construction methods that reduce the potential impact on the receiving environment. Where residual local impacts arise at various road outfalls, culvert crossings and displacement of flood storage, cumulative impacts do not arise downstream in the River Corrib or to Galway Bay given the very large dilution available and the travel distances involved.

There will be no perceptible hydrological cumulative impact between the M17/M18 Tuam to Gort Motorway Scheme and the proposed road development.

The N59 Maam Cross to Oughterard Road Project and N59 Maigh Cuilinn (Moycullen) Bypass Road Project also lie within the catchment of the River Corrib upstream of the proposed road development. Both N59 road schemes have been designed with modern road drainage systems and construction methods that reduce the potential impact on the receiving environment. Where local impacts arise at various road outfalls and culvert crossings and displacement of flood storage and changes to river and stream morphology, these impacts do not translate downstream in the River Corrib (given the very large dilution available and the travel distances involved) as perceptible impacts that would combine with residual impacts from the proposed road development. There will be no perceptible hydrological cumulative impact between the N59 Maam Cross to Oughterard to Road Project and the N59 Maigh Cuilinn (Moycullen) Bypass Road Project with the proposed road development.

The proposed Galway Harbour Port Extension is located in the Galway City Coastal catchment and at the mouth of the River Corrib Estuary downstream of the proposed road development. Hydrological residual impacts have been identified in the Galway Harbour Company, Galway Harbour Extension Environmental Impact Statement and include potential changes in salinity levels, current velocities and current directions, pollution risks during construction, maintenance dredging impacts and changes in wave climate.

The proposed road development will have no noticeable effect on the flow regime, salinity, sedimentation process or water quality downstream in the River Corrib Estuary and Inner Galway Bay, both during construction and operation stages. Therefore, no cumulative hydrological impacts will occur between the proposed Galway Harbour Port Extension and the proposed road development, even if the construction phases for both projects were to coincide.

There are a number of elements of the Galway Transport Strategy (GTS) located within the same hydrological catchments as the proposed road development. The relevant elements of the GTS that could have an impact on hydrology include:

- The upgrading of pedestrian network
- The upgrading of cycle network which includes the Bearna Greenway, the Galway to Dublin Cycleway (Galway City to Oranmore)[18], the Galway to Oughterard Greenway[19] and non-greenway elements
- Expansion of Public Bike Hire Scheme (currently under construction)
- The upgrading of public transport network including increased frequency of buses and a new cross city access link (including the N17 Tuam Bus Corridor Scheme)
- The upgrading of road network which includes modifications to the existing road infrastructure and the proposed road development

The GTS is at the plan stage so each individual measure will be subject to further detail design. The detailed design shall be in compliance with the surface water management and water quality objectives set out in the various development plans. Therefore, there will be no negative cumulative impacts associated with this development.

19.5.12 Biodiversity

This section of the chapter presents the assessment carried out to examine whether the proposed road development along with any other projects or plans could cumulatively result in a likely significant effect on biodiversity.

[18] The GTS includes that portion of the Galway to Dublin Cycleway between Galway City and Oranmore.

[19] The GTS includes that portion of the Galway to Oughterard Greenway between Galway City and Moycullen.

All of the projects and plans listed in **Section 19.5.1** have been assessed for cumulative impacts with respect to biodiversity. In addition, the following projects were also considered in the assessment:

- Sáilín to Silverstrand Coastal Protection Scheme
- Salthill Coastal Protection Works (Blackrock to Galway Golf Club)

The potential for other plans or projects to act cumulatively with the proposed road development to adversely affect the integrity of any European sites, is considered in Section 12 of the NIS (termed "in combination effects" in the context of the NIS assessment). The four European sites within the ZoI of the proposed road development are Lough Corrib cSAC, Galway Bay Complex cSAC, Lough Corrib SPA and Inner Galway Bay SPA. There is no potential for any other plans or projects to act in combination with the proposed road development to adversely affect the integrity of any other European sites, as they are beyond the ZoI of the proposed road development.

The assessment identified those plans and projects which have the potential to impact on Lough Corrib cSAC, Galway Bay Complex cSAC, Lough Corrib SPA and Inner Galway Bay SPA and assessed whether they had the potential to adversely affect the integrity of these European sites. Any plan or proposed project that could potentially affect these European sites in combination with the proposed road development must adhere to the overarching policies and objectives of the relevant land use plan(s), as dependent on the location of the specific plan or proposed project. These are the *Galway County Development Plan 2015-2021*, the *Galway City Council Development Plan 2017-2023*, the *Clare County Development Plan 2017-2022* and the *Mayo County Development Plan 2014-2020*. The protective policies and objectives in these land use plans will ensure the protection of European sites across the identified potential impact pathways.

As the proposed road development will not affect the integrity of Lough Corrib cSAC, Galway Bay Complex cSAC, Lough Corrib SPA or Inner Galway Bay SPA, and given the protection afforded to European sites under the overarching land use plans, it was concluded that there is no potential for adverse effects on the integrity of any European sites to arise as a consequence of the proposed road development acting in combination (or cumulatively) with any other plans or projects.

The potential for cumulative impacts to arise are limited to those residual impacts associated with the proposed road development and those effects the proposed road development will have on the receiving environment that are measurable in some way, but themselves will not result in a likely significant residual effect on biodiversity.

The residual impacts associated with the proposed road development relate to the following and are discussed in the sections below:

- Habitat loss, including both the permanent loss of Annex I habitats and habitats valued as being of local importance
- The potential loss of a Peregrine falcon nest site due to long-term disturbance/displacement impacts

- Impacts on bats as a result of the construction and operation of the proposed road development

The other impacts associated with the proposed road development that are measurable in some way, but themselves will not result in a likely significant effect on biodiversity are impacts on the existing hydrological and hydrogeological regimes, impacts on air quality and impacts to species as a result of disturbance or displacement. The land use zonings and environmental protection objectives that relate to this area are contained in the *Bearna Local Area Plan 2007-2017, Galway County Development Plan 2015-2021* and the *Galway City Council Development Plan 2017-2023*. There are also environmental protective policies and objectives in both the *Galway City Council Development Plan 2017*-2023 and the overarching *Galway County Development Plan 2015-2021*, and in River Basin Management Plan for Ireland (2018-2021) (draft for public consultation) for the area. The *Ardaun Local Area Plan 2018–2024* is subject to the protective policies and objectives in the *Galway City Council Development Plan 2017*-2023. The *Gaeltacht Local Area Plan 2008–2018* and the *Údarás na Gaeltachta's Strategic Plan 2014–2017*, in so far as they could interact cumulatively with the proposed road development given their spatial coverage, are subject to the protective policies and objectives in the *Galway County Development Plan 2015-2021* and the *Galway City Council Development Plan 2017*-2023.

Given the zonings and objectives that are in place in these plans, it is considered that there are no other plans or projects that are likely to result in a significant effect on biodiversity, cumulatively with the proposed road development, as a consequence of impacts on surface water and groundwater air quality and disturbance or displacement impacts.

19.5.12.1 Impacts from habitat loss

As outlined in **Section 8.4.2** of **Chapter 8, Biodiversity** habitat loss to development and land use change has been an ongoing impact locally which may have already had effects on local biodiversity. Those projects listed above in **Section 19.5.1** have, or are likely to, result in habitat impacts (including those of a high biodiversity value such as Annex I habitat types) which may also have knock-on effects on fauna species. Therefore, land use change and habitat losses are likely to continue to some degree and the loss and fragmentation of habitat associated with the proposed road development will contribute to this trend locally.

Habitat losses, regardless of their own habitat value, also have the potential to have an effect on the local fauna populations that they support. The most significant impact in that regard are the likely effects of habitat loss on the local bat populations; particularly the Menlo Castle Lesser horseshoe bat population (impacts on bats are discussed separately below).

The losses of areas of Annex I habitat associated with the proposed road development are considered to be at the highest level of geographic significance for the habitats involved. In addition, the proposed road development will be contributing to an existing trend of Annex I habitat loss locally. While the cumulative effect of habitat losses, would increase the magnitude of the impact, it does not increase the geographic scale of the impact significance associated with the proposed road development.

In relation to areas of locally important habitats that will be lost, given the habitat types involved and that at any greater geographic scale they are likely to remain in a favourable conservation condition, any cumulative losses of these habitat types are not likely to increase the impact significance.

The protective polices in the *Bearna Local Area Plan 2007-2017*, the *Galway City Council Development Plan 2017-2023* and the *Galway County Development Plan 2015-2021* to protect biodiversity will moderate any future impacts on biodiversity, including those related to Annex I habitat types. Where the losses can be compensated[20] for (see **Section 8.8** of **Chapter 8, Biodiversity**), this offsets the contribution of the proposed road development to existing losses of the habitat type in question whilst ensuring that there is no potential for other developments to result in a significant cumulative impact.

19.5.12.2 Impacts on Peregrine falcon

Peregrine falcon is an Annex I species but is not listed as a Special Conservation Interest (SCI) species for its breeding population in any SPAs within the ZoI of the proposed road development (the closest SPA with Peregrine falcon as an SCI is in Sligo). It is also on the Green BoCCI (breeding)[21] List. Birds on the Green list are considered to be those of least conservation concern in Ireland. The local Peregrine falcon population are valued as being of county importance as the local area supports more than 1% of the known nesting sites across counties Galway and Clare.

Due to the potential for long-term disturbance and displacement of the Lackagh Quarry Peregrine falcon pair from the existing nest site, the proposed road development is likely to result in a significant negative residual effect on Peregrine falcon, at the county geographic scale.

The two other Peregrine falcon nest sites that are present locally are likely to continue to support breeding Peregrine falcon. One site is an inactive quarry which is zoned for agricultural use and is therefore, not likely to see any increased disturbance from development; the second nest site is a regularly occupied site in an active quarry and the baseline levels of disturbance, to which the resident Peregrine pair are habituated, are likely to remain. Neither of these sites are likely to be affected by any of the projects listed above, given their locations relative to where those strategies/projects will be implemented. Existing pressures at the county level on suitable nest site availability are expected to continue and may act cumulatively at the county geographic scale, but there is not sufficient data available to quantify this. However, any additional pressures on the Peregrine falcon population will not increase the overall significance of the impact of the

[20] These are not compensatory measures in the context of the requirements of Article 6(4) of the Habitats Directive as they are not compensating for an impact that would adversely affect the integrity of any European site. As concluded in the NIS, the proposed road development will not result in such an impact on any European site

[21] Birds of Conservation Concern in Ireland (BoCCI) after Colhoun & Cummins, 2013

proposed road development to a national level impact given that the species is currently considered to be of a low conservation concern for its national population.

Therefore, there are no other projects that are likely to cumulatively act along with the proposed road development to increase the predicted impact significance of the proposed road development on Peregrine falcon from the likely significant negative residual effect, at the county geographic scale.

19.5.12.3 Impacts on bats

The predicted residual impacts on bats include loss of roosts, loss of foraging habitat and the barrier/severance effect posed by roads.

Some proportion of existing roost sites in the vicinity of the proposed road development may deteriorate over time and become unsuitable for bats to use (e.g. derelict structures and old trees). Therefore, the roost sites that will be affected by the proposed road development could potentially contribute to natural declines in other roost sites locally.

Loss of foraging habitat and barriers to bat movements may result from development of zoned land within the northern fringes of Galway City. Lands used by bats which are also zoned for development include light industrial zoning (C2.1) near the N84 Headford Road and Ballindooley, which may affect the proposed artificial roost via increased light spill. The recreation and amenity zoning at NUIG may also interact with the flight paths of bats moving between the Aughnacurra roosts and Menlo Castle and the use of those lands by foraging bats (e.g. where additional lighting may be proposed in the future). However, all of these impacts would be controlled by the assessment of individual planning applications which would consider the effects on protected species such as bats as part of their appraisal by the competent authority, having regard to the protective environmental policies outlines in the *Bearna Local Area Plan 2007-2017*, the *Galway City Council Development Plan 2017-2023* and the *Galway County Development Plan 2015-2021* and the Ardaun Local Area Plan 2018-2024 [22] to protect biodiversity. Therefore, there are no additional cumulative impacts predicted regarding loss of foraging habitat or from barriers to bat movement.

19.5.13 Overall Cumulative Impact Assessment

The individual cumulative assessments for each environmental factor of each of the projects and plans have been considered above. No additional mitigation measures are required for any cumulative effects of the proposed road development with other projects and plans. Each of the projects and plans listed in **Section 19.5.1** as a whole have also been considered with the proposed road development and the assessment is presented below in **Table 19.3**. No additional cumulative impacts other than those already identified in the individual assessments will arise.

[22] Although a draft plan at the time of writing, it is included as it is likely to be adopted in 2018.

Table 19.3: Overall Cumulative Impact Assessment

Plan/Project	Potential Cumulative Impacts on Environmental Factors	Cumulative Impact (if any)
M17 Galway to Tuam Road Project (operational)	**Socio Economic:** Overall there will a positive cumulative impact in terms of connectivity between Connemara, Galway City and the rest of Ireland.	None
	Irish Language: Given the distance between the proposed road development and this project there will be no significant cumulative impact	
	Human Health: Given the distance between the proposed road development and this project there will be no significant cumulative impacts	
	Material Assets Non-Agriculture: Given the distance between the proposed road development and this project there will be no significant cumulative impacts	
	Material Assets Agriculture: This project in combination with the proposed road development will require <1% of the agricultural area of County Galway (346,881 ha). When considered along with upward agricultural productivity trends[23] the cumulative impact on agriculture in County Galway is not significant.	
	Air Quality and Climate: The traffic data used in the assessment for future years, considered this project and incorporates the cumulative impacts into the do-minimum traffic data. This project is complete and therefore there will be no additional cumulative increase in air quality pollutant levels. The cumulative impacts are considered by adding background concentrations to predicted concentrations. There will be no significant cumulative impacts on air quality.	
	Noise and Vibration: The traffic data used as part of the noise impact assessment is based on future modelled scenarios taking account of this project and the cumulative traffic noise impacts have been assessed at each of the receptor locations considered as part of this assessment. In this regard the cumulative road traffic noise impacts are incorporated into the calculated operational noise levels set out in **Chapter 17, Noise and Vibration**.	
	Landscape and Visual: Given the distance between the proposed road development and this project there will be no significant negative cumulative impacts	

[23] From 2010 – 2016 cattle numbers and sheep numbers increased 7% and 25% respectively – source CSO Table AAA08 and DAFM website.

Plan/Project	Potential Cumulative Impacts on Environmental Factors	Cumulative Impact (if any)
	Archaeology, Architectural and Cultural Heritage: Given the distance between the proposed road development and this project there will be no significant cumulative impacts	
	Soils and Geology: The residual impacts on soils and geology are imperceptible and therefore there will be no significant cumulative impacts	
	Hydrogeology: The zone of influence for this project is within a different groundwater body sub catchment to the proposed road development and therefore there will be no significant cumulative impacts	
	Hydrology: The residual impacts on hydrology are imperceptible and therefore there will be no significant cumulative impacts	
	Biodiversity: As the drainage for this project will ultimately discharge to the River Corrib and Galway Bay, there is the potential for cumulative effects on water quality in the River Corrib and in Galway Bay. Considering the mitigation measures considered and approved by An Bord Pleanála in granting consent for the project, the environmental protection policies included within the *Galway County Development Plan 2015-2021* and the residual impacts associated with the proposed road development, no significant negative cumulative impacts are likely.	
N18 Oranmore to Gort Road Project (operational)	**Socio Economic:** Overall there will be a positive cumulative impact in terms of connectivity between West County Galway, Galway City and the rest of Ireland.	None
	Irish Language: Given the distance between the proposed road development and this project there will be no significant cumulative impact	
	Human Health: Given the distance between the proposed road development and this project there will be no significant cumulative impacts	
	Material Assets Non-Agriculture: Given the distance between the proposed road development and this project there will be no significant cumulative impacts	
	Material Assets Agriculture: This project in combination with the proposed road development will require <1% of the agricultural area of County Galway (346,881 ha). When considered along with upward agricultural productivity trends from 2010 to 2016 the cumulative impact on agriculture in County Galway is not significant.	
	Air Quality and Climate: The traffic data used in the assessment for future years, considered this project and incorporates the cumulative impacts into the do-minimum traffic data. This project is complete and therefore there will be no additional cumulative	

Plan/Project	Potential Cumulative Impacts on Environmental Factors	Cumulative Impact (if any)
	increase in air quality pollutant levels. The cumulative impacts are considered by adding background concentrations to predicted concentrations. There will be no significant cumulative impacts on air quality.	
	Noise and Vibration: The traffic data used as part of the noise impact assessment is based on future modelled scenarios taking account of this project and the cumulative traffic noise impacts have been assessed at each of the receptor locations considered as part of this assessment. In this regard the cumulative road traffic noise impacts are incorporated into the calculated operational noise levels set out in **Chapter 17, Noise and Vibration**.	
	Landscape and Visual: Given the distance between the proposed road development and this project there will be no significant negative cumulative impacts	
	Archaeology, Architectural and Cultural Heritage: Given the distance between the proposed road development and this project there will be no significant negative cumulative impacts	
	Soils and Geology: The residual impacts on soils and geology are imperceptible and therefore there will be no negative significant cumulative impacts	
	Hydrogeology: The zone of influence for this project is within a different groundwater body sub catchment to the proposed road development and therefore there will be no significant negative cumulative impacts	
	Hydrology: The residual impacts on hydrology are imperceptible and therefore there will be no negative significant cumulative impacts	
	Biodiversity: As the drainage for this project will ultimately discharge to the River Corrib and Galway Bay, there is the potential for cumulative effects on water quality in the River Corrib and in Galway Bay. Considering the mitigation measures considered and approved by An Bord Pleanála in granting consent for the project, the environmental protection policies included within the *Galway County Development Plan 2015-2021* and the residual impacts associated with the proposed road development, no significant negative cumulative impacts are likely.	
N17 Tuam Bypass (operational)	**Socio Economic:** Overall there will be a positive cumulative impact in terms of connectivity between West County Galway, Galway City and the rest of Ireland.	None
	Irish Language: Given the distance between the proposed road development and this project there will be no significant cumulative impact	

Plan/Project	Potential Cumulative Impacts on Environmental Factors	Cumulative Impact (if any)
	Human Health: Given the distance between the proposed road development and this project there will be no significant cumulative impacts	
	Material Assets Non-Agriculture: Given the distance between the proposed road development and this project there will be no significant cumulative impacts	
	Material Assets Agriculture: This project in combination with the proposed road development will require <1% of the agricultural area of County Galway (346,881 ha). When considered along with upward agricultural productivity trends the cumulative impact on agriculture in County Galway is not significant.

Plan/Project	Potential Cumulative Impacts on Environmental Factors	Cumulative Impact (if any)
	Hydrogeology: The zone of influence for this project is within a different groundwater body to the proposed road development and therefore there will be no significant cumulative impacts	
	Hydrology: The residual impacts on hydrology are imperceptible and therefore there will be no significant cumulative impacts	
	Biodiversity: Any impacts on habitats or bats associated with this project will not affect the significance of the residual impacts associated with the proposed road development. As a project which lies within the River Corrib catchment, there is the potential for cumulative effects on water quality in the River Corrib and Galway Bay. Considering the mitigation measures considered and approved by An Bord Pleanála in granting consent for the project, the environmental protection policies included within the *Galway County Development Plan 2015-2021* and the residual impacts associated with the proposed road development, no significant negative cumulative impacts are likely.	
Galway Harbour Port Extension (planning stage)	**Socio Economic:** Overall there will be a positive cumulative impact on the economy of Galway City	None
	Irish Language: Given the distance between the proposed road development and this project there will be no significant cumulative impact	
	Human Health: Given the distance between the proposed road development and this project there will be no significant cumulative impacts	
	Material Assets Non-Agriculture: There is no overlap between the proposed road development and this project and therefore there will be no significant cumulative impacts	
	Material Assets Agriculture: Not applicable	
	Air Quality and Climate: Given the distance between the proposed road development and this project there will be no significant cumulative impacts during the construction phase.	
	Noise and Vibration: Galway Harbour Port Extension is set back a considerably distance from the proposed road development such that if under construction at the same time, no cumulative noise and vibration impacts would occur.	
	Landscape and Visual: Given the separation between the proposed road development and the port it is not expected that there will be any significant cumulative impacts	

Plan/Project	**Potential Cumulative Impacts on Environmental Factors**	**Cumulative Impact (if any)**
	Archaeology, Architectural and Cultural Heritage: Given the distance between the proposed road development and this project there will be no significant cumulative impacts	
	Soils and Geology: The residual impacts on soils and geology are imperceptible and therefore there will be no negative significant cumulative impacts	
	Hydrogeology: The zone of influence for this project is within transitional and coastal waters that are significantly downgradient to the proposed road development. The residual impacts on hydrogeology are imperceptible and there will be no negative significant cumulative impacts.	
	Hydrology: The residual impacts on hydrology are imperceptible and therefore there will be no negative significant cumulative impacts on downstream estuarine and coastal waters.	
	Biodiversity: There will be no significant negative cumulative impacts as the proposed road development will not have any residual impacts on biodiversity along the coastline or in Galway Bay.	
Sáilín to Silverstrand Coastal Protection Scheme	This project only has the potential for a cumulative impact with Biodiversity. **Biodiversity:** There will be no significant negative cumulative impacts as the proposed road development will not have any residual impacts on biodiversity along the coastline or in Galway Bay.	
Salthill Coastal Protection Works (Blackrock to Galway Golf Club)	This project only has the potential for a cumulative impact with Biodiversity. **Biodiversity:** There will be no significant negative cumulative impacts as the proposed road development will not have any residual impacts on biodiversity along the coastline or in Galway Bay.	
Galway Transport Strategy (GTS),	**Socio Economic:** The proposed road development will facilitate the full implementation of the GTS and to provide for improved public transport and facilities for pedestrians and cyclists. Therefore, there will be an overall positive cumulative impact.	None
	Irish Language: The proposed road development will facilitate the full implementation of the GTS and improve connectivity for people in the Gaeltacht areas. Therefore, there will be an overall positive cumulative impact.	

<table>
<tr><th>Plan/Project</th><th>Potential Cumulative Impacts on Environmental Factors</th><th>Cumulative Impact (if any)</th></tr>
<tr><td rowspan="8">which includes the following:
Investigation of prospective sites to the east of the city for Park and Ride
Bearna Greenway
(part of the Galway to Spiddal Greenway)
Galway to Oughterard (part of the Galway to Clifden) Greenway
Galway City to Oranmore (part of the Galway to Dublin) Cycleway</td><td>Human Health: The proposed road development will facilitate the full implementation of the GTS and to provide for improved public transport and facilities for pedestrians and cyclists and the associated health benefits in terms of physical activity, improved accessibility and social inclusion. Therefore, there will be an overall positive cumulative impact.</td><td rowspan="8"></td></tr>
<tr><td>Material Assets Non-Agriculture: Whilst the GTS may result in significant impacts on material assets non agriculture, none of these material assets are also impacted by the proposed road development and therefore there will be no significant cumulative impacts</td></tr>
<tr><td>Material Assets Agriculture: Any potential impacts on agricultural lands as a result of the GTS will not be significant. Therefore, there will be no cumulative impacts.</td></tr>
<tr><td>Air Quality and Climate: The main objective of the GTS is to address the current and future transport requirements of Galway City and its environs. This includes the provision of new transport infrastructure. The proposed road development has been assessed with reference to the of the Galway Transport Strategy measures. There will be no significant cumulative impacts on air quality.</td></tr>
<tr><td>Noise and Vibration: The main objective of the GTS is to address the current and future transport requirements of Galway City and its environs. This includes the provision of new transport infrastructure which has not yet been fully developed. The proposed road development has been broadly assessed with reference to the Galway Transport Strategy and review of traffic re-distribution as a result of the proposed road development has been considered along existing roads. The GTS measures are unlikely to further adversely impact the noise and vibration impacts along the proposed road development.</td></tr>
<tr><td>Landscape and Visual: The GTS measures are unlikely to further adversely impact the landscape or visual setting along the proposed road development. There will be no significant negative cumulative impacts</td></tr>
<tr><td>Archaeology, Architectural and Cultural Heritage: The proposed Galway to Oughterard (part of the Galway to Clifden) Greenway will see the reopening of the railway line and potentially the repair of railway heritage features. The proposed road development will impact on a portion of the original railway line route where it passes through Dangan Lower. Sections of the railway line have been removed over the years due to differing activities, meaning that the proposed road development will result in a slight negative cumulative impact on the route of the original railway line. The proposed Galway to Oughterard Greenway scheme will have a positive impact on the cultural heritage of the area, which will help to offset the potential negative cumulative impact associated with the proposed road development. No negative residual impacts have been identified in association with the route of the former railway.</td></tr>
<tr><td>Soils and Geology: It is not envisaged that the GTS measures will have a significant impact on soils and geology. Therefore, there will be no negative significant cumulative impacts</td></tr>
</table>

Plan/Project	Potential Cumulative Impacts on Environmental Factors	Cumulative Impact (if any)
	Hydrogeology: The GTS includes some realignment of local roads but these do not incorporate cuttings or structures that could impact on groundwater. Therefore, there will be no negative significant cumulative impacts	
	Hydrology: The GTS is at the plan stage so each individual measure will be subject to further detail design. The detailed design shall be in compliance with the surface water management and water quality objectives set out in the various development plans. Therefore, there will be no cumulative impacts associated with this development.	
	Biodiversity: Consideration of the GTS has also taken into account the full lengths of the greenways/cycleways of which only part are included within the GTS (e.g. Galway City to Oranmore Cycleway is part of the Galway to Dublin Cycleway). Considering the residual impacts associated with the proposed road development, the mitigation measures included within the GTS, and the environmental protection policies included within the *Galway County Development Plan 2015-2021* and the *Galway City Council Development Plan 2017-2023*, no significant negative cumulative impacts are likely.	
Galway City Development Plan 2017–2023	**Socio Economic:** The proposed road development will help achieve objectives in the Galway City Development Plan and there will be a positive impact on quality of life for Galway City residents, accessibility for employment and amenity, economic development due to reduced congestion and improved connectivity, and residential and commercial development potential. There will be no significant negative cumulative impacts.	None
	Irish Language: The Galway City Development Plan includes objectives to promote the Irish Language. There will be no significant cumulative impacts with the proposed road development.	
	Human Health: The Galway City Development Plan includes objectives to improve physical activity, improved accessibility and social inclusion. There will be no significant cumulative impacts with the proposed road development.	
	Material Assets Non-Agriculture: Not applicable	
	Material Assets Agriculture: Not applicable	
	Air Quality and Climate: Not applicable	
	Noise and Vibration: Not applicable	
	Landscape and Visual: Other than as considered in the landscape and visual assessment, it is not envisaged that any further significant cumulative impacts will arise from the proposed road development.	

Plan/Project	Potential Cumulative Impacts on Environmental Factors	Cumulative Impact (if any)
	Archaeology, Architectural and Cultural Heritage: There will be no cumulative impacts.	
	Soils and Geology: The Galway City Development Plan provides a series of objectives for waste management, and the sustainable management of construction and demolition (C&D) waste generated by development, while also outlining that development on contaminated lands include appropriate remediation measures. The Plan also sets out environmental protection policies. Therefore, there will be no significant cumulative impact.	
	Hydrogeology: Not applicable	
	Hydrology: The Galway City Development Plans set out a series of objectives for appropriate management of surface water and water quality of the existing environment. This will ensure that future planning applications are developed using design criteria to ensure that no there is no unacceptable hydrological impact on receiving watercourses or surface water sewers associated with planned developments. This will typically be achieved in terms of flood risk and stream morphology by utilising sustainable drainage systems (SuDS) and complying with the Flood Risk Management Planning Guidelines (2009). Therefore no significant cumulative impact with the proposed road development arises.	
	Biodiversity: The objectives within the City Council Development Plan, were assessed for potential cumulative impacts with the proposed road development. Considering the residual impacts associated with the proposed road development and the environmental protection policies included within the *Galway City Council Development Plan 2017-2023*, no significant negative cumulative impacts are likely.	
Galway County Development Plan 2015–2021	**Socio Economic:** The proposed road development will help achieve objectives in the Galway County Development Plan and there will be a positive impact on quality of life for Galway County residents, accessibility for employment and amenity, economic development due to reduced congestion and improved connectivity, and residential and commercial development potential. There will be no significant negative cumulative impacts.	None
	Irish Language: The Galway County Development Plan includes objectives to promote the Irish Language. There will be no significant cumulative impacts with the proposed road development.	
	Human Health: The proposed road development will help achieve objectives in the Galway County Development Plan and there will be a positive impact on quality of life for Galway County residents to improve physical activity, improved accessibility and social inclusion. There will be no significant cumulative impacts with the proposed road development.	
	Material Assets Non-Agriculture: Not applicable

Plan/Project	Potential Cumulative Impacts on Environmental Factors	Cumulative Impact (if any)
	Hydrology: Not applicable	
	Biodiversity: Considering the residual impacts associated with the proposed road development, and the environmental protection policies included within the *Galway County Development Plan 2015-2021* and the *Galway City Council Development Plan 2017-2023* no significant negative cumulative impacts are likely.	
Ardaun Local Area Plan 2018–2024	**Socio Economic:** The proposed road development will have a positive impact on residents living in Galway arising from improved accessibility for employment and amenity and economic development. This supports the objectives of this Plan. There will be no significant negative cumulative impacts.	None
	Irish Language: Not applicable.	
	Human Health: Not applicable.	
	Material Assets Non-Agriculture: Not applicable	
	Material Assets Agriculture: Not applicable	
	Air Quality and Climate: Not applicable	
	Noise and Vibration: Not applicable	
	Landscape and Visual: While the Ardaun LAP envisages significant changes to the landscape and visual setting of the area, it is likely that the measures proposed will be delivered on a phased basis over a long period of time. Nevertheless, depending on timing of delivery, scope exists for some limited or insignificant cumulative landscape and visual impacts to arise.	
	Archaeology, Architectural and Cultural Heritage: Not applicable	
	Soils and Geology: The Ardaun Local Area Plan outlines that proposed developments will be guided in general by the objectives, development standards and guidelines of the City Development. Therefore, the residual impact associated with future proposed or planned developments in relation to soils and geology is imperceptible. Therefore, there will be no significant cumulative impact.	
	Hydrogeology: Not applicable	
	Hydrology: This set out a series of objectives for appropriate management of surface water and water quality of the existing environment. This will ensure that future planning applications are developed using design criteria to ensure that no there is no	

Plan/Project	Potential Cumulative Impacts on Environmental Factors	Cumulative Impact (if any)
	unacceptable hydrological impact on receiving watercourses or surface water sewers associated with planned developments. This will typically be achieved in terms of flood risk and stream morphology by utilising sustainable drainage systems (SuDS) and complying with the Flood Risk Management Planning Guidelines (2009). Therefore, no significant cumulative impact with the proposed road development will arise.	
	Biodiversity: Considering the residual impacts associated with the proposed road development, and the environmental protection policies included within both the *Ardaun Local Area Plan 2018–2024* and the *Galway City Development Plan 2015-2021*, no significant negative cumulative impacts are likely.	

19.6 Transboundary Impacts

Transboundary impacts relate to potential impacts on other Member States, i.e. outside of the Republic of Ireland. Given the location of the proposed road development and extents of its zone of influence no transboundary impacts will arise.

20 Summary of Mitigation Measures and Residual Impacts

20.1 Introduction

An objective of the design of the proposed N6 Galway City Ring Road, hereafter referred to as the proposed road development, has been to reduce the adverse effects of the proposed road development on the environment to a practical minimum. Design measures and mitigation measures have been incorporated into the design of the proposed road development and will be applied during the construction and operation of the proposed road development.

Where unavoidable environmental effects have been identified during the environmental impact assessment process, measures have been proposed to mitigate these effects as much as reasonably possible. These mitigation measures are detailed in the respective chapters of the EIAR and are also presented in summary format in this chapter. These mitigation measures along with the design measures required for the proposed road development are presented in **Chapter 21, Schedule of Environmental Commitments** for ease of reference and inclusion in contract documents at a later stage.

Implementation of mitigation measures reduces the extent of effects occurring. However, there will be effects which are residual, after avoidance and mitigation have been considered i.e. residual impacts. All of the residual impacts are comprehensively detailed in the relevant chapters of the EIAR however, this chapter summarises the likely significant residual environmental impacts associated with the proposed road development. Throughout this document, where reference is made to 'residual impacts', it should also be understood to mean 'residual effects'.

20.2 Construction Phase

Table 20.1 below sets out the mitigation measures proposed in respect of each environmental factor along with a summary of the likely significant residual impacts predicted for the construction phase of the proposed road development.

Table 20.1: Assessment of Potential Impacts and Mitigation Measures – Construction Phase

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
Traffic		
Construction Traffic	The construction of the proposed road development will cause temporary short term traffic impacts on the local road network. The Construction Environmental Management Plan (CEMP), included in **Appendix A.7.5**, shall ensure that construction traffic impacts are minimised through the control of site access/egress routes and site access locations.	No likely significant residual impact.
General Construction Activity		
General Construction Activities	Mitigation measures for impacts to air quality (i.e. from dust), noise and vibration impacts, diversion of services and specific measures for soils and water are included in the respective sections of this table below. Every effort will be made to ensure that any negative environmental effects will be avoided, prevented or reduced during the construction phase. Any impacts to the existing environment such as deterioration of public roads used as haul routes will be repaired. Any structural damage caused to buildings/structures/wells as a result of the construction will undergo a full stabilisation and rehabilitation works. A Construction Environmental Management Plan (CEMP) has been prepared and is included in **Appendix A.7.5**. The CEMP will be updated and finalised by the Contractor prior to construction commencing and it will be updated with any additional measures which are required by the conditions attached to An Bord Pleanála's decision. All of the content provided in the CEMP will be implemented in full by the Contractor and its finalisation by the Contractor will not affect the robustness and adequacy of the information presented and relied upon in this EIAR. The plan has regard to the guidance contained in the handbook published by Construction Industry Research and Information Association (CIRIA) in the UK, *Environmental Good Practice on Site Guide, 4th Edition* (CIRIA 2015). The plan also has regard to the TII *Guidelines for the Creation, Implementation and Maintenance of an Environmental Operating Plan*. The CEMP summarises the overall environmental management strategy that will be adopted and implemented during the construction phase of the proposed road development. The purpose of the CEMP is to demonstrate how the proposed construction works can be delivered in a logical, sensible and safe sequence with the incorporation of specific environmental control measures relevant to construction works of this nature. The CEMP sets out the mechanism by which environmental protection is to be achieved during the construction phase of the proposed road development. Implementation of the CEMP will ensure disruption and nuisance are kept to a minimum. The CEMP has been prepared in conjunction with the Environmental Impact Assessment (EIA) Report and Natura Impact Statement (NIS), having regard to consultations with a range of specialists and environmental organisations, in particular, the National Parks and Wildlife Service (NPWS) and Inland Fisheries Ireland (IFI). The CEMP supports the information already provided in this EIAR and must be read in conjunction with the information already provided in this EIAR. In addition to the controls and mitigation presented below in **Table 20.1** and in the CEMP (**Appendix A.7.5**), please also refer to the following documents for additional details on construction methodologies for the significant structures: • River Corrib Bridge Constructability Examination **Appendix A.7.1** • Menlough Viaduct Constructability Examination **Appendix A.7.2** • Lackagh Tunnel Geotechnical and Hydrogeological Appraisal **Appendix A.7.3** • Galway Racecourse Tunnel Constructability Report **Appendix A.7.4** A construction management team shall be appointed for the duration of the construction phase. This team will supervise the construction of the proposed road development, including monitoring the performance of the Contractors to ensure that the proposed construction phase mitigation measures are implemented and that construction impacts and nuisance are minimised. The construction management team will liaise with neighbours and the general community during the construction phase to ensure that any disturbance is kept to a minimum. In order to help ensure the successful development, implementation and maintenance of the CEMP, the Contractor will be obliged to appoint a Site Environmental Manager (SEM). The SEM will possess sufficient training, experience and knowledge appropriate to the nature of the task to be undertaken. In particular, the SEM will require suitably qualified ecological experts to oversee ecologically sensitive elements of the construction works, ecological derogation licensing requirements and ecological monitoring. Further details on the roles and responsibilities of the SEM are provided throughout the CEMP document in **Appendix A.7.5**. The CEMP also outlines the communications strategy which will be adopted during the construction phase which ensures that awareness, education and information sharing procedures are adopted and implemented. Finally, the CEMP outlines the inspections, auditing and monitoring compliance strategy that will be adopted by the Contractor.	No likely significant residual impact.

Source / Scale of Effect	**Control and Mitigation**	**Significant Residual Impacts**
Debris	The following are the measures that will be taken to ensure that the construction site and surroundings are maintained to a high standard of cleanliness: • Daily inspections will be undertaken to monitor tidiness • A regular program of site tidying will be established to ensure a safe and orderly site • If necessary, scaffolding will have debris netting attached to prevent materials and equipment being scattered by the wind • Food waste will be strictly controlled on all parts of the site • Wheel wash facilities will be provided for vehicles exiting the construction site. Wheel wash run off will be stored in an onsite storage tank and will be disposed of by permitted waste haulage company at a permitted or licensed facility • In the unlikely event that mud is carried from the construction site to the public road, it will be cleaned as required and will not be allowed to accumulate • Loaded lorries and skips will be covered if required • Surrounding roads used by trucks for access to and egress from the site will be inspected regularly and cleaned, using an approved mechanical road sweeper, when required • In the event of any fugitive solid waste escaping the site, it will be collected immediately and removed to storage on site, and subsequently disposed of in the normal manner	No likely significant residual impact.
Waste Management	Waste generated during the construction phase will be carefully managed according to the accepted waste hierarchy which gives precedence to prevention, minimisation, reuse and recycling over disposal with energy recovery and finally disposal to landfill. This hierarchy will be implemented by identifying opportunities to firstly prevent waste from being produced, and secondly minimise the amount of waste produced. Where prevention and minimisation will not be feasible, ways to reuse or recycle waste will be sought, preferably on-site to avoid the impacts arising from transportation. If this is not feasible, opportunities to reuse or recycle the waste off-site will be investigated or waste will be sent to an energy recovery facility, and only where there is no alternative, will waste be disposed to landfill. All waste removed from the site will be collected only by Contractors with valid waste collection permits, under the Waste Management (Facility Permit and Registration) Regulations 2007 and (Amendment) Regulations 2008, 2014, 2015. All facilities to which waste will be taken will have appropriate waste licences or permits, under the Waste Management Act 1996, as amended, and the regulations thereunder, allowing them to accept the type of waste that is to be sent there. Hazardous waste generation will be minimised, and such waste will be recovered where feasible, and only disposed of if recovery is not feasible. Hazardous waste will be managed in accordance with the relevant legislation. All wastes from the construction of the proposed road development will be delivered to authorised waste facilities in accordance with the Waste Management Acts 1996-2016. By only using facilities with the appropriate waste permits/licence, Galway County Council will be satisfied that the Contractor will comply with the objectives of the Waste Management Act and that any environmental emissions (noise, dust, water) are managed at the destination site and therefore are legally the responsibility of the owner/operator of the destination site. In this manner Galway County Council can be satisfied that the off-site spoil management aspect of the development is legally compliant with environmental and waste management legislation. In general, construction waste materials may include general construction debris, scrap timber and steel, machinery oils and chemical cleaning solutions. The practice of excessive purchase of materials and equipment to allow for anticipated wastage will be avoided.	No likely significant residual impact.
Biodiversity		
General	All of the mitigation measures detailed below are included in the Schedule of Environmental Commitments (Refer to **Chapter 21, Schedule of Commitments**) which will be implemented by the Contractor under the supervision of the Project Ecologist (employed by the Employer) and/or the Ecological Clerk of Works (employed by the Contractor).	
Designated Areas for Nature Conservation	**European Sites** The mitigation measures that are specifically required to ensure that the proposed road development will not result in a likely significant effect (i.e. adversely affect the integrity of) on the European sites within its ZoI (Lough Corrib cSAC, Lough Corrib SPA, Galway Bay Complex cSAC and Inner Galway Bay SPA) are presented in Section 10 of the Natura Impact Statement (NIS). Following an assessment of the proposed road development on the identified relevant European sites, mitigation measures were developed to address the following potential impacts that were identified: • Habitat loss/fragmentation: mitigation measures to minimise habitat loss in Lough Corrib cSAC and to avoid loss of QI habitats within Lough Corrib cSAC during construction (Refer to section below on habitats and the CEMP **Appendix A.7.5**, River Corrib Bridge Constructability Examination **Appendix A.7.1**, Menlough Viaduct Constructability Examination **Appendix A.7.2**, Lackagh Tunnel Geotechnical and Hydrogeological Appraisal **Appendix A.7.3** • Habitat degradation – tunnelling/excavation: mitigation measures to maintain the structural integrity of the rock mass supporting QI habitats in Lough Corrib cSAC during the construction of the proposed Lackagh Tunnel (and its western approach) (Refer to Lackagh Tunnel Geotechnical and Hydrogeological Appraisal **Appendix A.7.3**) • Habitat degradation – hydrogeology: mitigation measures to avoid habitat degradation in Lough Corrib cSAC as a result of potential hydrogeological impacts during construction and operation (Refer to **Hydrogeology** section below and the CEMP **Appendix A.7.5**) • Habitat degradation – hydrology: mitigation measures to protect water quality in receiving watercourses during construction (Refer to **Hydrology** section below and the CEMP **Appendix A.7.5**)	No likely significant residual effect on any European sites.

Source / Scale of Effect	**Control and Mitigation**	**Significant Residual Impacts**
	• Habitat degradation – air quality: mitigation measures to control dust emissions during construction to prevent impacts on vegetation in Lough Corrib cSAC (Refer to **Hydrogeology** section below) • Habitat degradation – non-native invasive species: mitigation measures to avoid the introduction or spread of non-native invasive species to European sites during construction or operation (Refer to the Non-native Invasive Species Management Plan which forms part of the CEMP in **Appendix A.7.5**. • Disturbance/displacement: mitigation measures to avoid/reduce the disturbance/displacement effects of blasting on wintering birds using Ballindooley Lough (Refer to wintering birds section below) • Barrier effect: mitigation measures to avoid the proposed road development restricting Otter movement within the Bearna Stream catchment (Refer to Otter section below) • Mortality risk: mitigation measures to avoid mortality of the QI species of Lough Corrib cSAC. These include both measures to ensure that construction materials are not introduced into the River Corrib and to remove the risk of Otter being killed/injured due to collisions with road traffic (Refer to Otter section below). **Natural Heritage Areas and proposed Natural Heritage Areas** The potential for the proposed road development to significantly affect Lough Corrib pNHA or Galway Bay Complex pNHA is as per the corresponding European sites (Lough Corrib cSAC and Lough Corrib SPA in relation to Lough Corrib pNHA, and Galway Bay Complex cSAC and Inner Galway Bay SPA in relation to Galway Bay Complex pNHA). Therefore, the mitigation measures outlined above for European sites and as detailed in Section 10 of the NIS, will prevent the proposed road development resulting in a significant negative effect on Lough Corrib pNHA or Galway Bay Complex pNHA at the national geographic scale. The mitigation measures that are required to ensure that the proposed road development will not significantly affect Moycullen Bogs NHA are as follows: • Measures to control dust emissions during construction to prevent impacts to vegetation/habitats within Moycullen Bogs NHA at Tonabrocky – see Air Quality and Climate below. These include control measures such as spraying of exposed earthwork activities and site haul roads during dry weather, wheel washes, control of site vehicle speeds, road sweeping and dust screens. • Measures to avoid the introduction or spread of non-native invasive species to Moycullen Bogs NHA during construction or operation. These are detailed in the Non-native Invasive Species Management Plan which forms part of the CEMP in **Appendix A.7.5**. • Measures to control surface water runoff from the construction site to prevent an accidental pollution event affecting peatland habitats within Moycullen Bogs NHA at Tonabrocky – see Hydrology below	No likely significant residual effects on either Lough Corrib pNHA or Galway bay Complex pNHA or on any nationally designated areas for nature conservation.
Habitats	**Mitigation Measures to Minimise Habitat Loss** To minimise the loss of Annex I habitat, areas of these habitat types within the proposed development boundary but which are not required to construct the proposed road development will be retained and fenced off for the duration of construction. These are shown on **Figures 8.23.1** to **8.23.14**. To minimise the loss of habitat associated with the proposed road development, there are also areas within the proposed development boundary which are included for mitigation planting where general construction works will not be undertaken. These are shown on **Figures 8.23.1** to **8.23.14**. Where possible, woodland, scrub, treelines and hedgerows which lie within, or along the boundary of the proposed road development, that are not directly impacted by the proposed road alignment or drainage will be retained. These areas will be protected for the duration of construction works and fenced off at an appropriate distance. Vegetation to be retained is shown on **Figures 8.23.1** to **8.23.14** and on **Figures 12.2.01** to **12.2.14** (landscape design). Where possible, areas of river channel and bankside vegetation which lie within, or along the boundary of the proposed road development, that are not directly impacted by the proposed road alignment or drainage will be retained. These areas will be protected for the duration of construction works and fenced off at a distance of 5m from the stream/river bank. The Petrifying spring feature present in Lackagh Quarry, which lies c.25m to the north of the mainline of the proposed road development at Ch. 11+400, will be retained and shotcrete[1] will not be used as part of the quarry face stabilisation measures at the spring site. **Measures to Reduce the Potential for Impacts on Vegetation to be retained** Any vegetation (including trees, hedgerows or scrub adjacent to, or within, the proposed development boundary) which is to be retained shall be afforded adequate protection during the construction phase in accordance with the Guidelines for the Protection and Preservation of Trees, Hedgerows and Scrub Prior to, During and Post Construction of National Road Schemes (National Roads Authority, 2006b), as follows: • All trees along the proposed development boundary that are to be retained, both within and adjacent to the proposed development boundary (where the root protection area of the tree extends into the proposed development boundary), will be fenced off at the outset of works and for the duration of construction to avoid structural damage to the trunk, branches or root systems of	Despite these mitigation measures, the proposed road development will result in permanent area loss of the following Annex I habitat types, which are discussed further below: • Petrifying springs [*7220] • Residual alluvial forest [*91EO] • Limestone pavement [*8240] • Wet heath [4010] • Dry heath [4030] • Wet heath/Dry heath/*Molinia* mosaic [4010/4030/6410] • Calcareous grassland [6210] • *Molinia* meadow [6410] None of the areas of Annex I habitat that will be permanently lost are located within any European sites. In the case of the priority Annex I habitats lost outside European sites, this results in a likely significant residual effect at the international geographic scale. The exception is the loss of a Petrifying spring feature which results in a likely

[1] A concrete product which is sprayed at high velocity into a rock face as a structural/stabilising component.

<table>
<tr><th>Source / Scale of Effect</th><th>Control and Mitigation</th><th>Significant Residual Impacts</th></tr>
<tr><td></td><td>the trees. Temporary fencing will be erected at a sufficient distance from the tree so as to enclose the Root Protection Area (RPA) of the tree. The RPA will be defined based upon the recommendation of a qualified arborist.
• Where fencing is not feasible due to insufficient space, protection for the tree/hedgerow will be afforded by wrapping hessian sacking (or suitable equivalent) around the trunk of the tree and strapping stout buffer timbers around it.
• The area within the RPA will not be used for vehicle parking or the storage of materials (including soils, oils and chemicals). The storage of hazardous materials (e.g. hydrocarbons) or concrete washout areas will not be undertaken within 10m of any retained trees, hedgerows and treelines
○ A qualified arborist shall assess the condition of, and advise on any repair works necessary to, any trees which are to be retained or that lie outside of the proposed development boundary but whose RPA is impacted by the works. Any remedial works required will be carried out by a qualified arborist
○ A buffer zone of at least 5m will be maintained between construction works and retained hedgerows to ensure that the root protection areas are not damaged</td><td>significant negative residual effect at the county geographic scale.

For non-priority Annex I habitat types lost outside European sites, the habitat loss is considered to constitute a likely significant residual effect at the national geographic scale.

The habitat types, and areas lost, are summarised in Table 8.38 of Chapter 8, Biodiversity.
Similarly, despite the mitigation measures the proposed road development will result in likely significant residual effects, at the local geographic scale, on the following habitat of a local biodiversity value:
• Calcareous springs (FP1) - fifteen features
• Dry-humid acid grassland (GS3) - c.7.81ha
• Poor fen and flush (PF2) - c.0.13ha
• (Mixed) broadleaved woodland (WD1) - c.2.62ha
• Hedgerows (WL1) - c.7.8km
• Treelines (WL2) - c.4km</td></tr>
<tr><td>Measures to Reduce the Potential for Air Quality Impacts on biodiversity receptors during Construction</td><td>To control dust emissions during construction and protect many of the biodiversity receptors mitigation measures detailed below in the Air Quality and Climate section will be implemented.</td><td>No likely significant residual impact</td></tr>
<tr><td>Mitigation Measures to Reduce the Potential for Impacts to Water Quality in Receiving Watercourses</td><td>The mitigation measures to protect surface water during construction are detailed below in the Hydrology section and in the Construction Environmental Management Plan (CEMP) included in Appendix A.7.5 and in turn protect many of the biodiversity receptors.</td><td>No likely significant residual impact</td></tr>
<tr><td>Measures to Protect Groundwater Quantity and Groundwater Quality and potential impacts on biodiversity receptors</td><td>The mitigation measures to protect groundwater quantity and quality during construction are detailed in the Hydrogeology section below and in turn protect many of the biodiversity receptors.
Mitigation measures are also included below for Soils and Geology to restrict the use of fill material in areas where there is the potential for run off/infiltration to affect pH levels in adjoining peatland habitats within the operational hydrogeological Zone of Influence (ZoI) of the proposed road development.</td><td>No likely significant residual impact</td></tr>
<tr><td>Measures to Control and Prevent the Spread of Non-</td><td>The mitigation strategy in relation to non-native invasive plant species is outlined in the Non-native Invasive Species Management Plan included in the CEMP (see Appendix A.7.5) and will be implemented sufficiently far in advance of the proposed construction works commencing so as to allow time to adequately control all target non-native invasive species populations within the ZoI of the proposed road development, having regard to the specific timing/seasonal constraints that apply in relation to each individual species.</td><td>No likely significant residual impact.</td></tr>
</table>

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
native Invasive Species	The Non-Native Invasive Species Management Plan will direct the construction Contractor in implementing the specific mitigation measures required in relation to individual non-native invasive plant species and are required to protect many of the biodiversity receptors. As species may have spread, or their distribution may have changed, between the habitat surveys carried out for this EIAR and the commencement of construction works, the implementation of the Non-native Invasive Species Management Plan will include a pre-construction re-survey within the proposed development boundary. In accordance with the NRA guidance this survey will include accurate 1:5,000 scale mapping for the precise location of non-native invasive plant species. The pre-construction surveys will be undertaken by suitable experts with competence in identifying the species concerned. In accordance with the National Roads Authority, 2010a guidelines, where cut, pulled or mown noxious weed or non-native invasive plant species material arises, its disposal will not lead to a risk of further spread of the plants. Care will be taken near watercourses as water is a fast medium for the dispersal of plant fragments and seeds. Material that contains flower heads or seeds will be disposed of either by composting or burial at a depth of no less than 0.5m in the case of noxious weeds, or by incineration (at a licenced facility having regard to relevant legislation) or disposal to licensed landfill in the case of non-native invasive plant species. The taproots of docks and roots of creeping thistle are not suitable for composting or shallow burial, requiring disposal to landfill, incineration or burying at a depth of no less than 1.5m (practical only during the construction phase). Where burial is being used to dispose of Japanese knotweed, the material will be buried to a depth of 5m and overlain with a suitable geotextile membrane. All disposals will be carried out in accordance with the Waste Management Acts 1996-2011. In relation to aquatic non-native invasive plant species all construction works, and any aquatic survey work that may be carried out (e.g. electrofishing), will comply with best practice biosecurity protocols for aquatic work – for example IFI's Biosecurity Protocol for Field Survey Work (IFI, 2010).	
Rare and Protected Plants and Species	As there are no rare or legally protected plant species present within the ZoI of the proposed road development they will not be affected. Therefore, no mitigation measures are required.	No likely significant residual impact.
Otters	***Habitat degradation - water quality*** The mitigation measures relating to the protection of water quality in receiving watercourses during construction are outlined below for hydrology. ***Loss of breeding/resting sites*** As Otter could potentially establish new holt or couch sites within the ZoI of the proposed road development in the future, a pre-construction check of all suitable Otter habitat will be required within 12 months of any constructions works commencing.	No likely significant residual effect on Otter, at any geographic scale.
Bats	***Measures to Protect Bats during removal of Roosts*** It is an offence under Section 23 of the Wildlife Acts 1976-2017 and under Section 51 of the European Communities (Birds and Natural Habitats) Regulations, 2011 to kill a bat or to damage or destroy the breeding or resting place of any bat species. Under the European Communities (Birds and Natural Habitats) Regulations it is not necessary that the action should be deliberate for an offence to occur. This places an onus of due diligence on anyone proposing to carry out works that might result in such damage or destruction. Under Section 54 of S.I. 477 of 2011, a derogation may be granted by the Minister where there is no satisfactory alternative and the derogation is not detrimental to the maintenance of the populations of the species to which the Habitats Directive relates at a favourable conservation status in their natural range. Given the impacts on bats that are predicted for the proposed road development, a derogation licence under Section 54 of S.I. 477 of 2011 will be required. The Bat Derogation Licence application is included in **Appendix A.8.25**. The following mitigation measures are proposed in relation to structures either confirmed as supporting bat roosts or considered to have the potential to support roosting bats: • Prior to demolition of the 14 structures containing confirmed bat roosts, replacement artificial roosts will be in place to ensure that bats are able to access alternative resting places at the earliest opportunity. • Where possible, buildings with the confirmed bat roosts will not be demolished during the breeding period or hibernation period (April to mid-August and November-March) as the risk of accidental death or injury is higher at this time. Bats may use roosts in smaller numbers in winter but may nevertheless be present. Outside of these periods, the approach to demolition of bat roosts will determined on a case-by-case basis and subject to relevant licence conditions. • Buildings confirmed as bat roosts proposed for demolition will be marked on the ground with agreed paint marking to permit identification by Contractors. • Prior to demolitions, all structures that were confirmed as either having bats or having high potential for bats will be re-examined immediately prior to demolition to assess whether bats are present at the time of demolition. This will be an all-night examination to determine if bats enter the building during the night or early morning. This will provide adequate information to proceed with demolitions unless weather conditions were unsuitable for feeding bats. If bats are present, then they will require exclusion from the property over several nights or if possible physical removal by hand by a licenced bat specialist to be placed in a bat box or similar for release in the evening after capture. For structures which have not been confirmed as bat roosts but regarded to have high potential for bats, a bat detector assessment of the property to be demolished will be carried out, if demolitions are proposed during the period May – August (note this time period will not be permitted in the case of the confirmed bat roosts to be demolished). This will be an all-night examination to determine if bats enter the building during the night or early morning. This will provide adequate information to proceed with demolition unless weather conditions were unsuitable for feeding bats. If bats are present, then they will require exclusion from the property over several nights or if possible physical removal by hand by a licenced bat specialist to be placed in a bat box or similar for release in the evening after capture. • Once structures containing roosts are deemed to be clear of bats, the bat specialist will be on site to supervise the demolition procedure until the structure is no longer deemed able to support a bat roost. Bats may re-enter a partially demolished structure overnight so the bat specialist may be required to be present during demolition works until they are completed.	Significant residual impacts will still remain as some of the activities are unavoidable and can only be mitigated to a certain level of certainty: • Demolition of 14 buildings within the proposed development boundary which will affect local populations of Soprano pipistrelle bats, Common pipistrelle bats, Brown long-eared bats and Lesser horseshoe bats. • One maternity roost is being demolished, a Brown long-eared roost at Aughnacurra (PBR256) • One satellite roost for Lesser horseshoe bats will be demolished at Aughnacurra (PBR178) (believed to be a satellite roost for the Menlo Castle (PBR06) Lesser horseshoe maternity roost) • Loss of foraging habitat is regarded to be most significant in the Menlough area where woodland-pasture-hedgerow habitat is being lost and is within the CSZ for the nationally-important population of Lesser horseshoe bats. • Inevitable elevated mortality rates due to vehicle collisions. • Mortality and severance/barrier effects caused by the proposed road development on individual bats. Whilst best practice has been

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
	The following mitigation measures are proposed in relation to those trees identified as having high potential to support roosting bats. These include the two trees confirmed to have had bats present (PTR43, PTR48) or the 13 other trees to have high suitability, where either obvious potential roosting features are present, or where obscured by dense ivy cover, the tree is of an age and condition that there is a high chance that roosting features are present. **Figures 8.16.1** to **8.16.15** shows the locations of these trees but a more detailed drawing will be provided to the contractor prior to any felling works. Bats could occupy suitable roosting features at any time prior to the commencement of works. Therefore, there is an inherent risk that bats could be affected by the proposed felling works. The following mitigation procedures will be followed: • Felling of confirmed and potential tree roosts will be undertaken during the period September – October as during this period bats are capable of flight and may avoid the risks from tree felling if proper measures are undertaken, but also are neither breeding nor in hibernation • Use of detectors alone may not be sufficient to record bat emergence and re-entry in darkness. Therefore, prior to felling of confirmed and potential tree roosts, an emergence survey using infra-red illumination and video camera(s) and bat detectors will be carried out on the night immediately preceding the felling operation to determine if bats are present • Where it is safe and appropriate to do so for both bats and humans, such trees may be felled using heavy plant to push over the tree. In order to ensure the optimum warning for any roosting bats that may still be present, the tree will be pushed lightly two to three times, with a pause of approximately 30 seconds between each nudge to allow bats to become active. The tree should then be pushed to the ground slowly and should remain in place until it is inspected by a bat specialist • Trees should only be felled “in section” or “soft felled” where the sections can be rigged to avoid sudden movements or jarring of the sections • Where remedial works (e.g. pruning of limbs) is to be undertaken to trees deemed to be suitable for bats, the affected sections of the tree will be checked by a bat specialist (using endoscope under a separate derogation licence held by that individual) for potential roost features before removal. For limbs containing potential roost features high in the tree canopy, this will necessitate the rigging and lowering of the limb to the ground (with the potential roost feature intact) for inspection by the bat specialist before it is cut up or mulched. If bats are found to be present, they will be removed by a bat specialist licenced to handle bats and released in the area in the evening following capture Prior to felling the two confirmed tree roosts (PTR43 and PTR48) replacement bat boxes will be in place to ensure that bats are able to access alternative resting places at the earliest opportunity. The location of the bat boxes in these instances will be within the proposed development boundary but the precise height and location will be decided by the bat specialist. If any additional bat tree roosts are confirmed, and will be removed by the proposed felling works, then appropriate alternative roosting sites will be provided in the form of replacement bat boxes. ***Measures to preserve flight paths across Construction areas*** It has been identified that during the construction phase, the removal of woodland and hedgerows and other intervention in the landscapes used by bats can open up habitats to the extent that bats will not want to risk crossing the new open space to reach other roosts and foraging areas on the other side. This severance of flight paths will continue throughout the construction phase. The *Report WC1060 Development of a Cost-Effective Method for Monitoring the Effectiveness of Mitigation for Bats crossing linear infrastructure* includes best practice principles to address the general lack of evidence to show that many “conventional” mitigation measures work. These principles are reproduced below and have been adopted in the mitigation strategy for the proposed road development: • *“Mitigation should be integrated into the scheme from the earliest opportunity - mitigation should be considered during the planning and design stage of the infrastructure so that it can be incorporated effectively* • *Crossing structures should be placed on the exact location of existing bat commuting routes - attempts should not be made to divert bats from their existing commuting routes* • *Crossing structures should not require bats to alter flight height or direction: this will depend on the topography of the site: If the road is to be elevated above ground level an underpass may be used to preserve the commuting route below it, or if the road is in a cutting a green bridge may be used to carry the commuting route over the road* • *Crossing structures should maintain connectivity with existing bat commuting routes: connectivity must be maintained with undisturbed bat flight paths (e.g. treelines, hedgerows, woodland rides and streams), and bat habitat (e.g. woodland) within the surrounding landscape. Crossing structures should not be exposed or sited within open ground* • *Over-the-road structures such as green bridges should be planted with vegetation: vegetation should be continuous and connected (see above) and sufficiently mature before road construction (e.g. by planting either relatively mature trees or fast growing tree species in advance of construction commencing)* • *Underpasses should be of sufficient height: underpasses should be as spacious as possible with height being the critical factor. The minimum requirements for underpass height will be species-specific. Required heights will generally be lower for woodland-adapted species (~3 m) compared to generalist edge-adapted species (~6 m), but larger underpasses will accommodate more species* • *Green bridges should be of sufficient width: In addition to being vegetated, green bridges should be as wide as possible, to provide a large area for bats to commute across. Further research is needed to determine exact dimensions. We found a 30m wide green bridge to be effective in this study* • *Crossing structures should be unlit: The effects of light on bats are species-specific and lighting should be avoided* • *Access and connectivity must be maintained: It is important that access to crossing structures is maintained (e.g. grilles should not be installed on underpasses) and that connecting vegetation is retained indefinitely or for as long as the mitigation structure is required* • *Disturbance should be minimised during installation of mitigation structures: For example, by limiting noise and light pollution along the bat flight path, minimising vegetation clearance, installing suitable temporary crossing structures (which should also be subject to monitoring and evaluation), completing the installation as quickly as possible and ideally avoiding the summer months when bats are most active”* The installation of temporary fencing across sites to replace connecting features has been used and appears to have only been monitored as part of one project in Switzerland (Britschgi et al, 2004). In this study, a 1m wide x 1.5-2m high artificial hedgerow was recorded to be followed by a proportion of the bats in a roost. It is proposed to apply similar measures in key locations to ensure that there are linear features to connect habitats across the construction footprint.	followed in the design of the proposed road development and the inclusion of underpasses/culverts and a wildlife overpass, a small proportion of the local bat population will inevitably fly over the proposed road development and be vulnerable to vehicle collisions. A small proportion of the population will also be adversely affected by the barrier effect posed by the proposed road development across the landscape. The effect of this residual impact on Lesser horseshoe bats is predicted to be significant at a national geographic scale. The impact on other bat species is predicted to be significant at a local geographic scale. These residual impacts have been addressed further by the proposal for specific compensatory measures, which are further discussed in **Section 20.4.2** below.

<table>
<tr><th>Source / Scale of Effect</th><th>Control and Mitigation</th><th>Significant Residual Impacts</th></tr>
<tr><td></td><td>In order to inform siting of mitigation measures, including the temporary fencing described above during the construction phase, a series of infra-red/thermal camera surveys using a series of cameras and bat detectors along linear features in the following locations will be carried out in the optimum activity season. This will help to identify the preferred crossing points at the following sections:
Area 1: North of Bearna Woods
Area 2: Aughnacurra
Area 3: River Corrib to Coolough Road
Area 4: West of N84 Headford Road
Area 5: Ballindooley to Castlegar
Each area will be surveyed three times to record bats in flight in these locations with the precise vantage points for cameras to be determined during daytime surveys.
Any existing features that are identified as preferred crossing points and are scheduled for removal will be retained until the last moment and a portable artificial crossing structure put alongside it prior to its removal, so at no stage there is a gap across the construction site at night. The use of the temporary fence as an artificial crossing structure will be monitored three times over two weeks following installation. If the artificial crossing structure is not at the same location as a proposed permanent crossing point (e.g. the wildlife overpass at Castlegar) then it shall be moved gradually over several nights to realign it with the permanent crossing point.
The nature of the artificial crossing structure may comprise lengths of camouflage netting, recycled Christmas trees roped together, portable planters or artificial plants that can be easily moved at morning and evening to ensure that the crossing is in place each night.
Proposed monitoring programme
As the baseline level of bat activity and roost occupancy can change over time, pre-construction monitoring will be carried out in advance of construction works commencing to ensure that the data against which the post-construction monitoring will be compared to is as up-to-date as possible. Monitoring of the effectiveness of the bat mitigation and compensation measures will also be undertaken during and post-construction. Where the monitoring identifies issues with either the mitigation or compensation measures, these will be remediated to ensure that those measures will achieve their aims with respect to mitigating or compensating for impacts on the local bat populations.

Pre-construction monitoring
Pre-construction monitoring is required to provide data against which the post-construction monitoring can be compared. Parameters will include:
• Occupancy levels in roosts (Menlo Castle, proposed artificial roost buildings including retrofitted retained buildings, bat boxes)
• Bat passage structures (culverts, underpasses and the Castlegar Wildlife Overpass)
• Diversity of bat species and abundance of bat activity adjacent to the proposed road development
Occupancy levels in Menlo Castle will be measured by emergence surveys using infra-red video camera recording monthly from mid-April to September in the year of or immediately prior to construction commencing (whichever of the two is closer to the construction commencement).
Monitoring for bat usage of proposed bat passage structures will focus on recording bats using existing flight paths at proposed underpasses near Menlo Castle, the N59 Letteragh Junction and the proposed Castlegar Wildlife Overpass. Pre-construction baseline data is required on numbers of bats and flight height so that this can be compared to a post-construction scenario. Such data will be collected using focused infra-red camera and detector surveys carried out at least on three separate occasions at each location in the optimum survey period. In accordance with CEDR (2016) guidance it is proposed that this pre-construction monitoring involves a minimum of two separate surveys in the breeding season and two separate (in time) surveys in mid-August to late-September, to reflect periods of landscape-scale movements, and that these surveys take place for two bat activity seasons (May-August) following completion of the construction of the proposed road development.
The risk of adverse effects on bat diversity and abundance adjacent to the proposed road development can never be ruled out completely; but not all populations will be affected in the same location in the same way and therefore ongoing monitoring is regarded to be good practice to enhance our understanding of the effects of road developments and the effectiveness of mitigation measures. Diversity of bat species and abundance of bat activity adjacent to the proposed road development will be monitored using standardised survey transects from the edge of the proposed road development outwards as described by Berthinussen & Altringham (2015). These transects will be used to record bat activity across the lands flanking the corridor of the proposed road development. It is proposed that six transects are surveyed pre-construction in locations of high bat activity where underpasses or an overpass are proposed.
Refer to the Operational Biodiversity section below in relation to “During and Post Construction Monitoring”</td><td></td></tr>
<tr><td>Badger</td><td>Badger, and their breeding and resting places, are protected under the Wildlife Acts and it is an offence under that legislation to intentionally kill or injure a Badger or to wilfully interfere with or destroy their breeding or resting places (setts).
A comprehensive suite of mitigation measures has been incorporated into the proposed road development to ensure that Badgers are not intentionally killed or injured and that any impacts to their breeding or resting places will not affect their conservation status, at any geographic scale, and will not give rise to any likely significant effects on the species.
The mitigation measures described below follow the recommendations set out in the Guidelines for the Treatment of Badgers during the Construction of National Road Schemes (National Roads Authority, 2006). These guidelines set out the best practice approach in considering and mitigating impacts on Badgers during construction works.</td><td>No likely significant residual effect on Badger, at any geographic scale.</td></tr>
</table>

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
	A detailed summary of the mitigation measures as they relate to each of the Badger setts within the ZoI of the proposed road development is presented in **Appendix A.8.24**. The non-interference zones (30m, 50m and 150m), as they relate to each of the Bader setts within the ZoI of the proposed road development, are shown on **Figures 8.23.1** to **8.23.14**. As the usage of setts by Badgers can change over time, a pre-construction check of the activity status of all setts will be required within 12 months of any constructions works commencing within the ZoI of the setts discussed below. ***Disturbance/displacement*** In order to prevent any disturbance to Badger setts not directly affected by the proposed road development, no heavy machinery shall be used within 30m of Badger setts at any time. No works shall be under taken within 50m of active setts during the breeding season. Lighter machinery (generally wheeled vehicles) shall not be used within 20m of a sett entrance. Neither blasting nor pile driving shall be undertaken within 150m of active setts during the breeding season (December to June inclusive). Prior to works commencing, a non-interference zone of 30m will be established around each of the Badger setts within the ZoI of the proposed road development, as shown on **Figures 8.23.1** to **8.23.14**. If the sett is active, a non-interference zone will be extended to 50m during the breeding season (December to June inclusive). The fencing shall be as noted in **Chapter 7, Construction Activities** of a sufficient durability to maintain the exclusion zone throughout the construction period or, if required, until such time as the sett in question is excluded/removed. The mitigation measures, as they relate to each of the Badger setts within the ZoI of the proposed road development, are summarised in **Table 8.36** of **Chapter 8, Biodiversity** and illustrated on **Figures 8.23.1** to **8.23.14**. ***Loss of breeding/resting sites*** Where setts require exclusion and removal, or temporary exclusion for the duration of the construction period, this will be undertaken in accordance with the methodology detailed in the *Guidelines for the Treatment of Badgers during the Construction of National Road Schemes* (National Roads Authority, 2006): • All Badger setts requiring exclusion and removal will require a monitoring period of at least five days to confirm activity status in advance of any construction works commencing • If the sett is active, then it shall not be removed within the Badger breeding season (December to June inclusive). To exclude or remove an active Badger sett outside of this period, inactive entrances shall be soft and hard-blocked with one-way gates installed on active entrances. One-way gates will be tied open for three days before being set to exclude, and then monitored for a period of at least 21 days before the sett is deemed inactive and destroyed. If at any time during the monitoring period the sett becomes active, the exclusion process/programme must commence again from day 1 of the 21-day monitoring period • For inactive setts, entrances will be soft-blocked (lightly blocked with vegetation and soil) and if all entrances remain undisturbed for a period of five days the sett should be destroyed immediately. This can be undertaken at any time of the year for inactive setts • An artificial sett is required to mitigate for the loss of the main sett (S9), in conjunction with a subsidiary sett (S11), of the Lackagh Badger group. The requirements relating to the provision and design of the artificial sett are set out in **Appendix A.8.24**. The location of the artificial sett is shown on **Figures 8.23.1** to **8.23.14**[2]. • Inaccessible areas (see **Figures 8.3.1** to **8.3.14**) will require a pre-works survey for badger setts in advance of site clearance. If a sett is uncovered, works must cease and a non-interference zone of 30m established; extended to 50m during the breeding season if set is active (December to June inclusive). Sett removal will follow the process outlined above	
Other Mammal Species	***Habitat degradation - water quality*** The mitigation measures relating to the protection of water quality in receiving watercourses during construction are outlined are outlined below for hydrology.	No likely significant residual impact on any other mammal species, at any geographic scale.
Invertebrates	**White-clawed crayfish & Freshwater pearl mussel** As there are no records of White-clawed crayfish or Freshwater pearl mussel from the area within the ZoI of the proposed road development they will not be affected. Therefore, no mitigation measures are required. **Marsh whorl snail** <u>Habitat Degradation – Surface Water Quality</u> The mitigation measures relating to the protection of water quality in receiving watercourses during construction are outlined below for hydrology. <u>Habitat Degradation – Groundwater.</u> The mitigation measures relating to the protection of the groundwater resource during construction are outlined below for hydrogeology. ***Marsh fritillary butterfly*** <u>Mortality Risk</u>	**White-clawed crayfish & Freshwater pearl mussel** No likely significant residual impacts are predicted. **Marsh whorl snail** No likely significant residual impact on the Marsh whorl snail, at any geographic scale. **Marsh fritillary**

[2] The closer an artificial sett is to the main sett being removed, the more likely it is to be used by the affected Badger group. Therefore, the artificial sett is proposed to be located approximately 60m to the north of S9. As the sett must be in place several months before works commence and the sett S9 is removed, the affected Badgers will have sufficient time to either adjust to the construction works in the vicinity of the artificial sett (which will involve blasting and rock breaking), relocate to another sett (e.g. S10), or construct a new sett elsewhere within their territory. Any disturbance from the construction works will be short-term and, even if the artificial sett is vacated during construction, its proximity to the operational road is not likely to deter badgers from occupying the sett at that time.

<table>
<tr><th>Source / Scale of Effect</th><th>Control and Mitigation</th><th>Significant Residual Impacts</th></tr>
<tr><td></td><td>To avoid the destruction of Marsh fritillary eggs or the mortality of Marsh fritillary caterpillars, the following mitigation strategy will be implemented in relation to the site clearance works:
• All areas within the proposed development boundary, which have been identified as suitable habitat to support the Marsh fritillary butterfly, will be subject to a pre-construction larval web survey. This will be undertaken during the mid-August to the end of September window immediately preceding site clearance works
• If larval webs are present, they will be translocated to another area of suitable habitat; either outside of the proposed development boundary or, if within, to an area of suitable habitat that will remain unaffected by construction works for the duration
• Once all larval webs have been removed from the affected areas, or if no larval webs were recorded, the vegetation will be immediately cleared or cut to ground level to render the area unsuitable for the species to recolonise. The vegetation shall be maintained in this state until such time as the topsoil is removed</td><td>No likely significant residual impact on the Marsh fritillary butterfly, at any geographic scale.</td></tr>
<tr><td>Birds</td><td>Breeding Birds
Habitat Loss, Disturbance and Destruction of Breeding Habitat
<u>General</u>
Where feasible, vegetation (e.g. hedgerows, trees, scrub and grassland) will not be removed, between the 1 March and the 31 August, to avoid direct impacts on nesting birds. Where the construction programme does not allow this seasonal restriction to be observed, then these areas will be inspected by a suitably qualified ecologist for the presence of breeding birds prior to clearance. Areas found not to contain nests will be cleared within 3 days of the nest survey, otherwise repeat surveys will be required.
Barn owl
To minimise the effects of current levels of disturbance to the Barn owl nest site at Menlo Castle, and thereby reduce any cumulative effect that construction activities nearby may have, alternative nesting sites will be provided in the vicinity. Three Barn owl nest boxes will be erected across the area shown on Figures 8.23.1 to 8.23.14 and will consist of either nest boxes erected on suitable trees or pole-mounted nest boxes. Preference will be given to erecting nest boxes on suitable trees, where possible.
Tree mounted boxes will be erected at least 3m above ground level on a mature tree with few or no low branches to obscure the nest box. The selected tree shall be either isolated in a hedgerow or situated on a woodland edge with the access hole facing open ground.
Pole-mounted nest boxes will be erected at a minimum height of 4.5m above ground.
The nest box design (e.g. entrance hole size, floor area and depth from the bottom of the entrance hole to the nest) shall be in accordance with the design requirements published by The Barn Owl Trust (<u>http://www.barnowltrust.org.uk/</u>). Nest boxes will be inspected annually for defects/damage and cleaned out/repaired as required to ensure waterproofness and the internal box depth.
Peregrine falcon
To minimise the potential for construction works near Lackagh Quarry to disturb the Peregrine falcon nest site, works from the Lackagh Tunnel to the N84 Headford Road Junction will commence prior to mid-February. This will ensure that any construction related disturbance, if its magnitude displaces Peregrine from the quarry for the duration of construction works, can influence the selection of the nest site and will not impact upon an incubating female on the nest. The installation of rock bolts on the cliff faces in the vicinity of the nest site will be undertaken in a sensitive manner (as advised by a suitably experienced ecologist) so as to minimise any potential disturbance to the nest site during the breeding season, particularly if the nest site is occupied.
Wintering Birds
Measures to Protect Wintering Birds during Construction
Construction noise will be kept to a minimum in accordance with BS 5228 (2009).
The contract documents will specify that the Contractor, undertaking the construction of the works, will be obliged to take specific noise abatement measures and will comply with the best practice outlined in British Standard BS 5228 – 1: 2009 +A1 2014: Code of practice for noise and vibration control on construction and open sites – Noise and the NRA (now TII) guidelines Good Practice Guideline for the Treatment of Noise during the planning of National Road Schemes (National Roads Authority, 2014).
Blasting associated with the eastern approach to Lackagh Quarry (Ch. 11+800 to Ch. 12+100) will be carried out between the months of April to September (inclusive) to minimise the exposure of wintering birds at Ballindooley Lough to blasting-related disturbance.
Blasting associated with the cutting at Castlegar (Ch. 12+550 to Ch. 13+650) will take approximately nine months to complete, with an estimated five blast events per week. To minimise the exposure of wintering birds at Ballindooley Lough to blasting-related disturbance, all of those nine months must be in the April to September period (inclusive) within consecutive years.</td><td>Breeding birds
No likely significant residual impact on breeding bird species, at any geographic scale, with the exception of the Peregrine falcon. Due to the likely permanent loss of Lackagh Quarry as a nesting site, the proposed road development is likely to result in a significant negative residual effect on Peregrine falcon, at the county geographic scale.

Wintering birds
No likely significant residual impact on wintering bird species, at any geographic scale.</td></tr>
<tr><td>Amphibians</td><td>Habitat Loss, Disturbance & Mortality Risk
If works to clear any of the habitat features suitable to support amphibian species are to begin during the season where frogspawn or tadpoles may be present (February – mid-summer), or where breeding adult newts, their eggs or larvae may be present (mid-March – September), a pre-construction survey will be undertaken to determine whether breeding amphibians are present.
In the case of Common frog, any frog spawn, tadpoles, juvenile or adult frogs present will be captured and removed from affected habitat by hand net and translocated to the nearest area of available suitable habitat, beyond the ZoI of the proposed road development.
In the case of Smooth newt, individuals will be captured and removed from affected habitat either by hand net or by trapping and translocated to the nearest area of available suitable habitat, beyond the ZoI of the proposed road development. If used, the type and design of traps shall be approved by the NPWS. This is a standard and proven method of catching and translocating Smooth newt.</td><td>No likely significant residual impact on the Common frog or the Smooth newt, at any geographic scale.</td></tr>
</table>

Source / Scale of Effect	**Control and Mitigation**	**Significant Residual Impacts**
	If the size or depth of the habitat feature is such that it cannot be determined whether all amphibians have been captured, it will be drained under the supervision of a suitably experienced ecologist to confirm that no amphibian species remain before it is destroyed or infilled. Any mechanical pumps used to drain the habitat feature will have a screen fitted, and be sited, such that no amphibian species can be sucked into the pump mechanism. Any capture and translocation works shall be undertaken immediately in advance of site clearance/construction works commencing. ***Habitat Degradation – Surface Water Quality*** The mitigation measures relating to the protection of water quality in receiving watercourses during construction are outlined below for Hydrology.	
Reptiles	**Measures to Protect Reptiles during Construction** ***Habitat Loss, Disturbance & Mortality Risk*** Given the broad range of habitat types favoured by the Common lizard, and that the majority of the proposed road development passes through mosaics of such habitats, site clearance works at any time of year in suitable habitat are highly likely to encounter the species, cause disturbance and have the potential to kill or injure individuals. In order to minimise the risk of site clearance and construction works disturbing, or causing the mortality of, Common lizard the following schedule of site clearance works will be followed in the areas highlighted on **Figures 8.10.1** to **8.10.8**, where the presence of Common lizard has been confirmed: • grass, scrub or heath vegetation will be removed during the winter period, where possible, avoiding potential Common lizard hibernacula sites (dry sites which provide frost-free conditions e.g. stone walls, underground small mammal burrows, piles of dead wood or rubble) • where this is not possible and clearance will be undertaken during the active season (March through to September, inclusive), vegetation will be cut first to approximately 15cm, and then to the ground, under supervision of an ecologist. This will allow the opportunity for lizards to be displaced by the disturbance and leave the affected area • stone walls (or other potential hibernacula sites) will be removed during the active season (March through to September, inclusive) under the supervision of an ecologist, when they are less likely to be in use by torpid lizards	No likely significant residual impact on the Common lizard, at any geographic scale.
Fish	**Measures to Protect Fish Species during Construction** ***Habitat Loss*** The structures have been designed in consultation with IFI and in accordance with the design criteria set out in *Guidelines for the Crossing of Watercourses during the Construction of National Road Schemes* (National Roads Authority**,** 2005) and the *Guidelines on Protection of Fisheries During Construction Works in and Adjacent to Waters* (IFI, 2016). These measures, which include, in broad terms replicating the existing channel profile and substrate, will likely minimise the effects of habitat loss to a degree but it is acknowledged that this will be limited by the fact that they are artificial channels within a light limiting box structure. To minimise the effects of habitat loss on fish species, all sections of river/stream channel within the proposed development boundary, but not within the footprint of the proposed road development and associated infrastructure, will be protected from site clearance and construction works. Rivers/streams will be fenced off at a minimum distance of 5m from the river bank and within this zone the natural riparian vegetation will be retained. ***Habitat Degradation – Surface Water Quality*** The mitigation measures relating to the protection of water quality in receiving watercourses during construction are outlined below for hydrology ***Habitat Degradation – Groundwater*** The mitigation measures relating to the protection of the groundwater resource during construction are outlined below for Hydrogeology. ***Mortality Risk & Disturbance/Displacement*** To minimise the potential effects of construction works on fish species the following mitigation measures will be implemented: • No instream works will be carried out between the months of October and June (inclusive) to avoid the most sensitive time for fish species and fish species movements • Design of new sections of river channel shall be in accordance with the principles outlined in Channels & Challenges. Enhancing Salmonid Rivers. (O’Grady, 2006) • Immediately prior to rivers/streams being diverted into a newly constructed river channel or culvert, they will be electrofished (if required) to capture and transfer fish from the original channel to the new one. Once the watercourse has been diverted this will be followed by a manual search of the original watercourse to transfer any remaining fish to the new river/stream channel • Any water abstraction points required for dust suppression will be agreed with IFI and the suction head shall be screened to ensure that fish are not removed during the abstraction process ***Habitat Severance/Barrier Effect*** All temporary crossing structures used to cross watercourses during construction will be designed in accordance with the *Guidelines on Protection of Fisheries During Construction Works in and Adjacent to Waters* (IFI, 2016) and *Guidelines for the Crossing of Watercourses during the Construction of National Road Schemes* (National Roads Authority, 2005) to maintain fish and macroinvertebrate passage, and to prevent sedimentation and erosion.	No likely significant negative residual impact on fish species, at any geographic scale.

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
Soils		
Earthworks construction	Construction techniques that comply with the requirements of statutory bodies in terms of noise, vibration, soil and groundwater contamination and disposal of contaminated material for both soil and rock cuttings will be adopted. **Loss of Agricultural Land and Solid Geology** All excavated material, excluding a small potential volume of hazardous material, will be re-used as construction fill and material deposition areas minimising the loss of the feature. The Contractor will ensure acceptability of the material for re-use within the proposed road development with appropriate handling, processing and segregation of the material. **Introduction of Material derived from a different Lithology** A construction earthworks programme will be implemented as part of the CEMP included in **Appendix A.7.5**, which is finalised by the Contractor, for the proposed road development which categorises the source of material for each fill section. During the finalisation of this programme, the fill limitations outlined below will be incorporated. To prevent impact to the local peatland habitats, the following fill limitations will be incorporated at the locations identified **Table 9.18** of **Chapter 9, Soils and Geology**. • Only pavement and capping layers protected from surface water runoff and groundwater movements are permitted to be derived from non-native material • All other acceptable fill material will be derived from native material or other pH compatible material **Flood Barrier** A drainage layer or starter layer, in accordance with the TII publication CC-SCD-00606, will be implemented for the construction of embankments in areas prone to flooding. The introduction of a drainage layer will ensure hydraulic conductivity exists across the flood plain and removes the risk of the embankment acting as a flood barrier. **Earthworks Haulage** Earthworks haulage will be along predetermined routes within and outside the proposed development boundary as shown on **Figures 7.101** to **7.123** of **Chapter 7, Construction Activities**. The identified haulage routes are along existing national, regional and local routes or within the proposed development boundary. Where compaction occurs due to truck movements and other construction activities on unfinished surfaces, remediation works will be undertaken to reinstate the ground to its original condition. Where practicable, compaction of any soil or subsoil which is to remain in-situ along the proposed road development will be avoided. **Washout of Fines/Sediment Runoff** The use of granular fill material in embankment construction will remove the likelihood of the washout of fines. However, in the event the embankment will be constructed of local material, the introduction of a drainage layer or starter layer (as discussed in Flood Barrier section above) will reduce the likelihood of run-off of fine material. Alternatively, the introduction of a geotextile separator will reduce the potential impact in areas. A composite system, combining a drainage layer and a geotextile separator will be implemented in embankments constructed with cohesive fill material. Sediment control methods are outlined in the CEMP in **Appendix A.7.5** and in the Hydrology and Hydrogeology sections below. **Effect on Surrounding Ground** Ground settlement, horizontal movement and vibration monitoring will be implemented during construction activities to ensure that the construction does not exceed the design limitations. In situations where the site specific blast design has determined that blasting is not feasible in a particular location due to excessive ground vibrations, alternative extraction methods such as hydraulic breaking, hydraulic splitting, chemical splitting and electrical disintegration may be implemented and monitored. Monitoring will be implemented during blasting, during excavation of cuts, for overburden slopes steeper than 1V:2H (V= vertical slope, H = horizontal slope) and rock slopes steeper than 1V:1.5H. A geotechnical expert will be appointed by the Contractor and will be present to monitor the surrounding ground vibrations near sensitive receptors during blasting works. In the unlikely event that the blast vibration limit at the surface is exceeded, blasting works will cease on site until it is understood the basis for the increased vibration. The blast design will then be recalibrated and blasting works will proceed with continued monitoring. Allowable distances for the various construction methods are given in the section below on Noise and Vibration.	The small loss of the attribute (Limestone pavement (all outside European designated sites)) will result in a significant/moderate residual impact.
Reuse and processing of site material	A construction earthworks programme will be implemented for the proposed road development which categorises the source of material for each fill section. During the finalisation of this programme the fill limitations outlined above will be incorporated at the locations presented in **Table 9.18** of **Chapter 9, Soils and Geology**.	No likely significant residual impact.
Importation, exportation and disposal of materials	**Importation, exportation and disposal of materials** Importation of materials from outside the site will be minimised by ensuring that materials arising within the site area are used to the greatest extent possible. Any surplus material remaining which cannot be incorporated into the construction fill activities shall be placed in material deposition areas within the proposed road development. This will significantly reduce the deposition of material off-site. Hazardous material will be transported off site for disposal or recovery at appropriately licenced or permitted sites as outlined above in the section on Construction Activities and in the CEMP (**Appendix A.7.5**).	No likely significant residual impact.
Tunnelling	The adopted construction techniques will comply with the requirements of statutory bodies in terms of noise, vibration, soil and groundwater contamination and disposal of contaminated material.	

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
	During the construction of Lackagh Tunnel the supported rock face of Lackagh Quarry Face and retaining walls for the Western Approach will be monitored for movement. A geotechnical expert will be appointed by the Contractor and will be present to monitor the rock mass stability during their construction period. In the unlikely event that instability within the rock mass is observed, additional support measures will be installed to ensure that there is no impact to the surface above. The additional rock support measures comprise ground anchors, rock bolts, rock dowels, rock mesh, shotcrete or a combination of these measures, designed to the relevant design standards and best practice guidance documents. However, based on the conservative design approach it is considered that the risk of instability will be avoided and additional support measures will not be required. A geotechnical expert will be appointed by the Contractor and will be present to monitor the vibrations at the surface, including the areas of Limestone pavement, during blasting works for the construction of Lackagh Tunnel and the Western Approach. The blast target vibration limit is defined as 20% more conservative than the conservative design approach vibration limit of 25mm/sec at the ground surface which includes areas of Limestone pavement, which provides an added factor of safety to the construction works to ensure that blasting will not impact the structural integrity of the Limestone pavement. In the unlikely event that the blast target vibration limit at the surface is exceeded, blasting works will cease on site until it is understood the basis for the increased vibration. The blast design will then be recalibrated and blasting works will proceed with continued monitoring. For further information on Lackagh Tunnel is presented in **Section 9.3.2.5** of **Chapter 9 Soils and Geology** and **Appendix A.7.3**.	No likely significant residual impact.
Construction of Structures	Construction of structures will be completed in accordance with the CEMP in **Appendix A.7.5**. The construction of the River Corrib Bridge will meet the requirements of the: River Corrib Bridge Constructability Examination **Appendix A.7.1**; the Menlough Viaduct will meet the requirements of the Menlough Viaduct Constructability Examination **Appendix A.7.2**, the Lackagh Tunnel will meet the requirements of the Lackagh Tunnel Geotechnical and Hydrogeological Appraisal **Appendix A.7.3** and the Galway Racecourse Tunnel will meet the requirements of the Galway Racecourse Tunnel Constructability Report **Appendix A.7.4**. Ground settlements will be controlled through selection of the foundation type and method of construction which are suitable for the particular ground conditions. To minimise soil movements due to pile operations in the vicinity of sensitive receptors, each pile shall be constructed sequentially in a direction away from the sensitive receptor. Previously installed piles act as a shield as soil movements are greater in a direction away from the stiffer zone i.e. away from the piles and sensitive receptors. During construction, the Limestone pavement at Menlough Viaduct will be protected and will not be impacted by implementing a protection system comprising of geogrid, protection geotextile and layers of material as shown on **Plate 9.2** in **Chapter 9, Soils and Geology**. This will be removed once construction is complete. Refer to Menlough Viaduct Constructability Report in **Appendix A.7.2** for further details.	No likely significant residual impact.
Contaminated ground	No known areas of contaminated ground were located within the study area. Samples of ground suspected of contamination will be tested for contamination during the detailed investigation and ground excavated from these areas will be disposed of to a suitably licence or permitted sites in accordance with the current Irish Waste Management legislation. Good housekeeping (daily site clean-ups, use of disposal bins, etc.) on the site, and the proper use, storage and disposal of these substances and their containers will prevent soil contamination. For all activities involving the use of potential pollutants or hazardous materials, material such as concrete, fuels, lubricants and hydraulic fluids will be carefully handled and stored to avoid spillages. Potential pollutants shall also be adequately secured against vandalism and will be provided with proper containment according to codes of practice. Any spillages will be immediately contained and contaminated soil removed from the site and disposed of to an appropriately permitted or licenced site according to the current Irish Waste Management Legislation by the Contractor. The Contractor is required to make provision for removal of any concrete wash water. Concrete trucks will be directed back to their batching plant for washout. The arrangement for concrete deliveries to the site will be discussed with suppliers before commencement of work, outlining the agreed assessed routes, prohibiting on site washout and discussing emergency procedures.	No likely significant residual impact.
Karst features	As a minimum, the carriageway drainage network will be sealed in areas where the proposed road development crosses rock particularly prone to karstification. Through the use of engineered solutions, including an impermeable barrier, cement slurry or grout, direct run-off from the paved surface of the proposed road development will be prevented from entering into the rock along the proposed alignment, as this could cause further deterioration and instability of the rock mass. Individual mitigation measures will be assessed on a case by case basis, determined by the extent of karst and make-up of the proposed road development as outlined in the karst protocol which is part of the CEMP in **Appendix A.7.5**. Inspections of karst features will be undertaken by a hydrogeologist and/or geotechnical expert in order to determine the appropriate remediation measure. These remedial measures include but are not limited to the removal of all loose, soft, weak or voided soil material, backfilling voids with an agreed combination of boulders cobbles/chunk rock/cement slurry and installation of a high strength geosynthetic to form a competent, safe foundation platform. Mitigation measures for the protection of karst features are further outlined in the section below on Hydrogeology and included in the CEMP in **Appendix A.7.5** as part of the karst protocol.	No likely significant residual impact.
Hydrogeology		
Groundwater Quantity and Quality	Through the evolution of the design of the proposed road development measures were included in the design to reduce or avoid specific impacts where possible. The following measures were incorporated into the design of the proposed road development: • No dewatering of the bedrock aquifer will occur during construction at Menlough Viaduct or Lackagh Tunnel (or its approaches). Furthermore, the construction sequence will take into account the seasonal groundwater fluctuation. During the winter groundwater high it may be necessary to limit the depth of works so that dewatering is not required. • Galway Granite Batholith EW01, 02 (three cuttings), 04, 07 and 09: Groundwater intercepted will be collected and piped to the surface water receptor it would naturally have drained to.	There are no residual hydrogeological impacts to European sites. Residual profound hydrogeological impacts remain for groundwater level drawdown impacts below the location of five Annex I habitats,

Source / Scale of Effect	**Control and Mitigation**	**Significant Residual Impacts**

	• Limestone: Construction dewatering of the bedrock aquifer may seasonally be required in EW27 during peak groundwater levels. Any dewatering will be discharged to the same GWB.
	• Construction of the Galway Racecourse Tunnel and its approaches will require dewatering of the bedrock aquifer. All groundwater intercepted will be managed and discharged within the same GWB.
	• EW27: Groundwater will be controlled within the excavation by collection in drains or sumps. If groundwater is intercepted, it will be piped and discharged at an infiltration basin within the same GWB. Intercepted groundwater is controlled and infiltrates back to the same groundwater body.
	• Where infiltration basins are used for discharge of site runoff during construction the runoff will be managed on site, collected and treated as per the Sediment Erosion and Pollution Control Plan (Refer to **Section 8** of the CEMP in **Appendix A.7.5**).
	
	The design of the proposed road development includes dewatering of the bedrock aquifer in cuttings in the Galway Granite Batholith and in cuttings in the Visean Undifferentiated Limestone with the exception of the construction of Menlough Viaduct or Lackagh Tunnel (or its approaches). The drawdown from these cuttings has been assessed. Drawdown impacts are limited in extent and do not impact on European sites or National Heritage Areas. No hydrogeological mitigation is proposed with regard to the design of construction dewatering.
	
	For the Visean Undifferentiated Limestone due to the risk of karst features being intercepted in excavations for earthworks (including viaducts, bridges and tunnels) and infiltration basins, mitigation measures have been developed to preserve the hydraulic connectivity of the feature and then seal it from the excavation. The Karst Protocol mitigation measure will ensure that there is no impact on groundwater flow paths to water dependant receptors. Karst mitigation plan is detailed in the CEMP in **Appendix A.7.5** and is summarised below in the section below on Aquifer Specific Mitigation Measures.
	
	Those infiltration basins in the Lough Corrib Fen 1 (Menlough) GWB (S19a and S19b) shall have additional measures incorporated into their construction to provide further protection to the groundwater body. Infiltration basin S19a and S19b include lining the sides of the excavation to ensure vertical groundwater infiltration so that all discharges drain through the placed subsoil for the full thickness of the unsaturated zone.
	
	Following the evaluation of potential impacts as a result of the design which includes the above measures, specific mitigation measures have been developed to avoid, prevent, reduce and, if possible, remedy any significant adverse impacts on hydrogeology as outlined below.
	Mitigation of potential construction impacts will be achieved through the stringent implementation of good construction practice procedures and environmental controls so as minimise the opportunity for contaminated releases of construction runoff as set out in the CEMP (**Appendix A.7.5**). Such practices will include adequate bunding for oil containers, wheel washers and dust suppression on site roads, and regular plant maintenance.
	The following measures included in the CEMP will be implemented to control the potential for pollution from accidental spillages on site:
	• Stockpiling of contaminated material is not permitted
	• Good housekeeping (daily site clean-ups, use of disposal bins, etc.) on the site during construction, and the proper use, storage and disposal of these substances and their containers will prevent groundwater contamination
	• For all activities involving the use of potential pollutants or hazardous materials, under the CEMP, the Contractor will be required to ensure that material such as concrete, fuels, lubricants and hydraulic fluids will be carefully handled and stored to avoid spillages. Potential pollutants shall also be adequately secured against vandalism and will be provided with proper containment according to codes of practice. Any spillages will be immediately contained and contaminated soil removed from the site and properly disposed of.
	• The Contractor will finalise the Incident Response Plan in the CEMP in **Appendix A.7.5** prior to work commencing and regularly update it for pollution emergencies which will be developed by the appointed Contractor. The plan will identify actions to be taken in the event of a pollution incident as per CIRIA guidance. As recommended in the CIRIA guidance, the contingency plan for pollution emergencies includes the following:
	  ○ Containment measures
	  ○ Emergency discharge routes
	  ○ List of appropriate equipment and clean-up materials
	  ○ Maintenance schedule for equipment
	  ○ Details of trained staff, location and provision for 24-hour cover
	  ○ Details of staff responsibilities
	  ○ Notification procedures to inform the Environmental Protection Agency (EPA) or environmental department of the Galway County Council
	  ○ Audit and review schedule
	  ○ Telephone numbers of statutory water consultees
	  ○ List of specialist pollution clean-up companies and their telephone numbers
	  ○ No direct untreated point discharge of construction runoff to groundwater will be permitted.
		outside of any European sites, on the Galway Granite Batholith at:
		• Na Foraí Maola Thiar Ch. 0+650 to Ch. 0:750
		• Na Foraí Maola Thoir Ch. 1+1250 to Ch. 1+500
		• Troscaigh Thiar (Ch. 1+850 to Ch. 2+400)
		• Aille (Ch. 3+300 to Ch. 3+900)
		• Ballyburke (Ch. 4+800 to Ch. 5+900)

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
Groundwater dependant receptors	○ Where a pollution incident is detected, construction works will be stopped until the source of the construction pollution has been identified and remedied. ○ Pollution control facilities and procedures set out in the Sediment, Erosion and Pollution Control Construction Management Plan included in the CEMP in **Appendix A.7.5** will be implemented if required. ○ The pollution control and treatment facilities will be installed and the monitoring network including instrumentation and procedures established prior to construction activities taking place on the ground in the vicinity of watercourses and sensitive surface and groundwater receptors. It is envisaged that the pollution control facilities will be monitored daily to ensure their continued function. A number of mitigation measures have also been developed specifically for groundwater dependent receptors. These are detailed below for aquifer, supply wells and habitats. **Aquifer** Aquifer specific mitigation measures are implemented where karst or high permeability zones are encountered during the construction programme. In the event of karst being encountered the Karst Protocol shall be implemented, which is documented in the CEMP (**Appendix A.7.5**). Application of the Karst Protocol are summarised below to detail where they will be implemented: • Where karst features are encountered during construction works these will be assessed by a hydrogeologist and an engineering geologist. These features will require their extent across the proposed road development to be delineated. In the case of excavations (road cuttings, tunnels, bridge pier excavations) then the karst feature shall be excavated and backfilled with course fill and sealed. This will prevent runoff draining into the feature and therefore protect against accidental spillage. On this basis, construction runoff will not discharge to a karst pathway and will receive natural attenuation and dilution in the aquifer • With regard to karst features being intercepted in excavations for earthworks (including viaducts, bridges and tunnels) and infiltration basins. The Karst Protocol preserves the hydraulic connectivity of the feature using granular material to fill but then seals the karst from the excavation using a liner (geotextile and or concrete depending on the site specifics) that will prevent linkage between excavation and the karst • Where dewatering of the bedrock aquifer is proposed, groundwater level monitoring will be installed before construction, during the construction phase and 12 months following construction to enable potential effects from dewatering to be identified. In the shallow cuts of the proposed road development there will be minimal dewatering of the bedrock aquifer required; nonetheless, a monitoring programme will be in place. If the monitoring indicates there is a measureable impact beyond that stated in this EIAR, then work with the potential to increase drawdown will be made safe and cease until the hydrogeological assessment is revised based on the site conditions and mitigation employed if appropriate • In order to reduce potential contamination impacts, stockpiling of contaminated material and leachate generation will be prohibited. In the situation that potential contaminated material is encountered it will be tested and disposed of in an appropriate manner and in line with current water management legislation. If it is not possible to immediately remove contaminated material, then it will be stored on, and covered by, polythene sheeting to prevent rain water infiltrating through the material. The time frame between excavation and removal will be kept to an absolute minimum **Supply Wells** The mitigation measures listed below will be adopted during the construction phase of the proposed road development: • Five wells (W50-10, W50-12, W50-13, W50-14 and W50-15) will be lost during the construction of the proposed road development. These will each be mitigated by providing a replacement well, connecting to mains supply where available or by financial compensation. Where wells have to be abandoned as part of the proposed road development they will be sealed and abandoned in general accordance with Well Drilling Guidelines produced by the Institute of Geologists of Ireland (IGI 2007) • Replacement wells, storage tank, associated pumping equipment and pipework for Wells W50-13 and W50-14 will be commissioned and tested to ensure adequate yield rates in advance of wells W50-13 and W50-14 being decommissioned • Wells outside of the proposed development boundary but within the drawdown zone of influence may be impacted by reduced groundwater levels during construction. All wells within 150m of the proposed development boundary (or 50m from the calculated drawdown ZoI if greater) will be monitored for water level on a monthly basis for 12 months before construction, during construction and for 12 months after construction. If the monitoring indicates that the proposed road development has impacted on a supply or geothermal well then mitigation will be applied • Standard mitigation measures and aquifer specific mitigation measures are employed for protection of groundwater. To ensure the protection of quality of groundwater potable supplies, all wells within 150m of the proposed development boundary will be monitored for water quality on a monthly basis. These wells will be monitored for standard drinking water quality parameters on a monthly basis for 12 months before construction, during construction and for 12 months after construction. If the monitoring indicates that the proposed road development has impacted on a supply, then mitigation will be applied **GWDTE** Those GWDTE that have been flagged as being at risk are all in areas where the groundwater pathways are karstic. In this regard the Karst Protocol (in the CEMP **Appendix A.7.5**), as detailed in the previous sections above, forms part of mitigation to prevent groundwater quality or quantity being impacted. Additional mitigation is also employed to ensure that European sites are not impacted.	

<table>
<tr><th>Source / Scale of Effect</th><th>Control and Mitigation</th><th>Significant Residual Impacts</th></tr>
<tr><td></td><td>Construction activities represent a potential source of impact on the water quality of the Coolagh Lakes, which form part of the Lough Corrib cSAC, from uncontrolled construction site runoff and potential contamination of the groundwater from construction spillages. There will be no surface water discharges to the Coolagh lakes and all runoff will be treated before being discharged to ground at infiltration basins. Infiltration basins are designed to include settlement to remove sediment and have an appropriate thickness of subsoil below invert level.

Pouring of the concrete in excavations (River Corrib Bridge, Menlough Viaduct and Lackagh Tunnel) will only be undertaken when the excavation has been inspected by a qualified hydrogeologist. Inspection of the full depth and extent of each excavation will be undertaken to identify if any significant flow paths, such as the karst enhancement of the bedrock permeability, are present. If no significant flow paths are present, then the hydrogeologist will document accordingly and confirm that there is no risk to groundwater from concrete leakage. If significant pathways are present then impacts which may arise from flow along these pathways shall be designed by the hydrogeologist based on the karst mitigation plan, these may comprise of installing a high permeability zone to replace the groundwater pathways which would be removed by the foundations and/or sealing the linkage from excavation to protect the karst. The design of the mitigation measures shall be approved by a qualified hydrogeologist to confirm that there will be no negative impacts to groundwater.
These above measures will ensure that the risk of pollution of groundwater bodies is controlled. These mitigation measures are employed during construction, the impacts on groundwater quality beneath the site will be of Negligible Magnitude and Imperceptible Significance.</td><td></td></tr>
<tr><td colspan="3">Hydrology</td></tr>
<tr><td>Drainage, general flood risk water quality, channel morphology and key ecological receptors</td><td>As is normal practice the CEMP included in Appendix A.7.5 will be finalised by the Contractor in advance of the commencement of construction and the following will be implemented as part this plan:
• An Incident Response Plan detailing the procedures to be undertaken in the event of spillage of chemical, fuel or other hazardous wastes, logging of non-compliance incidents and any such risks that could lead to a pollution incident, including flood risks (Refer to Section 10 of the CEMP in Appendix A.7.5)
• A Sediment Erosion and Pollution Control Plan (Refer to Section 8 of the CEMP in Appendix A.7.5). This shall include water quality monitoring and method statements to ensure compliance with environmental quality standards specified in the relevant legislation (i.e. surface water regulations and Salmonid Regulations 1988)
• All necessary permits and licenses for instream construction works associated with the provision of culverts, bridges and outfalls. OPW Section 50 consent has been received for all culverts and bridges proposed in the EIAR. Changes to these structures as part of the detailed design and construction stage will require new Section 50 consent to be obtained
• Inform and consult with OPW Western Arterial Drainage Section who have responsibility for the Corrib-Mask Arterial Drainage scheme and the ongoing control of river and lake levels at the Salmon Weir Barrage in Galway City
• Continue to inform and consult with Inland Fisheries Ireland (IFI)
• Continue to inform and consult with National Parks and Wildlife Service (NPWS)

Construction activities will be required to take cognisance of the following guidance documents for construction work on, over or near water:
• Guidelines on Protection of Fisheries During Construction Works in and Adjacent to Waters (Inland Fisheries Ireland, 2016)
• Shannon Regional Fisheries Board – Protection and Conservation of Fisheries Habitat with particular reference to Road Construction
• Requirements for the Protection of Fisheries Habitat during Construction and Development Works at River Sites (Eastern Regional Fisheries Board)
• Central Fisheries Board Channels and Challenges – The Enhancement of Salmonid Rivers
• CIRIA C793 The SUDS Manual
• CIRIA C624 Development and Flood Risk – guidance for the construction industry
• CIRIA C532 Control of Water Pollution from Construction Sites Guidance for Consultants and Contractors
• CIRIA C648 Control of Water Pollution from Linear Construction Projects, technical guidance
• CIRIA C649 Control of Water Pollution from Linear Construction Projects, site guide
• Guidelines for the Crossing of Watercourses during the Construction of National Road schemes (NRA, 2006)
• Road Drainage and the Water Environment DN-DNG-03065 (TII, June 2015)
• Vegetated Drainage Systems for Road Runoff DN-DNG-03063 (TII, June 2015)

Based on the above guidance documents concerning control of construction impacts on the water environment, the following outlines the principal mitigation measures that will be prescribed for the construction phase in order to protect all catchment, watercourse and ecologically protected areas from direct and indirect impacts:
• All constructional compound areas will be required to be located on dry land and set back from river and stream channels and out of floodplain areas. Floodplain areas include the Flood Risk Zones A and B and therefore all construction compound areas need to be on lands above the 1000year return period flood level
• The storage of oils, fuel, chemicals, hydraulic fluids, etc. will not occur within 100m of the River Corrib or within the Floodplain Area as defined above</td><td>The will be no significant residual negative hydrological impacts on drainage and flood risk, water quality, channel morphology or key ecological receptors.</td></tr>
</table>

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
	• Surface water flowing onto the construction area will be minimised through the provision of temporary berms, diversion channels and cut-off ditches, where appropriate • Management of excess material stockpiles to prevent siltation of watercourse systems through runoff during rainstorms will be undertaken. This may involve allowing the establishment of vegetation on the exposed soil and the diversion of runoff water off these stockpiles to the construction settlement ponds and avoiding stockpiling of material in vicinity of sensitive watercourses • Where construction works are carried out adjacent to turloughs, fens, stream and river channels and lakes, protection of such waterbodies from silt load shall be carried out through use of reserved grassed buffer areas, timber fencing with silt fences or earthen berms. These measures will provide adequate treatment of constructional site runoff waters before reaching the watercourses • Use of settlement ponds, silt traps and bunds and minimising construction activities within watercourses. Where pumping of water is to be carried out, filters will be used at intake points and discharge will be through a sediment trap or sedi-mat • All watercourses that occur in areas of land that will be used for site compound/storage facilities will be fenced off at a minimum distance of 5m. In addition, measures will be implemented to ensure that silt laden or contaminated surface water runoff from the compound site does not discharge directly to the watercourse. Compounds shall not be constructed on lands designated as Flood Zone A or B in accordance with the OPW's The Planning System and Flood Risk Management Guidelines (November 2009). Site compounds will not be permitted in a European Sites (i.e. Lough Corrib cSAC) • Protection measures will be put in place to ensure that all hydrocarbons used during the construction phase are appropriately handled, stored and disposed of in accordance with the TII document "Guidelines for the crossing of watercourses during the construction of National Road Schemes". All chemical and fuel filling locations will be contained within bunded areas and set back a minimum of 10m from watercourses and floodplain areas • Foul drainage from all site offices and construction facilities will be contained and disposed of in an appropriate manner to prevent pollution • The construction discharge will be treated such that it will not reduce the environmental quality standard of the receiving watercourses • Riparian vegetation along the identified sensitive watercourses will be fenced off to provide a buffer zone of a minimum distance of 5m except for proposed crossing points for its protection • The use and management of concrete (which has a deleterious effect on water chemistry and aquatic habitats and species) in or close to watercourses will be carefully controlled to avoid spillage. Where on-site batching is proposed, this activity will be carried out well away from watercourses. Washout from such mixing plants will be carried out only in a designated contained impermeable area • All material deposition areas must be adequately bunded and compartmentalised such that the rainwater outflow from these facilities is adequately controlled and treated prior to reaching the receiving surface watercourses. The sediment control requirements are set out in the in the Sediment, Erosion and Pollution Control Construction Management Plan section of the CEMP (refer to **Appendix A.7.5**) To minimise the risk of contamination to the Galway Bay Complex cSAC a detailed Sediment, Erosion and Pollution Control Management Plan for the construction phase has been developed and included in the CEMP in **Appendix A.7.5**, which provides for avoidance, reduction, mitigation and monitoring. Construction hydrological and water quality impacts on the Galway Bay Complex cSAC and Inner Galway Bay SPA will be avoided.	

N83 Tuam Road Flood Risk	Provision of a storage area on the eastern side of the N83 Tuam Road to mitigate loss of flood storage from a pluvial flood risk area. The flood relief mitigation measures to eliminate this flood risk and reduce the existing flood risk in this area are as follows (refer also to **Figure 11.6** of **Chapter 11, Hydrology**):
	• Prevent the upgraded portion of the N83 Tuam Road from spilling laterally northwards into the driveways of existing flood risk houses by:
	  ○ Upgrade and provide effective road drainage network along the existing N83 Tuam Road. The proposed upgraded road drainage for the N83 portion extends for a length of 780m
	  ○ Provide interceptor drain to capture rapid hill slope runoff from the southeast reaching the N83 Tuam Road
	  ○ Provide for infiltration of this interceptor drain for the less severe rain storm events
	  ○ Connect this interceptor drain to the proposed flood compensation storage
	• Compensate flood storage lost by providing compensation storage of 8,030m^3 in the form of an excavated rectangular engineered storage pond with the base elevation of 16m OD and a top design water level elevation of 17.5m OD
	• Connect this compensation storage to the remaining low-lying natural flood storage area located to the northwest of the proposed road development so that both storage areas are hydraulically linked via culverts
	• Provide for a permanent pumping station and rising mains from the proposed compensation flood storage facility to discharge to the existing storm sewer with a pumping capacity of 250l/s
	
	Refer also to **Table 11.41** in **Chapter 11, Hydrology** which outlines the required storage volumes required for the catchment for a range of return periods and durations events.
	
	• The required flood storage, with an available pumping rate of 0.25cumec (i.e. 250l/s) from the engineered storage pond, is 20,700m^3 for the 100year event which is further increased to 24,800m^3 to include for 20% climate change
		There will be a moderate to significant positive residual impact on flooding and flood risk at N83 Tuam Road Twomileditch area, as the proposed mitigation measure will reduce the flood risk to the existing road and to the six remaining houses.
		
		However negative slight residual flood impacts associated with the N83 flood relief measures will remain:
		• Discharge of flood water into the Terryland Basin at 250 l/s resulting in slight increase in flood levels within the Terryland River channel. The impact of this discharge on flood levels in the Terryland Basin is minor representing a slight permanent residual impact on flood levels

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
	• The available storage provided in the engineered storage pond at a top water level of 17.5m OD is compensation storage of 8,030m^3 and the remaining (with proposed road development) natural storage provided of 18,470m^3 gives a total available flood storage of 26,500m^3, which is sufficient to achieve to meet and exceed the required storage.	• Reduction of available capacity within the existing storm sewer located to immediately south in the City North Business Park (the full bore capacity in the pipe is estimated to be 900l/s and therefore the proposed maximum discharge of 250l/s will reduce the available capacity by 27% This is considered a slight impact • Residual flood risk at the N83 Tuam Road associated with potential breakdown of the storm water pumping station, and blockage of storage area and associated drains and outfalls. This is considered slight in light of regular monthly inspections proposed
Landscape and Visual		
Site clearance and construction activities	Mitigation of landscape and visual impacts for the proposed road development shall have regard to the approach as set out in the following NRA/TII guidance documents: • Guidelines for the Creation and Maintenance of an Environmental Operating Plan (2007) • A Guide to Landscape Treatments for National Road Schemes in Ireland (2006) • Guidelines for the Protection and Preservation of Trees, Hedgerows and Scrub Prior to, During and Post Construction of National Road Schemes (2006) • Guidelines on the Management of Noxious Weeds and Non-Native Invasive Plant Species on National Roads (Revision 1, 2010) • Standard Construction Details (2000-2017) • Specification for Works (2000-2017) Landscape mitigation proposals shall take account of the approaches and principles as set out in A Guide to Landscape Treatments for National Road Schemes in Ireland, in particular to Chapter 4: Components of the Roadside Landscape; Chapter 5: Soil Geographic Factors; and Chapter 6: Landscape Treatments. Unless otherwise qualified in the following or in Chapter 8, Biodiversity, seeding and planting proposals, including species and planting type and species shall be in accordance with Chapter 6 of the Landscape Guidelines, adapted as required for local environmental and landscape conditions During the construction stage, the CEMP in **Appendix A.7.5** will be finalised and adopted by the Contractor'. Adherence to the CEMP will be a contract requirement and this will ensure good working practices are followed so as to minimise and manage any significant, negative environmental impacts arising from construction. As well as other items, the CEMP includes the mitigation set out within this chapter and incorporates these measures as part of their implementation. Mitigation will ensure that the works will have continuous monitoring under the CEMP so as to ensure adequate protection of areas outside of the construction works. Specific measures shall ensure that: • Site machinery shall operate within the proposed road development construction area • Storage areas shall be located so as to avoid impacting further on existing residential and other property, woodlands, trees, hedgerows, drainage patterns, etc. • Solid site hoarding of minimum 2.0m in height shall be provided alongside construction works adjoining residential property or recreational amenities • Solid hoarding or similar, of minimum 2.0m in height shall be provided along any side of a proposed construction compound, where they are located within 100m of residential properties • Construction compounds shall be fully-decommissioned and reinstated to their pre-construction condition at the end of the construction contract unless these areas have been identified as habitat compensation or material deposition areas • Side slopes and other landscape areas along the proposed road development shall be prepared for soiling, and either seeded and/or planted at the earliest possible opportunity. As such, some scope may exist for undertaking significant areas of seeding and planting prior to the end of the construction works. However, due to construction programming and seasonal restrictions, it is also likely that significant planting works will not be undertaken until the end of the major construction phase.	There will be significant residual impacts during construction until such time as the proposed landscape mitigation proposals establish and become increasingly effective.
Archaeology, Architectural and Cultural Heritage		
Construction activities including site clearance and demolition works	The proposed mitigation measures for the archaeological, architectural and cultural heritage are outlined below and detailed in **Appendix A.13.11**: A summary of all sites, structures, potential impacts and proposed mitigation is included in **Tables 13.21** to **13.26** in **Section 13.8** of **Chapter 13, Archaeological, Architectural and Cultural Heritage**. • A programme of archaeological test trenching will be carried out within the footprint of the proposed road development prior to construction going ahead. This will target the sites and areas of archaeological and cultural heritage potential as outlined in **Section 13.5.3** of **Chapter 13, Archaeological, Architectural and Cultural Heritage** as well as previously undisturbed areas within the proposed development boundary	No likely significant residual impact.

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
	• Test trenching will be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be identified, if that is deemed the most appropriate manner in which to proceed • Prior to demolition, the thatched cottage BH 12 will be subject to a full measured, written and photographic survey. This will be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist • The demesne landscape associated with Menlo Castle (DL 8), at Dangan Lower (DL7) and at Bushypark House (DL4) will be subject to a detailed photographic and written record prior to the construction of the proposed road development. This will be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist • All Cultural Heritage (CH) sites listed in **Table 13.17** of **Chapter 13, Archaeological, Architectural and Cultural Heritage** that include built heritage remains will be subject to a detailed written and photographic survey (to include test trenching where appropriate). This shall be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be identified, if that is deemed the most appropriate manner in which to proceed • Archaeological wade or underwater assessments will be carried out at any natural water courses (AAPs) to be impacted upon by the proposed road development by disturbance to their banks or beds. This shall be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be identified, if that is deemed the most appropriate manner in which to proceed • Any section of Townland Boundary to be impacted upon will be subject to a detailed written and photographic survey (to include test trenching where appropriate). This shall be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be identified, if that is deemed the most appropriate manner in which to proceed • Excavation of all previously recorded archaeological sites – where these fall, in whole or in part, within the footprint of the development – will be carried out under Ministerial Direction consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.	
Agriculture		
Construction activities	• The landowner will be provided with access to all separated land parcels during the construction of the proposed road development. Where temporary disruptions to this access occur landowners will be notified in advance • Where existing water and electricity supplies are disrupted during the construction phase an alternative water source or electricity supply will be made available e.g. water tanker or electric cable ducting. If access to surface drinking water sources are permanently restricted alternative groundwater supplies will be provided (or compensation to allow farmer drill his own well) • Suitable boundary fencing will be erected to delineate the line of the proposed development boundary and prevent disturbance to adjacent land • A key contact person will be appointed during the construction phase to facilitate communications between affected landowners and to facilitate the re-organisation of farm enterprises by farmers during critical times • Landowners with lands adjoining sites where either rock breaking, blasting or piling takes place will be notified in advance of these activities • The impacts on water quality will be minimised by way of a programme of mitigation measures for surface and ground water sources as described in the sections above on Hydrogeology and Hydrology • The spread of dust onto adjoining lands will be minimised by way of mitigation measures set out in the section below on Air Quality and Climate. Typically, the impact of dust on agricultural grazing livestock is not significant • Where drainage outfalls are temporarily altered or land drains blocked or damaged an adequate drainage outfall will be maintained and land drains will be repaired	The 48 Significant, 8 very significant and 12 profound construction impacts will remain and will be dealt with as part of the land acquisition process and will be agreed at a later date with a valuer. Compensation does not form part of the EIA process and is therefore not considered further.
Material Assets Non Agriculture		
Properties	• In the event of an approval of the Protected Road Scheme and Motorway Scheme and approval under Section 51 of the Roads Act 1993 (as amended), by An Bord Pleanála and subject to the availability of funding, Notice to Treat will be served firstly on owners, lessees and occupiers of the dwelling houses and commercial properties to be acquired, within six months of the scheme becoming operative, unless an application has been made for Judicial Review, in which case the Notice to Treat will be served in accordance with the provisions of Section 217 (6A) of the Planning and Development Act 2000 as inserted by the Compulsory Purchase Orders (Extension of Time Limits) Act 2010. Compensation will be agreed or determined by the property arbitrator as soon as possible after service of Notice to Treat. After compensation has been agreed or determined and satisfactory title has been produced, part payment can be made while the	The residual impacts from all of the very significant/significant impacts, 54 residential properties, eight commercial properties and one residential planning permission, which will be acquired and/or demolished to accommodate the proposed road development, remain as very

<table>
<tr><th>Source / Scale of Effect</th><th>Control and Mitigation</th><th>Significant Residual Impacts</th></tr>
<tr><td></td><td>claimant remains for an agreed period in the property to be acquired. This will facilitate the claimant in removing uncertainty and will facilitate arrangements being made, as early as possible, to secure a replacement property.

Where existing access to property is affected, this will be reinstated or an alternative access provided.
Where part of a property or land surrounding a property is to be acquired, appropriate accesses have been designed and appropriate boundary treatment will be constructed.
The proposed road development severs the NUIG Sporting Campus facilities. During construction, restricted access across the construction area at the NUIG Sporting Campus facilities will be maintained.
Alternative pitch facilities will be provided to replace the existing pitches directly impacted by the proposed road development. The facilities include a floodlit 3G GAA pitch and a floodlit 3G training area and associated site infrastructure for the drainage of these pitches and furniture such as ball-stop netting. The proposed road development also intercepts the existing sports pavilion resulting in direct impacts to its western end and the building will be modified as follows:

the existing western plant room, 1 no. changing room, 1 no. storage area, 1 no. weights area and associated access hallways on both ground floor and upper levels will be demolished
the western plant room and its associated plant will be relocated
construction and reconfiguration of internal and external walls, roof, windows and door locations.

During the construction of the River Corrib Bridge, alternative access along the bank of the River Corrib will be provided
Temporary stables will be provided for Galway Racecourse during the construction of the proposed road development until such time as the Galway Racecourse Tunnel is complete and the permanent stables are constructed.
Mitigation measures as detailed in individual accommodation works agreements, such as boundary treatment, domestic entrances, property condition surveys (as outlined below for Noise and Vibration), provision of ducting to facilitate services, maintenance of access during construction amongst other items will remove impacts related to the properties with partial landtake. Compensatory measures for the loss of land, buildings and other injurious affection will form part of the land acquisition process and will be agreed at a later date with a valuer. Compensation does not form part of the EIA process and is therefore not considered further.
</td><td>significant/significant impacts as no mitigation is possible to reduce the impact. The residual impact post compensation cannot be assessed as the compensation to be agreed as part of the land acquisition is outside the scope of the EIA process.

Mitigation measures as detailed in individual accommodation works agreements will remove the residual impacts related to the properties with partial landtake.

There are no residual impacts on dwellings from which part of the road bed will be acquired or on services or services infrastructure.

The residual impacts on NUIG Sporting Campus remain as very significant in the absence of a new university sports masterplan. The proposed road development will effectively divide the sports campus into two, removing the two centrally located grass based sand carpet full sized GAA pitches. In tandem with this the existing context of the existing sporting changing facilities setting and curtilage will be altered completely. With an appropriate level of masterplanning and implementation of the following in such, a masterplan would reduce the residual impact to moderate:

The sporting campus at Dangan will require a new sporting campus plan and strategy to re-accommodate the removed pitches and ancillary sports pavilion. This must be in line with the university’s overall strategic sport’s vision
The removal of the existing sports fields will require replacement by similar or more likely improved facilities which allow for the more intensive use of the remaining reduced campus footprint
Utilities, roads and access and egress routes around the campus will require complete re-planning to re-integrate with the proposed road development
The remaining sports pitches will require remodelling to accommodate a more intensive use of the existing campus footprint
The landscape setting of the existing campus will need to be developed to screen the visual effects of the proposed River Corrib Bridge from the surrounding pitches.
</td></tr>
</table>

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
		• Ancillary supporting facilities such as car parking and changing facilities will require remodelling The residual impact on NUIG Sporting Campus post compensation cannot be assessed as the compensation to be agreed as part of the land acquisition is outside the scope of the EIA process. There will be a positive residual impact on Galway Racecourse once the mitigation measures have been constructed with the provision of enhanced access to the premises and a new stable yard.
Services/Utilities	Each of the utility diversions associated with the proposed road development have been planned with ongoing and detailed engagement with relevant utility providers during the preparation of this EIAR. This engagement will continue prior to and during the construction phases. Each diversion has been assessed from both a construction point of view, but also from an operational point of view. Where the infrastructure for service providers is impacted, this will be diverted or reinstated in accordance with service providers' requirements prior to construction. Service users will be notified in advance of any temporary disruption or outages necessitated by the construction works. The disruption to services or outages will be carefully planned so the duration is minimised. Public water supply and foul water systems affected will be reconnected. All necessary diversions will be carried out in accordance with the local authority and Irish Water's requirements. Where private potable water supplies are impacted, a new well or alternative water supply or financial compensation for the loss of the well will be provided. Mitigation for interference with septic tanks will be agreed by the valuer at a later stage.	No likely significant residual impacts.
Air and Climate Change		
Air quality	Emissions to air during earthmoving and construction will occur, although the prevailing weather, the size of the site and its distance from sensitive receptors will assist in facilitating the management of any effects. The focus of the control procedures will therefore be to reduce the generation of airborne material. The assessment of potential construction impacts includes the implementation of 'standard mitigation', as stated in the TII Guidelines. This shall include the following measures: • Spraying of exposed earthwork activities and site haul roads during dry weather • Provision of wheel washes at exit points • Control of vehicle speeds and speed restrictions. It is proposed that site traffic is restricted to 20 km/hr. This will help to minimise the occurrence of dust re-suspension • Sweeping of hard surface roads In addition, the following measures will be implemented. These measures are based on best practice as outlined in the British Research Establishment (BRE) document 'Controlling particles, vapour and noise pollution from construction sites' and the Institute of Air Quality Management (IAQM) 'Guidance on the assessment of dust from demolition and construction', 2016. • A public communication strategy will be implemented by the Contractor which will outline procedures to inform members of the community on activities that may be disruptive, further details are contained in the CEMP in **Appendix A.7.5**. This appendix also includes details of a complaints register which will be implemented during the construction phase • Exhaust emissions from vehicles operating within the site, including trucks, excavators, diesel generators or other plant equipment, will be controlled by the Contractor through regular servicing of machinery • During dry periods when dust generation is likely or during windy periods, construction areas and vehicles delivering material with dust forming potential will also be sprayed with water, as appropriate • Areas where materials will be handled and stockpiled will be positioned away from main site access roads. These areas will also be designed to minimise their exposure to wind – all stockpiles shall be kept to the minimum practicable height with gentle slopes • There shall be no long-term stockpiling on site and storage time will be minimised • Material drop heights from plant to plant or from plant to stockpile will be minimised • Water suppression will be used during the demolition of buildings • Crushing and concrete batching plant will be located as far from sensitive receptors as is reasonably practicable. All storage bins and transfer points will be covered. Silos will be fitted with reverse jet air filters	No likely significant residual impact.

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
Climate	Dust screens will be implemented at locations where there is the potential for air quality impacts during the construction phase i.e. at locations where sensitive receptors are located within 100m of the works. In addition, a 2m dust screen will be provided at the locations in the areas of the overlap of the proposed road development and the Lough Corrib cSAC and where the proposed road development is adjacent to Moycullen Bogs NHA. Employee awareness is also a most important way that dust may be controlled on any site. Staff training and the vigilant management of operations ensure that all dust suppression methods are implemented and continuously inspected. Further details on employee training are provided in the CEMP in **Appendix A.7.5**. Dust deposition and PM_{10}/$PM_{2.5}$ monitoring shall be carried out to confirm the effectiveness of the mitigation measures. Dust deposition monitoring will also be conducted at a number of locations in the vicinity of the proposed road development. At a minimum, monitoring will be carried out at the two nearest sensitive receptors at locations where works of a 'major' scale is proposed while works are taking place in proximity. Monitoring will be carried out using the Bergerhoff method, i.e. analysis of dust collecting jars left on-site (German Standard VDI 2119, 1972). Results will be compared to the TA Luft guidelines. Should an exceedance of the TA Luft limit occur during the construction phase or a complaint be received in relation to dust levels, additional mitigation measures, for example more regular spraying of water, will be implemented. At least one month of dust deposition monitoring will be carried out in advance of the commencement of works to determine a baseline. In addition, it is proposed to carry out particulate monitoring (PM_{10} and $PM_{2.5}$) at the nearest sensitive receptors upwind and downwind of the construction works where sensitive receptors have been identified within 25m of the works. This monitoring programme will take place when works likely to generate dust are being carried out. The monitoring will allow direct comparison with the PM_{10} and $PM_{2.5}$ air quality standards on a daily basis. The particulate and dust deposition limits will be used to determine potential occurrences of dust nuisance associated with the proposed construction works. Should the limit values be approaching an exceedance during the construction works, the levels will be recorded by the Contractor. An investigation will subsequently be carried out to determine potential causes and the options available to reduce the level of dust. All potential causes for the high dust levels will be analysed. These will include the construction works taking place, potential off site sources and meteorological conditions. Should the construction works taking place be identified as the primary cause of the high level, the Contractor will ensure that the mitigation measures listed above are improved upon. Should high dust levels continue to occur following these improvements, the Contractor will provide alternative mitigation measures and/or will modify the construction works taking place. The following mitigation measures will be implemented during the construction phase of the development so as to minimise CO_2 emissions: • Materials required for the construction works will be sourced locally where possible. There are operational quarries located in proximity to the proposed road development. Rock crushing will be undertaken on site where possible, to reduce the requirement to import crushed stone to site • The Construction Traffic Management Plan outlined in the CEMP in **Appendix A.7.5** will be implemented in full. This will minimise congestion and encourage car sharing and the use of public transport • Materials will be handled efficiently on site to minimise the waiting time for loading and unloading, thereby reducing potential emissions. • Engines will be turned off when machinery is not in use • The regular maintenance of plant and equipment will be carried out • Materials with a reduced environmental impact will be used where available, such as: ○ Ground Granulated Blast Furnace Slag (GGBS) and Pulverished Fly Ash (PFA) will be used as replacements for Portland cements ○ Recycled steel The Contractor will be required to implement an Energy Management System for the duration of the works. This will include the following at a minimum: • Use of thermostatic controls on all heating systems in site buildings • The use of insulated temporary building structures • The use of low energy equipment and power saving functions on all computer systems • The use of low flow tap fittings and showers • The use of solar/thermal power to heat water for the on-site welfare facilities including sinks and showers.	No likely significant residual impact.
Noise and Vibration		
Noise	Mitigation measures for the construction phase are set out below in order to reduce potential impacts as far as practicable to within the adopted design goals for noise and vibration.	No likely significant residual impact.

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
	The contract documents will clearly specify the construction noise criteria included in **Chapter 17, Noise and Vibration** which the construction works must operate within. The Contractor undertaking the construction of the works will be obliged to take specific noise abatement measures and comply with the recommendations of BS 5228-1:2009+A1:2014 Code of Practice for Noise and Vibration Control on Construction and Open Sites - Noise and the European Communities (Noise Emission by Equipment for Use Outdoors) Regulations, 2001. These measures will ensure that: • No plant used on site will be permitted to cause an ongoing public nuisance due to noise • The best means practicable, including proper maintenance of plant, will be employed to minimise the noise produced by on site operations • All vehicles and mechanical plant will be fitted with effective exhaust silencers and maintained in good working order for the duration of the contract • Compressors will be attenuated models fitted with properly lined and sealed acoustic covers which will be kept closed whenever the machines are in use and all ancillary pneumatic tools shall be fitted with suitable silencers • Machinery that is used intermittently will be shut down or throttled back to a minimum during periods when not in use • Any plant, such as generators or pumps that is required to operate before 07:00hrs or after 19:00hrs will be surrounded by an acoustic enclosure or portable screen • During the course of the construction programme, the Contractor will be required to manage the works to comply with the limits detailed in Table 17.1 of **Chapter 17, Noise and Vibration** using methods outlined in BS 5228-1:2009+A1 2011. Part 1 - Noise BS 5228 -1:2009+A1 2011includes guidance on several aspects of construction site practices, which include, but are not limited to: • Selection of quiet plant • Control of noise sources • Screening • Hours of work • Liaison with the public • Monitoring Further comment is offered on these items in the following paragraphs and in **Appendix A.17.2**, however specific control measures relating to construction activities undertaken by the Contractor will be set out within the construction noise and vibration management plan. Noise control measures that will be considered in the plan will include the selection of quiet plant, enclosures and screens around noise sources, limiting the hours of work and noise monitoring. Further information on these measures is provided below. The Contractor will be required to conduct construction noise predictions prior to works taking place and put in place the most appropriate noise control measures depending on the level of noise reduction required at any one location. **Selection of Quiet Plant** The potential for any item of plant to generate noise will be assessed prior to the item being brought onto the site. The least noisy item of plant will be selected wherever possible. Should a particular item of plant already on the site be found to generate high noise levels, the first action will be to identify whether or not said item can be replaced with a quieter alternative. For static plant such as compressors and generators used at work areas such as construction compounds etc., the units will be supplied with manufacturers' proprietary acoustic enclosures where possible. The Contractor will evaluate the choice of piling, excavation, breaking or other working method taking into account various ground conditions and site constraints. Where possible, where alternative lower noise generating equipment that would economically achieve, in the given ground conditions, equivalent structural/ excavation/ breaking results, these will be selected to minimise potential disturbance. The decision regarding the type of pile, excavation technique, rock breaking, crushing etc. to be used on a site will normally be governed by other engineering, environmental constraints. In these instances, it may not be possible for technical reasons to replace a noisy process by a quieter alternative (e.g. rotary bored piling over driven piles). Even if it is possible, the adoption of a quieter method may prolong the overall process (e.g. manual rock breaking versus blasting); the net result being that the overall disturbance to the community will not necessarily be reduced. **General Comments on Noise Control at Source** If replacing a noisy item of plant is not a viable or practical option, consideration will be given to noise control "at source". This refers to the modification of an item of plant, or the application of improved sound reduction methods in consultation with the supplier or the best practice use of equipment and materials handling to reduce noise. In practice, a balance may need to be struck between the use of all available techniques and the resulting costs of doing so. It is therefore proposed to adopt the concept of "*Best Available Techniques*" as defined in EC Directive 96/61. In this context "best" means "*the most effective in achieving a high general level of protection of the environment as a whole*". The expression "*available techniques*" means "*those techniques developed on a scale which allows implementation…., under economically and technically viable conditions, taking into consideration the costs and advantages, whether or not the techniques are used or produced within the State, as long as they are reasonably accessible to the operator carrying on the activity*". The term "*techniques*" includes "*both the technology used and the way in which the installation is designed, built, managed, maintained, operated and decommissioned*".	

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
	Thus, the concept of Best Available Techniques requires a degree of balance between the attainment of environmental benefits and the likely cost implications. In the identification of Best Available Techniques, regard will be had to a wide range of factors, however, emphasis will be given to "*practical suitability*" and the need "*to reduce an emission and its impact on the environment as a whole*". Proposed techniques will also be evaluated in light of their potential effect on occupational health and safety. The following outline guidance relates to practical noise control at source techniques which relate to specific site considerations: • For mobile plant items such as cranes, dump trucks, excavators and loaders, the installation of an acoustic exhaust and/or maintaining enclosure panels closed during operation can reduce noise levels by up to 10dB. Mobile plant will be switched off when not in use and not left idling • For piling plant, noise reduction can be achieved by enclosing the driving system in an acoustic shroud. For steady continuous noise, such as that generated by diesel engines, it is possible to reduce the noise emitted by fitting a more effective exhaust silencer system or utilising an acoustic canopy to replace the normal engine cover • For percussive tools such as pneumatic concrete breakers, rock drills and tools a number of noise control measures include fitting muffler or sound reducing equipment to the breaker 'tool' and ensuring any leaks in the air lines are sealed. Erection of localised screens around breaker or drill bit when in operation in close proximity to noise sensitive boundaries are other suitable forms of noise reduction • For concrete mixers, control measures will be employed during cleaning to ensure no impulsive hammering is undertaken at the mixer drum • For all materials handling, the Contractor will ensure that best practice site noise control measures are implemented including ensuring that materials are not dropped from excessive heights and drop chutes/dump trucks are lined with resilient materials. This is an important consideration for site compounds where materials are loaded and unloaded. Site compounds in close proximity to noise sensitive areas (refer to **Table 17.10** of **Chapter 17, Noise and Vibration**) will incorporate a strict noise control policy relating to materials handling • Where compressors, generators and pumps are located in areas in close proximity to noise sensitive properties/ areas and have potential to exceed noise criterion, these will be surrounded by acoustic lagging or enclosed within acoustic enclosures providing air ventilation • Resonance effects in panel work or cover plates can be reduced through stiffening or application of damping compounds; rattling and grinding noises can be controlled by fixing resilient materials in between the surfaces in contact • Demountable enclosures can also be used to screen operatives using hand tools and may be moved around site as necessary • All items of plant will be subject to regular maintenance. Such maintenance can prevent unnecessary increases in plant noise and can serve to prolong the effectiveness of noise control measures **Screening** Typically screening is an effective method of reducing the noise level at a receiver location and can be used successfully as an additional measure to other forms of noise control. The effectiveness of a noise screen will depend on the height and length of the screen, its mass, and its position relative to both the source and receiver. The length of the screen should in practice be at least five times the height, however, if shorter sections are necessary then the ends of the screen will be wrapped around the source. *BS 5228 -1:2009+A1 2011*states that on level sites the screen should be placed as close as possible to either the source or the receiver. The construction of the barrier will be such that there are no gaps or openings at joints in the screen material. In most practical situations the effectiveness of the screen is limited by the sound transmission over the top of the barrier rather than the transmission through the barrier itself. In practice screens constructed of materials with a mass per unit of surface area greater than 10 kg/m^2 will give adequate sound insulation performance. As an example, the use of a standard 2.4m high construction site hoarding will provide a sufficient level of noise screening once it is installed at a suitable position between the source and receiver. Annex B of *BS 5228-1:2009+A1:2014* (Figures B1, B2 and B3) provide typical details for temporary and mobile acoustic screens, sheds and enclosures that can be constructed on site from standard materials. In addition, careful planning of the site layout will also be considered. Within site compounds, the placement of site buildings such as offices and stores between the site and sensitive locations can provide a good level of noise screening. Similarly, in some instances materials such as topsoil or aggregate along the route of the proposed road development can provide a degree of noise screening if placed between the source and the receiver. **Hours of Work** Construction activity will mostly take place during daytime hours Monday to Friday and Saturdays (ref **Section 17.2.2.1** of **Chapter 17, Noise and Vibration**). Depending on the noise emission levels experienced and associated noise impact, the Contractor will be flexible and able to conduct certain works at hours which reflect periods when the neighbouring properties have lower sensitivities to noise. It will be necessary to work overtime (including weekends) and night shifts at certain critical stages during the project. Over the expected 36-month construction phase there will be up to 10 weeks of night time working along different sections of the proposed road development primarily to facilitate bridge works over existing roads. Consideration will be given to the scheduling of activities in a manner that reflects the location of the site and the nature of neighbouring properties. Each potentially noisy event/activity will be considered on its individual merits and scheduled according to its noise level, proximity to sensitive locations and possible options for noise control. In situations where a particularly noisy activity is scheduled e.g. activities identified in **Table 17.9, Chapter 17, Noise and Vibration** (rock breaking/crushing/impact piling etc.) or other activities of similar noise level, the use of other on-site activities will be scheduled to control cumulative noise levels. **Liaison with the Public**	

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
	On typical road construction sites, the major sources of noise are essentially mobile and the noise received at any control points will therefore vary from day to day as work proceeds. The duration of piling, excavation, breaking and other high noise or vibration activities works is usually short in relation to the length of construction work as a whole, and the amount of time spent working near to sensitive areas can represent only a part of the overall period. It is important, therefore, that clear forms of communication are established between the Contractor and noise sensitive areas in proximity so that residents or building occupants are aware of the likely duration of activities likely to generate higher noise or vibration. A designated noise liaison officer will be appointed to site during construction works. All noise complaints will be logged and followed up in a prompt fashion by the liaison officer. **Monitoring** During the construction phase noise monitoring will be undertaken at the nearest sensitive locations to ensure construction noise limits outlined in **Table 17.1** of **Chapter 17, Noise and Vibration** are not exceeded. Noise monitoring will be conducted in accordance with the International Standard ISO 1996: *Acoustics – Description, measurement and assessment of environmental noise* Part 1 (2016) and Part 2 (2017). The selection of monitoring locations will be based on the nearest sensitive buildings to the working area which will progress along the length of the road construction. It is recommended that noise control audits are conducted at regular intervals throughout the construction programme in conjunction with noise monitoring. The purpose of the audits will be to ensure that all appropriate steps are being taken to control construction noise emissions and to identify opportunities for improvement, where required.	
Blasting and Air Overpressure	Air overpressure from a blast is difficult to control because of its variability, however, much can be done to reduce the effect and the control of the blast design at source. In terms of blast design control, specific guidance will be obtained from the recommendations contained within BS 5228-2:2009+A1:2014 Code of Practice for Noise and Vibration Control on Construction and Open Sites – Vibration in relation to blasting operations in addition to experienced blast control techniques used by the Contractor. These will include some or all of the following: • All blasting will be undertaken by professionally trained blast Contractors • Restriction of hours within which blasting can be conducted (09:00 –18:00hrs) • Trial blasts will be tested in less sensitive areas to assist in blast designs and identify potential zones of influence • Explosive charges will be properly confined by a sufficient amount of stemming • Blasting Contractors will ensure that the minimum amount of primer cord is used, and that no primer cord is located above ground • Profiling will be carried out after each blast in order to ensure the geometry of the rock face can be established, enabling the optimum burden and spacing to be applied for subsequent blasts; • The design, execution and completion of any blasting within 150 metres of any existing structure shall require special considerations. This will include the use of pre and post condition structural surveys by a competent structural engineer • Ground vibration and air over pressure (AOP) will be recorded simultaneously for each blast at the most sensitive locations, depending on the works area being blasted • When blasting moves into a new area, an initial low level blast will be carried out (i.e. a low Maximum Instantaneous Charge (MIC)) and monitoring will be carried out simultaneously at a number of sensitive properties in different directions in order to generate specific scaled distance graphs • The scaled distance graphs will be used to determine the optimum MIC for subsequent blasts area in order control vibration and AOP limits below the relevant limit values (as set out in **Section 17.2.1** of **Chapter 17, Noise and Vibration**) at the nearest sensitive buildings	No likely significant residual impact.
Vibration	In line with best practice mitigation measures from vibration sources, good communication and public relations are a key factor in reducing any startle effects to residents. In this instance, a Public Communications Strategy will be implemented by the Contractor prior to the commencement of any blast works. In such cases, the following recommended mitigation measures are proposed: • Relevant nearby residents will be notified before any work and blasting starts (e.g. a minimum of 24-hour written notification) • The firing of blasts will be undertaken, where possible, at similar times to reduce the 'startle' effect • Ongoing circulars will be issued informing people of the progress of the blasting works • The implementation of an onsite documented complaints procedure will be maintained by the Contractor • The use of independent monitoring will be undertaken by external bodies for verification of results The TII Guidelines recommend that in order to ensure that there is no potential for vibration damage during construction, vibration from construction activities should be limited to the values set out in **Table 17.3, Chapter 17, Noise and Vibration**. On review of the likely vibration levels associated with construction activities, it may be concluded that the construction of the proposed road development is not expected to give rise to vibration that is either significantly intrusive or capable of giving rise to structural or cosmetic damage to buildings. In the case of vibration levels giving rise to human discomfort, in order to minimise such impacts, the following measures shall be implemented during the construction period:	No likely significant residual impact.

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
	• A clear communication programme will be established to inform adjacent building occupants in advance of any potential intrusive works which may give rise to vibration levels likely to exceed perceptible levels. The nature and duration of the works will be clearly set out in all communication circulars • Alternative less intensive working methods and/or plant items shall be employed, where feasible • Appropriate vibration isolation shall be applied to plant, where feasible • Cut off trenches to isolate the vibration transmission path shall be installed where required • In the case of impact piling or demolition works for instance, a reduction in the input energy per blow shall be considered where required • Monitoring will be undertaken at identified sensitive buildings, where proposed works have the potential to be at or exceed the vibration limit values **Property Condition Surveys** Property condition surveys will be offered for all buildings within 50m of the proposed development boundary and those within 150m of proposed blasting works along the proposed road development. Property condition surveys will also be carried out at buildings and structures considered appropriate relative to their proximity to the works. Such property condition surveys shall be carried out by a Chartered Surveyor or Chartered Structural Engineer. Such property condition surveys, subject to the written agreement of relevant property owners, shall be carried out in two stages as the follows: • the first stage shall consist of pre-construction condition surveys including photographic records which shall be carried out prior to the commencement of construction • the second stage shall consist of post-construction condition surveys which shall include photographic records **Disturbance of Particularly Vibration-Sensitive Equipment and Processes** The location of potentially vibration sensitive activities have been identified for manufacturing facilities within the Parkmore and Racecourse Business Parks. This location is in proximity to an area where blasting will take place as part of the proposed tunnel at Ballybrit. The most effective form of mitigation for this type of sensitive process is through on-going consultation with the property owners as the design and construction of the proposed road development progresses. This will involve baseline vibration monitoring and the use of trial blasts using an initial low level charge with simultaneously vibration measurements undertaken at the building. This information will be used to determine acceptable vibration levels for the facility relating to the sensitivity of the operating equipment. The results of this trial assessment will then set appropriate agreed limits values at the facility in question which will be monitored during subsequent blasts or other excavation methodologies. Where no safe limit is determined, the timing and scheduling of blasts will be undertaken in consultation with the facility when no sensitive operations are taking place. Given the short time period over which an individual blast takes place (i.e. a number of seconds), this approach is deemed to be feasible.	
Human Beings, Population and Health		
Socio-economics	This section should be read in conjunction with **Tables 18.13** and **18.14** in **Chapter 18, Human Beings, Population and Health,** which detail specific measures proposed for potential socio-economic impacts. Many of these measures have been included in the design of the proposed road development. These include the provision of crossing facilities at the Foraí Maola Road, Troscaigh Road, Bearna to Moycullen Road L1321, Cappagh Road and Ballymoneen Road junctions to facilitate pedestrian and/or cyclist crossings of the proposed road development. Pedestrian crossing facilities are also proposed at the terminus of the N59 Link Road North Junction at the N59 Moycullen Road (Bushypark Junction) and at the slip road connections with the N84 Headford Road Junction. Cycle lanes are proposed to facilitate access to the Miller's Lane pitches and Gort na Bró and at the N84 Headford Road Junction. The following specific mitigation measures are proposed to improve journey amenity and minimise severance: • Provide pedestrian crossing facilities at junctions with minor roads serving local rural communities • Provide temporary visual screening from construction works at St. James' Church cemetery in Bushypark and at St. James' School, Bushypark • Provide pedestrian crossing facility at Bushypark Junction with N59 Link Road North during construction and operation • Avoid any prolonged severance and minimise duration of use by construction traffic of An Seanbóthar • Provide for alternative access along the bank of the River Corrib, along with prior advice for walkers, if access restrictions apply due to construction of the overhead bridge crossing • Phase construction works to minimise impacts on racing events at Galway Racecourse • Provide directional signage for access to the car dealership and An Post Sorting Centre on N83 during construction • Provide pedestrian crossing facilities at N84 Headford Road Junction during construction and operation • Provide a footpath within the proposed development boundary along School Road, Castlegar • Provide directional signage for a Briarhill Business Park, including a car dealership located here during both the construction • Take measures to ensure that cul-de-sacs or adjacent lands are not used for illegal parking in the operational phase Material Assets Non-Agriculture above outlines the proposed mitigation measures for the NUIG Sporting Campus facilities and Galway Racecourse.	There will be a significant residual impact as a result of the demolition of 44 dwellings and further acquisition of dwellings on those involved in the compulsory purchase process but also the integrity of the communities left behind in terms of their identity. There will also be a signification residual impact on the two building providers which are to be acquired. Material Assets Non-Agriculture above outlines the residual impacts on NUIG Sporting Campus and Galway Racecourse.
Irish Language	Mitigation measures proposed to protect the Irish Language are as follows: • During construction, all public notifications and all public project updates are provided in both Irish and English languages.	No likely significant residual impact.

Source / Scale of Effect	Control and Mitigation	Significant Residual Impacts
	• While it is expected that day-to-day communications involved in the construction of the proposed road development will be through the English language, the Main Contractor shall have the capacity to communicate and correspond through the use of the Irish language and to devote adequate and proportionate staff resources to dealing with any individual wishing to correspond and communicate through the Irish language.	
Human health	In the event of an approval of the Protected Road Scheme and Motorway Scheme and approval under Section 51 of the Roads Act 1993 (as amended), by An Bord Pleanála and subject to the availability of funding, Notice to Treat will be served firstly on owners, lessees and occupiers of the dwelling houses and commercial properties to be acquired, within six months of the scheme becoming operative, unless an application has been made for Judicial Review, in which case the Notice to Treat will be served in accordance with the provisions of Section 217 (6A) of the Planning and Development Act 2000 as inserted by the Compulsory Purchase Orders (Extension of Time Limits) Act 2010. Compensation will be agreed or determined by the property arbitrator as soon as possible after service of Notice to Treat. After compensation has been agreed or determined and satisfactory title has been produced, part payment can be made while the claimant remains for an agreed period in the property to be acquired. This will facilitate the claimant in removing uncertainty and will facilitate arrangements being made, as early as possible, to secure a replacement property. Mitigation measures proposed for the potential air quality, noise, water and soils are specified above in the respective sections. The implementation of these mitigation measures, emissions including air and noise will be adequately controlled to ensure no adverse effect on human health.	Likely significant residual impacts on those whose properties are to be acquired or demolished are as above for socio-economic.

20.3 Operational Phase

Table 20.2 below sets out the mitigation measures proposed for each environmental factor along with the significant residual impacts and their environmental consequence for the operational phase of the proposed road development.

Table 20.2: Assessment of Potential Impacts and Mitigation Measures – Operational Phase

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
Traffic		
	The traffic modelling indicates that for the Opening (2024) and Design (2039) Years there are no traffic impacts of major significance and therefore no mitigation measures are required.	The proposed road development will provide benefits to existing and new public transport services and walking and cycling routes on the adjoining local and regional road network and other measures proposed by the Galway Transport Strategy. No likely significant negative residual impact.
Waste Management		
Maintenance	There will be small quantities of operational waste likely to be generated from the proposed road development which will be delivered to authorised waste facilities in accordance with the Waste Management Acts 1996 to 2016.	No likely significant residual impact.
Biodiversity		
Designated Areas for Nature Conservation	**European Sites and Natural Heritage Areas and proposed Natural Heritage Areas** In addition to the construction measures proposed to minimise significant residual impacts on European Sites and Natural Heritage Areas and proposed Natural Heritage Area, the following measures for the operational phase are also proposed. Refer also the NIS in relation to European Sites: • Habitat degradation – hydrogeology: mitigation measures to avoid habitat degradation in Lough Corrib cSAC as a result of potential hydrogeological impacts during operation • Habitat degradation – non-native invasive species: mitigation measures to avoid the introduction or spread of non-native invasive species to European sites and Moycullen Boys NHA during operation. These are detailed in the Non-native Invasive Species Management Plan which forms part of the CEMP in **Appendix A.7.5** • Barrier effect: mitigation measures to avoid the proposed road development restricting Otter movement within the Bearna Stream catchment Mortality risk: mitigation measures to remove the risk of Otter being killed/injured due to collisions with road traffic	No likely significant residual impacts.
Habitats	Areas of Annex I habitat within the proposed development boundary which are identified to be retained and fenced off during the construction of the proposed road development will also be avoided during the operational phase. There will be no fencing within Annex I habitats that are located within Lough Corrib cSAC. Areas of compensatory habitat, including the habitat planting as part of the species mitigation measures for the construction phase will be maintained and monitored during the operational phase and remediation works undertaken if deemed necessary. Refer also to the section below in relation to Compensatory Measures.	No likely significant residual impact.
Measures to Protect Groundwater Quantity and Groundwater Quality and potential impacts on biodiversity receptors	The mitigation measures to protect groundwater quantity and quality during operation are detailed below for Hydrogeology and in turn protect many of the biodiversity receptors.	No likely significant residual impact.
Measures to Control and Prevent the Spread of Non-native Invasive Species	The mitigation strategy in relation to non-native invasive plant species which will protect many biodiversity receptors is as per that outlined above for the construction phase. These are detailed in the Non-native Invasive Species Management Plan which forms part of the CEMP in **Appendix A.7.5**	No likely significant residual impact.

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
Rare and Protected Plants and Species	As there are no rare or legally protected plant species present within the ZoI of the proposed road development they will not be affected. Therefore, no mitigation measures are required.	No likely significant residual impact.
Otters	**Habitat Severance/Barrier Effect and Collision Risk** Otters use many of the watercourses crossed by the proposed road development. To avoid Otter road casualties, Otter passage facilities will be provided at all watercourses used by Otter (e.g. raised ledges within structures, or separate dry 600mm pipes installed adjacent to culverts). Mammal underpasses will be constructed in accordance with the Guidelines for the Treatment of Otters prior to the Construction of National Road Schemes (National Roads Authority, 2008c). The locations where Otter passage facilities will be provided are listed in **Table 8.36** of **Chapter 8, Biodiversity** and are shown on **Figures 8.23.1** to **8.23.14**. Mammal-resistant fencing will be required to prevent Otter accessing the proposed road development and to guide Otters to the mammal underpasses. Mammal-resistant fencing will be installed in accordance with the specification outlined in Guidelines for the Treatment of Otters prior to the Construction of National Road Schemes (National Roads Authority, 2008c) and TIIs mammal resistant fencing specification (currently CC-SCD-00320/00319). The locations where mammal-resistant fencing is to be installed are shown on **Figures 8.23.1** to **8.23.14**. In accordance with the recommendations described in the Guidelines for the Treatment of Otters prior to the Construction of National Road Schemes (National Roads Authority, 2008c), quarterly monitoring of the effectiveness of the mitigation measures will be undertaken in the first year after the completion of construction works (for example, fencing inspections to check for gaps and underpass inspection to check for blockages)	No likely significant residual impact.
Bats	**Measures to reducing mortality risk and barrier effects within the design and operation of the proposed road development** The mitigation to address significant barrier effects has been designed to reflect current best practice. The two main approaches employed for the proposed road development include underpasses of a suitable size where the design of the proposed road development is on embankment and a wildlife overpass where it is in cut. These two measures are the only options that have been demonstrated to be effective at a population level (CEDR, 2016, (Elmeros and Dekker, 2016, Abbot et al 2012a, 2012b). Underpasses are proposed in important crossing point areas and are aligned with existing landscape features that are known to be used by bats as a result of the surveys. Underpasses in the Menlough - Bóthar Nua area and N84 Headford Road areas are regarded to be of critical importance for Lesser horseshoe bat and other bat movements across this landscape. **Table 8.35** of **Chapter 8, Biodiversity** sets out the schedule of structures which provide bat passage and states the function that they serve in terms of mitigating the potential barrier effect. The size and location of the underpasses and culverts took into account the research carried out by Abbott (2012a, b) and the advice provided in the CEDR, COST341 and WC1060 reports. Refer also to **Figures 8.23.1** to **8.23.14**. In addition to the structures specifically designed for bat passage, there are other structures such as where minor roads pass underneath the proposed road development which will be used by bats as safe crossing points. The section from the N84 Headford Road to N83 Tuam Road is almost entirely in cut and installing underpasses is not possible, therefore the only effective option is a wildlife overpass (referred to throughout this report as the Castlegar Wildlife Overpass). The Castlegar Wildlife Overpass is a critical component of the strategy. It will allow bats to fly across the proposed road development between the roosts and foraging habitats on the north side and Coopers Cave and foraging areas to the south at this location. A width below 20m is not recommended as although evidence shows that species will still use these bridges, the frequency of use is reduced. The proposed overpass at Castlegar is therefore 30m wide. The proposed planting design comprises of a double hedgerow in the middle section of the overpass (to mimic a 4m wide bóithrín). Each of the hedgerows will then diverge out to create a “mouth" at the entrance to the overpass on both sides of the proposed road development to funnel bats in to the centre of the overpass. No lighting will be provided at or on any of the structures which have been designed to provide bat passage, with the exception of S06/01 where lighting will be provided to allow for safe use by pedestrians. All of the bat underpasses (as well as artificial roosts) that are designed for Lesser horseshoe bats will have connecting woody vegetation features. Other bats species are not as reliant on hedgerows and woodland edges. Whilst there are many existing landscape features outside of the proposed development boundary, the bat mitigation strategy cannot rely on these in the long term as they may be subject to interventions by third parties. In effect, what will be created is a hedgerow corridor leading up to underpasses in the section of the proposed road development between Aughnacurra and Castlegar. This planting provides a guaranteed green corridor connecting up the underpasses/overpasses and will allow bats to adapt more easily to any future landscape scale losses of connecting habitat features. The hedgerow planting leading up to underpasses will be maintained and the growth of the hedgerow monitored for 5 years following completion and remediation works undertaken if deemed necessary **Proposed monitoring programme** As the baseline level of bat activity and roost occupancy can change over time, pre-construction monitoring will be carried out in advance of construction works commencing to ensure that the data against which the post-construction monitoring will be compared to is as up-to-date as possible. Monitoring of the effectiveness of the bat mitigation and compensation measures will also be undertaken during and post-construction. Where the monitoring identifies issues with either the mitigation or compensation measures (e.g. light spill affecting usage), these will be remediated to ensure that those measures will achieve their aims with respect to mitigating or compensating for impacts on the local bat populations. Refer to the Construction section above in relation to **Pre-construction monitoring**. ***During and Post Construction Monitoring*** <u>Roost Monitoring</u>	Significant residual impacts will still remain following the implementation of the mitigation measures as some of the activities are unavoidable and can only be mitigated to a certain level of certainty. These are the same as those outlined above for the construction stage. These residual impacts have been addressed further by the proposal for specific compensatory measures noted in **Section 20.4.2** below.

<table>
<tr><th>Source/Scale of Effect</th><th>Control and Mitigation</th><th>Significant Residual Impacts</th></tr>
<tr><td></td><td>Monitoring of occupancy of the artificial roost buildings (including retrofitted retained buildings) and bat boxes will commence immediately after their installation to determine how soon they are used. They will be installed prior to the main site clearance phase; therefore, all monitoring can be by visual inspection according to the following schedule:
• Emergence counts at Menlo Castle roost: emergence counts will be undertaken during the construction works and in 5 years following construction in May, July and August. These counts will be made using infra-red video camera recording at the same time as visual inspections of bats using the proposed new roost site adjacent to Menlo Castle in order to get an overall count of bats at this location
• Artificial roost buildings: Occupancy of the proposed artificial roost buildings (including retrofitted structures) during the works and post-construction will be undertaken in the 5 years following completion of construction. Surveys will be undertaken in mid-winter for hibernation use and in May and July for use during breeding season. Surveys will include checks for individuals and also for droppings (where necessary using DNA analysis). Droppings will be removed after each check to ensure that the subsequent survey only records usage in the interim period. The roosts will be monitored annually for Lesser horseshoe bats and counts sent to the NPWS as part of the national Lesser horseshoe bat monitoring programme. This monitoring may be undertaken by NPWS staff, Galway bat group or others to be decided by the local authority. Remote modes of monitoring using new technology may mean that visits to the roosts are not always required and that infra-red images inside the roost can be sent wirelessly. Should the monitoring of the roosts suggest that bats are not using them, additional focused surveys will be undertaken to try to understand bat movements in the locality and aim to address any issues. Any changes that may be deemed necessary will be coordinated and communicated to ensure that they do not conflict with any of the impact predictions or mitigation measures prescribed in this report. Temperature and humidity probes coupled with data loggers will be installed in the roosts for two years post construction of the roost and measures taken (e.g. fitting vents, increasing period of water tanks in the hibernation roost area) to address any issues arising
• Bat boxes: The authors are not aware of any minimum or recommended standard for bat box monitoring. After installation, boxes will be visually inspected quarterly per year for the first two years. Research into the effectiveness of mitigation measures has indicated that occupancy of bat boxes averages 50% since bats may prefer existing alternative roost sites in the locality. Any boxes not showing signs of occupancy after that time may be relocated to alternative locations within the proposed development boundary nearby where they may be of benefit to the local bat population. In years 3-5 after installation the boxes will be checked in late March and September to record usage in winter and summer and to avoid disturbance during the sensitive hibernation times
• Bat boxes will be checked for a minimum of 5 years after erection

<u>Monitoring crossing points</u>
Monitoring will comprise acoustic detector and infra-red camera recording at the culverts at the five locations previously surveyed pre-construction, namely:
• Area 1: North of Bearna Woods
• Area 2: Aughnacurra
• Area 3: River Corrib to Bothár Nua
• Area 4: West of N84 Headford Road
• Area 5: Ballindooley to Castlegar, including the Castlegar Wildlife Overpass
This will quantify the usage by bats compared to non-usage (e.g. using other flight paths). This will allow a determination as to whether the bat passage structures are being effective at a population level (where it is assumed that 90% of the bats are able to pass underneath the proposed road development). Monitoring will be repeated at all locations to provide a robust dataset. In the event that the proposed bat passage structures including the Castlegar Wildlife Overpass are not deemed to be effective, then further focused surveys will be required to determine the causes and address them in a reasonable manner where possible (for example, controlling lighting, addressing local landscape changes). Any changes that may be deemed necessary will need to be coordinated and communicated to ensure that they do not conflict with any of the impact predictions or mitigation measures prescribed in this report.
In accordance with CEDR (2016) guidance it is proposed that this post-construction monitoring involves a minimum of two separate surveys in the breeding season and two separate (in time) surveys in mid-August to late-September, to reflect periods of landscape-scale movements, and that these surveys take place for two bat activity seasons (May-August) following completion of the construction of the proposed road development.
The monitoring programme described above also relates to the compensation measures for bats described in Section 8.9.2 of Chapter 8, Biodiversity and repeated below in Section 20.4.2.
<u>Diversity and abundance adjacent to the proposed road development corridor</u>
Transects of bat activity will be taken across the same locations as the pre-construction transects in order to identify any displacement effects caused by disturbance impacts during construction and operation. Whilst the application of the Berthinussen & Altringham (2015) methodology is not without its limitations as it has only been applied to open agricultural landscapes, it is nevertheless a foundation for a reproducible survey method that is appropriate to the proposed road development. If a displacement effect is detected (decreased abundance and diversity close to the proposed road development) then further focused surveys will be required to determine the causes and address them where possible (for example, controlling lighting, addressing local landscape changes through additional planting). Any changes that may be deemed necessary will need to be coordinated and communicated to ensure that they do not conflict with any of the impact predictions or mitigation measures prescribed in this report. It is proposed that monitoring takes place during construction and two bat activity seasons following completion of the construction of the proposed road development</td><td></td></tr>
<tr><td>Badgers</td><td>Habitat Severance/Barrier Effect and Mortality Risk
Badger passage facilities provided at locations listed in Table 8.36 of Chapter 8, Biodiversity and shown on Figures 8.23.1 to 8.23.14 will protect badgers during the operational phase.</td><td>No likely significant residual effect on Badger, at any geographic scale.</td></tr>
</table>

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
	A number of the mammal passage structures lie within the modelled light spill zone and artificial lighting may affect their usage by Badger: structures C07/04, C07/01(b) and C12/01. Screening will be provided to ensure that the approaches and entrances to these structures are unaffected by light spill. Mammal-resistant fencing will be required to guide badgers to the underpasses and will be installed in accordance with the specification outlined in *Guidelines for the Treatment of Badgers prior to the Construction of National Road Schemes*, and TIIs mammal resistant fencing specification (currently CC-SCD-00320/00319), and will include badger proofing of emergency access roads and other similar access points, where located in areas where mammal-resistant fencing is to be installed. The locations where mammal-resistant fencing is to be installed are shown on **Figures 8.23.1** to **8.23.14**. In accordance with the recommendations described in the *Guidelines for the Treatment of Badgers during the Construction of National Road Schemes* (National Roads Authority, 2006), quarterly monitoring of the effectiveness of the mitigation measures will be undertaken in the first year after the completion of construction works. (for example, fencing inspections to check for gaps and underpass inspection to check for blockages)	
Other mammal species (excluding bats)	***Habitat Severance/Barrier Effect*** The combination of the network of dedicated mammal passage facilities, along with the bridge and viaduct structures (the proposed River Corrib Bridge and the Menlough Viaduct), and the retained lands above the proposed Lackagh Tunnel and the Galway Racecourse Tunnel provide a high degree of landscape permeability along the proposed road development for all of the other mammal species recorded, or likely to be present, with the study area. The locations are described in **Table 8.36** of **Chapter 8, Biodiversity** and shown on **Figures 8.23.1** to **8.23.14**. Wildlife passage facilities have been shown to be used by small mammal species such as Hedgehog, Pygmy shrew and Wood mouse (Dolan 2006; Eldridge & Wynn 2011); although their effectiveness has not been tested. However, it is likely that the high permeability of the proposed road development will reduce the effects of any severance, barrier effect or collision risk that may be associated with the proposed road development (Haigh, 2012) such that the species' conservation status would not be affected.	No likely significant residual effect on any other mammal species (excluding bats), at any geographic scale.
Invertebrates	**White-clawed crayfish & Freshwater pearl mussel** As there are no impacts, no mitigation measures are required. **Marsh whorl snail** ***Habitat Degradation – Groundwater*** The mitigation measures relating to the protection of the groundwater resource during operation are described below for Hydrogeology. **Marsh fritillary** No likely significant negative effects on Marsh fritillary are predicted during operation and no mitigation measures are required.	**White-clawed crayfish & Freshwater pearl mussel** No likely significant residual impact. **Marsh whorl snail** No likely significant negative residual impact on the Marsh whorl snail, at any geographic scale. **Marsh fritillary** No likely significant negative residual impact on the Marsh fritillary butterfly, at any geographic scale.

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
Birds	**Breeding Birds** ***Habitat loss, Habitat Severance/Barrier Effect and Mortality Risk*** Planting of woodland, hedgerow and grassland habitats along the proposed road development as detailed in the landscape drawings (**Figures 12.2.01** to **12.2.14**) will provide compensatory habitat for some bird species. In some instances, such as in large areas of improved agricultural grassland with no vegetated field boundaries, this will improve the diversity of bird habitat. Many species may not nest near a road development due to disturbance (e.g. drowning out of bird song by traffic noise). Whilst the planting is not likely to fully offset the loss of breeding habitat (due to the proximity of road traffic disturbance on the operational road) it is likely to provide additional foraging habitat for some species. To further minimise the effects of breeding habitat loss, a total of 20 nest boxes will be erected by a qualified ecologist in suitable locations away from the busy junctions/roadways. The siting and type of nest boxes will be decided on by an ecologist at locations where trees will be planted or retained along the proposed road development; as shown on **Figures 12.2.01** to **12.2.15**. ***Barn owl*** Sections along the proposed road development will be planted with dense low growing scrub cover (e.g. blackthorn) to discourage Barn owls from foraging near the proposed road development. The planting will be of a density to minimise the lag time between planting and obtaining sufficient ground cover to deter foraging Barn owl. In areas where there is a high probability that Barn owls may regularly attempt to cross the proposed road development (the section of embankment between Ch. 9+600 and Ch. 10+100), lines of closely spaced (approximately 2m centres) trees, greater than 3m in height, will be planted along the top of the embankments of the proposed road development; outside of the safety barrier and clear zone. The understorey will also be densely planted. This is to present a solid vegetated barrier to deflect Barn owl from these high-risk areas and/or force birds to fly over the proposed road development above the road traffic. All mitigation planting will be in place at the earliest feasible stage during construction to ensure that the mitigation is functioning as soon as possible, following the opening of the proposed road development. The locations where planting will be used to reduce the risk of Barn owl mortality from road traffic are shown on **Figures 8.23.1** to **8.23.14** and on the landscape drawings (**Figures 12.2.01** to **12.2.14**). The following monitoring measures are proposed: • Surveys will be undertaken of roadside planting at the end of years one and two with the objective of identifying and replacing failed plantings. • A road casualty survey to record barn owl mortalities along the route of the proposed road development will be conducted once per week for a period of two years by a suitably qualified and experienced ornithologist. The proposed road development will be driven at a steady pace in both directions so that all sections and both sides of the route will be surveyed correctly. Where noted, all barn owl mortalities will be assigned to either the "breeding" season (March to July) or "non-breeding" season (August to January). Location details of the casualty will be recorded, including a 10-digit GPS co-ordinate, position on the route (central median, hard shoulder, or verge) and orientation (southbound, northbound, eastbound, and westbound). The age class of the bird will be determined and classed as either "pre-breeding" if first or second calendar year recovered before March, or "adult" if the bird is second calendar year recovered later than March or older. The adjacent habitat feature will be noted. This methodology is in line with that utilised for *Barn Owl population status and the extent of road mortalities in relation to the Tralee Bypass* (O'Clery et al., 2016); • Monitoring to determine activity and breeding status of all active sites within 5km of the proposed road development over two breeding seasons (March to July). This will be carried out concurrently with the road casualty survey, and will involve visits to known and potential nesting sites to determine brood size and breeding success. Where accessible, nests will be visited in order to ring owlets (subject to an appropriate licence from the NPWS). A report summarising the findings of the above monitoring will be submitted at the end of year two to the NPWS. The report may include further recommendations pending survey outcomes. **Wintering Birds** **Measures to Protect Wintering Birds during Operation** ***Disturbance/Displacement*** Despite the assessment conclusion that disturbance during operation of the proposed road development is not likely to result in any population level effects on wintering birds, hedgerow planting along the proposed development boundary (at the locations shown on the landscape drawings (**Figures 12.2.01** to **12.2.14**) will further minimise the potential disturbance to wintering birds from road traffic.	**Breeding birds** No likely significant residual effect on breeding bird species, at any geographic scale, with the exception of the Peregrine falcon. Due to the likely permanent loss of Lackagh Quarry as a nesting site, the proposed road development is likely to result in a significant negative residual effect on Peregrine falcon, at the county geographic scale. **Wintering birds** No likely significant residual effect on wintering bird species, at any geographic scale.

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
Amphibians, Reptiles	**Measures to Protect Amphibians during Operation** ***Habitat Severance & Barrier Effect*** The combination of the network of wildlife passage facilities, culverts, bridges and viaduct structures (e.g. the proposed River Corrib Bridge and the Menlough Viaduct) provide a high degree of landscape permeability along the proposed road development. This will serve to maintain connectivity at a local scale between sites used by amphibian species and is predicted to reduce any long-term severance or barrier effects associated with the proposed road development such that the conservation status of amphibian species is not likely to be negatively affected. The locations are described in **Table 8.36** of **Chapter 8, Biodiversity** and shown on **Figures 8.23.1** to **8.23.14**.	No likely significant residual effect on the Common frog or the Smooth newt, Common lizard, at any geographic scale.
Soils		
Lackagh Tunnel	During the operational phase, monitoring of the rock mass stability will continue. The rock and overburden retaining systems in Lackagh Quarry and Western Approach will continue to be monitored as part of the TII (Transport Infrastructure Ireland) maintenance schedule. In the extremely unlikely event that instability within the rock mass is observed additional support measures outlined above **Sections** Error! Reference source not found. and Error! Reference source not found. of **Chapter 9, Soils and Geology**, for the construction phase will be installed to ensure that there is no impact to the structural integrity of the Limestone pavement. However, based on the conservative design approach, (the installed composite support system and monitoring during construction) it is considered that the risk of instability will be avoided and additional support measures will not be required. Operation mitigations measures for Lackagh Tunnel are further discussed in **Appendix A.7.3**. The implementation of the design, construction methodology control measures and mitigations measures results in no other operational phase mitigation measures for avoiding potential direct and indirect impact to the soils and geology environment for the proposed road development.	No likely significant residual impact.
Hydrogeology		
Groundwater Quantity and Quality	During the operational phase of the proposed road development inspection and maintenance will occur to ensure that the infiltration basins continue to operate as intended for the design life of the proposed road development. Infiltration basins will be inspected regularly to confirm that no observable subsidence in the infiltration has occurred due to karst. There are no guidelines on the inspection frequency for infiltration basins, however, based on the mitigation measures implemented the risk of subsidence occurring is considered to be low and inspection is recommended on 5-year frequency. If karst features and potential pathways are found to be present during inspection, then the Karst Protocol developed for the construction phase will be implemented to ensure that no preferential pathways have formed within the infiltration basin.	Residual hydrogeological impacts remain for groundwater level drawdown impacts below the location of five Annex I habitats on the Galway Granite Batholith noted above for the construction stage.
Hydrology		
Flood Risk	The proposed design flood level for the relief measures at the N83 Tuam Road include for the 100 year return period flood event with a 20% allowance for climate change is 17.5m OD Malin which will prevent flooding of the driveways to the dwellings and the N83 Tuam Road. The flood relief mitigation measures to eliminate the flood risk of the proposed road development and reduce the existing flood risk in this area are described above in **Table 20.1** for hydrology. To minimise the residual flood risk associated with the blockage of flood relief culverts and associated drainage assets, the following operational mitigation measure is recommended: • Regular (monthly) inspection of N83 Flood Relief facilities be carried out to ensure that the system is in proper working order and performing as designed.	The will be no likely significant residual negative hydrological impacts on drainage and general flood risk, water quality, channel morphology or key ecological receptors. As noted above in **Table 20.1** under Hydrology, there will be a significant positive residual impact on the N83 Tuam Road flood risk. However negative slight residual flood impacts associated with the N83 flood relief measures noted in **Table 20.1** will remain.
Landscape and Visual		
Project-wide Landscape Measures	Measures proposed to mitigate the landscape and visual impacts of the operation stage of the proposed road development are considered under Project-wide Measures and Specific Measures. **Project-wide measures** are outlined below and shown on **Figures 12.4.01** to **12.4.14** of **Chapter 12, Landscape and Visual** • Cut slopes on mainline, link roads and local roads	During the initial operation stage landscape and visual impacts will continue to arise from the physical presence and operation of the proposed road development. The proposed road development will be a significant and prominent new element in the landscape – at least until such stage as landscape mitigation proposals establish and become increasingly effective.

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
	○ Cut slopes shall be finished to even gradients, topsoiled unless otherwise stated in this table or elsewhere in the EIAR. Slopes shall be free of rubble and stones over 50mm diameter. All such rubble/stone shall be removed or buried. Unless otherwise stated slopes shall be seeded to a low maintenance non-agricultural grassland or to a diverse grass/wildflower sward, as appropriate. Steep slopes may be hydro-seeded. ○ Where exposed, stable rock cuttings/slopes will be retained as a landscape feature along the proposed road corridor. • Embankments on mainline, link roads, and local roads ○ Embankments shall be finished to even gradients, topsoiled unless otherwise stated in this table or elsewhere in the EIAR. Slopes shall be free of rubble and stones over 50mm diameter. All such rubble/stone shall be removed or buried. Unless otherwise stated slopes shall be seeded to a low maintenance non-agricultural grassland or to a diverse grass/wildflower sward, as appropriate. Steep slopes may be hydro-seeded. • Verges & Roundabouts on mainline, link roads, and local roads ○ Verges will be provided along both sides of mainline. Verges will also be provided around junctions and along local road re-alignments and tie-ins. Verges and roundabouts shall be finished to even or gently flowing gradients, with minimum 200mm topsoil. Areas shall be stone buried or raked will be free of rubble and stones over 25mm diameter. Verges and roundabouts will be seeded to low-maintenance seed mix. • Ponds, swales, 'V-drains' etc. ○ All slopes shall be evenly graded and free of rubble and stones over 50mm diameter. Slopes shall be seeded to low maintenance non-agricultural grassland or to a grass/wildflower sward, allowing for natural development over time. Steep slopes on pond edges and 'V-drains' may be hydro-seeded. ○ Areas around ponds shall be a diverse landscape of low maintenance grassland/species-rich grass wildflower sward and plantings of scrub planting and/or low-canopy woodland and shrub planting. Hedgerows of blackthorn and hawthorn, hazel and holly, without tree species, shall be established along non-roadside boundaries. ○ Non-palisade type fencing (e.g. paladin or timber and anti-climb netwire fencing) shall be installed to secure pond areas. • Noise barriers/bunds ○ Where possible hedgerow scrub and shrub planting and/or low-canopy woodland of native species shall be established as either a narrow planting of 3.0m minimum width or double-staggered hedgerow along the full off-road face of barriers. ○ Low-canopy and/or shrub planting of native species shall be established on the off road face of bunds. The planting shall include ash*, birch, blackthorn, elder, hawthorn, hazel, holly, rowan and/or willow species as appropriate. Plants shall be 90 to 120cm in height at planting. *** Note**: Due to the risk of Ash Dieback (*Chalara fraxinea*) and until further notice, ash (*Fraxinus* species) is no longer approved by the TII for planting schemes. This does not impact on the use of Mountain ash – also known as rowan (*Sorbus aucuparia*). ○ Transparent noise barriers will be used on the River Corrib Bridge • Plants and planting areas ○ All tree species over 150cm in height together with all Pine shall be appropriately staked and tied. All failed, dead or defective plants shall be replaced before the end of each and every year of defect aftercare. ○ Full planting area will be free of stones over 50mm in diameter. • Grass areas ○ Grass areas shall provide full sward cover within 12 months of seeding. Any failed, bare or defective areas shall be re-seeded between March – May and/or August – September in each and every year of defect aftercare. • Unauthorised access, parking and/or encampment ○ Landscape proposals shall avoid creating areas considered as being suitable for unauthorised parking and shall use landscape proposals to deter and prevent such use. • Remnant areas ○ Any post-construction remnant lands shall be treated to a diverse range of grassland and/or planting proposals to include a minimum 30% planting, amended as locally appropriate. The remaining area shall be treated as locally appropriate low maintenance grass/species-rich sward. The above project-wide measures will be applied over the entire proposed road development, depending on the nature of the particular road section. Where feasible landscape measures shall include for the re-connection of existing field boundaries and hedgerows along the proposed road development. Where appropriate trees species as noted above and in **Tables 12.8** of **Chapter 12, Landscape and Visual**, shall be randomly spaced in a visually naturalistic manner within such hedgerows. This approach will be locally modified to incorporate other landscape treatments, which may negate the requirement for the hedgerow, *e.g.* blocks of native woodland planting (see Landscape Guidelines, Section 6.2: Tree and Shrub Treatments) or semi-natural meadows (see Landscape Guidelines, Section 6.1: Grassland Treatments) where it is considered appropriate	As such, initial operational-stage landscape and visual impacts will continue to be pronounced and negative in the short-term (*i.e.* pre-establishment stage). With the development of mitigation planting, the significance and severity of landscape and visual impacts will gradually abate over time. Negative visual impact will also continue to arise for residential and other properties located close to or adjoining the boundary of the proposed road development for some time (*i.e*. post-establishment stage). Therefore, significant or notable residual landscape impacts will continue to arise: Along the edge of Sruthán Na Libeirtí, Bearna On the open elevated landscapes of Ballagh, Rahoon, Letteragh, Barnacranny and Dangan Upper On the recreation sports and amenity landscape of NUIG Sports Campus On the lowland landscape valley of the River Corrib, and the setting of Menlo Castle On the limestone landscape of Menlough and Coolough On the rolling landscape through Castlegar, south of Ballindooley Lough Locations of these significant landscape impacts are provided on **Figures 12.4.01** to **12.4.14**. Significant or notable residual visual impacts will continue to arise for properties: At the crossing of local roads north and northeast of Bearna (Foraí Maola Road, Troscaigh Road, Ann Gibbons Road, Aille Road) At the crossing of local roads northwest of Galway (Cappagh Road, Ballymoneen Road, Rahoon Road and Letteragh Road) To either side of the crossing of the N59 Moycullen Road north of Galway (The Heath, Barnacranny, Ard na Locha, Aughnacurra and at Bushypark/Ballagh) On the recreation sports and amenity landscape of NUIG Sports Campus On the lowland landscape valley of the River Corrib, and setting of Menlo Castle At the crossing of Bóthar Nua and Seanbóthar north/northeast of Galway City At the crossing of the N84 Headford Road, at Castlegar, (including crossing of School Road) and at the N83 Tuam Road, northeast of Galway

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
	to have open sections along the proposed carriageway. Open sections shall allow for views to the wider landscape where they do not impinge on requirements for screening for residential properties or other amenities. Proposals will ensure that planting is distributed along the proposed road development and the associated local road realignments and will vary from locally appropriate hedgerow reinstatement, with tree-planting, where appropriate; to wider plantings of landscape and screen planting; to the establishment of larger areas of scrub/shrub planting and new woodland for integration of the development within the wider landscape. The approach will provide a density and diversity of plantings and improve the biodiversity structure of the new landscape (see Landscape Guidelines, Section 6.2: Tree and Shrub Treatments). Treatments will take into consideration the assessment and recommendations of the mitigation measures described in the Biodiversity section and will ensure that, species which are locally indigenous and native are utilised in the proposed plantings. However, detailed proposals in terms of their nature and approach will consider the locally impacted environment and in terms of species may include non-invasive, non-native plants, *e.g.* within residential areas where existing garden plantings are disturbed. Where areas are in cut or fill, a grass or meadow sward will be established over the slope except in areas of cutting through stable rock (see Landscape Guidelines, Section 4.2: Cuttings and Embankments). Except where otherwise required, it is not proposed to plant either cut or fill slopes in their entirety, but to encourage a more naturalistic and locally sympathetic grouping of plantings within a semi-natural grass sward. Slopes may also be seeded to wildflower grassland and hydro-seeding may be utilised for seeding of steep slopes. It is expected that significant extent of rock cutting will arise on the proposed road development. Stable rock slopes will be retained as an exposed face for natural colonisation and as a local landscape features. Along the length of the proposed road development, landscape areas within junctions and small areas of severed fields, plots or other property acquired for the construction of the proposed road development will be varyingly treated including being planted in a semi-natural copse like scrub plantings and native woodland species (see Landscape Guidelines, Section 4.6: Additional Plots and Other Areas). Such planted blocks dispersed along the proposed road development will assist in the improvement of the longer-term visual character of the proposed road development and local surrounds. Particular attention shall be given to an appropriate extent and scale of planting in and surrounding junctions (see Landscape Guidelines, Section 4.3: Junctions, Interchanges and Roundabouts) and embankments (see Landscape Guidelines, Section 4.2.2: Embankments). Certain areas along the length of the proposed road development have been set aside for drainage requirements/pollution control/attenuation. Where proposed these will be securely fenced and planted with locally appropriate hedgerows, shrubs and/or screen planting located along the proposed development boundary to minimise any visual impact from off road areas. However, it is noted that these features also offer the potential to provide for improved landscape diversity and habitat. Proposed planting will generally be established using bare-root transplants, whips and feathered plants which adapt readily to disturbed ground conditions. A proportion, totalling not less than 5% of ‘Half-standard’ (6-8cm girth & 200cm-250cm tall) and a further 5% ‘Standard’ (8-10cm girth & 250cm-300cm tall) trees shall be used to supplement these plantings, especially in the vicinity of residential areas. All planting mixes will take cognisance of, and include native and local species as identified in the **Chapter 8, Biodiversity**. These requirements have been adapted and further detailed as appropriate to particular areas as set out in **Table 12.8** of **Chapter 12, Landscape and Visual**. Where used, tree species will be selected from a list of primarily native, naturalised and indigenous species, which will include alder, common ash (*subject to planting restrictions at time of works*), common birches, common oaks, mountain ash, Scots pine and willow species. Planting sizes will be from 75cm to 400cm in height and tree species will be planted at average 2.0m centres within the wider planting mix. Shrub planting species utilised will be selected from a list of primarily native and indigenous species, which will include, blackthorn, elder, hawthorn, hazel, holly, guelder rose, spindle, willows and other plants found naturalised in the affected localities. Planting sizes will vary from 30 to 75cm in height and shrub species will be planted at between 1.0 and 1.5m centres depending of landscape type, see **Table 12.8** of **Chapter 12, Landscape and Visual**. Hedge planting will be primarily of blackthorn and hawthorn interspersed with other species such as elder, hazel, holly and those found locally. Hawthorn within hedgerows shall be planted at between 75 to 90cm in height and at 500mm centres in each of 2 double staggered rows or wider plantings where a denser effect is required. The hedgerow will be interspersed with standard-sized randomly spaced tree species such as alder, common ash and oaks, as appropriate to particular locality. Areas to be seeded to meadow will be thinly topsoiled (5cm layer) and seeded with a locally appropriate seed mix. Mainline and side road verges will be cultivated, topsoiled minimum 200mm deep and stone buried to remove stones down to 25mm diameter prior to seeding to a low-maintenance grass seed mix. Where lighting is proposed, the lighting design shall meet the requirements of BS EN 13201-2:2003 and BS5489-1: 2003, Code of Practice for Design of Road Lighting. Lighting of Roads and Public Amenity Areas and shall comply with the requirements of the DMRB TD 34-91. The detailed lighting design shall be completed in a manner, which will minimise glare and will ensure that light-spill effect is minimised.	At Ballybrit/Parkmore, at Racecourse Avenue, Ballybrit Crescent, Monivea Road and Coolagh-Briarhill east of Galway
Specific Landscape Measures	In specific locations barriers and/or earth bunds may be provided to reduce the impact of noise. Such barriers will also have the effect of providing immediate visual screening of traffic from properties. Such features shall, wherever possible, be integrated within the proposed landscaping measures. The Noise and Vibration section below outlines the assessment of noise impact and the requirements for such mitigation.	

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
	Specific mitigation measures are set out on **Figures 12.4.01** to **12.4.14** and in **Table 12.8** of **Chapter 12, Landscape and Visual** which is summarised below. The measures include construction-related aspects such as avoidance/minimising impact on property boundaries and landscape features as well as provision of solid screen hoarding during the construction phase for those properties particularly impacted by the works. All of the following specific mitigation measures will be taken account of in the detailed design and implementation of landscape measures: • Location of cut-off drains at the top of cuttings and at the bottom of embankments • The location and requirements for maintenance access along the mainline of the proposed road development • Locations where rock is encountered in cuttings. Such rock faces may be retained as geological features of the corridor of the proposed road development • The location and integration of noise barriers within the landscape design • Clearance zones (TD19 - Safety Barrier Standards) • Sight-lines, including at junctions and to carriageway signage, etc. A series of significant retaining walls, and a bridge over the N59 Moycullen Road, are proposed in the Dangan area between Ch. 8+300 and Ch. 8+670. This is both an existing residential area and a gateway into the city. Where feasible reinforced earth retaining wall approaches will be incorporated so as allow for a green landscape finish to all or part of the retaining structures. A limestone finish will be used where structural walls are required and for the abutments of the proposed bridge over the N59 Moycullen Road. The stone will consist of natural limestone, matching the character of the local stone, with a strong horizontal axis of between 5 to 1 and 7 to 1 (*i.e.* horizontal to vertical dimension). Landscape Measures also take account of the specific protection and mitigation measures detailed in **Chapter 8, Biodiversity**. In particular, the measures include: • Retained habitats, trees and hedgerows on land-take boundaries, etc. will be fenced-off and protected during construction works • Specific measures are proposed at a number of locations for mitigation of potential impact on Bat species. This includes: o the provision of artificial bat roosts – with specific planting to encourage use o the provision of a planted wildlife overbridge (Ch. 12+700) with tie-in planting to local hedgerows and proposed planting on the boundary of the proposed road development, which will maximise potential benefit and use o dense planting, with trees for improvement of connectivity along the boundary of the proposed road development: o west of the crossing of the L1323 Letteragh (Ch. 7+200 – Ch. 7+280) o along embankments to either side of the proposed bridge over the River Corrib o between the crossing of the N84 Headford Road at Ballindooley and School Road at Castlegar o hedgerow planting for improvement of connectivity of habitats to the east of Menlo Castle o hedgerow and copse planting for enhancement of foraging habitat to the north of Menlo Castle • In order to deter Barn Owls from foraging close to the proposed road development, embankments and cuttings, other than rock cuttings or cut slopes left to naturally regenerate, will be densely planted with low growing scrub (e.g. blackthorn, hawthorn) from Ch. 8+550 to Ch. 17+500 • In order to deter Barn Owls from over flying the proposed road development, planting of closely-spaced trees (approx. 2m centres) greater than 3m in height will be established along the top of the embankments between Ch. 9+600 and Ch. 10+100 • All mitigation planting will take place at the earliest opportunity feasible during the construction stage so as to maximise establishment prior to road opening **Table 12.8, Specific Landscape and Visual Mitigation Elements and Treatments is outlined below**. • 6.0m wide Screen Planting: (Planting at 1.0m centres for visual screening shall be of a minimum of 6m in width. The planting shall extend for a minimum of 100m to either side of any adjoining residential property or amenity. (refer to **Figures 12.4.01** to **12.4.14**)). o Planting will include a dense planting at 1m centres of alder, birch, blackthorn, elder, geulder rose, holly, hawthorn, hazel, rowan, and willow species. Shrubs shall be planted at between 60 to 90cm in height. o Scots pine of minimum 60cm in height at planting shall comprise 20% of the overall plant numbers and holly at a minimum of 45cm in height shall comprise a further 15%. o Tree species, planted equally at half-standard (6-8cm girth) and standard size (8-10cm girth), shall comprise minimum 10% of the mix. • 3.0m wide Screen Planting: (Where space is limited planting at 1.0m centres for visual screening shall be of a minimum of 3m in width. The planting shall extend for a minimum of 100m to either side of any adjoining residential property or amenity. (refer to **Figures 12.4.01** to **12.4.14**)) o Planting will include a dense planting at 1m centres of alder, birch, blackthorn, elder, geulder rose, holly, hawthorn, hazel, rowan, and willow species. Shrubs shall be planted at between 60 to 90cm in height. o Scots pine of minimum 60cm in height at planting shall comprise 20% of the overall plant numbers and holly at a minimum of 45cm in height shall comprise a further 15%. o Tree species, planted equally at half-standard (6-8cm girth) and standard size (8-10cm girth), shall comprise minimum 20% of the mix. • Stone Wall Boundaries (Stone walls as indicated on **Figures 12.4.01** to **12.4.14**))	

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
	• Where indicated stone walls will be replaced along impacted sections of property and road boundaries on local roads. The stone from the disturbed sections of existing walls will be retained and re-used (generally granite to west; limestone to east) where possible to reinstate these new boundaries. The boundary walls may be backed by hedgerows of locally appropriate species, i.e. blackthorn, hawthorn and holly to west and hazel, hawthorn and holly to east. Elsewhere, where stone walls are removed the stone will be retained and made available for re-use by the adjacent property owners for the construction of a new stone wall on their side of the proposed development boundary if they wish. Boundary Hedgerow (Typical double staggered hedgerow with tree planting, where locally appropriate) ○ Primarily blackthorn (30%), hawthorn (40%) and holly (10%) hedgerow in west interspersed with other species (20%) such as elder, willow, and those found locally. ○ Primarily hazel (30%), hawthorn (40%) and holly (10%) hedgerow to east interspersed with other species (20%) such as blackthorn elder, willow, and those found locally. ○ Hawthorn plants shall be of c.90cm in height and planted at 50cm centres in each of two double staggered rows, 25cm apart. Other plants of c.50cm in height shall be interspersed. ○ The hedgerow may be interspersed with 'half-standard-sized' (6-8cm girth) alder, birch and/or oak trees planted at random spacings but averaging a min. of 1 tree per 25 linear metre. Limited tree species, such as birch and mountain ash may also be included as 'whips' at 150cm in height. • Retaining Walls and structure over the N59 Moycullen Road: (Use of reinforced earth retaining systems and limestone finishes for structural elements. Retaining Wall Structures R08/01; R08/02; R08/07 & R08/04; and Bridge Structure S08/02 (Ch. 8+300 to Ch. 8+670)) ○ Where feasible reinforced earth retaining wall approaches will be incorporated so as allow for a green landscape finish to all or part of the retaining structures. ○ Planting of trees shall also be provided along the base of the structure. These shall include smaller growing species such as alder, birch and rowan planted as Selected Standards (i.e. 14cm girth or greater) ○ A limestone finish will be used for the external finish of the abutments of the proposed bridge over the N59 Moycullen Road and where structural walls are required. The stone will consist of natural limestone, matching the character of local stone, with a strong horizontal axis of between 5 to 1 and 7 to 1 (i.e. horizontal to vertical dimension). • Bat habitat enhancement (New 2m wide tree and shrub hedgerow, with occasional planted copses located north and east of Menlo Castle.) ○ New hedgerow of native species will be established with plants at 0.5m staggered centres in each of 5 rows located 0.5m apart to sub-divide existing open fields. ○ Standard-sized trees species (min 8-10cm girth, 2.4m high) will be planted at 15m staggered centres in each of the 3 central rows. Diverse range of shrub species will be planted between trees in the central rows and throughout the outer 2 rows. ○ Circa 15m diameter woodland copses will be established within open fields using similar approach, densities and species. ○ Planting will be protected by stock-proof fence, c.1.25m high located at 1.0m offset to either side of the outer row of the new hedgerow. ○ Tree species to include alder, birch, oak, rowan, planted as standards (as above) and whips (1.25m high). Shrubs to comprise mainly blackthorn, hawthorn and hazel (combined 60%), with elder, holly, spindle, willow etc. ○ Hawthorn plants shall be of between c.90cm in height and all other shrubs shall be c.60cm in height. • Wildlife Overpass: (Ballindooley/Castlegar, Structure S12/02 (Ch. 12+700)) ○ Wildlife overpass (c.30m wide) will be landscaped to provide for connective habitat across proposed road development. Planting to consist of a central narrow grass path bounded on either side by tree-lined hedgerows of native species. ○ Soil depths to vary from minimum c.45cm depth at edges to c.1.5m depth along centre-line of both hedgerows. Planted element of both hedgerow lines will be c.2m wide with standard-sized trees (min 8-10cm girth, 2.4m high) planted at 3m staggered centres in each of 2 rows in each hedgerow. Diverse range of shrub species will be planted between trees and along the line of each hedgerow. ○ Planting to tie-in to proposed planting leading east and west on upper slopes of cuttings on both sides of the proposed road development. This will form a continuous hedgerow/planted network. ○ Tree species to include alder, birch, oak, rowan, planted as standards (as above) and whips (1.25m high). Shrubs to comprise mainly blackthorn, hawthorn and hazel (combined 60%), with elder, holly, spindle, willow etc. ○ Hawthorn plants shall be of between c.90cm in height and all other shrubs shall be c.60cm in height. • Barn Owl Tree Planting: (Typical double staggered treeline with dense underplanting, between Ch. 9+600 and Ch. 10+100. ○ Deterrent tree planting to comprise alder, birch and/or rowan planted at 3m in height (min 12-14cm girth) and at 2.0m centres in each of 2 rows 1.5m apart. ○ Dense low scrub planting to comprise blackthorn (50%), hawthorn (20%), hazel (10%) and holly (10%) hedgerow in west interspersed with other species (10%) such as elder, willow, and those found locally. ○ Hawthorn plants shall be of c.90cm in height and planted at 50cm centres. Blackthorn and other plants shall be of c.50cm in height and planted at 50cm centres in staggered rows, 50cm apart. • Barn Owl Scrub Planting (Dense low scrub planting on all embankments and cut slopes (other than rock cuttings or cut slopes left to naturally regenerate) from Ch. 8+550 to Ch. 17+540): ○ Dense low scrub planting to comprise blackthorn (50%), hawthorn (20%) hazel (10%) and holly (10%) interspersed with other species (10%) such as elder, willow, and those found locally.	

<table>
<tr><th>Source/Scale of Effect</th><th>Control and Mitigation</th><th>Significant Residual Impacts</th></tr>
<tr><td></td><td>Hawthorn plants shall be of c.90cm in height and planted at 50cm centres. Blackthorn and other plants shall be of c.50cm in height and planted at 50cm centres in staggered rows, 50cm apart.
Compensatory Habitat Areas: (CHA) Along Proposed Road Development: Refer to ‘CHA’ locations on Figures 12.4.01 to 12.4.14). Areas identified for compensatory habitat for mitigation of potential ecological impacts will be as outlined above for biodiversity</td><td></td></tr>
<tr><td colspan="3">Archaeology, Architectural and Cultural Heritage</td></tr>
<tr><td>General</td><td>The proposed mitigation measures for the operational phase are detailed below. These measures are proposed to mitigate the indirect impacts of the operational phase of the proposed road development on these features. It is noted that these measures will be carried out during or prior to the construction phase:
Archaeological sites, AH 15, 16, 29, 11, 12, 23 and 26 will be subject to a detailed photographic and written landscape record to preserve their current setting prior to the construction and operation of the proposed road development. This shall be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.
Protected structures, BH 1, 7, 9, 10 and 17 will be subject to a detailed photographic and written landscape record to preserve their current setting prior to the construction and operation of the proposed road development. This shall be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.
Cultural heritage sites CH 20, 23, 8, 25, 30, 35, 42 and 54 will be subject to a detailed photographic and written landscape record to preserve their current setting prior to the construction of the proposed road development. This shall be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.</td><td>Whilst the proposed mitigation measures will record the current context of those sites which will be indirectly impacted, they will not fully remove the residual impact of the proposed road development on the setting of the following sites:
AH 15/BH 19 Menlo Castle – post mitigation the operation of the proposed road development will have an indirect moderate negative impact on the castle
AH 16/BH 10 Summer House – post mitigation the operation of the proposed road development will have an indirect moderate negative impact on the castle</td></tr>
<tr><td colspan="3">Agriculture</td></tr>
<tr><td>Operational Road</td><td>The loss of agricultural land due to the construction of the proposed road development is a permanent loss which cannot be mitigated except through compensation.
Landowners who lose buildings to the proposed road development will be compensated. Compensation payments will enable farmers to replace buildings.
All separated land parcels will be accessible either via the local road network, via accommodation access roads and access tracks.
Where existing water and electricity supplies to fields or farm yards are severed, the supply will be reinstated by provision of ducting where possible. Alternatively, where ducting is not feasible a permanent alternative water source or electricity supply will be made available. Compensation payments will enable farmers to replace power and water supplies.
Landowners may have to build additional farm facilities (e.g. cattle holding and testing pens) on their separated land. Field boundaries and paddock systems may have to be re-organised to take into account the altered shape of fields. These matters are addressed in the compensation payments.
Water from the proposed road development will be diverted to attenuation ponds before discharging to watercourses or to ground. The drainage design of the proposed road development will intersect existing field drains and carry the drainage water to suitable outfalls.
Other injury impacts such as loss of shelter, removal of field boundaries, disruption of farm roads and field paddock systems and the increased potential for trespass on to private land due to the proposed road development are taken into account in this assessment. Statutory compensation will be used to compensate landowners for residual effects and to allow the landowners to execute mitigation measures and re-instatement works on their own land.
Landscaping along the proposed road development will minimise the visual impact on farms along the route of the proposed road development and will over time improve shelter in affected farms.</td><td>The 41 Significant, 8 very significant and 4 profound impacts will remain and will be dealt with as part of the land acquisition process and will be agreed at a later date with a valuer. Compensation does not form part of the EIA process and is therefore not considered further</td></tr>
<tr><td colspan="3">Material Assets Non Agriculture</td></tr>
<tr><td>Operational Road</td><td>The proposed road development will result in a 20 per cent reduction of the NUIG Sporting Campus at Dangan, due to the encumbrance caused by the viaduct support structures. This will result in the removal of two grass based GAA sized playing pitches.

As a consequence, the NUIG Sporting Campus will require a new sporting campus plan and strategy. The provision of a viaduct structure at the NUIG Sporting Campus will provide access to the north and south of the Sporting Campus and the River Corrib during the operational phase, maintaining connectivity and permeability beneath the proposed road development.
The current road which provides access to Hewlett Packard and Boston Scientific will become a through road at the operational phase of the proposed road development. The additional traffic will present new severance compared with the Do-Nothing scenario. However, a speed of 50kph will limit speeds and traffic will be generally for local access only.
The stable yard and associated facilities for Galway Racecourse will be relocated as shown on Figure 15.4.1 and detailed in Appendix A.15.2 mitigating the operational impacts on the racecourse.

Noise barriers will be provided across the length of the proposed road development to mitigate potential increase in noise as detailed in noise and vibration and shown on Figures 17.1.1 to 17.1.15.</td><td>The residual impacts from all of the very significant/significant impacts, 54 residential properties, eight commercial properties and one residential planning permission, which will be acquired and/or demolished to accommodate the proposed road development, remain as very significant/significant impacts as no mitigation is possible to reduce the impact. The residual impact post compensation cannot be assessed as the compensation to be agreed as part of the land acquisition are outside the scope of the EIA process.
The residual impact on NUIG Sporting Campus post compensation cannot be assessed as the compensation to be agreed as part of the land acquisition is outside the scope of the EIA process.
There will be a positive residual impact on Galway Racecourse once the mitigation measures have been</td></tr>
</table>

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
		constructed with the provision of enhanced access to the premises and a new stable yard.
Air and Climate Change		
Air Quality	As it is predicted that all air quality standards for the protection of human health and vegetation will be complied with, no specific mitigation measures are required.	No likely significant residual impact.
Climate	The *Transport Infrastructure Ireland Environmental Impact Assessment of National Road Schemes – A Practical Guide* notes that climate change issues are largely outside the scope of an EIAR for individual road schemes as the issues and mitigation measures are the subject of specific policies and strategies set out by government. However, it is anticipated that the proposed road development will assist with the removal of traffic congestion from within Galway City and its environs by transferring existing and future traffic from the existing road network to the new road infrastructure. Therefore, journey times will reduce and journey time certainty will increase for both public transport and private vehicle users. The reduction in traffic congestion will facilitate the reallocation of available road space for cyclists, pedestrians and reconfigure the public transport network. This will result in reducing the number of short commuter journeys by car by facilitating journeys by bicycle/on foot. The positive impact of this modal shift is difficult to quantify in terms of carbon emissions, however, it will help to reduce emissions. Improvements to the Galway bus network have been identified as necessary to better cater for existing and future travel patterns in Galway City. The reallocation of road space for public transport will assist with the delivery of an improved bus network resulting in carbon emission reductions. In addition, the provision of improved public transport, traffic management measures, cycling and walking facilities and the introduction of the ‘Cross-city Link’ by the GTS will encourage a modal shift in line with Smarter Travel - A Sustainable Transport Future, A New Transport Policy for Ireland 2009 – 2020. This shift has the potential to reduce greenhouse gas emissions associated with the proposed road development in the future. CO_2 emissions for the average new car fleet were reduced to 120g/km by 2012 through EU legislation on improvements in vehicle motor technology and by an increased use of biofuels. The National Mitigation Plan outlines a number of existing mitigation measures and future possible mitigation measures under consideration relating to road transport, as follows: Existing: • Taxation system where a lesser road tax is paid where CO_2 emissions are within lower bands • Grants provided by Sustainable Energy Authority Ireland (SEAI) to incentivise the purchase of electric vehicles • Deploy natural gas refuelling stations and gas injection facilities • Using intelligent transport systems (ITS) to enhance the efficiency of infrastructure and fuel use in a transport network Under consideration: • Further measures to accelerate the take-up of low carbon technologies • Increase in carbon tax on transport fuel • The motor tax and VRT system could be further amended in line with improvements to energy efficiency and emissions reductions in cars and vans to additionally incentivise or maintain the advantages of purchasing of the lowest emitting vehicles • encourage the take-up of alternatively fuelled vehicles, removing or reducing supports or preferential treatment for petrol and diesel fuelled vehicles • Reduce maximum speed limits on motorways to 110km/hr in order to reduce emissions. It is noted that the design speed for the proposed road development at 100km/hr is less than the 120km/hr that usually applies to motorway schemes	It is expected that potential carbon emissions generated by the proposed road development can be offset by measures outlined in the Galway Transport Strategy, removing congestion in Galway City and measures outlined in the National Mitigation Plan.
Noise and Vibration		
Operational Road	The mitigation measures required to reduce traffic noise levels are specified based on the predicted noise levels for the Design Year of 2039 and noise mitigation is required for 102 properties along the proposed route of the proposed road development for the Design Year. Low Noise Road Surface (LNRS) will be used to reduce noise generated at source. Noise barriers as detailed in **Table 17.14** in **Chapter 17, Noise and Vibration** and **Figures 17.1.01** to **17.1.14** will be implemented to reduce noise levels along the propagation path between the source (proposed road development) and the specific receivers (houses, schools, churches etc.). These screens may be constructed as earth bunds, proprietary noise barriers or a combination of both.	No likely significant residual impact.
Human Beings		
Socio-economics	**Socio-economics** The provision of crossing facilities at the Foraí Maola Road, Troscaigh Road, Bearna to Moycullen Road L1321, Cappagh Road and Ballymoneen Road junctions to facilitate occasional pedestrian and/or cyclist crossings of the proposed road development. Pedestrian crossing facilities are also proposed at the terminus of the N59 Link Road North Junction at the N59	**Socio-economics** There will be significant positive residual impacts (and in some cases profound) due to improvements in

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
	Moycullen Road (Bushypark Junction) and at the slip road connections with the N84 Headford Road Junction. Cycle lanes are proposed to facilitate access to the Miller's Lane pitches and Gort na Bró and at the N84 Headford Road Junction. The following specific mitigation measures are proposed to improve journey amenity and minimise severance: • Provide pedestrian crossing facilities at junctions with minor roads serving local rural communities • Provide pedestrian crossing facility at Bushypark Junction with N59 Link Road North during construction and operation • Provide pedestrian crossing facilities at N84 Headford Road Junction during construction and operation • Provide a footpath within the proposed development boundary along School Road, Castlegar • Provide directional signage for a Briarhill Business Park, including a car dealership located here during both the construction and operational phases The proposed road development will facilitate the full implementation of all of the walking, cycling and public transport measures set out in the GTS. The transference of traffic from the existing N6 through Galway City to the proposed road development will provide an opportunity for improved pedestrian and cycle paths and crossing facilities, including continuity at major junctions and a modal shift to alternatives to the private car. Improved walking and cycling journey amenity is contingent on these appropriate facilities being provided. When implemented, such facilities will provide a significant improvement to pedestrian and cyclist journey amenity combined with reduced severance. Material Assets Non-Agriculture above outlines the proposed mitigation measures for the NUIG Sporting Campus facilities and Galway Racecourse.	journey times and connectivity between locations to the east and west of Galway City. Slight residual impacts on tourism during the construction phase will be replaced by a very significant net positive impact due to the improved connectivity provided by the proposed road development and by improved access into Galway City. The transfer of traffic from existing highly congested routes on the existing N6 and other roads, for example, in Doughiska, represents a significant to profound positive impact on journey times and journey amenity of drivers, cyclists and pedestrians as well as on the general amenity of people living and working alongside these roads. A profound positive residual impact will apply to businesses operating from the Parkmore Business Park and other nearby commercial/industrial estates in terms of much improved access to the N83 Tuam Road and between this road and the N6. This positive impact applies also to the business Boston Scientific, although a degree of severance will be introduced between existing and proposed facilities which will be mitigated by vehicle and pedestrian crossing facilities.
Irish Language Human health	**Irish Language** Place names shall be cited in accordance with the relevant Place Name Order issued under the Official Languages Act 2003 **Human health** Mitigation measures proposed for the potential air quality, noise, water and soils are specified above in the respective sections. The implementation of these mitigation measures, emissions, including air and noise will be adequately controlled to ensure no adverse effect on human health.	**Irish Language** There will be positive residual impact on the Irish Language once the proposed road development is operational. **Human Health** **Health Protection** From a community perspective, overall the implementation of the mitigation measures will result in a residual slightly positive impact. Similarly, from a psychological health point of view overall from community perspective the impacts of the proposed road development are assessed as being positive. Again, there are individuals who may be adversely affected and principal among these are likely to be those whose homes are to be compulsorily acquired. The residual impact will be positive. **Health Improvements** There is the potential for a very significant opportunity for health improvements associated with the proposed road development. These include the potential for economic development as well as tourism which in

Source/Scale of Effect	Control and Mitigation	Significant Residual Impacts
		itself is associated with an improvement in health status. There is the potential for improvements in social health with a reduction in unemployment and particularly long-term unemployment. Such a potential if realised will bring with it benefits including reduced inequality in society. There is also potential for increased opportunity to exercise. There is the potential for reduced traffic accidents with a corresponding reduction in mortality and morbidity. Ease of access and egress has the potential to improve social interaction. It also will allow quicker and more reliable access for emergency services such as ambulances. The residual impact will be positive. **Improvement of Access to Services** There is potential for significant improvement in access to services. The benefits of this apply to both the residents of Galway City and beyond. The residual impact will be very positive.

20.4 Compensatory Measures

20.4.1 Human Beings

Compensation for the acquisition of property is to be agreed as part of the land acquisition and is outside the scope of the EIA process and therefore, not discussed any further in this chapter.

20.4.2 Biodiversity

Where there are significant residual biodiversity impacts as a result of the proposed road development, despite the mitigation measures proposed, compensatory measures are proposed to offset or reduce the predicted impacts[3]. These are not compensatory measures in the context of the requirements of Article 6(4) of the Habitats Directive as they are not compensating for an impact that would adversely affect the integrity of any European site. As concluded in the NIS, the proposed road development will not adversely affect the integrity of any European site.

Habitat loss

The areas of residual alluvial forest [*91E0], Dry heath [4030], Calcareous grassland [6210] and *Molinia* meadow [6410] that will be lost outside of any European site as a result of the proposed road development will be compensated for. In each case the area of each habitat type being provided is greater than that being lost.

The losses of Limestone pavement habitat (outside any European site), a Petrifying spring (outside any European site) and Wet heath habitat [4010] (outside any European site), associated with the proposed road development cannot be directly compensated. However, areas of related habitats will be created to provide a biodiversity gain for both peatland and limestone associated habitats locally. The area of Dry heath habitat being created is c.7.06ha which is greater than the combined losses associated with this habitat type and any Wet heath/*Molinia* meadow mosaics (c.4.78ha). The area of Calcareous grassland habitat being created is c.7.14ha which is greater than the combined losses of Limestone pavement and Calcareous grassland habitat combined (c.1.24ha).

The full details of the Habitat Compensation Management Plan for each of the Annex I habitat types being compensated for, including monitoring, are presented in **Appendix A.8.26**. The areas where compensatory habitats will be created are shown on **Figures 8.23.1** to **8.23.14**.

In compensating for the losses of these habitat types, the proposed road development is not likely to result in a significant residual effect, at any geographic scale, on Residual alluvial forest [*91E0], Dry heath [4030], Calcareous grassland [6210] or Molinia meadow [6410] post compensation measures.

---

[3] “Compensation describes measures taken to make up for residual effects resulting in the loss of, or permanent damage to ecological features despite mitigation” (CIEEM, 2016)

This is summarised below in **Table 20.3**.

There are a number of habitat types of a local biodiversity importance that will be permanently lost as a result of the proposed road development, and where significant residual negative effects are likely:

- Calcareous springs (FP1)
- Dry-humid acid grassland (GS3)
- Poor fen and flush (PF2)
- (Mixed) broadleaved woodland (WD1)
- Hedgerows (WL1)
- Treelines (WL2)

Of these, the planting proposed in the landscape design will compensate for the loss of the areas of (mixed) broadleaved woodland (WD1), hedgerows (WL1) and treelines (WL2) by providing the equivalent, or greater, area to that being permanently lost to the proposed road development, as follows:

- (Mixed) broadleaved woodland (WD1) - > 2.62ha
- Hedgerows (WL1) - > 7.8km
- Treelines (WL2) - > 4km

In compensating for the losses of these habitat types, the proposed road development is not likely to result in a significant residual effect, at any geographic scale, on (mixed) broadleaved woodland (WD1), hedgerows (WL1) and treelines (WL2).

However, the proposed road development is likely to have a significant residual negative effect, at the local geographic scale, as a result of the permanent loss of fifteen calcareous spring features (FP1), c.7.81ha of Dry-humid acid grassland (GS3) and c.0.13ha of poor fen and flush habitat (PF2).

Table 20.3: Summary of Residual Priority Annex I/Annex I habitat loss outside any European site after compensation

Annex I habitat type	Permanent Area of Habitat Loss	Area of Compensatory Habitat Created	Residual Habitat Loss	Residual Impact Significance Post-compensation
Petrifying springs [*7220]	One Petrifying spring feature	n/a	One Petrifying spring feature	Likely significant residual effect at the county geographic scale
Residual alluvial forest [*91E0]	c.0.1ha	c.0.18ha	None	No likely significant residual effect
Limestone pavement [*8240]	c.0.54ha	n/a	c.0.54ha	Likely significant residual effect at the international geographic scale
Wet heath [4010]	c.2.06ha	n/a	c.2.06ha	Likely significant residual effect at the national geographic scale
Dry heath [4030]	c.1.85ha	c.7.06ha	None	No likely significant residual effect
Wet heath/Dry heath/*Molinia* [4010/4030/6410]	c.0.87ha	n/a	c.0.87ha[4]	Likely significant residual effect at the national geographic scale
Calcareous grassland [6210]	c.0.7ha	c.7.14ha	None	No likely significant residual effect
Molinia meadow [6410]	c.0.28ha	c.0.49ha	None	No likely significant residual effect

Bats

Loss of the more "significant" roosts (e.g. maternity roosts or roosts used by Lesser horseshoe bats) will be compensated by the erection of replacement structures (artificial roosts) in locations close to the original roost.

[4] Assumed to be Wet heath, the loss of which cannot be directly compensated for.

There is a dual purpose to the artificial roosts. Firstly, to ensure that there is no net loss of roosting opportunities for the bats confirmed to be roosting within the proposed development boundary. Secondly, it has been recognised that there will be an inevitable increase in mortality rates due to road collisions as suggested by scientific evidence (see **Section 8.5.6.2.2**). So the second function of the replacement roosts is to create improved conditions for bats to breed and to offset the likely increase in mortality.

Four artificial roost structures are proposed at the following locations:

- Aughnacurra
- Menlo Castle
- Menlo Woods
- Ballindooley

The detailed fit-out of these artificial roosts will follow the recommendations of an experienced bat ecologist and further consultation with the Vincent Wildlife Trust will take place to ensure that their experiences in these techniques are taken into account and are detailed in **Chapter 8, Biodiversity**.

Artificial roost structures will be screened from the effects of construction phase disturbance by means of solid hoarding or brushwood screens with an appropriate buffer zone around the roost. The dimensions of the planting will depend on the local topography and surrounding landscape and will be decided on a case-by-case basis by the bat ecologist.

It should be noted that the mitigation strategy, outlined above in **Section 20.2**, has included ensuring that passage underneath the proposed road development in the vicinity of the roosts has been facilitated by including culverts underneath the proposed road development in locations as close to the roosts as possible.

<u>Retrofitting of Existing Structures</u>

At Ch. 12+960 the detached converted garage (next to PBR183) to the south of the proposed road development to be retained and converted for use by several species including Brown long-eared bats and Lesser horseshoe bats. This building is in a strategically-important location as it will connect to the linear planting on the south side of the proposed road development and is just c.250m from the proposed Castlegar Wildlife Overpass in and within a local ecological corridor leading to Cooper’s Cave, a proven hibernation and mating site for Lesser horseshoe bats. This structure will undergo minor interior and exterior modifications to create warm areas in the roof space for summer roosting and breeding and also cold conditions for hibernation. **Plate 8.9** in **Chapter 8, Biodiversity** shows this location.

<u>Bat Boxes</u>

Bat boxes will preferably be located near the roosts to be lost but not immediately adjacent to the proposed road development where risk of collision with vehicles is highest.

Bat boxes will be erected by, or under the supervision of, a bat specialist.

These bat boxes will target Common and Soprano pipistrelle bats and Brown long-eared bats and will consist of Schwegler Type 1FF and 2FN bat boxes (or equivalent) as these have been demonstrated as being successful for these species in Ireland[5]. Mounting boxes on poles close to the edge of tree canopies will also allow the long-term retention of the boxes, as opposed to mounting boxes on small trees which have limited longevity.

A rocket box (as shown in **Appendix A.8.25** - see Drawing GCOB-3000-D-002 in Annex F of the bat derogation licence application) will be installed at Ch. 3+320 near the roost at PBR241 (ref **Figure 8.21.1**) rather than a bat box fixed to the building itself so as not to detract from its cultural heritage value.

Box locations, as shown on **Figure 8.24.1** to **8.24.15**, will include the following:

- Ch. 3+320: Rocket box to be erected to west of the building PBR241
- Ch. 10+050: 5 boxes to be erected along the edge of the tree canopy near the underpass
- Ch. 11+400: 4 boxes to be erected on the entrance road into Lackagh Quarry
- Ch. 15+100: 4 bat boxes to be erected south of Galway Racecourse

In the case of bat boxes provided as replacements for bat tree roosts to be felled, boxes will be Schwegler Type 1F bat boxes (or equivalent) erected on suitable trees or structures retained within the proposed development boundary in the vicinity of the tree to be lost where possible. The type and siting of any bat boxes required will be determined by the bat specialist at that time but preliminary areas for bat boxes have been identified in the areas of woodland around Menlough, Coolagh, on retained structures and the quarry walls at Lackagh Quarry and in areas near attenuation and infiltration ponds.

All new roosts, retrofitted structures and bat boxes will be erected in advance of the commencement of site clearance so that replacement roosts are available to bats and that there is reasonable chance that they will have discovered them prior to loss of the existing roost. Boxes can be erected at any time of year and preferably as soon as the necessary consents are in place for the proposed road development.

<u>Protection of proposed artificial roosts during construction works</u>

- Newly created roosts and bat boxes within the proposed development boundary will be protected from the adverse effects of noise and lighting during the construction phase as it is an essential element of the mitigation strategy that they are accessible and usable by bats during this time
- All existing and proposed artificial roosts retained within the proposed development boundary will be surrounded with wooden panels to a height that allows shading and shelter of key roost access features
- Planting around the existing and proposed artificial roosts retained within the proposed road development will include fast growing shrub species, or fast-

[5] McAney K. and Hanniffy, R. (2015) *The Vincent Wildlife Trust's Irish Bat Box Schemes* http://www.mammals-in-ireland.ie/wp-content/uploads/2015/11/Ireland-Bat-Box-Project-Report-WEB.pdf

growing willow if the ground conditions permit. Planting will aim to guide bats away from the open construction zone toward linear features. Use of non-native species may be appropriate in some locations where it is important to get vegetation established

- All structures will be locked and not used for other purposes such as storage of materials or shelter without agreement from the Ecological Clerk of Works
- The maintenance of the existing and proposed artificial roosts retained within the proposed development boundary, in a state that they are accessible and usable by bats, will be carried out by the Contractor until the completion of the proposed road development whereby it will be taken in charge by the local authority. Maintenance will include standard building repairs over time and responding to the results of the roost monitoring (e.g. increasing or reducing humidity)

<u>Compensation for loss of foraging habitat</u>

Approximately 7ha of woodland-pasture-hedgerow-scrub habitat will be removed from the area between the River Corrib and An Bóthar Nua in Menlough. This habitat is used by the Lesser horseshoe bat population and therefore there is a risk that there may be reduced breeding success if replacement planting is not made available.

An area of land has been identified which is within the known core foraging area of the Menlo Castle roost (PBR06) but is not optimal feeding habitat. It is composed of open fields of varying size used for low density cattle grazing. Hedgerows in this area will be augmented and thickets of hazel, hawthorn, holly and oak will be provided in several of the fields to create pockets of wood and grassland habitat. Grazing will continue on the lands as it has been shown that foraging over grazed land is preferred to ungrazed lands (Downes et al, 2016).

Connectivity to foraging areas will also be secured through tying the proposed planting strips to hedgerows and woodland edges.

Planting of new hedgerows in fields between the proposed road development and Menlo Castle will improve the foraging resources of this core foraging area. Such planting will include additional native hedgerows planted across the existing fields to increase the lengths of hedgerows close to the proposed new roost for Lesser horseshoe bats (refer to **Section 8.6.7.2**). The fields will still be grazed and the hedgerows can be fitted with field gates as required providing gaps are kept to a minimum.

The area of habitat enhancement for the purposes of offsetting the loss of suitable bat habitat due to the proposed road development amounts to approximately 8ha. (refer to **Figure 8.24.7**).

The monitoring programme for bats outlined in **Tables 20.1** and **20.2** above also relates to the compensation measures for bats described in this section.

Summary

The proposed road development, despite the implementation of the mitigation and compensation measures proposed, will have the following likely significant residual effects on biodiversity:

- A likely significant residual effect, at the international geographic scale, for the permanent loss of c.0.54ha of the priority Annex I habitat Limestone pavement [*8240]
- A likely significant residual effect, at the national geographic scale, for the permanent loss of c.2.93ha of the Annex I habitat Wet heath [4010][6]
- A likely significant residual effect, at the county geographic scale, for the permanent loss of a Petrifying spring [*7220] feature at Lackagh Quarry
- A likely significant residual effect, at the county geographic scale, for the potential permanent loss of a Peregrine falcon nest site at Lackagh Quarry
- A likely significant residual effect, at the local geographic scale, on all bat species due to the presence of the proposed road development within their foraging areas
- A likely significant residual effect, at the local geographic scale, for the permanent loss of 15 calcareous springs (FP1) at Lackagh Quarry, c.7.81ha of Dry-humid acid grassland (GS3) and c.0.13ha of Poor fen and flush habitat (PF2)

These significant residual impacts will also affect the following local biodiversity areas:

- Coast Road (R336) to the N59 Moycullen Road local biodiversity area

  Residual impact at the national geographic scale for the loss of Wet heath [4010] habitat

  Residual impact at the local geographic scale for the loss of Dry-humid acid grassland (GS3) and Poor fen and flush habitat (PF2) along with impacts on bat species present here

- River Corrib and the Coolagh Lakes local biodiversity area

  Residual impact at the local geographic scale due to impacts on bat species present here

- Menlough to Coolough Hill local biodiversity area

  Residual impact at the international geographic scale for the loss of Limestone pavement [*8240] habitat

  Residual impact at the county geographic scale for the loss of Petrifying springs [*7220] and impact on the Peregrine falcon

[6] As noted in **Table 8.40**, this is comprised c.2.09ha of Wet heath dominated habitat and an additional c.0.82ha of habitat mosaic which contains Wet heath.

Residual impact at the local geographic scale from the loss of Calcareous springs (FP1) and along with impacts on bat species present here

- Ballindooley – Castlegar local biodiversity area

  Residual impact at the local geographic scale due to impacts on bat species present here

- Doughiska local biodiversity area

  Residual impact at the international geographic scale for the loss of Limestone pavement [*8240] habitat

  Residual impact at the local geographic scale due to impacts on bat species present here

Although the significant residual effects associated with the losses of Limestone pavement and Wet heath habitat cannot be directly compensated for, areas of related habitats will be created to provide an overall biodiversity gain for both peatland and limestone associated habitats locally. The area of Dry heath habitat being provided is c.7.06ha which is greater than the combined losses of all peatland habitats combined (c.4.78ha). The area of Calcareous grassland habitat being provided is c.7.14ha which is greater than the combined losses of Limestone pavement and Calcareous grassland habitat combined (c.1.24ha).

20.5 Overview

Galway City and its environs have critical transport issues that require urgent resolution. There are however significant constraints for developing new transport infrastructure for Galway given (i) the physical form of the city, (ii) the limited space available, (iii) the built environment and residential areas on both sides of the River Corrib, and (iv) the presence of designated ecological sites.

Given these constraints the proposed road development will result in significant residual impacts as outlined above in this chapter. However, this must be viewed and balanced in the context of the overall benefit that the proposed road development will deliver, described above and in **Chapter 3, Need for the Proposed Road Development**.

Numerous alternatives have been considered which are more damaging in terms of property demolitions and other potential environmental impacts in comparison to the proposed road development. However, there are very significant/significant residual impacts remaining including but not limited to the demolition of 44 residential properties and the further acquisition of 10 residential properties, demolition of four commercial properties and the further acquisition of one commercial property and acquisition of one residential planning permission and a significant residual impact to NUIG Sporting Campus.

The proposed road development is a key element of the Galway Transport Strategy and represents the best solution to the transport issues described in **Chapter 3, Need for the Proposed Road Development** and supports more sustainable travel for the following reasons:

- It will provide a **strategic route** across the River Corrib without the need to go through the city
- This strategic route will be of a **high standard** cross-section and will provide the **capacity required for the strategic traffic** serving the city and connecting the county to the national network
- Improves **connectivity to the Western Region** i.e. the county areas and hinterland beyond the city zone
- Moreover, access to this strategic route is limited to the junctions which will **protect the road asset in the future** and means that its **capacity is secure**
- This route is of European importance given that the **TEN-T comprehensive network designation** extends west of the city to the terminus of proposed road development and will provide a link to the Western Region of the standard of a comprehensive route in accordance with TEN-T
- This route provides connections to **essential city links** to better distribute traffic
- By **tackling the city's congestion issues**, it will provide a **better quality of life** for the city's inhabitants and provide a much **safer environment** in which to live
- By **reducing the number of cars** on the roads within the city centre and improving streetscapes, workers and students are facilitated to commute using **multi-modal transport means**. This includes travelling on foot, by bicycle and on the public transport system
- Provides connectivity to the national roads via junctions to maximise the transfer of cross-city movements to the new road infrastructure, thus **releasing and freeing the existing city centre zone from congestion** caused by traffic trying to access a city centre bridge to cross the River Corrib
- Attracts traffic from the city centre zone thus facilitating reallocation of road space to public transport leading to **improved journey time reliability for public transport**
- **Caters for the strong demand** between zones on either side of the city
- Provides additional river crossing with **connectivity back to the city** either side of the bridge crossing
- Facilitates **improved city centre environment** for all due to reduced congestion, thus **encouraging walking and cycling** as safe transport modes

The N6 Galway City Ring Road is the optimum transport solution and is consistent with proper planning and sustainable development and this view is supported /validated by the inclusion of policy support for both GTS and constituent measures, including the N6 Galway City Ring Road, in the relevant Galway Development Plans.

21 Schedule of Environmental Commitments

This chapter of the EIAR collates all of the design and mitigation measures (referred to in this chapter as Environmental Commitments) to be implemented during the construction of the proposed N6 Galway City Ring Road, here after referred to as the proposed road development, to reduce/avoid as far as practical significant impacts on the receiving environment.

The following environmental commitments are an integral element of the application for Approval. Further work will develop the design of the proposed road development in a manner such that there is no material change in terms of significant adverse effects on the environment. Opportunities may be identified to further reduce the significance of adverse impact and, in some cases, improve the residual impact. In this way the design measures, mitigation strategies, objectives and implementation measures set out below may be refined so to provide the optimum solution based on available construction techniques and technologies at the time of construction.

Best practice and good construction practice when referred to in this document refer to measures contained in modern guidance documents which set out the practice and procedures for environmental protection during construction and operational phases of a road project.

Where Legislation, Standards or Guidance Documents are referred to it should be noted that at the time of construction or operation of the proposed road development any amendments to these documents are applicable.

This section provides a summary of the main commitments under each of the environmental headings listed. Full details of the various commitments should be obtained by reference to the individual chapters of the EIAR as a whole.

In the following tables "C" denotes a commitment which refers mainly to the construction phase and "O" denotes a commitment which refers mainly to the operational phase of the proposed road development.

21.1 General

Ref No.	Stage	Commitments
1.1	C	Contract documents will include a requirement for the Contractor to update and finalise the Construction Environmental Management Plan (CEMP) (**Appendix A.7.5**) for the proposed road development prior to construction once appointed and to implement and maintain it during the construction phase.
1.2	C	The final Schedule of Environmental Commitments will be included in the CEMP. The CEMP will detail implementation methodologies for all environmental commitments.
1.3	C	There will be a contract management team appointed by the client on site for the duration of the construction phase. The team will supervise the construction of the works including monitoring the Contractor's performance to ensure that the proposed construction phase environmental commitments are implemented and that construction impacts and nuisance are minimised.
1.4	C	The construction management team will liaise with neighbours and the general community during the construction phase to ensure that any disturbance is kept to a minimum.
1.5	C	The Contractor's team will include a Senior Environmental Manager (SEM) who will be responsible for implementation of the Construction Environmental Management Plan (CEMP) during construction. The SEM will draw up a schedule of monitoring required, listing the type of report expected and detailing to who the reports should be sent, etc. It is the responsibility of the SEM to ensure that all monitoring is carried out by competent persons. Where the monitoring results fall outside the range contractually required, the SEM is responsible for initiating and reporting on corrective action. This may require the alteration of relevant Environmental Control Measures. The SEM will provide a briefing for all of the Contractor's senior management including the Project Manager, Programme Manager, Construction Manager, Design Engineers, Structures Agents and Site Agents on the CEMP and the Environmental Commitments/Requirements that must be met during the construction phase. The Employer's Site Monitoring Team will be monitoring compliance with the CEMP.
1.6	C	Pollution control measures will be installed upstream of each outfall from the proposed road development. These measures will include an appropriate combination of filter drains, attenuation ponds, swales, petrol and oil interceptors, wetlands and infiltration trenches/ponds (ref **Chapter 5, Description of the Proposed Road Development**).
1.7	C	When the proposed road development is in cutting or on embankment less than 1.5m high, combined filter drains will be provided. Where the proposed road development is on embankment between 1.5m and 6.0m, carriageway runoff will be picked up in surface water channels alongside the carriageway.
1.8	C	Where filter drains and swales cannot be used, alternative forms of vegetated pollution control will be employed prior to outfalling to surface waters such as treatment wetlands.
1.9	C	Treatment wetlands will have a permanent pool of minimum depth and a volume to cater for the first flush rainfall event.
1.10	C	In areas of extreme or high vulnerability groundwater areas or karstified areas, sealed drainage systems will be used.

Ref No.	Stage	Commitments
1.11	C	Flow restriction and attenuation storage measures will be provided at each surface water outfall from the mainline and link roads of the proposed road development.
1.12	C	Attenuation ponds will cater for storm events up to the 1 in 100-year storm period event. An overflow discharge facility will be provided for storm events in excess of 1 in 100-year return periods.
1.13	C	Petrol/Oil Interceptors will be employed at every outfall from the mainline and link roads of the proposed road development.
1.14	C	A minimum emergency spillage containment volume of 25m^3 will be provided at all outfall locations from the mainline of the proposed road development as per DN-DNG-03022.
1.15	C	Side roads (regional, local and minor access roads) with kerbs will be drained using gullies with carrier drains or combined filter/carrier drains. Piped drains will discharge to an outfall, a sealed drain, sufficiently sized existing drainage systems, a ditch, a swale or to the mainline drainage system. Where topography and surface watercourse conditions dictate, a soakaway or infiltration trench/basin may be required.
1.16	C	Side roads that do not require kerbs will be drained using either over-the-edge drainage or combined filter drains. The surface water will discharge to a sufficiently sized existing drainage system, an outfall, a sealed drain, a ditch, a swale or to the mainline drainage system.
1.17	C	Access will be provided to all elements of the drainage system including the spillage containment facilities, the pollution control and the attenuation ponds.
1.18	C	Throughout the course of the construction of the proposed road development, on-going visual inspections and monitoring of the haul routes along public roads will be undertaken to ensure any damage caused by construction traffic is recorded and that the relevant local authority is notified. Arrangements will be made to repair any such damage to an appropriate standard in a timely manner such that any disruption is minimised. Upon completion of the construction of the proposed road development, the surveys carried out at pre-construction phase shall be repeated and a comparison of the pre and post construction surveys carried out to determine any sites requiring remediation work post construction.
1.19	C	All project staff and material suppliers will be required to adhere to the Construction Traffic Management Plan (CTMP). As outlined within the CTMP, the Contractor shall agree and implement monitoring measures to confirm the effectiveness of the CTMP and compliance will be monitored by the resident engineer on behalf of the client. Regular inspections/spot checks will also be carried out to ensure that all project staff and material supplies follow the agreed measures adopted in the CTMP.
1.20	C	Any structural damage caused to buildings/structures/wells as a result of the construction will undergo a full stabilisation and rehabilitation works.
1.21	C	The following are the measures that will be taken to ensure that the construction site and surroundings are maintained to a high standard of cleanliness: Daily inspections will be undertaken to monitor tidiness. A regular program of site tidying will be established to ensure a safe and orderly site. If necessary, scaffolding will have debris netting attached to prevent materials and equipment being scattered by the wind.

Ref No.	Stage	Commitments
		Food waste will be strictly controlled on all parts of the site. Wheel wash facilities will be provided for vehicles exiting the construction site. Wheel wash run off will be stored in an onsite storage tank and will be disposed of by permitted waste haulage company at a permitted or licensed facility. In the unlikely event that mud is carried from the construction site to the public road, it will be cleaned as required and will not be allowed to accumulate. Loaded lorries and skips will be covered if required. Surrounding roads used by trucks for access to and egress from the site will be inspected regularly and cleaned, using an approved mechanical road sweeper, when required. In the event of any fugitive solid waste escaping the site, it will be collected immediately and removed to storage on site, and subsequently disposed of in the normal manner.

21.2 Waste

Ref No.	Stage	Commitments
7.1	C	Waste generated during the construction phase will be carefully managed according to the accepted waste hierarchy which gives precedence to prevention, minimisation, reuse and recycling over disposal with energy recovery and finally disposal to landfill.
7.2	C	The waste hierarchy will be implemented by identifying opportunities to firstly prevent waste from being produced, and secondly minimise the amount of waste produced.
7.3	C	Where prevention and minimisation will not be feasible, ways to reuse or recycle waste will be sought, preferably on-site to avoid the impacts arising from transportation. If this is not feasible, opportunities to reuse or recycle the waste off-site will be investigated or waste will be sent to an energy recovery facility, and only where there is no alternative, will waste be disposed of to landfill.
7.4	C	All waste removed from the site will be collected only by Contractors with valid waste collection permits, under the Waste Management (Facility Permit and Registration) Regulations 2007 and (Amendment) Regulations 2008, 2014, 2015. All facilities to which waste will be taken will have appropriate waste licences or permits, under the Waste Management Acts 1996 - 2011, and the regulations thereunder, allowing them to accept the type of waste that is to be sent there.
7.5	C	Hazardous waste generation will be minimised, and such waste will be recovered where feasible, and only disposed of if recovery is not feasible. Hazardous waste will be managed in accordance with the relevant legislation.
7.6	C	All wastes from the construction of the proposed road development will be delivered to authorised waste facilities in accordance with the Waste Management Acts 1996-2011. By only using facilities with the appropriate waste permits/licence, Galway County Council will be satisfied that the Contractor will comply with the objectives of the Waste Management Act and that any environmental emissions (noise, dust, water) are managed at the destination site and therefore are legally the responsibility of the

Ref No.	Stage	Commitments
		owner/operator of the destination site. In this manner Galway County Council can be satisfied that the off-site spoil management aspect of the development is legally compliant with environmental and waste management legislation.
7.7	C	In general, construction waste materials may include general construction debris, scrap timber and steel, machinery oils and chemical cleaning solutions. The practice of excessive purchase of materials and equipment to allow for anticipated wastage will be avoided.
		The Construction and Demolition Waste Co-Ordinator will arrange for a waste audit of the proposed road development once construction has fully commenced on site and of any facilities to which waste from the proposed road development is delivered as required. The Employer will receive summaries of any audit reports which will be completed within three months of the end of each calendar year. The effectiveness and accuracy of the documentation will be monitored on a regular basis via routine site visits.
7.8	O	Operational waste will be delivered to authorised waste facilities in accordance with the Waste Management Acts 1996 to 2016.
		Following construction, the Non-native Invasive Species Management Plan will be updated for the operational phase, taking into account the results of the detailed construction non-native invasive species management plan and operational maintenance requirements. Follow on treatment methods such as chemical treatment may be employed if specified in the requirements for ongoing control.

21.3 Human Beings, Population and Health

Ref No.	Stage	Commitments
18.1	C/O	Provide pedestrian crossing facilities at junctions with minor roads serving local rural communities.
18.2	C	Provide temporary visual screening from construction works at St. James' Church cemetery in Bushypark and at St. James' School, Bushypark.
18.3	C/O	Provide pedestrian crossing facility at Bushypark Junction with N59 Link Road North during construction and operation
18.4	C	Avoid any prolonged severance and minimise duration of use by construction traffic of An Seanbóthar.
18.5	C	Provide for alternative access along the bank of the River Corrib, along with prior advice for walkers, if access restrictions apply due to construction of the overhead bridge crossing.
18.6	C	Phase construction works to minimise impacts on racing events at Galway Racecourse.
18.7	C	Provide directional signage for access to car dealership and An Post sorting centre on N83 during construction.
18.8	C/O	Provide pedestrian crossing facilities at N84 Headford Road Junction during construction and operation.
18.9	C/O	Provide a footpath within the proposed development boundary along School Road, Castlegar.

Ref No.	Stage	Commitments
18.10	C	Provide directional signage for a Briarhill Business Park, including a car dealership located here during both the construction.
18.11	C/O	Take measures to ensure that cul-de-sacs or adjacent lands are not used for illegal parking in the operational phase.
18.12	C	During construction, all public notifications and all public project updates are provided in both Irish and English languages.
18.13	C	While it is expected that day-to-day communications involved in the construction of the proposed road development will be through the English language, the Contractor shall have the capacity to communicate and correspond through the use of the Irish language and to devote adequate and proportionate staff resources to dealing with any individual wishing to correspond and communicate through the Irish language.
18.14	O	Placenames shall be cited in accordance with the relevant Placename Order issued under the Official Languages Act 2003.

21.4 Material Assets Non-Agriculture

Ref No.	Stage	Commitments
15.1	C	In the event of an approval of the Protected Road Scheme and Motorway Scheme and approval under Section 51 of the Roads Act 1993 (as amended), by An Bord Pleanála and subject to the availability of funding, Notice to Treat will be served firstly on owners, lessees and occupiers of the dwelling houses and commercial properties to be acquired, within six months of the scheme becoming operative, unless an application has been made for Judicial Review, in which case the Notice to Treat will be served in accordance with the provisions of Section 217 (6A) of the Planning and Development Act 2000 as inserted by the Compulsory Purchase Orders (Extension of Time Limits) Act 2010. Compensation will be agreed or determined by the property arbitrator as soon as possible after service of Notice to Treat. After compensation has been agreed or determined and satisfactory title has been produced, part payment can be made while the claimant remains for an agreed period in the property to be acquired. This will facilitate the claimant in removing uncertainty and will facilitate arrangements being made, as early as possible, to secure a replacement property.
15.2	C	Where existing access to property is affected, this will be reinstated or an alternative access provided.
15.3	C	Where the infrastructure for service providers is impacted, this will be diverted or reinstated in accordance with service providers' requirements prior to construction.
15.4	C	During construction, restricted access across the construction area at the NUIG Sporting Campus facilities will be maintained.

Ref No.	Stage	Commitments
15.5	C	Alternative pitch facilities will be provided to replace the existing pitches directly impacted by the proposed road development. The facilities include a floodlit 3G GAA pitch and a floodlit 3G training area and associated site infrastructure for the drainage of these pitches and furniture such as ball-stop netting. The proposed road development also intercepts the existing sports pavilion resulting in direct impacts to its western end and the building will be modified as follows: • The existing western plant room, 1 no. changing room, 1 no. storage area, 1 no. weights area and associated access hallways on both ground floor and upper levels will be demolished. • The western plant room and its associated plant will be relocated. • Construction and reconfiguration of the internal and external walls, roof, windows and door locations.
15.6	C	During the construction of the River Corrib Bridge, alternative access to that along the bank of the River Corrib will be provided.
15.7	C	Temporary stables will be provided for Galway Racecourse during the construction of the proposed road development until such time as the Galway Racecourse Tunnel is complete and the permanent stables and associated facilities are constructed.
15.8	C	Mitigation measures as detailed in individual accommodation works agreements, such as boundary treatment, domestic entrances, property condition surveys (as outlined below for Noise and Vibration), provision of ducting to facilitate services, maintenance of access during construction amongst other items will remove impacts related to the properties with partial landtake.
15.9	C	Where the infrastructure for service providers is impacted, this will be diverted or reinstated in accordance with service providers' requirements prior to construction. Service users will be notified in advance of any temporary disruption or outages necessitated by the construction works. The disruption to services or outages will be carefully planned so the duration is minimised.
15.10	C	Public water supply and foul water systems affected will be reconnected. All necessary diversions will be carried out in accordance with the local authority and Irish Water's requirements. Where private potable water supplies are impacted, a new well or alternative water supply or financial compensation for the loss of the well will be provided.

21.5 Material Assets – Agriculture

Ref No.	Stage	Commitments
14.1	C	The landowner will be provided with access to all separated land parcels during the construction of the proposed road development. Where temporary disruptions to this access occur landowners will be notified in advance.
14.2	C	Where existing water and electricity supplies are disrupted during the construction phase an alternative water source or electricity supply will be made available e.g. water tanker or electric cable ducting. If access to surface drinking water sources are permanently restricted alternative groundwater supplies will be provided (or compensation to allow farmer drill his own well).
14.3	C	Suitable boundary fencing will be erected to delineate the line of the proposed development boundary and prevent disturbance to adjacent land.
14.4	C	A key contact person will be appointed during the construction phase to facilitate communications between affected landowners and to facilitate the re-organisation of farm enterprises by farmers during critical times.
14.5	C	Landowners with lands adjoining sites where either rock breaking, blasting or piling takes place will be notified in advance of these activities.
14.6	C	The impacts on water quality will be minimised by way of a programme of environmental commitments for surface and ground water sources as described in Hydrogeology and Hydrology sections.
14.7	C	The spread of dust onto adjoining lands will be minimised by way of environmental commitments set out in the air section. Typically, the impact of dust on agricultural grazing livestock is not significant.
14.8	C	Where drainage outfalls are temporarily altered or land drains blocked or damaged an adequate drainage outfall will be maintained and land drains will be repaired.
14.9	O	All separated land parcels will be accessible either via the local road network, via accommodation access roads and access tracks.
14.10	O	Where existing water and electricity supplies to fields or farm yards are severed, the supply will be reinstated by provision of ducting where possible. Alternatively, where ducting is not feasible a permanent alternative water source or electricity supply will be made available. Compensation payments will enable farmers to replace power and water supplies.
14.11	O	Water from the proposed road development will be diverted to attenuation ponds before discharging to watercourses or to ground. The drainage design of the proposed road development will intersect existing field drains and carry the drainage water to suitable outfalls.
14.12	O	Landscaping along the proposed road development will minimise the visual impact on farms along the route of the proposed road development and will over time improve shelter in affected farms.

21.6 Air Quality and Climate

Ref No.	Stage	Commitments
16.1	C	The assessment of potential construction impacts contained in **Section 16.5.3** of **Chapter 16, Air Quality and Climate** includes the implementation of ‘standard mitigation’, as stated in the TII Guidelines. This shall include the following measures: • Spraying of exposed earthwork activities and site haul roads during dry weather. • Provision of wheel washes at exit points. • Control of vehicle speeds and speed restrictions. It is proposed that site traffic is restricted to 20km/hr. This will help to minimise the occurrence of dust re-suspension. • Sweeping of hard surface roads.
16.2	C	The following measures will be implemented. These measures are based on best practice as outlined in the British Research Establishment (BRE) document ‘Controlling particles, vapour and noise pollution from construction sites’ and the Institute of Air Quality Management (IAQM) ‘Guidance on the assessment of dust from demolition and construction’, 2016. • A public communication strategy will be implemented by the Contractor which will outline procedures to inform members of the community on activities that may be disruptive, further details are contained in the CEMP in **Appendix A.7.5**. This appendix also includes details of a complaints register which will be implemented during the construction phase. • Exhaust emissions from vehicles operating within the site, including trucks, excavators, diesel generators or other plant equipment, will be controlled by the Contractor through regular servicing of machinery. • During dry periods when dust generation is likely or during windy periods, construction areas and vehicles delivering material with dust forming potential will also be sprayed with water, as appropriate. • Areas where materials will be handled and stockpiled will be positioned away from main site access roads. These areas will also be designed to minimise their exposure to wind – all stockpiles shall be kept to the minimum practicable height with gentle slopes. • There shall be no long-term stockpiling on site and storage time will be minimised. • Material drop heights from plant to plant or from plant to stockpile will be minimised. • Water suppression will be used during the demolition of buildings. • Crushing and concrete batching plant will be located as far from sensitive receptors as is reasonably practicable. All storage bins and transfer points will be covered. Silos will be fitted with reverse jet air filters.
16.3	C	Dust screens will be implemented at locations where there is the potential for air quality impacts during the construction phase at locations where sensitive receptors are located within 100m of the works. In addition, a 2m dust screen will be provided at the locations in the areas of the overlap of the proposed road development and the Lough Corrib cSAC and where the proposed road development is adjacent to Moycullen Bogs NHA.
16.4	C	Staff training and the vigilant management of operations ensure that all dust suppression methods are implemented and continuously inspected.

Ref No.	Stage	Commitments
		Further details on employee training are provided in the CEMP in **Appendix A.7.5**.
16.5	C	Dust deposition and PM_{10}/$PM_{2.5}$ will be carried out to confirm the effectiveness of the environmental commitments.
16.6	C	Dust deposition monitoring will be conducted at a number of locations in the vicinity of the proposed road development. At a minimum, monitoring will be carried out at the two nearest sensitive receptors at locations where works of a 'major' scale is proposed while works are taking place in proximity. Monitoring will be carried out using the Bergerhoff method, i.e. analysis of dust collecting jars left on-site (German Standard VDI 2119, 1972). Results will be compared to the TA Luft guidelines. Should an exceedance of the TA Luft limit occur during the construction phase or a complaint be received in relation to dust levels, additional environmental commitments, for example more regular spraying of water, will be implemented. At least one month of dust deposition monitoring will be carried out in advance of the commencement of works to determine a baseline.
16.7	C	It is proposed to carry out particulate monitoring (PM_{10} and $PM_{2.5}$) at the nearest sensitive receptors upwind and downwind of the construction works where sensitive receptors have been identified within 25m of the works. This monitoring programme will take place when works likely to generate dust are being carried out. The monitoring will allow direct comparison with the PM_{10} and $PM_{2.5}$ air quality standards on a daily basis.
16.8	C	The particulate and dust deposition limits will be used to determine potential occurrences of dust nuisance associated with the proposed construction works. Should the particulate and dust deposition limit values be approaching an exceedance during the construction works, the levels will be recorded by the Contractor. An investigation will subsequently be carried out to determine potential causes and the options available to reduce the level of dust.
16.9	C	All potential causes for the high dust levels will be analysed. These will include the construction works taking place, potential off site sources and meteorological conditions. Should the construction works taking place be identified as the primary cause of the high level, the Contractor will ensure that the environmental commitments listed above are improved upon. Should high dust levels continue to occur following these improvements, the Contractor will provide alternative environmental commitments and/or will modify the construction works taking place.
16.10	C	The following environmental commitments will be implemented during the construction phase of the development so as to minimise CO_2 emissions: • Materials required for the construction works will be sourced locally where possible. There are operational quarries located in proximity to the proposed road development. Rock crushing will be undertaken on site where possible, to reduce the requirement to import crushed stone to site. • The Construction Traffic Management Plan outlined in the CEMP in **Appendix A.7.5** will be implemented in full. This will minimise congestion and encourage car sharing and the use of public transport. • Materials will be handled efficiently on site to minimise the waiting time for loading and unloading, thereby reducing potential emissions. • Engines will be turned off when machinery is not in use.

Ref No.	Stage	Commitments
		• The regular maintenance of plant and equipment will be carried out. • Materials with a reduced environmental impact will be used where available, such as: Ground Granulated Blast Furnace Slag (GGBS) and Pulverished Fly Ash (PFA) will be used as replacements for Portland cements and Recycled steel.
16.11	C	The Contractor will be required to implement an Energy Management System for the duration of the works. This will include the following at a minimum: • Use of thermostatic controls on all heating systems in site buildings. • The use of insulated temporary building structures. • The use of low energy equipment and power saving functions on all computer systems. • The use of low flow tap fittings and showers. • The use of solar/thermal power to heat water for the on-site welfare facilities including sinks and showers.

21.7 Noise and Vibration

Ref No.	Stage	Commitments
17.1	C	The Contractor undertaking the construction of the works will be obliged to take specific noise abatement measures and comply with the recommendations of BS 5228-1:2009+A1:2014 Code of Practice for Noise and Vibration Control on Construction and Open Sites - Noise and the European Communities (Noise Emission by Equipment for Use Outdoors) Regulations, 2001. These measures will ensure that: • No plant used on site will be permitted to cause an ongoing public nuisance due to noise. • The best means practicable, including proper maintenance of plant, will be employed to minimise the noise produced by on site operations. • All vehicles and mechanical plant will be fitted with effective exhaust silencers and maintained in good working order for the duration of the contract. • Compressors will be attenuated models fitted with properly lined and sealed acoustic covers which will be kept closed whenever the machines are in use and all ancillary pneumatic tools shall be fitted with suitable silencers. • Machinery that is used intermittently will be shut down or throttled back to a minimum during periods when not in use. • Any plant, such as generators or pumps that is required to operate before 07:00hrs or after 19:00hrs will be surrounded by an acoustic enclosure or portable screen. • During the course of the construction programme, the Contractor will be required to manage the works to comply with the limits detailed in Table 17.1 using methods outlined in BS 5228-1:2009+A1 2011. Part 1 – Noise.
17.2	C	The Contractor will be required to conduct construction noise predictions prior to works taking place and put in place the most appropriate noise control measures depending on the level of noise reduction required at any one location.

Ref No.	Stage	Commitments
17.3	C	The potential for any item of plant to generate noise will be assessed prior to the item being brought onto the site. The least noisy item of plant will be selected wherever possible. Should a particular item of plant already on the site be found to generate high noise levels, the first action will be to identify whether or not said item can be replaced with a quieter alternative.
17.4	C	For static plant such as compressors and generators used at work areas such as construction compounds etc., the units will be supplied with manufacturers' proprietary acoustic enclosures where possible.
17.5	C	The Contractor will evaluate the choice of piling, excavation, breaking or other working method taking into account various ground conditions and site constraints. Where possible, where alternative lower noise generating equipment that would economically achieve, in the given ground conditions, equivalent structural/ excavation/ breaking results, these will be selected to minimise potential disturbance.
17.6	C	If replacing a noisy item of plant is not a viable or practical option, consideration will be given to noise control "at source". This refers to the modification of an item of plant, or the application of improved sound reduction methods in consultation with the supplier or the best practice use of equipment and materials handling to reduce noise. In practice, a balance may need to be struck between the use of all available techniques and the resulting costs of doing so. It is therefore proposed to adopt the concept of "Best Available Techniques", as defined in EC Directive 96/61.
17.7	C	Proposed noise mitigation techniques will also be evaluated in light of their potential effect on occupational health and safety. The following outline guidance relates to practical noise control at source techniques which relate to specific site considerations: • For mobile plant items such as cranes, dump trucks, excavators and loaders, the installation of an acoustic exhaust and/or maintaining enclosure panels closed during operation can reduce noise levels by up to 10dB. Mobile plant will be switched off when not in use and not left idling. • For piling plant, noise reduction can be achieved by enclosing the driving system in an acoustic shroud. For steady continuous noise, such as that generated by diesel engines, it is possible to reduce the noise emitted by fitting a more effective exhaust silencer system or utilising an acoustic canopy to replace the normal engine cover. • For percussive tools such as pneumatic concrete breakers, rock drills and tools a number of noise control measures include fitting muffler or sound reducing equipment to the breaker 'tool' and ensuring any leaks in the air lines are sealed. Erection of localised screens around breaker or drill bit when in operation in close proximity to noise sensitive boundaries are other suitable forms of noise reduction. • For concrete mixers, control measures will be employed during cleaning to ensure no impulsive hammering is undertaken at the mixer drum. • For all materials handling, the Contractor will ensure that best practice site noise control measures are implemented including ensuring that materials are not dropped from excessive heights and drop chutes/dump trucks are lined with resilient materials. This is an important consideration for site compounds where materials are loaded and unloaded. Site compounds in close proximity to noise sensitive areas (refer to **Table 17.10** of **Chapter 17, Noise and**

Ref No.	Stage	Commitments
		Vibration) will incorporate a strict noise control policy relating to materials handling. • Where compressors, generators and pumps are located in areas in close proximity to noise sensitive properties/ areas and have potential to exceed noise criterion, these will be surrounded by acoustic lagging or enclosed within acoustic enclosures providing air ventilation. • Resonance effects in panel work or cover plates can be reduced through stiffening or application of damping compounds; rattling and grinding noises can be controlled by fixing resilient materials in between the surfaces in contact. • Demountable enclosures can also be used to screen operatives using hand tools and may be moved around site as necessary. • All items of plant will be subject to regular maintenance. Such maintenance can prevent unnecessary increases in plant noise and can serve to prolong the effectiveness of noise control measures.
17.8	C	As per *BS 5228 -1:2009+A1* screens on level sites shall be placed as close as possible to either the source or the receiver. The construction of the barrier will be such that there are no gaps or openings at joints in the screen material. Annex B of *BS 5228-1:2009+A1:2014* (Figures B1, B2 and B3) provide typical details for temporary and mobile acoustic screens, sheds.
17.9	C	The Contractor will carefully plan the site layout. Within site compounds, the placement of site buildings such as offices and stores between the site and sensitive locations can provide a good level of noise screening. Similarly, in some instances materials such as topsoil or aggregate along the route of the proposed road development can provide a degree of noise screening if placed between the source and the receiver.
17.10	C	Construction activity will mostly take place during daytime hours Monday to Friday and Saturdays (ref **Section 17.2.2.1** of **Chapter 17, Noise and Vibration**). Depending on the noise emission levels experienced and associated noise impact, the Contractor will be flexible and able to conduct certain works at hours which reflect periods when the neighbouring properties have lower sensitivities to noise.
17.11	C	It will be necessary to work overtime (including weekends) and night shifts at certain critical stages during the project. Over the expected 36-month construction phase there will be up to 10 weeks of night time working along different sections of the proposed road development primarily to facilitate bridge works over existing roads.
17.12	C	Consideration will be given to the scheduling of activities in a manner that reflects the location of the site and the nature of neighbouring properties. Each potentially noisy event/activity will be considered on its individual merits and scheduled according to its noise level, proximity to sensitive locations and possible options for noise control. In situations where a particularly noisy activity is scheduled e.g. activities identified in **Table 17.9** of **Chapter 17, Noise and Vibration** (rock breaking/crushing/impact piling etc.) or other activities of similar noise level, the use of other on-site activities will be scheduled to control cumulative noise levels.
17.13	C	A designated noise liaison officer will be appointed to site during construction works to establish a clear form of communication between the Contractor and residents or building occupants in noise sensitive areas. All noise complaints will be logged and followed up in a prompt fashion by the liaison officer.

Ref No.	Stage	Commitments
17.14	C	During the construction phase noise monitoring will be undertaken at the nearest sensitive locations to ensure construction noise limits outlined in **Table 17.1** are not exceeded. Noise monitoring will be conducted in accordance with the International Standard ISO 1996: Acoustics – Description, measurement and assessment of environmental noise Part 1 (2016) and Part 2 (2017). The selection of monitoring locations will be based on the nearest sensitive buildings to the working area which will progress along the length of the road construction. It is recommended that noise control audits are conducted at regular intervals throughout the construction programme in conjunction with noise monitoring. In the case of vibration monitoring during construction the use of independent monitoring will be undertaken by external bodies for verification of results. Monitoring will be undertaken at identified sensitive buildings, where proposed works have the potential to be at or exceed the vibration limit values.
17.15	C	In terms of blast design control, specific guidance will be obtained from the recommendations contained within BS 5228-2:2009+A1:2014 Code of Practice for Noise and Vibration Control on Construction and Open Sites – Vibration in relation to blasting operations in addition to experienced blast control techniques used by the Contractor. These will include some or all of the following: • All blasting will be undertaken by professionally trained blast contractors. • Restriction of hours within which blasting can be conducted (09:00 – 18:00hrs). • Trial blasts will be tested in less sensitive areas to assist in blast designs and identify potential zones of influence. • Explosive charges will be properly confined by a sufficient amount of stemming. • Blasting contractors will ensure that the minimum amount of primer cord is used, and that no primer cord is located above ground. • Profiling will be carried out after each blast in order to ensure the geometry of the rock face can be established, enabling the optimum burden and spacing to be applied for subsequent blasts. • The design, execution and completion of any blasting within 150 metres of any existing structure shall require special considerations. This will include the use of pre and post condition structural surveys by a competent structural engineer. • Ground vibration and air over pressure (AOP) will be recorded simultaneously for each blast at the most sensitive locations, depending on the works area being blasted. • When blasting moves into a new area, an initial low level blast will be carried out (i.e. a low Maximum Instantaneous Charge (MIC)) and monitoring will be carried out simultaneously at a number of sensitive properties in different directions in order to generate specific scaled distance graphs. • The scaled distance graphs will be used to determine the optimum MIC for subsequent blasts area in order control vibration and AOP limits below the relevant limit values (as set out in **Section 17.2.1**) at the nearest sensitive buildings.
17.16	C	In line with best practice mitigation measures from vibration sources, good communication and public relations are a key factor in reducing any startle effects to residents. In this instance, a Public Communications Strategy

Ref No.	Stage	Commitments
		will be implemented by the Contractor prior to the commencement of any blast works. In such cases, the following recommended environmental commitments are proposed: • Relevant nearby residents will be notified before any work and blasting starts (e.g. a minimum of 24-hour written notification). • The firing of blasts will be undertaken, where possible, at similar times to reduce the 'startle' effect. • Ongoing circulars will be issued informing people of the progress of the blasting works. • The implementation of an onsite documented complaints procedure will be maintained by the Contractor. • The use of independent monitoring will be undertaken by external bodies for verification of results.
17.17	C	Vibration from construction activities should be limited to the values set out in **Table 17.3** of **Chapter 17, Noise and Vibration**.
17.18	C	In the case of vibration levels giving rise to human discomfort, in order to minimise such impacts, the following measures shall be implemented during the construction period: • A clear communication programme will be established to inform adjacent building occupants in advance of any potential intrusive works which may give rise to vibration levels likely to exceed perceptible levels. The nature and duration of the works will be clearly set out in all communication circulars. • Alternative less intensive working methods and/or plant items shall be employed, where feasible. • Appropriate vibration isolation shall be applied to plant, where feasible. • Cut off trenches to isolate the vibration transmission path shall be installed where required. • In the case of impact piling or demolition works for instance, a reduction in the input energy per blow shall be considered where required. • Monitoring will be undertaken at identified sensitive buildings, where proposed works have the potential to be at or exceed the vibration limit values.
17.19	C	Property condition surveys will be offered for all buildings within 50m of the proposed development boundary and those within 150m of proposed blasting works along the proposed road development. Property condition surveys will also be carried out at buildings and structures considered appropriate relative to their proximity to the works. Such property condition surveys shall be carried out by a Chartered Surveyor or Chartered Structural Engineer. Such property condition surveys, subject to the written agreement of relevant property owners, shall be carried out in two stages as the follows: • the first stage shall consist of pre-construction condition surveys including photographic records which shall be carried out prior to the commencement of construction. • the second stage shall consist of post-construction condition surveys which shall include photographic records.
17.20	C	The location of potentially vibration sensitive activities have been identified for manufacturing facilities within the Parkmore and Racecourse

Ref No.	Stage	Commitments
		Business Parks. This location is in proximity to an area where blasting will take place as part of the proposed tunnel at Ballybrit. The most effective form of mitigation for this type of sensitive process is through on-going consultation with the property owners as the design and construction of the proposed road development progresses. This will involve baseline vibration monitoring and the use of trial blasts using an initial low level charge with simultaneously vibration measurements undertaken at the building. This information will be used to determine acceptable vibration levels for the facility relating to the sensitivity of the operating equipment. The results of this trial assessment will then set appropriate agreed limits values at the facility in question which will be monitored during subsequent blasts or other excavation methodologies. Where no safe limit is determined, the timing and scheduling of blasts will be undertaken in consultation with the facility when no sensitive operations are taking place. Given the short time period over which an individual blast takes place (i.e. a number of seconds), this approach is deemed to be feasible.
17.21	O	Low Noise Road Surface (LNRS) will be used to reduce noise generated at source.
17.22	O	Noise barriers as detailed in **Table 17.14** in **Chapter 17, Noise and Vibration** and **Figures 17.1.01** to **17.1.14** will be implemented to reduce noise levels along the propagation path between the source (proposed road development) and the specific receivers (houses, schools, churches etc.). These screens may be constructed as earth bunds, proprietary noise barriers or a combination of both.

21.8 Landscape and Visual

Ref No.	Stage	Commitments
12.1	C	Landscape mitigation proposals shall take account of the approaches and principles as set out in A Guide to Landscape Treatments for National Road Schemes in Ireland, in particular to Chapter 4: Components of the Roadside Landscape; Chapter 5: Soil Geographic Factors; and Chapter 6: Landscape Treatments. Unless otherwise qualified in the following or in Chapter 8, Biodiversity, seeding and planting proposals, including species and planting type and species shall be in accordance with Chapter 6 of the Landscape Guidelines (A Guide to Landscape Treatments for National Road Schemes in Ireland) adapted as required for local environmental and landscape conditions.
12.2	C	Site machinery shall operate within the proposed road development construction area.
12.3	C	Storage areas shall be located so as to avoid impacting further on existing residential and other property, woodlands, trees, hedgerows, drainage patterns, etc.
12.4	C	Solid site hoarding of minimum 2.0m in height shall be provided alongside construction works adjoining residential property or recreational amenities
12.5	C	Solid hoarding or similar, of minimum 2.0m in height shall be provided along any side of a proposed construction compound, where they are located within 100m of residential properties.
12.6	C	Construction compounds shall be fully-decommissioned and reinstated to their pre-construction condition at the end of the construction contract

Ref No.	Stage	Commitments
		unless these areas have been identified as habitat compensation or material deposition areas.
12.7	C	Side slopes and other landscape areas along the proposed road development shall be prepared for soiling, and either seeded and/or planted at the earliest possible opportunity. As such, some scope may exist for undertaking significant areas of seeding and planting prior to the end of the construction works. However, due to construction programming and seasonal restrictions, it is also likely that significant planting works will not be undertaken until the end of the major construction phase.
12.8	C	All mitigation planting will take place at the earliest opportunity feasible during the construction stage so as to maximise establishment prior to road opening.
Project Wide Measures		
12.9	O	Cut slopes on mainline, link roads and local roads: Cut slopes shall be finished to even gradients, topsoiled unless otherwise stated in this table or elsewhere in the EIAR. Slopes shall be free of rubble and stones over 50mm diameter. All such rubble/stone shall be removed or buried. Unless otherwise stated slopes shall be seeded to a low maintenance non-agricultural grassland or to a diverse grass/wildflower sward, as appropriate. Steep slopes may be hydro-seeded. Where exposed, stable rock cuttings/slopes will be retained as a landscape feature along the proposed road corridor.
12.10	O	Embankments on mainline, link roads, and local roads: Embankments shall be finished to even gradients, topsoiled unless otherwise stated in this table or elsewhere in the EIAR. Slopes shall be free of rubble and stones over 50mm diameter. All such rubble/stone shall be removed or buried. Unless otherwise stated slopes shall be seeded to a low maintenance non-agricultural grassland or to a diverse grass/wildflower sward, as appropriate. Steep slopes may be hydro-seeded.
12.11	O	Verges & Roundabouts on mainline, link roads, and local roads: Verges will be provided along both sides of mainline. Verges will also be provided around junctions and along local road re-alignments and tie-ins. Verges and roundabouts shall be finished to even or gently flowing gradients, with minimum 200mm topsoil. Areas shall be stone buried or raked will be free of rubble and stones over 25mm diameter. Verges and roundabouts will be seeded to low-maintenance seed mix.
12.12	O	Ponds, swales, ‘V-drains’ etc.: All slopes shall be evenly graded and free of rubble and stones over 50mm diameter. Slopes shall be seeded to low maintenance non-agricultural grassland or to a grass/wildflower sward, allowing for natural development over time. Steep slopes on pond edges and ‘V-drains’ may be hydro-seeded. Areas around ponds shall be a diverse landscape of low maintenance grassland/species-rich grass wildflower sward and plantings of scrub planting and/or low-canopy woodland and shrub planting. Hedgerows of blackthorn and hawthorn, hazel and holly, without tree species, shall be established along non-roadside boundaries. Non-palisade type fencing shall be secure pond areas.

Ref No.	Stage	Commitments
12.13	O	Noise barriers/bunds: Where possible hedgerow scrub and shrub planting and/or low-canopy woodland of native species shall be established as either a narrow planting of 3.0m minimum width or double-staggered hedgerow along the full off-road face of barriers. Low-canopy and/or shrub planting of native species shall be established on the off road face of bunds. The planting shall include ash*, birch, blackthorn, elder, hawthorn, hazel, holly, rowan and/or willow species as appropriate. Plants shall be 90 to 120cm in height at planting. *** Note**: Due to the risk of Ash Dieback (*Chalara fraxinea*) and until further notice, ash (*Fraxinus* species) is no longer approved by the TII for planting schemes. This does not impact on the use of Mountain ash – also known as rowan (*Sorbus aucuparia*). Transparent noise barriers will be used on the River Corrib Bridge.
12.14	0	Plants and planting areas: All tree species over 150cm in height together with all Pine shall be appropriately staked and tied. All failed, dead or defective plants shall be replaced before the end of each and every year of defect aftercare. Full planting area will be free of stones over 50mm in diameter.
12.15	O	Grass areas: Grass areas shall provide full sward cover within 12 months of seeding. Any failed, bare or defective areas shall be re-seeded between March – May and/or August – September in each and every year of defect aftercare.
12.16	O	Unauthorised access, parking and/or encampment: Landscape proposals shall avoid creating areas considered as being suitable for unauthorised parking and shall use landscape proposals to deter and prevent such use.
12.17	O	Remnant areas: Any post-construction remnant lands shall be treated to a diverse range of grassland and/or planting proposals to include a minimum 30% planting, amended as locally appropriate. The remaining area shall be treated as locally appropriate low maintenance grass/species-rich sward.
12.18	O	Where feasible landscape measures shall include for the re-connection of existing field boundaries and hedgerows along the proposed road development. Where appropriate trees species as noted in Mitigation Tables 12.7 and 12.8 of the EIAR, shall be randomly spaced in a visually naturalistic manner within such hedgerows.
12.19	O	Where areas are in cut or fill, a grass or meadow sward will be established over the slope except in areas of cutting through stable rock (see Landscape Guidelines, Section 4.2: Cuttings and Embankments). Except where otherwise required, it is not proposed to plant either cut or fill slopes in their entirety, but to encourage a more naturalistic and locally sympathetic grouping of plantings within a semi-natural grass sward. Slopes may also be seeded to wildflower grassland and hydro-seeding may be utilised for seeding of steep slopes. It is expected that significant extent of rock cutting will arise on the proposed road development. Stable rock slopes will be retained as an exposed face for natural colonisation and as a local landscape features.
12.20	O	Along the length of the proposed road development, landscape areas within junctions and small areas of severed fields, plots or other property

Ref No.	Stage	Commitments
		acquired for the construction of the proposed road development will be varyingly treated including being planted in a semi-natural copse like scrub plantings and native woodland species. (see Landscape Guidelines, Section 4.6: Additional Plots and Other Areas). Such planted blocks dispersed along the proposed road development will assist in the improvement of the longer-term visual character of the proposed road development and local surrounds. Particular attention shall be given to an appropriate extent and scale of planting in and surrounding junctions (see Landscape Guidelines, Section 4.3: Junctions, Interchanges and Roundabouts) and embankments (see Landscape Guidelines, Section 4.2.2: Embankments).
12.21	O	Certain areas along the length of the proposed road development have been set aside for drainage requirements/pollution control/attenuation. Where proposed these will be securely fenced and planted with locally appropriate hedgerows, shrubs and/or screen planting located along the proposed development boundary to minimise any visual impact from off road areas. However, it is noted that these features also offer the potential to provide for improved landscape diversity and habitat.
12.22	O	Proposed planting will generally be established using bare-root transplants, whips and feathered plants which adapt readily to disturbed ground conditions. A proportion, totalling not less than 5% of ‘Half-standard’ (6-8cm girth & 200cm-250cm tall) and a further 5% ‘Standard’ (8-10cm girth & 250cm-300cm tall) trees shall be used to supplement these plantings, especially in the vicinity of residential areas. All planting mixes will take cognisance of, and include native and local species as identified in the **Chapter 8, Biodiversity**. These requirements have been adapted and further detailed as appropriate to particular areas as set out in **Table 12.8** of **Chapter 12, Landscape and Visual** of the EIAR.
12.23	O	Where used, tree species will be selected from a list of primarily native, naturalised and indigenous species, which will include alder, common ash (subject to planting restrictions at time of works), common birches, common oaks, mountain ash, Scots pine and willow species. Planting sizes will be from 75cm to 400cm in height and tree species will be planted at average 2.0m centres within the wider planting mix.
12.24	O	Shrub planting species utilised will be selected from a list of primarily native and indigenous species, which will include, blackthorn, elder, hawthorn, hazel, holly, guelder rose, spindle, willows and other plants found naturalised in the affected localities. Planting sizes will vary from 30 to 75cm in height and shrub species will be planted at between 1.0 and 1.5m centres depending of landscape type, see **Table 12.8** of the EIAR.
12.25	O	Hedge planting will be primarily of blackthorn and hawthorn interspersed with other species such as elder, hazel, holly and those found locally. Hawthorn within hedgerows shall be planted at between 75 to 90cm in height and at 500mm centres in each of 2 double staggered rows or wider plantings where a denser effect is required. The hedgerow will be interspersed with standard-sized randomly spaced tree species such as alder, common ash and oaks, as appropriate to particular locality.
12.26	O	Areas to be seeded to meadow will be thinly topsoiled (5cm layer) and seeded with a locally appropriate seed mix. Mainline and side road verges will be cultivated, topsoiled minimum 200mm deep and stone buried to remove stones down to 25mm diameter prior to seeding to a low-maintenance grass seed mix.

Ref No.	Stage	Commitments
12.27	O	Where lighting is proposed, the lighting design shall meet the requirements of BS EN 13201-2:2003 and BS5489-1: 2003, Code of Practice for Design of Road Lighting. Lighting of Roads and Public Amenity Areas and shall comply with the requirements of the DMRB TD 34-91. The detailed lighting design shall be completed in a manner, which will minimise glare and will ensure that light-spill effect is minimised.
Specific Measures		
12.28	O	In specific locations barriers and/or earth bunds may be provided to reduce the impact of noise. Such features shall, wherever possible, be integrated within the proposed landscaping measures.
12.29	O	All of the following specific environmental commitments will be taken account of in the detailed design and implementation of landscape measures: • Location of cut-off drains at the top of cuttings and at the bottom of embankments. • The location and requirements for maintenance access along the mainline of the proposed road development. • Locations where rock is encountered in cuttings. Such rock faces may be retained as geological features of the corridor of the proposed road development. • The location and integration of noise barriers within the landscape design. • Clearance zones (TD19 - Safety Barrier Standards). • Sight-lines, including at junctions and to carriageway signage, etc.
12.30	O	Where feasible reinforced earth retaining wall approaches will be incorporated so as allow for a green landscape finish to all or part of the retaining structures. A limestone finish will be used where structural walls are required and for the abutments of the proposed bridge over the N59 Moycullen Road. The stone will consist of natural limestone, matching the character of the local stone, with a strong horizontal axis of between 5 to 1 and 7 to 1 (i.e. horizontal to vertical dimension).
12.31	O	Landscape Measures also take account of the specific protection and environmental commitments detailed in **Chapter 8, Biodiversity**. In particular, the measures include: • Retained habitats, trees and hedgerows on land-take boundaries, etc. will be fenced-off and protected during construction works. • Specific measures are proposed at a number of locations for mitigation of potential impact on Bat species. This includes: o the provision of artificial bat roosts – with specific planting to encourage use. o the provision of a planted wildlife overbridge (Ch. 12+700) with tie-in planting to local hedgerows and proposed planting on the boundary of the proposed road development, which will maximise potential benefit and use. o dense planting, with trees for improvement of connectivity along the boundary of the proposed road development: o west of the crossing of the L1323 Letteragh (Ch. 7+200 – Ch. 7+280). o along embankments to either side of the proposed bridge over the River Corrib.

Ref No.	Stage	Commitments
		o between the crossing of the N84 Headford Road at Ballindooley and School Road at Castlegar. o hedgerow planting for improvement of connectivity of habitats to the east of Menlo Castle. o hedgerow and copse planting for enhancement of foraging habitat to the north of Menlo Castle. • In order to deter Barn Owls from foraging close to the proposed road development, embankments and cuttings, other than rock cuttings or cut slopes left to naturally regenerate, will be densely planted with low growing scrub (e.g. blackthorn, hawthorn) from Ch. 8+550 to Ch. 17+500. • In order to deter Barn Owls from over flying the proposed road development, planting of closely-spaced trees (approx. 2m centres) greater than 3m in height will be established along the top of the embankments between Ch. 9+600 and Ch. 10+100.
12.32	O	6.0m wide Screen Planting (Planting at 1.0m centres for visual screening shall be of a minimum of 6m in width. The planting shall extend for a minimum of 100m to either side of any adjoining residential property or amenity. (refer to **Figures 12.4.01** to **12.4.14**)). • Planting will include a dense planting at 1m centres of alder, birch, blackthorn, elder, geulder rose, holly, hawthorn, hazel, rowan, and willow species. Shrubs shall be planted at between 60 to 90cm in height. • Scots pine of minimum 60cm in height at planting shall comprise 20% of the overall plant numbers and holly at a minimum of 45cm in height shall comprise a further 15%. • Tree species, planted equally at half-standard (6-8cm girth) and standard size (8-10cm girth), shall comprise minimum 10% of the mix.
12.33	O	3.0m wide Screen Planting (Where space is limited planting at 1.0m centres for visual screening shall be of a minimum of 3m in width. The planting shall extend for a minimum of 100m to either side of any adjoining residential property or amenity. (refer to **Figures 12.4.01** to **12.4.14**)). • Planting will include a dense planting at 1m centres of alder, birch, blackthorn, elder, geulder rose, holly, hawthorn, hazel, rowan, and willow species. Shrubs shall be planted at between 60 to 90cm in height. • Scots pine of minimum 60cm in height at planting shall comprise 20% of the overall plant numbers and holly at a minimum of 45cm in height shall comprise a further 15%. • Tree species, planted equally at half-standard (6-8cm girth) and standard size (8-10cm girth), shall comprise minimum 20% of the mix.
12.34	O	Stone Wall Boundaries (Stone walls as indicated on **Figures 12.4.01** to **12.4.14**). • Where indicated stone walls will be replaced along impacted sections of property and road boundaries on local roads. The stone from the disturbed sections of existing walls will be retained and re-used (generally granite to west; limestone to east) where possible to reinstate these new boundaries. The boundary walls may be backed by hedgerows of locally appropriate species, i.e. blackthorn, hawthorn and holly to west and hazel, hawthorn and holly to east. Elsewhere, where stone walls are removed the stone will be retained and made available for re-use by the adjacent property owners for

Ref No.	Stage	Commitments
		the construction of a new stone wall on their side of the proposed development boundary if they wish.
12.35	O	Boundary Hedgerow (Typical double staggered hedgerow with tree planting, where locally appropriate). • Primarily blackthorn (30%), hawthorn (40%) and holly (10%) hedgerow in west interspersed with other species (20%) such as elder, willow, and those found locally. • Primarily hazel (30%), hawthorn (40%) and holly (10%) hedgerow to east interspersed with other species (20%) such as blackthorn elder, willow, and those found locally. • Hawthorn plants shall be of c.90cm in height and planted at 50cm centres in each of two double staggered rows, 25cm apart. Other plants of c.50cm in height shall be interspersed. • The hedgerow may be interspersed with 'half-standard-sized' (6-8cm girth) alder, birch and/or oak trees planted at random spacings but averaging a min. of 1 tree per 25 linear metre. Limited tree species, such as birch and mountain ash may also be included as 'whips' at 150cm in height.
12.36	O	Retaining Walls and structure over the N59 Moycullen Road (Use of reinforced earth retaining systems and limestone finishes for structural elements. Retaining Wall Structures R08/01; R08/02; R08/07 & R08/04; and Bridge Structure S08/02 (Ch. 8+300 to Ch. 8+670)) • Where feasible reinforced earth retaining wall approaches will be incorporated so as allow for a green landscape finish to all or part of the retaining structures. • Planting of trees shall also be provided along the base of the structure. These shall include smaller growing species such as alder, birch and rowan planted as Selected Standards (i.e. 14cm girth or greater). • A limestone finish will be used for the external finish of the abutments for the proposed bridge over the N59 Moycullen Road and where structural walls are required. The stone will consist of natural limestone, matching the character of local stone, with a strong horizontal axis of between 5 to 1 and 7 to 1 (i.e. horizontal to vertical dimension).
12.37	O	Bat habitat enhancement (new 2m wide tree and shrub hedgerow, with occasional planted copses located north and east of Menlo Castle.) • New hedgerow of native species will be established with plants at 0.5m staggered centres in each of 5 rows located 0.5m apart to sub-divide existing open fields. • Standard-sized trees species (min 8-10cm girth, 2.4m high) will be planted at 15m staggered centres in each of the 3 central rows. Diverse range of shrub species will be planted between trees in the central rows and throughout the outer 2 rows. • Circa 15m diameter woodland copses will be established within open fields using similar approach, densities and species • Planting will be protected by stock-proof fence, c.1.25m high located at 1.0m offset to either side of the outer row of the new hedgerow. • Tree species to include alder, birch, oak, rowan, planted as standards (as above) and whips (1.25m high). Shrubs to comprise mainly blackthorn, hawthorn and hazel (combined 60%), with elder, holly, spindle, willow etc. • Hawthorn plants shall be of between c.90cm in height and all other shrubs shall be c.60cm in height.

Ref No.	Stage	Commitments
12.38	O	Wildlife Overpass (Ballindooley/Castlegar, Structure S12/02 (Ch. 12+700)) • Wildlife overpass (c.30m wide) will be landscaped to provide for connective habitat across proposed road development. Planting to consist of a central narrow grass path bounded on either side by tree-lined hedgerows of native species. • Soil depths to vary from minimum c.45cm depth at edges to c.1.5m depth along centre-line of both hedgerows. Planted element of both hedgerow lines will be c.2m wide with standard-sized trees (min 8-10cm girth, 2.4m high) planted at 3m staggered centres in each of 2 rows in each hedgerow. Diverse range of shrub species will be planted between trees and along the line of each hedgerow. • Planting to tie-in to proposed planting leading east and west on upper slopes of cuttings on both sides of the proposed road development. This will form a continuous hedgerow/planted network. • Tree species to include alder, birch, oak, rowan, planted as standards (as above) and whips (1.25m high). Shrubs to comprise mainly blackthorn, hawthorn and hazel (combined 60%), with elder, holly, spindle, willow etc. • Hawthorn plants shall be of between c.90cm in height and all other shrubs shall be c.60cm in height.
12.39	O	**Barn Owl Planting** <u>Typical double staggered treeline with dense under planting, between Ch. 9+600 and Ch. 10+100.</u> • Deterrent tree planting to comprise alder, birch and/or rowan planted at 3m in height (min 12-14cm girth) and at 2.0m centres in each of 2 rows 1.5m apart. • Dense low scrub planting to comprise blackthorn (50%), hawthorn (20%), hazel (10%) and holly (10%) hedgerow in the west interspersed with other species (10%) such as elder, willow, and those found locally. • Hawthorn plants shall be of c.90cm in height and planted at 50cm centres. Blackthorn and other plants shall be of c.50cm in height and planted at 50cm centres in staggered rows, 50cm apart. <u>Dense low scrub planting on all embankments and cut slopes (other than rock cuttings or cut slopes left to naturally regenerate) from Ch. 8+550 to Ch. 17+540.</u> • Dense low scrub planting to comprise blackthorn (50%), hawthorn (20%) hazel (10%) and holly (10%) interspersed with other species (10%) such as elder, willow, and those found locally. • Hawthorn plants shall be of c.90cm in height and planted at 50cm centres. Blackthorn and other plants shall be of c.50cm in height and planted at 50cm centres in staggered rows, 50cm apart. • Compensatory Habitat Areas (CHA) along the proposed road development will be as detailed in **Appendix A.8.26**.

21.9 Archaeology, Architectural and Cultural Heritage

Ref No.	Stage	Commitments
13.1	C	Archaeological monitoring and investigations will be undertaken as part of the site clearance works for the construction of the proposed road development in order to record and preserve any buried findings using the appropriate methods. This programme of archaeological test trenching will be carried out within the footprint of the proposed road development prior to construction going ahead. This will target the sites and areas of archaeological and cultural heritage potential as outlined in **Section 13.5.3** of **Chapter 13, Archaeology, Architectural and Cultural Heritage** as well as previously undisturbed areas within the proposed development boundary.
13.2	C	Test trenching will be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be identified, if that is deemed the most appropriate manner in which to proceed.
13.3	C	Prior to demolition, the thatched cottage BH 12 will be subject to a full measured, written and photographic survey. This will be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.
13.4	C	The demesne landscape associated with Menlo Castle (DL 8), at Dangan Lower (DL7) and at Bushypark House (DL4) will be subject to a detailed photographic and written record prior to the construction of the proposed road development. This will be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.
13.5	C	All Cultural Heritage (CH) sites listed in **Table 13.17** of **Chapter 13, Archaeology, Architectural and Cultural Heritage** that include built heritage remains will be subject to a detailed written and photographic survey (to include test trenching where appropriate). This shall be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be identified, if that is deemed the most appropriate manner in which to proceed.
13.6	C	Archaeological wade or underwater assessments will be carried out at any natural water courses (AAPs) to be impacted upon by the proposed road development by disturbance to their banks or beds. This shall be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be identified, if that is deemed the most appropriate manner in which to proceed.
13.7	C	Any section of Townland Boundary to be impacted upon will be subject to a detailed written and photographic survey (to include test trenching where appropriate). This shall be carried out under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist. Full provision will be made available for the excavation of any archaeological features and/or deposits that may be

Ref No.	Stage	Commitments
		identified, if that is deemed the most appropriate manner in which to proceed.
13.8	C	Excavation of all previously recorded archaeological sites – where these fall, in whole or in part, within the footprint of the development – will be carried out under Ministerial Direction in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.
13.9	C/O	Archaeological sites (AH) 15, 16, 29, 11, 12, 23 and 26 will be subject to a detailed photographic and written landscape record to preserve their current setting prior to the construction and operation of the proposed road development. This shall be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.
13.10	C/O	Protected Structures (BH) 1, 7, 9, 10 and 17 will be subject to a detailed photographic and written landscape record to preserve their current setting prior to the construction and operation of the proposed road development. This shall be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.
13.11	C/O	Cultural Heritage Sites (CH) 20, 23, 8, 25, 30, 35, 42 and 54 will be subject to a detailed photographic and written landscape record to preserve their current setting prior to the construction of the proposed road development. This shall be carried out by a suitably qualified person or team under Ministerial Directions in consultation with the Department of Culture, Heritage and the Gaeltacht and a TII Project Archaeologist.

21.10 Soils and Geology

Ref No.	Stage	Commitments
9.1	C	Construction techniques that comply with the requirements of statutory bodies in terms of noise, vibration, soil and groundwater contamination and disposal of contaminated material for both soil and rock cuttings will be adopted.
9.2	C	All excavated material, excluding a small potential volume of hazardous material, will be re-used as construction fill and material deposition areas minimising the loss of the feature. The Contractor will ensure acceptability of the material for re-use within the proposed road development with appropriate handling, processing and segregation of the material.
9.3	C	A construction earthworks programme will be implemented as part of the CEMP included in **Appendix A.7.5**, which will be finalised by the Contractor, for the proposed road development which categorises the source of material for each fill section. During the finalisation of this programme, the fill limitations outlined below will be incorporated. To prevent impact to the local peatland habitats, the following fill limitations will be incorporated at the locations identified **Table 9.18** of **Chapter 9, Soils and Geology** • Only pavement and capping layers protected from surface water runoff and groundwater movements are permitted to be derived from non-native material

Ref No.	Stage	Commitments
		• All other acceptable fill material will be derived from native material or other pH compatible material
9.4	C	A drainage layer or starter layer, in accordance with the TII publication CC-SCD-00606, will be implemented for the construction of embankments in areas prone to flooding. The introduction of a drainage layer will ensure hydraulic conductivity exists across the flood plain and removes the risk of the embankment acting as a flood barrier.
9.5	C	Earthworks haulage will be along predetermined routes within and outside the proposed development boundary as shown on **Figures 7.101** to **7.123**. The identified haulage routes are along existing national, regional and local routes or within the proposed development boundary. Where compaction occurs due to truck movements and other construction activities on unfinished surfaces, remediation works will be undertaken to reinstate the ground to its original condition. Where practicable, compaction of any soil or subsoil which is to remain in-situ along the proposed road development will be avoided.
9.6	C	In the event the embankment will be constructed of local material, the introduction of a drainage layer or starter layer will reduce the likelihood of run-off of fine material. Alternatively, the introduction of a geotextile separator will reduce the potential impact in areas. A composite system, combining a drainage layer and a geotextile separator will be implemented in embankments constructed with cohesive fill material. Sediment control methods are outlined in the CEMP in **Appendix A.7.5**.
9.7	C	Ground settlement, horizontal movement and vibration monitoring will be implemented during construction activities to ensure that the construction does not exceed the design limitations. In situations where the site specific blast design has determined that blasting is not feasible in a particular location due to excessive ground vibrations, alternative extraction methods such as hydraulic breaking, hydraulic splitting, chemical splitting and electrical disintegration may be implemented and monitored. Monitoring will be implemented during blasting, during excavation of cuts, for overburden slopes steeper than 1V:2H (V= vertical slope, H = horizontal slope) and rock slopes steeper than 1V:1.5H. The Employer's Site Monitoring Team will be monitoring the reports on a weekly basis to ensure compliance with the commitments in relation to vibration limits.
9.8	C	A geotechnical expert will be appointed by the Contractor and will be present to monitor the surrounding ground vibrations near sensitive receptors during blasting works. The Employer's Site Monitoring Team will be monitoring the reports on a weekly basis to ensure compliance with the commitments in relation to vibration limits.
9.9	C	A trial blast, and will be carried out as part of a blast assessment. The monitored trial blast will be undertaken in the same bedrock formation by the blasting contractor in a controlled location, not exceeding the vibration limitations of the local sensitive receptors, posing no risk to sensitive receptors including Annex I habitat in Lough Corrib cSAC. The trial blast will calibrate the blast design to a site specific design. The blast target vibration limit is defined as 20% more conservative than the conservative design approach vibration limit of 25mm/sec at the ground surface which includes areas of Limestone pavement at Lackagh Tunnel. In addition, the Limestone pavement will be monitored during the tunnelling works for any effects from the blast vibrations. In the unlikely event that the blast target vibration limit at the surface is exceeded, blasting works will cease on site until it is understood the basis for the

Ref No.	Stage	Commitments
		increased vibration. The blast design will then be recalibrated and blasting works will proceed with continued monitoring. Allowable distances for the various construction methods are given in the section below on Noise and Vibration. The Employer's Site Monitoring Team will inspect the trial blast reports to check compliance with the limitation limits in vibration at surface.
9.10	C	Importation of materials from outside the site will be minimised by ensuring that materials arising within the site area are used to the greatest extent possible. Any surplus material remaining which cannot be incorporated into the construction fill activities shall be placed in material deposition areas within the proposed road development. Hazardous material will be transported off site for disposal or recovery at appropriately licence or permitted sites as outline above for Construction Activities.
9.11	C	Construction of structures will be completed in accordance with the CEMP in **Appendix A.7.5**. The construction of the River Corrib Bridge will meet the requirements of the: River Corrib Bridge Constructability Examination **Appendix A.7.1**; the Menlough Viaduct will meet the requirements of the Menlough Viaduct Constructability Examination **Appendix A.7.2**, the Lackagh Tunnel will meet the requirements of the Lackagh Tunnel Geotechnical and Hydrogeological Appraisal **Appendix A.7.3** and the Galway Racecourse Tunnel will meet the requirements of the Galway Racecourse Tunnel Constructability Report **Appendix A.7.4**. The adopted construction techniques will comply with the requirements of statutory bodies in terms of noise, vibration, soil and groundwater contamination and disposal of contaminated material.
9.12	C	For the construction of Lackagh Tunnel a hydrogeology and geotechnical expert will be appointed by the Contractor and will be present to monitor at all times when the construction activities have the potential to impact on groundwater or the Annex I habitats at the surface, namely Limestone pavement and Calcareous grassland. This includes the supported rock face of Lackagh Quarry Face and retaining walls for the Western Approach. Monitoring of the exposed rock slopes and retaining walls will be carried out during construction and operation to ensure there is no impact to the Annex I habitat. In the extremely unlikely event that instability is observed additional support measures will be installed to ensure that there is no impact to the Annex I habitat. The additional support measures comprise ground anchors, rock bolts, rock dowels, rock mesh, shotcrete or a combination of these measures, designed to the relevant design standards (Eurocode 7, BS8081) and best practice guidance documents. The Employer's Site Monitoring Team will review weekly monitoring reports to check stability of rock slopes in Lackagh Quarry.
9.13	O	The rock and overburden retaining systems in Lackagh Quarry and Western Approach will continue to be monitored as part of the TII (Transport Infrastructure Ireland) maintenance schedule to ensure that they continue to operate as intended for the design life of the proposed road development. In the extremely unlikely event that instability within the rock mass is observed additional support measures (e.g. rock bolts, rock dowels, rock mesh, shotcrete or a combination of these measures will be

Ref No.	Stage	Commitments
		installed to ensure that there is no impact to the structural integrity[1] of the Limestone pavement.
9.14	C	Ground settlements will be controlled through selection of the foundation type and method of construction which are suitable for the particular ground conditions. To minimise soil movements due to pile operations in the vicinity of sensitive receptors, each pile shall be constructed sequentially in a direction away from the sensitive receptor. Previously installed piles act as a shield as soil movements are greater in a direction away from the stiffer zone i.e. away from the piles and sensitive receptors.
9.15	C	During construction, the Limestone pavement at Menlough Viaduct will be protected and will not be impacted by implementing a protection system comprising of geogrid, protection geotextile and layers of material. Refer to Menlough Viaduct Constructability Report in Appendix A.7.2 for further details.
9.16	C	Samples of ground suspected of contamination will be tested for contamination during the detailed investigation and ground excavated from these areas will be disposed of to a suitably licence or permitted sites in accordance with the current Irish Waste Management legislation.
9.17	C	Good housekeeping (daily site clean-ups, use of disposal bins, etc.) on the site, and the proper use, storage and disposal of these substances and their containers will prevent soil contamination. For all activities involving the use of potential pollutants or hazardous materials, material such as concrete, fuels, lubricants and hydraulic fluids will be carefully handled and stored to avoid spillages. Potential pollutants shall also be adequately secured against vandalism and will be provided with proper containment according to codes of practice. Any spillages will be immediately contained and contaminated soil removed from the site and disposed of to an appropriately permitted or licenced site according to the current Irish Waste Management Legislation by the Contractor.
9.18	C	The Contractor is required to make provision for removal of any concrete wash water. Concrete trucks will be directed back to their batching plant for washout. The arrangement for concrete deliveries to the site will be discussed with suppliers before commencement of work, outlining the agreed assessed routes, prohibiting on site washout and discussing emergency procedures.
9.19	C	As a minimum, the carriageway drainage network will be sealed in areas where the proposed road development crosses rock particularly prone to karstification. Through the use of engineered solutions, including an impermeable barrier, cement slurry or grout, direct run-off from the paved surface of the proposed road development will be prevented from entering into the rock along the proposed alignment, as this could cause further deterioration and instability of the rock mass. Individual mitigation measures will be assessed on a case by case basis, determined by the extent of karst and make-up of the proposed road development as outlined in the karst protocol which is part of the CEMP in **Appendix A.7.5**. Inspections of karst features will be undertaken by a hydrogeologist and/or geotechnical expert in order to determine the appropriate remediation measure. These remedial measures include but are not limited to the removal of all loose, soft, weak or voided soil material, backfilling voids with an agreed combination of boulders cobbles / chunk rock / cement

[1] Structural Integrity of the rockmass that supports the mosaic of Limestone pavement and Calcareous grassland is the physical and mechanical geotechnical properties that control the behaviour of the geotechnical Limestone pavement environment

Ref No.	Stage	Commitments
		slurry and installation of a high strength geosynthetic to form a competent, safe foundation platform.

21.11 Hydrogeology

Ref No.	Stage	Commitments
10.1	C	No dewatering will occur during construction at Menlough Viaduct or Lackagh Tunnel (or its approaches). Furthermore, the construction sequence will take into account the seasonal groundwater fluctuation. During the winter groundwater high it may be necessary to limit the depth of works so that dewatering is not required.
10.2	C	Galway Granite Batholith EW01, 02 (three cuttings), 04, 07 and 09: Groundwater intercepted will be collected and piped to the surface water receptor it would naturally have drained to.
10.3	C	Limestone: Construction dewatering of the bedrock aquifer may seasonally be required in EW27 during peak groundwater levels. Any dewatering will be discharged to the same groundwater body.
10.4	C	Construction of the Galway Racecourse Tunnel and its approaches will require dewatering of the bedrock aquifer. All groundwater intercepted will be managed and discharged within the same groundwater body.
10.5	C	EW27: Groundwater will be controlled within the excavation by collection in drains or sumps. If groundwater is intercepted, it will be piped and discharged at an infiltration basin within the same groundwater body. Intercepted groundwater is controlled and infiltrates back to the same groundwater body.
10.6	C	Where infiltration basins are used for discharge of site runoff during construction the runoff will be managed on site, collected and treated as per the Sediment Erosion and Pollution Control Plan (Refer to Section 8 of the CEMP in **Appendix A.7.5**).
10.7	C	Infiltration basin S19a and S19b include lining the sides of the excavation to ensure vertical groundwater infiltration so that all discharges drain through the placed subsoil for the full thickness of the unsaturated zone.
10.8	C	The following measures included in the CEMP will be implemented to control the potential for pollution from accidental spillages on site: • Stockpiling of contaminated material is not permitted. • Good housekeeping on the site during construction, and the proper use, storage and disposal of these substances and their containers will prevent groundwater contamination. • For all activities involving the use of potential pollutants or hazardous materials, under the CEMP, the Contractor will be required to ensure that material such as concrete, fuels, lubricants and hydraulic fluids will be carefully handled and stored to avoid spillages. Potential pollutants shall also be adequately secured against vandalism and will be provided with proper containment according to codes of practice. Any spillages will be immediately contained and contaminated soil removed from the site and properly disposed of. • The Contractor will finalise the Incident Response Plan in the CEMP in **Appendix A.7.5** prior to work commencing and regularly update it for pollution emergencies which will be developed by the appointed

Ref No.	Stage	Commitments
		Contractor. The Contractor shall implement all the measures detailed in Incident Response Plan.
10.9	C	In the event of karst being encountered the Karst Protocol shall be implemented, which is documented in the CEMP (**Appendix A.7.5**): • Where karst features are encountered during construction works these will be assessed by a hydrogeologist and an engineering geologist. In the case of excavations (road cuttings, tunnels, bridge pier excavations) then the karst feature shall be excavated and backfilled with course fill and sealed. • With regard to karst features being intercepted in excavations for earthworks (including viaducts, bridges and tunnels) and infiltration basins. The Karst Protocol preserves the hydraulic connectivity of the feature using granular material to fill but then seals the karst from the excavation using a liner (geotextile and or concrete depending on the site specifics). • Where dewatering of the bedrock aquifer is proposed, groundwater level monitoring will be installed before construction, during the construction phase and 12 months following construction to enable potential effects from dewatering to be identified. If the monitoring indicates there is a measurable impact beyond that stated in this EIAR, then work with the potential to increase drawdown will be made safe and cease until the hydrogeological assessment is revised based on the site conditions and mitigation employed if appropriate. • In order to reduce potential contamination impacts, stockpiling of contaminated material and leachate generation will be prohibited. In the situation that potential contaminated material is encountered it will be tested and disposed of in an appropriate manner and in line with current water management legislation. If it is not possible to immediately remove contaminated material, then it will be stored on, and covered by, polythene sheeting to prevent rain water infiltrating through the material. The time frame between excavation and removal will be kept to an absolute minimum.
10.10	C	Five wells (W50-10, W50-12, W50-13, W50-14 and W50-15) will be lost during the construction of the proposed road development. These will each be mitigated by providing a replacement well, connecting to mains supply where available or by financial compensation. Where wells have to be abandoned as part of the proposed road development they will be sealed and abandoned in general accordance with Well Drilling Guidelines produced by the Institute of Geologists of Ireland (IGI 2007).
10.11	C	Replacement wells, storage tank, associated pumping equipment and pipework for Wells W50-13 and W50-14 will be commissioned and tested to ensure adequate yield rates in advance of wells W50-13 and W50-14 being decommissioned.
10.12	C	Wells outside of the proposed development boundary but within the drawdown zone of influence may be impacted by reduced groundwater levels during construction. All wells within 150m of the proposed development boundary (or 50m from the calculated drawdown ZoI if greater) will be monitored for water level on a monthly basis for 12 months before construction, during construction and for 12 months after construction. If the monitoring indicates that the proposed road development has impacted on a supply or geothermal well then mitigation will be applied.
10.13	C	To ensure the protection of quality of groundwater potable supplies, all wells within 150m of the proposed development boundary will be monitored for water quality on a monthly basis. All wells will be

Ref No.	Stage	Commitments
		monitored for standard drinking water quality parameters on a monthly basis for 12 months before construction, during construction and for 12 months after construction. If the monitoring indicates that the proposed road development has impacted on a supply, then mitigation will be applied.
10.14	C	The groundwater dependent terrestrial ecosystems (GWDTE) that have been flagged as being at risk are all in areas where the groundwater pathways are karstic. In this regard the Karst Protocol, as detailed above, forms part of mitigation to prevent groundwater quality or quantity being impacted. Additional mitigation is also employed to ensure that European sites are not impacted.
10.15	C	There will be no surface water discharges to the Coolagh lakes and all runoff will be treated before being discharged to ground at infiltration basins. Infiltration basins are designed to include settlement to remove sediment and have an appropriate thickness of subsoil below invert level.
10.16	C	Pouring of the concrete in excavations (River Corrib Bridge, Menlough Viaduct and Lackagh Tunnel) will only be undertaken when the excavation has been inspected by a qualified hydrogeologist. Inspection of the full depth and extent of each excavation will be undertaken to identify if any significant flow paths, such as the karst enhancement of the bedrock permeability, are present. If no significant flow paths are present, then the hydrogeologist will document accordingly and confirm that there is no risk to groundwater from concrete leakage. If significant pathways are present then impacts which may arise from flow along these pathways shall be designed by the hydrogeologist based on the karst mitigation plan, these may comprise of installing a high permeability zone to replace the groundwater pathways which would be removed by the foundations and/or sealing the linkage from excavation to protect the karst. The design of the mitigation measures shall be approved by a qualified hydrogeologist to confirm that there will be no negative impacts to groundwater.
10.17	O	During the operational phase of the proposed road development inspection and maintenance will occur to ensure that the infiltration basins continue to operate as intended for the design life of the proposed road development.
10.18	O	Infiltration basins require regular inspection to confirm that no observable subsidence in the infiltration has occurred due to karst. Inspection is recommended on 5-year frequency.
10.19	O	If karst features and potential pathways are found to be present during inspection, then the Karst Protocol developed for the construction phase will be implemented to ensure that no preferential pathways have formed within the infiltration basin.

21.12 Hydrology

Ref No.	Stage	Commitments
11.1	C	The CEMP included in **Appendix A.7.5** will be finalised by the Contractor in advance of the commencement of construction and the following will be implemented as part this plan: • An Incident Response Plan detailing the procedures to be undertaken in the event of spillage of chemical, fuel or other hazardous wastes, logging of non-compliance incidents and any such risks that could lead to a pollution incident, including flood risks. • A Sediment Erosion and Pollution Control Plan (Refer to Section 8 of the CEMP in **Appendix A.7.5**). This shall include water quality monitoring and method statements to ensure compliance with environmental quality standards specified in the relevant legislation. • All necessary permits and licenses for instream construction works associated with the provision of culverts, bridges and outfalls. OPW Section 50 consent has been received for all culverts and bridges proposed in the EIAR. Changes to these structures as part of the detailed design and construction stage will require new Section 50 consent to be obtained. • Inform and consult with OPW Western Arterial Drainage Section who have responsibility for the Corrib-Mask Arterial Drainage scheme and the ongoing control of river and lake levels at the Salmon Weir Barrage in Galway City. • Continue to inform and consult with Inland Fisheries Ireland (IFI). • Continue to inform and consult with National Parks and Wildlife Service (NPWS).
11.2	C	Construction activities will be required to take cognisance of the all relevant guidance documents for construction work on, over or near water including: • Guidelines on Protection of Fisheries During Construction Works in and Adjacent to Waters (Inland Fisheries Ireland, 2016). • Shannon Regional Fisheries Board – Protection and Conservation of Fisheries Habitat with particular reference to Road Construction. • Requirements for the Protection of Fisheries Habitat during Construction and Development Works at River Sites (Eastern Regional Fisheries Board). • Central Fisheries Board Channels and Challenges – The Enhancement of Salmonid Rivers. • CIRIA C793 The SuDS Manual. • CIRIA C624 Development and Flood Risk – guidance for the construction industry. • CIRIA C532 Control of Water Pollution from Construction Sites Guidance for Consultants and Contractors. • CIRIA C648 Control of Water Pollution from Linear Construction Projects, technical guidance. • CIRIA C649 Control of Water Pollution from Linear Construction Projects, site guide. • Guidelines for the Crossing of Watercourses during the Construction of National Road schemes (NRA, 2006). • Road Drainage and the Water Environment DN-DNG-03065 (TII, June 2015).

Ref No.	Stage	Commitments
		Vegetated Drainage Systems for Road Runoff DN-DNG-03063 (TII, June 2015).
11.3	C	As set out in the Sediment Erosion and Pollution Control Plan (Refer to **Section 8** of the CEMP), the sediment, erosion and pollution controls will be monitored and maintained throughout the construction of the proposed road development. This shall include the regular water quality monitoring for sediments and hydrocarbons (monitoring the sediment concentrations in the receiving water) and the inspection of the pollution control facilities and method statements to ensure compliance with environmental quality standards specified in the relevant legislation.
11.4	C	Separate from the on-going and detailed monitoring carried out by the Contractor as part of the CEMP; the Site Environmental Manager (SEM) shall carry out the inspection/ monitoring regime described below on behalf of the Employer. The results will be stored in the SEM's Monitoring file and will be available for inspection/ audit by the Client, NPWS or IFI and OPW (where relevant). All inspections/ monitoring/ results will be recorded on standard forms. Inspections will include the following: • Inspect the Principal Control Measures outlined in the CEMP on a weekly basis. Report findings to the Contractor. • Inspect surface water treatment measures (ponds, tanks, mini-dams, sandbags, etc.) on a daily basis and obtain turbidity readings in the outlet receiving water. • Inspect all outfalls to watercourses and groundwater bodies on a daily basis and obtain turbidity readings. Where excavation, deposition, pumping out or concreting works are on-going in the vicinity obtain turbidity readings three times per day in the outlet receiving water. • Daily visual inspection of watercourses to which there is a discharge from the works and those where there is construction works in the vicinity. • Wheel wash facilities shall be inspected on a weekly basis. • Stockpiles shall be monitored on a daily basis while being filled or emptied and otherwise on a weekly basis. • Control measures for works at or near water bodies shall be inspected on a daily basis. • Concrete operations at or near watercourses shall be supervised and designated chute washing out facilities shall be inspected on a daily basis. • Site compounds and satellite compounds shall be inspected on a weekly basis. • The Contractor's monitoring results shall be audited by the SEM on a frequent basis (6 times per quarter at a minimum). • The investigatory level for turbidity is defined as a 10ntu difference between the ambient upstream watercourse level and the level downstream of the works. • Notwithstanding the stringent prevention measures listed above, in the unlikely event of an accidental release of sediment to a watercourse causing plumes or in the unlikely event of an exceedance of the turbidity investigatory levels arising, the following shall take place: o It shall be investigated immediately and thoroughly by the SEM and the Contractor. o The Incident Response Plan shall be activated.

Ref No.	Stage	Commitments
		○ The relevant NPWS, IFI and local authority staff will be notified immediately. ○ The Contractor will be required to take immediate action to detect source of release, corrective action to prevent release and to implement measures to ensure that such discharges do not re-occur. ○ Works if stopped shall not recommence until appropriate corrective measures to avoid any repetition are put in place. Such measures shall be agreed with the SEM following consultation with the NPWS and IFI. ○ Works and/ or discharges from the works shall not recommence until written consent is received from the SEM. Where the SEM considers that the risk of a sediment release is high for a particular construction activity, he/she shall inform the Contractor and request protective action to be taken before the construction activity commences. The SEM will be delegated powers under the contract sufficient for these instructions to be issued and implemented.
11.5	C/O	Water Quality Monitoring will be required prior to, during and post construction. Baseline water quality sampling shall commence a minimum of six months prior to construction and conclude a minimum of three months after full operation has commenced to assess potential residual impact. Turbidity monitoring will be included in sensitive watercourses downstream of the proposed road development crossings. The local authority will make recommendations regarding all the water quality parameters to be assessed, the sampling interval and locations. However, as a minimum requirement there will be monthly water quality analysis from a minimum of one upstream and one downstream sampling point at each construction water outfall and surface water crossing point. Furthermore, turbidity monitoring will be carried out on a daily basis. The Employer's Site Monitoring Team will review weekly monitoring reports to check water quality at receiving watercourses.
11.6	C	The following outlines the principal environmental commitments that will be prescribed for the construction phase in order to protect all catchment, watercourse and ecologically protected areas from direct and indirect impacts: • All constructional compound areas will be required to be located on dry land and set back from river and stream channels and out of floodplain areas. Floodplain areas include the Flood Risk Zones A and B and therefore all constructional compound areas need to be on lands above the 1000year return period flood level. • The storage of oils, fuel, chemicals, hydraulic fluids, etc. will not occur within 100m of the River Corrib or within the Floodplain Area as defined above. • Surface water flowing onto the construction area will be minimised through the provision of temporary berms, diversion channels and cut-off ditches, where appropriate. • Management of excess material stockpiles to prevent siltation of watercourse systems through runoff during rainstorms will be undertaken. This may involve allowing the establishment of vegetation on the exposed soil and the diversion of runoff water off these stockpiles to the construction settlement ponds and avoiding stockpiling of material in vicinity of sensitive watercourses. • Where construction works are carried out adjacent to turloughs, fens, stream and river channels and lakes, protection of such waterbodies

Ref No.	Stage	Commitments
		from silt load shall be carried out through use of reserved grassed buffer areas, timber fencing with silt fences or earthen berms. These measures will provide adequate treatment of constructional site runoff waters before reaching the watercourses. • Use of settlement ponds, silt traps and bunds and minimising construction activities within watercourses. Where pumping of water is to be carried out, filters will be used at intake points and discharge will be through a sediment trap or sedi-mat. • All watercourses that occur in areas of land that will be used for site compound/storage facilities will be fenced off at a minimum distance of 5m. In addition, measures will be implemented to ensure that silt laden or contaminated surface water runoff from the compound site does not discharge directly to the watercourse. Compounds shall not be constructed on lands designated as Flood Zone A or B in accordance with the OPW's The Planning System and Flood Risk Management Guidelines (November 2009). Site compounds will not be permitted in a European Sites (i.e. Lough Corrib cSAC). • Protection measures will be put in place to ensure that all hydrocarbons used during the construction phase are appropriately handled, stored and disposed of in accordance with the TII document "Guidelines for the crossing of watercourses during the construction of National Road Schemes". All chemical and fuel filling locations will be contained within bunded areas and set back a minimum of 10m from watercourses and floodplain areas. • Foul drainage from all site offices and construction facilities will be contained and disposed of in an appropriate manner to prevent pollution. • The construction discharge will be treated such that it will not reduce the environmental quality standard of the receiving watercourses. • Riparian vegetation along the identified sensitive watercourses will be fenced off to provide a buffer zone for its protection to a minimum distance of 5m except for proposed crossing points. • The use and management of concrete in or close to watercourses will be carefully controlled to avoid spillage. Where on-site batching is proposed, this activity will be carried out well away from watercourses. Washout from such mixing plants will be carried out only in a designated contained impermeable area. • All material deposition areas must be adequately bunded and compartmentalised such that the rainwater outflow from these facilities is adequately controlled and treated prior to reaching the receiving surface watercourses. The sediment control requirements are set out in the Sediment, Erosion and Pollution Control Construction Management Plan section of the CEMP (refer to **Appendix A.7.5**)
11.7	O	The flood relief mitigation measures to eliminate the flood risk of the proposed road development in the N83 Tuam Road and reduce the existing flood risk in this area are described as follows (refer also to **Figure 11.6** and **Table 11.41** of **Chapter 10, Hydrology**): • Prevent the upgraded portion of the N83 Tuam Road from spilling laterally northwards into the driveways of existing flood risk houses by: o Upgrade and provide effective road drainage network along the existing N83 Tuam Road for a length of 780m

Ref No.	Stage	Commitments
		○ Provide interceptor drain to capture rapid hill slope runoff from the southeast reaching the N83 Tuam Road ○ Provide for infiltration of this interceptor drain for the less severe rain storm events ○ Connect this interceptor drain to the proposed flood compensation storage • Compensate flood storage lost by providing compensation storage of 8,030m^3 in the form of an excavated rectangular engineered storage pond. The base elevation of 16m OD and a top design water level elevation of 17.5m OD • Connect this compensation storage to the remaining low-lying natural flood storage area located to the northwest of the proposed road development so that both storage areas are hydraulically linked via culverts. • Provide for permanent a pumping station and rising mains from the proposed compensation flood storage facility to discharge to the existing storm sewer with maximum pumping capacity of 250l/s
11.8	O	Refer also to **Table 11.41** in **Chapter 11, Hydrology** which outlines the required storage volumes required for the catchment for a range of return periods and durations events. The required flood storage, with an available pumping rate of 0.25cumec (i.e. 250l/s) from the engineered storage pond, is 20,700m^3 for the 100year event which is further increased to 24,800m^3 to include for 20% climate change The available storage provided in the engineered storage pond at a top water level of 17.5m OD is compensation storage of 8,030m^3 and the remaining (with proposed road development) natural storage provided of 18,470m^3 gives a total available flood storage of 26,500m^3, which is sufficient to achieve to meet and exceed the required storage.
11.9	O	To minimise the residual flood risk associated with the blockage of flood relief culverts and associated drainage assets there will be regular (monthly) inspection of N83 Flood Relief facilities be carried out to ensure that the system is in proper working order and performing as designed.

21.13 Biodiversity

Ref No.	Stage	Commitments
General		
8.1	C/O	All measures within this section will be implemented by the Contractor under the supervision of the supervision of the Project Ecologist (employed by the Employer) and/or the Ecological Clerk of Works (employed by the Contractor).
Designated Areas for Nature Conservation		
8.2	C/O	The environmental commitments required to ensure that the proposed road development will not result in a likely significant effect (i.e. adversely affect the integrity of) on the European sites within its ZoI (Lough Corrib cSAC, Lough Corrib SPA, Galway Bay Complex cSAC and Inner Galway Bay SPA) include measures to: • Minimise the habitat loss in Lough Corrib cSAC and to avoid loss of QI habitats within Lough Corrib cSAC (refer to habitats section below). • maintain the structural integrity of the rock mass supporting QI habitats in Lough Corrib cSAC during the construction of the proposed Lackagh Tunnel (and its western approach) (refer to soils and geology environmental commitment 9.9, 9.11 to 9.17). • avoid habitat degradation in Lough Corrib cSAC as a result of potential hydrogeological impacts during construction and operation (refer to Hydrogeology Section). • protect water quality in receiving watercourses during construction (refer to Hydrology Section). • control dust emissions during construction to prevent impacts on vegetation in Lough Corrib cSAC (refer to Air Quality and Climate Section). • avoid the introduction or spread of non-native invasive species to European sites during construction or operation. • avoid/reduce the disturbance/displacement effects of blasting on wintering birds using Ballindooley Lough (Refer to wintering birds section below). • avoid the proposed road development restricting Otter movement within the Bearna Stream catchment (Refer to Otter section below). • avoid mortality of the QI species of Lough Corrib cSAC. These include both measures to ensure that construction materials are not introduced into the River Corrib and to remove the risk of Otter being killed/injured due to collisions with road traffic (Refer to Otter section below).
8.3	C/O	The environmental commitments that are required to ensure that the proposed road development will not significantly affect Moycullen Bogs NHA are as follows: • Avoid/reduce the disturbance/displacement effects of blasting on wintering birds using Ballindooley Lough (Refer to wintering birds section below). • Measures to control dust emissions during construction to prevent impacts to vegetation/habitats within Moycullen Bogs NHA at Tonabrocky – see Air Quality and Climate section below. These include control measures such as spraying of exposed earthwork

Ref No.	Stage	Commitments
		activities and site haul roads during dry weather, wheel washes, control of site vehicle speeds, road sweeping and dust screens. • Measures to avoid the introduction or spread of non-native invasive species to Moycullen Bogs NHA during construction or operation. These are detailed in the Non-Native Invasive Species Management Plan which forms part of the CEMP in **Appendix A.7.5**. • Measures to control surface water runoff from the construction site to prevent an accidental pollution event affecting peatland habitats within Moycullen Bogs NHA at Tonabrocky – see Hydrology section below.
Habitats		
8.4	C	To minimise the loss of Annex I habitat, areas of these habitat types within the proposed development boundary but which are not required to construct the proposed road development will be retained and fenced off for the duration of construction. These are shown on **Figures 8.23.1** to **8.23.14**.
8.5	C	To minimise the loss of habitat associated with the proposed road development, there are also areas within the proposed development boundary which are included for mitigation planting where general construction works will not be undertaken. These are shown on **Figures 8.23.1** to **8.23.14.**
8.6	C	The minimum working area to facilitate the construction of the supporting structures associated with the proposed River Corrib Bridge will be used. This area will be clearly delineated and fenced off at the outset of works and maintained for the duration of the construction programme. No works for the construction of the River Corrib Bridge within Lough Corrib cSAC boundary will be undertaken outside of this zone.
8.7	C	Where possible, woodland, scrub, treelines and hedgerows which lie within, or along the boundary of the proposed road development, that are not directly impacted by the proposed road alignment or drainage will be retained. These areas will be protected for the duration of construction works and fenced off at an appropriate distance. Vegetation to be retained is shown on **Figures 8.23.1** to **8.23.14** and on **Figures 12.2.01** to **12.2.14** (landscape design).
8.8	C	Where possible, areas of river channel and bankside vegetation which lie within, or along the boundary of the proposed road development, that are not directly impacted by the proposed road alignment or drainage will be retained. These areas will be protected for the duration of construction works and fenced off at a distance of 5m from the stream/river bank.
8.9	C	The Petrifying spring feature present in Lackagh Quarry, which lies c.25m to the north of the mainline of the proposed road development at Ch. 11+400, will be retained and shotcrete[2] will not be used as part of the quarry face stabilisation measures at the spring site.
8.10	C	Any vegetation (including trees, hedgerows or scrub adjacent to, or within, the proposed development boundary) which is to be retained shall be afforded adequate protection during the construction phase in accordance with the Guidelines for the Protection and Preservation of Trees, Hedgerows and Scrub Prior to, During and Post Construction of National Road Schemes (National Roads Authority, 2006), as follows:

[2] A concrete product which is sprayed at high velocity into a rock face as a structural/stabilising component.

Ref No.	Stage	Commitments
		• All trees along the proposed development boundary that are to be retained, both within and adjacent to the proposed development boundary (where the root protection area of the tree extends into the proposed development boundary), will be fenced off at the outset of works and for the duration of construction to avoid structural damage to the trunk, branches or root systems of the trees. Temporary fencing will be erected at a sufficient distance from the tree so as to enclose the Root Protection Area (RPA) of the tree. The RPA will be defined based upon the recommendation of a qualified arborist. • Where fencing is not feasible due to insufficient space, protection for the tree/hedgerow will be afforded by wrapping hessian sacking (or suitable equivalent) around the trunk of the tree and strapping stout buffer timbers around it. • The area within the RPA will not be used for vehicle parking or the storage of materials (including soils, oils and chemicals). The storage of hazardous materials (e.g. hydrocarbons) or concrete washout areas will not be undertaken within 10m of any retained trees, hedgerows and treelines: o A qualified arborist shall assess the condition of, and advise on any repair works necessary to, any trees which are to be retained or that lie outside of the proposed development boundary but whose RPA is impacted by the works. Any remedial works required will be carried out by a qualified arboris. o A buffer zone of at least 5m will be maintained between construction works and retained hedgerows to ensure that the root protection areas are not damaged.
8.11	C	The mitigation strategy outlined in the Non-Native Invasive Species Management Plan included in the CEMP (see **Appendix A.7.5**) will be implemented sufficiently far in advance of the proposed construction works commencing so as to allow time to adequately control all target non-native invasive species populations within the Zone of Influence (ZoI) of the proposed road development, having regard to the specific timing/seasonal constraints that apply in relation to each individual species.
8.12	C	The implementation of the Non-Native Invasive Species Management Plan will include a pre-construction re-survey within the proposed development boundary. In accordance with the NRA guidance this survey will include accurate 1:5,000 scale mapping for the precise location of non-native invasive plant species. The pre-construction surveys will be undertaken by suitable experts with competence in identifying the species concerned.
8.13	C	In accordance with the *Guidelines on the Management of Noxious Weeds and Non-native Invasive Plant Species on National Roads* (National Roads Authority, 2010), where cut, pulled or mown noxious weed or non-native invasive plant species material arises, its disposal will not lead to a risk of further spread of the plants. Care will be taken near watercourses as water is a fast medium for the dispersal of plant fragments and seeds. Material that contains flower heads or seeds will be disposed of either by composting or burial at a depth of no less than 0.5m in the case of noxious weeds, or by incineration (at a licenced facility having regard to relevant legislation) or disposal to licensed landfill in the case of non-native invasive plant species.
8.14	C	The taproots of docks and roots of creeping thistle are not suitable for composting or shallow burial, requiring disposal to landfill, incineration

Ref No.	Stage	Commitments
		or burying at a depth of no less than 1.5m (practical only during the construction phase). Where burial is being used to dispose of Japanese knotweed, the material will be buried to a depth of 5m and overlain with a suitable geotextile membrane. All disposals will be carried out in accordance with the Waste Management Acts 1996 - 2011.
8.15	C	In relation to aquatic non-native invasive species all construction works, and any aquatic survey work that may be carried out (e.g. electrofishing), will comply with best practice biosecurity protocols for aquatic work – for example IFI's Biosecurity Protocol for Field Survey Work (IFI, 2010).
8.16	O	Areas of Annex I habitat within the proposed development boundary which are identified to be retained and fenced off during the construction of the proposed road development will also be avoided during the operational phase.
8.18	C/O	There will be no fencing within Annex I habitats that are located within Lough Corrib cSAC.
8.19	C/O	Areas of compensatory habitat will be created, managed and monitored as set out in the Compensatory Habitat Management Plan in **Appendix A.8.26**.
Otters		
8.20	C	A pre-construction check of all suitable Otter habitat will be required within 12 months of any constructions works commencing.
8.21	O	Otter passage facilities will be provided at all watercourses used by Otter (e.g. raised ledges within structures, or separate dry 600mm pipes installed adjacent to culverts). Mammal underpasses will be constructed in accordance with the *Guidelines for the Treatment of Otters prior to the Construction of National Road Schemes* (National Roads Authority, 2008). The locations where Otter passage facilities will be provided are listed in **Table 8.36** of **Chapter 8, Biodiversity** and shown on **Figures 8.23.1** to **8.23.14**.
8.22	O	Mammal-resistant fencing will be installed in accordance with the specification outlined in *Guidelines for the Treatment of Otters prior to the Construction of National Road Schemes* (National Roads Authority, 2008). The locations where mammal-resistant fencing is to be installed are shown on **Figures 8.23.1** to **8.23.14**.
8.23	O	Quarterly monitoring of the effectiveness of the environmental commitments will be undertaken in the first year after the completion of construction works.
Bats		
8.24	C	The Bat Derogation Licence included in **Appendix A.8.25** will be submitted to National Parks and Wildlife for their approval.
8.25	C	The environmental commitments set out in the Bat Derogation Licence included in **Appendix A.8.25** shall be adhered to by the Contractor.
8.26	O	The schedule of structures to provide bat passage and the function that they serve in terms of mitigating the potential barrier effect are as per **Table 8.35** of **Chapter 8, Biodiversity** and **Figures 8.23.1** to **8.23.14**.
8.27	O	The proposed planting design associated with the Castlegar Wildlife Overpass comprises of a double hedgerow in the middle section of the overpass (to mimic a 4m wide bóithrín). Each of the hedgerows will then diverge out to create a “mouth" at the entrance to the overpass on both sides of the proposed road development to funnel bats in to the centre of

Ref No.	Stage	Commitments
		the overpass. **Plate 2**, of **Chapter 8, Biodiversity**, shows the schematic design and location of the proposed overpass.
8.28	O	No lighting will be provided at or on any of the structures which have been designed to provide bat passage, with the exception of S06/01 where lighting will be provided to also allow for safe use by pedestrians. All of the bat underpasses (as well as artificial roosts) that are designed for Lesser horseshoe bats will have connecting woody vegetation features. Other bats species are not as reliant on hedgerows and woodland edges. Whilst there are many existing landscape features outside of the proposed development boundary, the bat mitigation strategy cannot rely on these in the long term as they may be subject to interventions by third parties. In effect, what will be created is a hedgerow corridor leading up to underpasses in the section of the proposed road development between Aughnacurra and Castlegar. This planting provides a guaranteed green corridor connecting up the underpasses/overpasses and will allow bats to adapt more easily to any future landscape scale losses of connecting habitat features. The hedgerow planting leading up to underpasses will be maintained and the growth of the hedgerow monitored for 5 years following completion and remediation works undertaken if deemed necessary.
8.29	C	As the baseline level of bat activity and roost occupancy can change over time, pre-construction monitoring will be carried out in advance of construction works commencing to ensure that the data against which the post-construction monitoring will be compared to is as up-to-date as possible (refer to Bat Derogation Licence included in **Appendix A.8.25**). Monitoring of the effectiveness of the bat mitigation and compensation measures will also be undertaken during and post-construction. Where the monitoring identifies issues with either the mitigation or compensation measures (e.g. light spill affecting usage), these will be remediated to ensure that those measures will achieve their aims with respect to mitigating or compensating for impacts on the local bat populations (refer to Bat Derogation Licence included in **Appendix A.8.25**).
Badgers		
8.30	C	A detailed summary of the environmental commitments as they relate to each of the Badger setts within the ZoI of the proposed road development is presented in **Appendix A.8.24** and summarised in **Table 8.36** of **Chapter 8, Biodiversity**. The non-interference zones (30m, 50m, and 150m) as they relate to each of the Badger setts within the ZoI of the proposed road development are illustrated on **Figures 8.23.1** to **8.23.14**. A pre-construction check of the activity status of all setts will be required within 12 months of any constructions works commencing within the ZoI of the setts discussed below.
8.31	C	In order to prevent any disturbance to Badger setts not directly affected by the proposed road development: • No heavy machinery shall be used within 30m of Badger setts at any time. • No works shall be undertaken within 50m of active setts during the breeding season. • Lighter machinery (generally wheeled vehicles) shall not be used within 20m of a sett entrance. • Neither blasting nor pile driving shall be undertaken within 150m of active setts during the breeding season (December to June inclusive)

Ref No.	Stage	Commitments
8.32	C	Prior to works commencing, a non-interference zone of 30m will be established around each of the Badger setts within the ZoI of the proposed road development, as shown on **Figures 8.23.1** to **8.23.14**. If the sett is active, non-interference zone will be extended to 50m during the breeding season (December to June inclusive). The fencing shall be as noted in **Chapter 7, Construction Activities** of a sufficient durability to maintain the exclusion zone throughout the construction period or, if required, until such time as the sett in question is excluded/removed.
8.33	C	Where setts require exclusion and removal, or temporary exclusion for the duration of the construction period, this will be undertaken in accordance with the methodology detailed in the Guidelines for the Treatment of Badgers during the Construction of National Road Schemes (National Roads Authority, 2006): • All Badger setts requiring exclusion and removal will require a monitoring period of at least five days to confirm activity status in advance of any construction works commencing. • If the sett is active, then it shall not be removed within the Badger breeding season (December to June inclusive). To exclude or remove an active Badger sett outside of this period, inactive entrances shall be soft and hard-blocked with one-way gates installed on active entrances. One-way gates will be tied open for three days before being set to exclude, and then monitored for a period of at least 21 days before the sett is deemed inactive and destroyed. If at any time during the monitoring period the sett becomes active, the exclusion process/programme must commence again from day 1 of the 21-day monitoring period. • For inactive setts, entrances will be soft-blocked (lightly blocked with vegetation and soil) and if all entrances remain undisturbed for a period of five days the sett should be destroyed immediately. This can be undertaken at any time of the year for inactive setts.
8.34	C	An artificial sett is required to mitigate for the loss of the main sett (S9), in conjunction with a subsidiary sett (S11), of the Lackagh Badger group. The requirements relating to the provision and design of the artificial sett are set out in **Appendix A.8.24**. The location of the artificial sett is shown on **Figures 8.23.1** to **8.23.14**.
8.35	C	Inaccessible areas (see **Figures 8.3.1** to **8.3.14**) will require a pre-works survey for badger setts in advance of site clearance. If a sett is uncovered, works must cease and a non-interference zone of 30m established; extended to 50m during the breeding season if set is active (December to June inclusive). Sett removal will follow the process outlined above.
8.36	O	To avoid badger road casualties, mammal passage facilities will be provided at strategic locations along the route of the proposed road development. Mammal underpasses will be constructed in accordance with the *Guidelines for the Treatment of Badgers during the Construction of National Road Schemes* (National Roads Authority, 2006). Where engineering constraints conflict with the recommended locations at detailed design phase, mammal underpasses may be moved to the nearest most suitable location, but not more than c.250m away. The locations where Badger passage facilities will be provided are listed in **Table 8.36** and are shown on **Figures 8.23.1** to **8.23.14**.
8.37	O	A number of the mammal passage structures lie within the modelled light spill zone and artificial lighting may affect their usage by Badger: structures C07/04, C07/01(b) and C12/01. Screening will be provided to

Ref No.	Stage	Commitments
		ensure that the approaches and entrances to these structures are unaffected by light spill.
8.38	O	Mammal-resistant fencing will be required to guide badgers to the underpasses and will be installed in accordance with the specification outlined in *Guidelines for the Treatment of Badgers prior to the Construction of National Road Schemes* and will include badger proofing of emergency access roads and other similar access points, where located in areas where mammal-resistant fencing is to be installed. The locations where mammal-resistant fencing is to be installed are shown on **Figures 8.23.1** to **8.23.14**.
8.39	O	In accordance with the recommendations described in the *Guidelines for the Treatment of Badgers during the Construction of National Road Schemes* (National Roads Authority, 2006), quarterly monitoring of the effectiveness of the environmental commitments will be undertaken in the first year after the completion of construction works.
Other mammal species (excluding bats)		
8.40	O	The schedule of structures to provide for mammal passage, as per **Table 8.36** and as shown on **Figures 8.23.1** to **8.23.14**, are required to ensure permeability for all other mammal species across the proposed road development during operation.
Invertebrates		
8.41	C	To avoid the destruction of Marsh fritillary eggs or the mortality of Marsh fritillary caterpillars, the following mitigation strategy will be implemented in relation to the site clearance works: • All areas within the proposed development boundary, which have been identified as suitable habitat to support the Marsh fritillary butterfly, will be subject to a pre-construction larval web survey. This will be undertaken during the mid-August to the end of September window immediately preceding site clearance works. • If larval webs are present, they will be translocated to another area of suitable habitat; either outside of the proposed development boundary or, if within, to an area of suitable habitat that will remain unaffected by construction works for the duration. • Once all larval webs have been removed from the affected areas, or if no larval webs were recorded, the vegetation will be immediately cleared or cut to ground level to render the area unsuitable for the species to recolonise. The vegetation shall be maintained in this state until such time as the topsoil is removed.
Birds		
8.42	C	Where feasible, vegetation (*e.g.* hedgerows, trees, scrub and grassland) will not be removed, between the 1 March and the 31 August, to avoid direct impacts on nesting birds. Where the construction programme does not allow this seasonal restriction to be observed, then these areas will be inspected by a suitably qualified ecologist for the presence of breeding birds prior to clearance. Areas found not to contain nests will be cleared within 3 days of the nest survey, otherwise repeat surveys will be required.
8.43	O	Planting of woodland, hedgerow and grassland habitats along the proposed road development as detailed in the landscape drawings (**Figures 12.2.01** to **12.2.14**) will provide compensatory habitat for some bird species.

Ref No.	Stage	Commitments
8.44	O	To further minimise the effects of breeding habitat loss, a total of 20 nest boxes will be erected by an ecologist in suitable locations away from the busy junctions/roadways. The siting and type of nest boxes will be decided on by an ecologist at locations where trees will be planted or retained along the proposed road development; as shown on **Figures 12.2.01** to **12.2.14**.
8.45	C	To minimise the effects of current levels of disturbance to the Barn owl nest site at Menlo Castle, and thereby reduce any cumulative effect that construction activities nearby may have, alternative nesting sites will be provided in the vicinity. Three Barn owl nest boxes will be erected across the area shown on **Figures 8.23.1** to **8.23.14** and will consist of either nest boxes erected on suitable trees or pole-mounted nest boxes. Preference will be given to erecting nest boxes on suitable trees, where possible. Tree mounted boxes will be erected at least 3m above ground level on a mature tree with few or no low branches to obscure the nest box. The selected tree shall be either isolated in a hedgerow or situated on a woodland edge with the access hole facing open ground. Pole-mounted nest boxes will be erected at a minimum height of 4.5m above ground. The nest box design (e.g. entrance hole size, floor area and depth from bottom of entrance hole to nest) shall be in accordance with the design requirements published by The Barn Owl Trust (http://www.barnowltrust.org.uk/). Nest boxes will be inspected annually for defects/damage and cleaned out/repaired as required to ensure waterproofness and the internal box depth.
8.46	O	Sections along the proposed road development will be planted with dense low growing scrub cover (e.g. blackthorn) to discourage Barn owls from foraging near the proposed road development. The planting will be of a density to minimise the lag time between planting and obtaining sufficient ground cover to deter foraging Barn owl.
8.47	O	In areas where there is a high probability that Barn owls may regularly attempt to cross the proposed road development (the section of embankment between Ch. 9+600 and Ch. 10+100), lines of closely spaced (approximately 2m centres) trees, greater than 3m in height, will be planted along the top of the embankments of the proposed road development; outside of the safety barrier and clear zone. The understorey will also be densely planted. This is to present a solid vegetated barrier to deflect Barn owl from these high-risk areas and/or force birds to fly over the proposed road development above the road traffic.
8.48	O	All mitigatory planting will be in place at the earliest feasible stage during construction to ensure that the mitigation is functioning as soon as possible. The locations where planting will be used to reduce the risk of Barn owl mortality from road traffic are shown on **Figures 8.23.1** to **8.23.14** and on the landscape drawings (**Figures 12.2.01** to **12.2.14**).
8.53	O	Following implementation of all environmental commitments for Barn Owls and completion of construction of the proposed road development, the following monitoring measures are proposed: • Surveys will be undertaken of roadside planting schemes at the end of years one and two with the objective of identifying and replacing failed plantings. • A road casualty survey to record barn owl mortalities along the route of the proposed development will be conducted once per week for a period of two years by a suitably qualified and experienced ornithologist. The proposed road development will be driven at a

Ref No.	Stage	Commitments
		steady pace in both directions so that all sections and both sides of the route will be covered. Where noted, all barn owl mortalities will be assigned to either the "breeding" season (March to July) or "non-breeding" season (August to January). Location details of the casualty will be recorded, including a 10-digit GPS co-ordinate, position on the route (central median, hard shoulder, or verge) and orientation (southbound, northbound, eastbound, and westbound). The age class of the bird will be determined and classed as either "pre-breeding" if first or second calendar year recovered before March, or "adult" if the bird is second calendar year recovered later than March or older. The adjacent habitat feature will be noted. This methodology is in line with that utilised for Barn Owl population status and the extent of road mortalities in relation to the Tralee Bypass (O'Clery et al., 2016). • Monitoring to determine activity and breeding status of all active sites within 5km of the proposed road development over two breeding seasons (March to July). This will be carried out concurrently with the road casualty survey, and will involve visits to known and potential nesting sites to determine brood size and breeding success. Where accessible, nests will be visited in order to ring owlets (subject to an appropriate licence from the NPWS). A report summarising the findings of the above monitoring will be submitted at the end of year two to the NPWS. The report may include further recommendations pending survey outcomes.
8.54	C	To minimise the potential for construction works near Lackagh Quarry to disturb the Peregrine falcon nest site, works from the Lackagh Tunnel to the N84 Headford Road Junction will commence prior to mid-February. The installation of rock bolts on the cliff faces in the vicinity of the nest site will be undertaken in a sensitive manner (as advised by a suitably experienced ecologist) so as to minimise any potential disturbance to the nest site during the breeding season, particularly if the nest site is occupied.
8.55	C	Construction noise will be kept to a minimum in accordance with BS 5228 (2009).
8.56	C	Blasting associated with the eastern approach to Lackagh Quarry (Ch. 11+800 to Ch. 12+100) will be carried out between the months of April to September (inclusive) to minimise the exposure of wintering birds at Ballindooley Lough to blasting-related disturbance.
8.57	C	Blasting associated with the cutting at Castlegar (Ch. 12+550 to Ch. 13+650) will take approximately nine months to complete, with an estimated five blast events per week. To minimise the exposure of wintering birds at Ballindooley Lough to blasting-related disturbance, all of those nine months must be in the April to September period (inclusive) within consecutive years.
Amphibians		
8.58	C	If works to clear any of the habitat features suitable to support amphibian species are to begin during the season where frogspawn or tadpoles may be present (February – mid-summer), or where breeding adult newts, their eggs or larvae may be present (mid-March – September), a pre-construction survey will be undertaken to determine whether breeding amphibians are present.
8.59	C	In the case of Common frog, any frog spawn, tadpoles, juvenile or adult frogs present will be captured removed from affected habitat by hand net

Ref No.	**Stage**	**Commitments**
		and translocated to the nearest area of available suitable habitat, beyond the ZoI of the proposed road development.
8.60	C	In the case of Smooth newt, individuals will be captured and removed from affected habitat either by hand net or by trapping and translocated to the nearest area of available suitable habitat, beyond the ZoI of the proposed road development. If used, the type and design of traps shall be approved by the NPWS. This is a standard and proven method of catching and translocating Smooth nest.
8.61	C	If the size or depth of the habitat feature is such that it cannot be determined whether all amphibians have been captured, it will be drained under the supervision of a suitably experienced ecologist to confirm that no amphibian species remain before it is destroyed or infilled. Any mechanical pumps used to drain the habitat feature will have a screen fitted, and be sited, such that no amphibian species can be sucked into the pump mechanism.
8.62	C	Any capture and translocation works shall be undertaken immediately in advance of site clearance/construction works commencing.
8.63	O	The schedule of structures to provide for mammal passage, as per **Table 8.36** and as shown on **Figures 8.23.1** to **8.23.14**, are required to ensure permeability for amphibian species across the proposed road development during operation.
Reptiles		
8.64	C	In order to minimise the risk of site clearance and construction works disturbing, or causing the mortality of, Common lizard the following schedule of site clearance works will be followed in the areas highlighted on **Figures 8.10.1** to **8.10.8**, where the presence of Common lizard has been confirmed: • grass, scrub or heath vegetation will be removed during the winter period, where possible, avoiding potential Common lizard hibernacula sites (dry sites which provide frost-free conditions e.g. stone walls, underground small mammal burrows, piles of dead wood or rubble). • where this is not possible and clearance will be undertaken during the active season (March through to September, inclusive), vegetation will be cut first to approximately 15cm, and then to the ground, under supervision of an ecologist. This will allow the opportunity for lizards to be displaced by the disturbance and leave the affected area. • stone walls (or other potential hibernacula sites) will be removed during the active season (March through to September, inclusive) under the supervision of an ecologist, when they are less likely to be in use by torpid lizards.
8.65	O	The schedule of structures to provide for mammal passage, as per **Table 8.36** and as shown on **Figures 8.23.1** to **8.23.14**, are required to ensure permeability for the Common lizard across the proposed road development during operation.
Fish		
8.66	C	To minimise the effects of habitat loss on fish species, all sections of river/stream channel within the proposed development boundary, but not within the footprint of the proposed road development and associated infrastructure, will be protected from site clearance and construction works. Rivers/streams will be fenced off at a minimum distance of 5m

Ref No.	Stage	Commitments
		from the river bank and within this zone the natural riparian vegetation will be retained.
8.67	C	To minimise the potential effects of construction works on fish species the following environmental commitments will be implemented: • No instream works will be carried out between the months of October and June (inclusive) to avoid the most sensitive time for fish species and fish species movements. • Design of new sections of river channel shall be in accordance with the principles outlined in Channels & Challenges. Enhancing Salmonid Rivers. (O'Grady, 2006). • Immediately prior to rivers/streams being diverted into a newly constructed river channel or culvert, they will be electrofished (if required) to capture and transfer fish from the original channel to the new one. Once the watercourse has been diverted this will be followed by a manual search of the original watercourse to transfer any remaining fish to the new river/stream channel). • Any water abstraction points required for dust suppression will be agreed with IFI and the suction head shall be screened to ensure that fish are removed during the abstraction process.
8.68	C	All temporary crossing structures used to cross watercourses during construction will be designed in accordance with the *Guidelines on Protection of Fisheries During Construction Works in and Adjacent to Waters* (IFI, 2016) and *Guidelines for the Crossing of Watercourses during the Construction of National Road Schemes* (National Roads Authority, 2005) to maintain fish and macroinvertebrate passage, and to prevent sedimentation and erosion.
